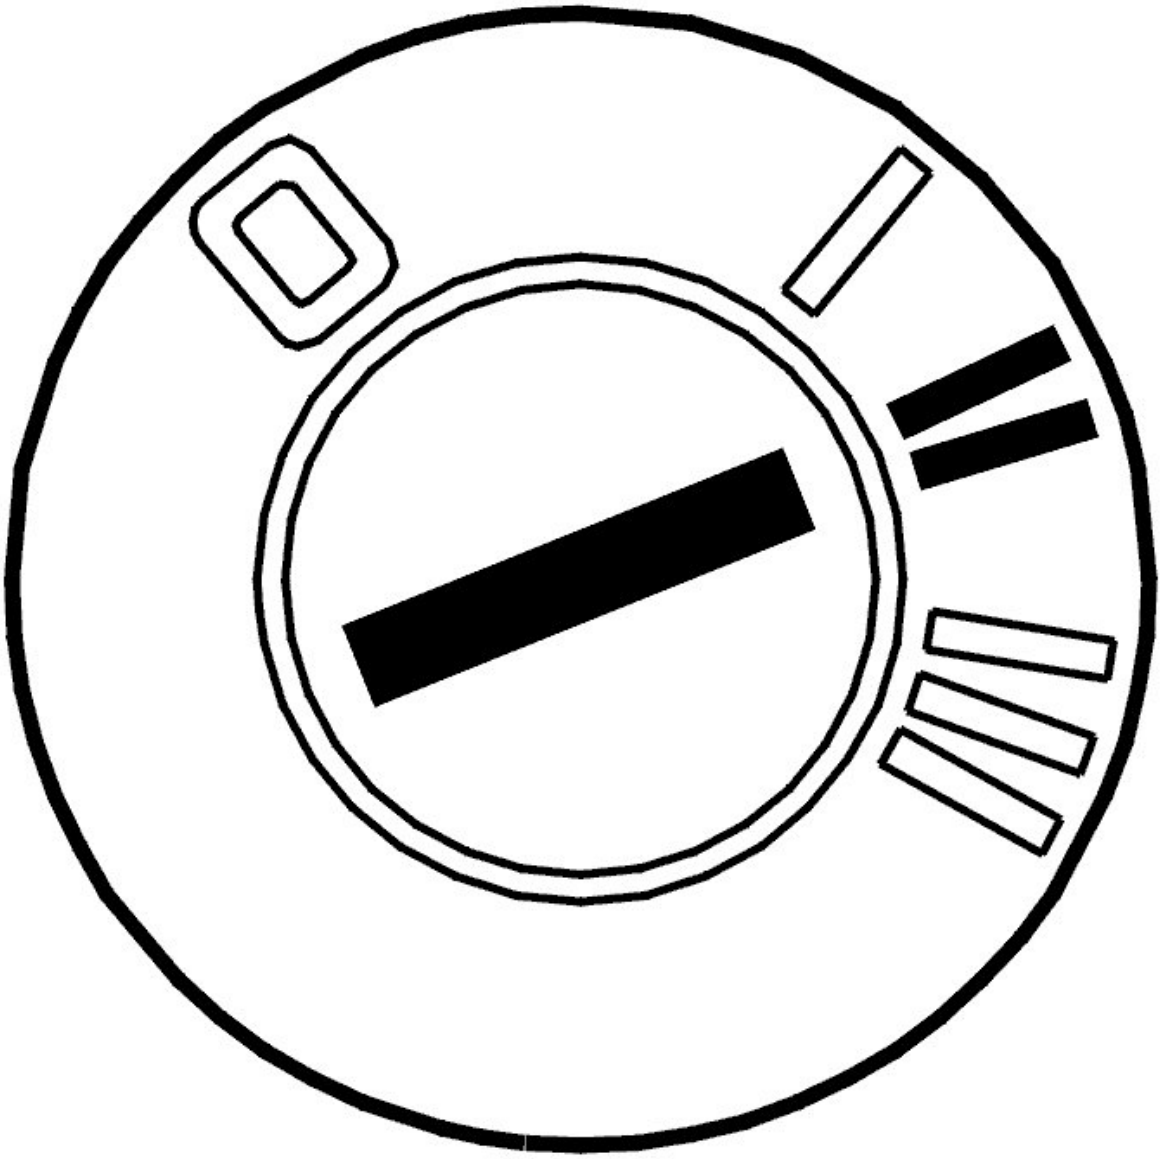
NO - FAILED

Reading Off Extended Diagnostic Trouble Code (DTC) Information, Engine control Module (ECM)

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

Detailed diagnostic trouble code information readout

Detailed diagnostic trouble code information readout, engine control module (ECM)



This service is an expanded air to fault tracing intermittent faults. It is primarily intended for use when the fault cannot be found using standard fault tracing for the diagnostic trouble code (DTC).

1. Ignition on.
2. Click the VCT2000 to activate the readout.
3. Read off stored diagnostic trouble codes (DTCs) in the upper list window.
4. Select the diagnostic trouble code from the upper list window to read the information on the code.

Description of detailed diagnostic trouble code information readout, B5244T5, B5254T2 See: Scan Tool Testing and Procedures/Vehicle Communication Information, Engine Control Module (ECM)/Description of Detailed Diagnostic Trouble Code Information Readout

Continue - **DONE**

Numeric Result 0 - Communication fault

Communication fault

Communication has been interrupted for one of the following reasons:

- The ignition is switched off
- VCT2000 disconnected from the data link connector (DLC)
- VCT2000 disconnected from the VIDA cart
- Communication problems in VIDA application or in car.
- No voltage in the data link connector (DLC).

Check therefore:
- That the control module power supply and ground terminal are fault-free.
- That the fuse for the data link connector (DLC) is intact.
- that the ignition is on
- that the battery voltage (system voltage) is normal (approximately 12 V).

If necessary a battery charger can be connected during the test.
For information about charge currents and the battery, see: Battery, charging See: Starting and Charging/Battery/Service Precautions/Technician Safety Information/Battery, Charging
- that VCT2000 is correctly connected to the VIDA cart and the data link connector (DLC)
- that VCT2000 and the wiring is fault-free.

Other information
- For information about fuse and terminal numbers, see the relevant Wiring Diagram.

Try to establish communication again or exit reading off diagnostic trouble codes (DTCs). Depending on the communication fault, select one of the following options.
1. Try again
2. Fault-trace more comprehensively for the communication problem that has occurred
3. Exit fault-tracing / Read off from the next system.

Which alternative is requested?

1 - Engine Control Module

2 - Checking a communication fault

3 - **FAILED**

Checking a communication fault

Checking communication errors

Selecting car model

Select car model to obtain relevant troubleshooting information.

Select one of the following model alternatives
1. S40 (04-) / V50.
2. V70 (00-), V70 XC (01-) / XC70, S60, S80 and XC90.
3. V70 (-00), V70 XC and S70 / C70.
4. S40 (-04)/ V40.

1 - car model S40 (04-) / V50

2 - car model V70 (00-), V70 XC (01-) / XC70, S60, S80 and XC90

3 - car model V70 (-00), V70 XC and S70 / C70

4 - Checking communication errors car model S40 (-04) / V40

Checking communication errors, car model S40 (04-) / V50

Hint: Test the communication with another corresponding vehicle to decide if the malfunction is in the vehicle or in VIDA/VCT/cable harness. If the communication works on another vehicle, the malfunction is in the vehicle.

Hint: For current information about each circuit and signals, see wiring diagram and signal description for each system.

Diagnostic outlet

- Check the voltage feed to diagnostic outlet #16. The voltage shall match battery voltage.
- Check the cable for power ground and signal ground to diagnostic outlet #4 and #5.

Hint: When VCT2000 is connected to the diagnostic outlet (is supplied with voltage), the indicator diode shall be activated with a green light. Then the indicator diode flashes quickly when communication takes place with a control module. In case of certain internal malfunctions on VCT2000 the indicator diode is activated with a red light!

Communication cables

- For communication problems with control units on**the high-speed network**, check communication cables between diagnostic outlet #6/ #14 and central electronic module (CEM) #B11/ #B12 for open circuit, short-circuit to ground and short-circuit to voltage according to references above.
- For communication problems with control units on**the low-speed network**, check communication cables between diagnostic outlet #3/#11 and central electronic module (CEM) #B16/#B15 for open circuit, short-circuit to ground and short-circuit to voltage according to references above.
- Also check the communication cables for the low and high-speed net between the central electronic module (CEM) and the other connected control modules according to troubleshooting above.

Control modules

- Check that the control module's voltage feed and ground connection are trouble-free.

Caution! If none of the above checks help, try reading out diagnostic trouble codes in the central electronic module (CEM). Done via VIDA vehicle communication. A prerequisite for being able to communicate with the control modules in the vehicle is that the central electronic module (CEM) is active and can be communicated with. If communication is not possible with the central electronic module (CEM), check the voltage feed and ground for the central electronic module (CEM).

VCT2000 and cable harness

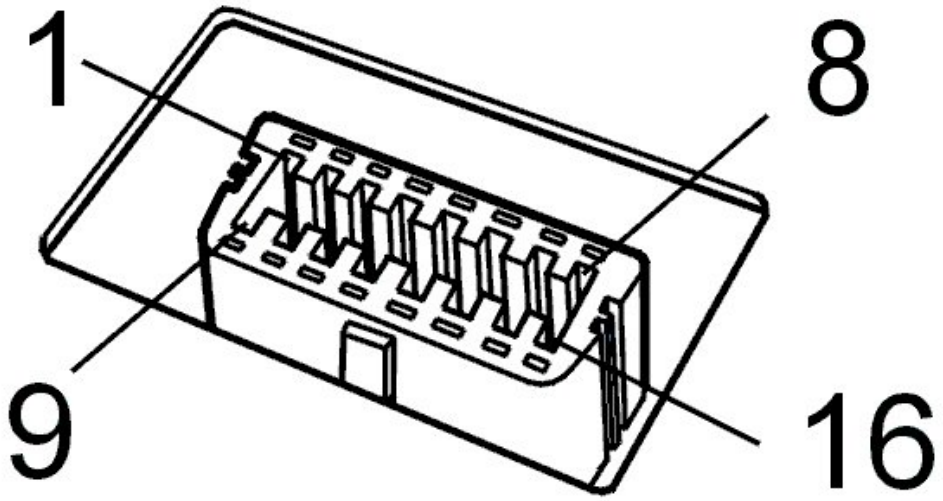
- Connect VCT2000 to the vehicle so that it is supplied with voltage. Test VCT2000 by selecting the system's self-test and VCT Test in the VIDA main menu. If any malfunction is found according to the test, first replace the cable harness then the VCT2000, if the test still indicates a malfunction.
- If no malfunctions were found after troubleshooting according to above, try with a new cable harness and/or new VCT2000.

VIDA

- If no malfunctions were found after troubleshooting according to above, try performing a complete system reset of VIDA.

Other information

- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals



Continue - Fault Found

Checking communication errors, car model V70 (00-), V70 XC (01-) / XC70, S60, S80 and XC90

Hint: Test the communication with another corresponding vehicle to decide if the malfunction is in the vehicle or in VIDA/VCT/cable harness. If the communication works on another vehicle, the malfunction is in the vehicle.

Hint: For current information about each circuit and signals, see wiring diagram and signal description for each system.

Different speed on the CAN-communication can lead to problems

Volvo's vehicles have different speed of communication on the high-speed part of the CAN-network (HS-CAN), depending on model year.
- Model year -2004 communicates with 250 kbit/s.
- Model year 2005- communicates with 500 kbit/s.

Due to this, it is very important to specify correct vehicle profile before any communication is started with the vehicle's HS-CAN. This is normally done by pressing on " Retrieve VIN" or by manually specifying vehicle parameters under "Vehicle profile".
If the wrong model year has been selected, it may lead to blocking of the CAN-net, diagnostic trouble codes being stored in several control modules or missing response from control modules at continued communication. The following control modules may be affected by this problem:
- Brake control module (BCM)/(ABS)
- Engine control module (ECM)
- Electronic Throttle Module (ETM)
- Suspension Module (SUM)
- Central electronic module (CEM)
- Transmission control module (TCM)
- Steering wheel angle sensor module (SAS)
- Steering Wheel Module (SWM)
- Electrical Power Steering Module (EPS)

If this happens, take the following action:
- Turn off the ignition and remove the ignition key. Insert the key again in position II.
- If the above does not work, remove the battery cable and connect it again after a minute to reset the control modules.
- Select the correct vehicle profile in VIDA and erase the diagnostic trouble codes. Check that the symptoms have disappeared.

Diagnostic outlet
- Check the voltage feed to diagnostic outlet #16. The voltage shall match battery voltage.
- Check the cable for power ground and signal ground to diagnostic outlet #4 and #5.

Hint: When VCT2000 is connected to the diagnostic outlet (is supplied with voltage), the indicator diode shall be activated with a green light. Then the indicator diode flashes quickly when communication takes place with a control module. In case of certain internal malfunctions on VCT2000 the indicator diode is activated with a red light!

Communication cables
- Check the communication cable (k-line) between diagnostic outlet #7 and central electronic module (CEM) #D6 and other connected control modules for open circuit, short-circuit to ground and short-circuit to voltage.

Caution! In case of malfunction on this communication cable, communication cannot be established on either the low or high-speed network. First when communication takes place on this cable, the low and high-speed cables between the diagnostic outlet and central electronic module (CEM) are connected to the rest of the network in the vehicle. This is controlled via a relay in the central electronic module (CEM). This relay is only found on vehicles of model year -2004.

- For communication problems with control units on**the high-speed network**, check communication cables between diagnostic outlet #6/ #14 and central electronic module (CEM) #B7/ #B8 for open circuit, short-circuit to ground and short-circuit to voltage according to references above.
- For communication problems with control units on**the low-speed network**, check communication cables between diagnostic outlet #3/#11 and central electronic module (CEM) #B19/#B20 for open circuit, short-circuit to ground and short-circuit to voltage according to references above.
- Also check the communication cables for the low and high-speed net between the central electronic module (CEM) and the other connected control modules according to troubleshooting above.

Control modules
- Check that the control module's voltage feed and ground connection are trouble-free.

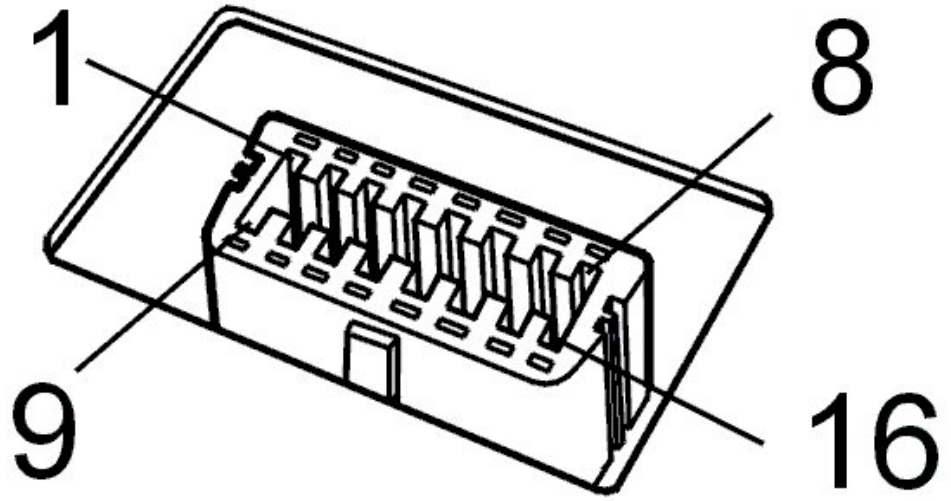
Caution! If none of the above checks help, try reading out diagnostic trouble codes in the central electronic module (CEM). Done via VIDA vehicle communication. A prerequisite for being able to communicate with the control modules in the car is that the central electronic module (CEM) is active and can be communicated with. If communication is not possible with the central electronic module (CEM), check the voltage feed and ground for the central electronic module (CEM).

VCT2000 and cable harness
- Connect VCT2000 to the vehicle so that it is supplied with voltage. Test VCT2000 by selecting the system's self-test and VCT Test in the VIDA main menu. If any malfunction is found according to the test, first replace the cable harness then the VCT2000, if the test still indicates a malfunction.
- If no malfunctions were found after troubleshooting according to above, try with a new cable harness and/or new VCT2000.

VIDA
- If no malfunctions were found after troubleshooting according to above, try performing a complete system reset of VIDA.

Other information

- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals



Continue - Fault Found

Checking communication errors, car model V70 (-00), V70 XC and S70/C70

Hint: Test the communication with another corresponding vehicle to decide if the malfunction is in the vehicle or in VIDA/VCT/cable harness. If the communication works on another vehicle, the malfunction is in the vehicle.

Hint: For current information about each circuit and signals, see wiring diagram and signal description for each system.

Diagnostic outlet
- Check the voltage feed to diagnostic outlet #16. The voltage shall match battery voltage.
- Check the cable for power ground and signal ground to diagnostic outlet #4 and #5.

Hint: When VCT2000 is connected to the diagnostic outlet (is supplied with voltage), the indicator diode shall be activated with a green light. Then the indicator diode flashes quickly when communication takes place with a control module. In case of certain internal malfunctions on VCT2000 the indicator diode is activated with a red light!

Communication cables
- Check the communication cable (k-line) between diagnostic outlet #7 and the driver information module (DIM) #B4 and other connected control modules for open circuit, short-circuit to ground and short-circuit to voltage.

Caution! In case of malfunction on this communication cable, communication cannot be established on the high-speed network. First when communication takes place on this cable, the high-speed cables between the diagnostic outlet and driver information module (DIM) are connected to the high-speed network in the vehicle. This is controlled via a relay in the driver information module (DIM).

- Check communication cables between diagnostic outlet #6/#14 and the driver information module (DIM) #A19/#A20 for open circuit, short-circuit to ground and short-circuit to voltage according to references above.
- Also check the communication cables for the**high-speed network**between the driver information module (DIM) and the other connected control modules according to troubleshooting above.

Communication cable for cruise control as own system (not integrated)
- Check the communication cable between diagnostic outlet #13 and cruise control for open circuit, short-circuit to ground and short-circuit to voltage according to references above.

Communication cable for engine management system Fenix 5.2
- Check the communication cable between diagnostic outlet #3 and engine control module (ECM) for open circuit, short-circuit to ground and short-circuit to voltage according to references above.

Control modules
- Check that the control module's voltage feed and ground connection are trouble-free.

Caution! Model year 99- and control modules on the CAN-network. If none of the above checks help, try reading out diagnostic trouble codes in the driver information module (DIM). Done via VIDA vehicle communication. A prerequisite for being able to communicate with the control modules in the vehicle is that the driver information module (DIM) is active and can be communicated with. If communication is not possible with the driver information module (DIM), check the voltage feed and ground for the control module.

VCT2000 and cable harness

- Connect VCT2000 to the vehicle so that it is supplied with voltage. Test VCT2000 by selecting the system's self-test and VCT Test in the VIDA main menu. If any malfunction is found according to the test, first replace the cable harness then the VCT2000, if the test still indicates a malfunction.
- If no malfunctions were found after troubleshooting according to above, try with a new cable harness and/or new VCT2000.

Classification of Diagnostic Trouble Codes

Classification of diagnostic trouble codes

In principle, malfunctions can be classified in two categories, intermittent or permanent.
Permanent malfunctions.

The easiest malfunctions to identify and confirm as a malfunction are the permanent malfunctions. A permanent malfunction is a malfunction when something has "broken" and remains like that until it is repaired.
Intermittent malfunctions.

The intermittent malfunctions are, as opposed to the permanent malfunctions, are both difficult to identify and confirm. The malfunction exists but is neither active nor present all the time. The malfunction comes and goes briefly under very rare conditions.
For the intermittent malfunctions, the degree of intermittence can also be determined, that is, how intermittent the malfunction is (how often/seldom the malfunction appears).

Hint: For assessment of intermittence, stored counters are used together with the diagnostic trouble code.

Common permanent malfunction causes are:

- Open circuits or short-circuits on cables or in connectors caused by mechanical damage, vibrations, corrosion, oxidation, moisture, etc.

Common intermittent malfunction causes are:

- Loose connections or contact resistance caused by vibrations, corrosion, oxidation, moisture, etc.
- Brief short-circuits to both ground and voltage caused by damage to cables, moisture in connectors, etc.
- Electro-magnetic interference.

Malfunction causes may be both electrical, mechanical or related to software.
Intermittent malfunctions (or malfunctions that occur under unknown conditions) may also be malfunctions that only occur during certain operation or ambient conditions.
E.g., that the window or seat for some reason jams in its end-position when using automatic function, or that the climate control unit supplies poor heat in a certain position when it rains outside.

Designation of Trouble Codes

Designation of trouble codes

The diagnostics tool VIDA shows the diagnostic trouble code in plain text according to the following example:
TCM-001F Speed sensor Signal missing Permanent malfunction

This diagnostic trouble code consists of the following parts:

- Prefix for control system in question (**TCM**) to show what system the diagnostic trouble code belongs to. *
- Diagnostic trouble code number (**001F**) to decide which diagnostic trouble code is stored. Number of digits in the diagnostic trouble code number may vary. *, **
- Title (**Speed sensor**) is a text that shows to which component/function the diagnostic trouble code refers. *
- Qualifier (**Signal missing**) is used to show **how the control module has perceived the signal from, e.g., the sensor, or how it detected the monitored function.** In this case, the control module has perceived that the signal is missing. There a re a number of other qualifiers for, e.g., too high signal, incorrect signal, too high flow, too low flow, etc. *, **.
  - If the qualifier is, e.g., "Too high signal", the control module interprets that the signal from the sensor is too high. This may mean that, e.g., the voltage is too high, current is too high, frequency is too high, or the pulse ratio (% duty) is too high, all depending on which type of signal it is. Malfunction causes may be, e.g., open circuit or short-circuiting to voltage.
  - If the qualifier is "Too low signal", the control module interprets that the signal from the sensor is too low. Malfunction causes may be, e.g., open circuit, shirt-circuiting to ground, contact resistance in connections.
  -

Note! Information about which type of signal that the control module detects and what conditions are required to detect that a malfunction is found again in the diagnostic trouble code information.

- Status (**Permanent malfunction**) to show the malfunction's status, that is, if the malfunction has been detected in the present driving cycle or not. There are two different status texts, permanent or intermittent. When the control module's diagnosis cannot decide the malfunction's

status, the diagnostic trouble code is shown without status text. *
* When reading out diagnostic trouble codes using diagnostic socket with light-emitting diode, you get a three-digit flash code. Then this code is translated to a diagnostic trouble code text using the service information.
For example, if the control module flashes the code 1-2-3 from Engine control module (ECM), it can be translated to, e.g., diagnostic trouble code 1-2-3 Engine temperature sensor. Volvo Diagnostic Key and Volvo System Tester translate these flash codes directly to plain text (add a title). In these diagnostic systems it is not possible to show qualifier or status.
** For systems with diagnostic version called Generic Global Diagnostics (GGD) (adheres to standard ISO/DIS 15031-6.4) the diagnostic trouble code number consists of a letter and six characters. The letter alternatives are B, C, P and N, which means Body, Chassis, Powertrain and Network and indicate to which "function" in the vehicle the diagnostic trouble code belongs. The six following characters may consist of both letters (A-F) and digits (0-9) and indicate the component to which the malfunction refers as well as what type of malfunction. See following example.
BCM-C006A16 Multi-axial acceleration sensor. General electric malfunction. Too low voltage

Status For Diagnostic Trouble Codes (DTCs)

Overview

Status for diagnostic trouble codes (DTCs)

When one or more faults occur in the component signals used by the engine control module (ECM), the control module sometimes encounters problems distinguishing the root cause of the fault. This is because certain diagnostic functions cannot be run due to physical factors. In addition there are internal causes for other diagnostic trouble codes (DTCs). Therefore, it is now possible to read the diagnostic trouble codes (DTCs) before they have been finally validated, in a prioritized order as follows.

Hint: Depending on the status and the internal connections between the diagnostic functions, the engine control module (ECM) can check the validation (differentiate between a root cause and a secondary cause) if the car is driven again. (The majority of diagnostic functions can be checked by switching the ignition on and off 2-3 times) This gives the control module time to compare all the diagnostic functions. It is possible to read the conditions for each diagnostic trouble code (DTC) and diagnostic functions in the section.

Note! Carry out fault-tracing first on the diagnostic trouble codes (DTCs) that correspond to the symptom.

Stored

(Stored)
The engine control module (ECM) has validated this as a root cause. Fault-tracing can be carried out.

NYS-VRC

(Not Yet Stored-Validated to Root Cause)
(Not Yet Stored-Validated to Root Cause)
This status may change to Stored after the next operating cycle (waits for other diagnostic trouble code(s) (DTC)).
Fault-tracing can be carried out when difficulties are experienced when dealing with this diagnostic trouble code (DTC).

NYS-NV

(Not Yet Stored-Not Validated)
(Not Yet Stored-Not Validated)
This status can change to Stored after the next operating cycle (the ignition or engine is switched off-> on).
Fault-tracing can be carried out when difficulties are experienced when dealing with this diagnostic trouble code (DTC).

Temporary

(Temporary)
Indicates if there is a fault, only in this duty cycle. (If the fault disappears, the status changes to Erased).
Carry out fault-tracing if no other diagnostic trouble codes (DTCs) correspond to the fault symptom.

Stored-VNR

(Stored-Validated to Not Root cause)
(Stored-Validated to Not Root Cause)
Fault-tracing must not be carried out.

NYS-VNR

(Not Yet Stored-Validated to Not Root cause)
(Not Yet Stored-Validated to Not Root Cause)
Fault-tracing must not be carried out.

Hint: "Not validated" indicates that the diagnostic function for the diagnostic trouble code (DTC) has still not been completed.

Erased

(Erased)
Only fault traced in cases when there is a connection to a symptom reported by the customer and no other diagnostic trouble codes (DTCs) are stored.

Note! Erased status is indicated when a fault occurs in every other operating cycle.

Conversion Table Standardized Diagnostic Trouble Codes (DTCs)/Volvo Diagnostic Trouble Codes

Conversion table standardized diagnostic trouble codes/Volvo diagnostic trouble codes

Information

Background

OBD II is a diagnostics system designed to meet statutory requirements. A standardized instrument for fault-tracing can be plugged in to the data link connector (DLC) (OBD II socket) to read diagnostic trouble codes (DTCs) and system parameters. OBD II contains only emissions related diagnostic trouble codes (DTCs) and parameters. It cannot provide the comprehensive range of information available from the Volvo On-board diagnostics system.
Volvo has its own diagnostic trouble code (DTC) designations that adhere to the in-house Volvo On-board Diagnostics protocol (called DII from model year 1999).

Table explanations

The table below is a conversion table between standardized diagnostic trouble codes (DTCs) (SAE/ISO) and the equivalent Volvo diagnostic trouble codes (DTCs) (DII).
SAE/ISO DTC: Standardized diagnostic trouble code as per SAE J2012/ISO 15031-6. The DTC can be read out from the vehicle using a standardized diagnostics system for emission-related faults certified as per OBD II. The readout is taken with a generic scantool, a fault tracing instrument standardized as per SAE J1978/ISO 15031-4.
Volvo DII DTC: Volvo-specific diagnostic trouble code as per Volvo Onboard Diagnostics protocol. Can be read out from cars from model year 1999 using VIDA.

DTC designation: Volvo DTC designation. Used in VIDA.
Fault type: Volvo's method of specifying the fault. Used in VIDA.

Note! An SAE/ISO diagnostic trouble code can correspond to several DII diagnostic trouble codes. All of these must therefore by rectified in order for the corresponding SAE/ISO diagnostic trouble code to disappear.Several SAE/ISO diagnostic trouble codes may also refer to the same DII diagnostic trouble code.There are DII diagnostic trouble codes for non emission-related malfunctions that do not correspond to any SAE/ISO diagnostic trouble code.

Table

SAE/ISO DTCs	Volvo DII DTCs	Diagnostic trouble code (DTC) designation	Fault type
P0016	ECM-670C	Camshaft position, inlet	High
P0016	ECM-670D	Camshaft position, inlet	Low
P0017	ECM-671C	Camshaft position, exhaust	High
P0017	ECM-671D	Camshaft position, exhaust	Low
P0026	ECM-6110	Camshaft control, inlet	Slow
P0026	ECM-611B	Camshaft control, inlet	Faulty
P0027	ECM-6140	Camshaft control exhaust	Slow
P0027	ECM-614B	Camshaft control exhaust	Faulty
P0030	ECM-244B	Front heated oxygen sensor, bank 1 heating	Signal missing
P0031	ECM-244D	Front heated oxygen sensor, bank 1 heating	Signal too low
P0032	ECM-244C	Front heated oxygen sensor, bank 1 heating	Signal too high
P0036	ECM-223B	Rear heated oxygen sensor, bank 1	Signal missing
P0037	ECM-223D	Rear heated oxygen sensor, bank 1	Signal too low
P0038	ECM-223C	Rear heated oxygen sensor, bank 1	Signal too high
P0040	ECM-24A0	Front heated oxygen sensors mixed up	Faulty signal
P0041	ECM-2240	Rear heated oxygen sensors, mixed up	Faulty signal
P0050	ECM-254B	Front heated oxygen sensor, bank 2 heating	Signal missing
P0051	ECM-254D	Front heated oxygen sensor, bank 2 heating	Signal too low
P0052	ECM-254C	Front heated oxygen sensor, bank 2 heating	Signal too high
P0053	ECM-2400	Front heated oxygen sensor, bank 1 heating	Faulty signal
P0053	ECM-240B	Front heated oxygen sensor, bank 1 heating	Signal missing
P0053	ECM-240C	Front heated oxygen sensor, bank 1 heating	Signal too high
P0053	ECM-240D	Front heated oxygen sensor, bank 1 heating	Signal too low
P0056	ECM-233B	Rear heated oxygen sensor, bank 2	Signal missing
P0057	ECM-233D	Rear heated oxygen sensor, bank 2	Signal too low
P0058	ECM-233C	Rear heated oxygen sensor, bank 2	Signal too high
P0059	ECM-2500	Front heated oxygen sensor, bank 2 heating	Faulty signal
P0059	ECM-250B	Front heated oxygen sensor, bank 2 heating	Signal missing
P0059	ECM-250C	Front heated oxygen sensor, bank 2 heating	Signal too high
P0059	ECM-250D	Front heated oxygen sensor, bank 2 heating	Signal too low
P0071	ECM-1410	Ambient temperature sensor	Faulty signal
P0071	ECM-141B	Ambient temperature sensor	Signal missing
P0072	ECM-140D	Ambient temperature sensor	Signal too low
P0073	ECM-140C	Ambient temperature sensor	Signal too high
P0075	ECM-612B	Intake camshaft reset valve	Signal missing
P0076	ECM-612D	Intake camshaft reset valve	Signal too low
P0077	ECM-612C	Intake camshaft reset valve	Signal too high
P0078	ECM-616B	Exhaust camshaft reset valve	Signal missing
P0079	ECM-616D	Exhaust camshaft reset valve	Signal too low
P0079	ECM-616D	Exhaust camshaft reset valve	Signal too low
P0080	ECM-616C	Exhaust camshaft reset valve	Signal too high
P0087	ECM-290D	Fuel pressure	Signal too low
P0088	ECM-290C	Fuel pressure	Signal too high

DTC Table (P Codes / ECM Codes) Part 1

P0089	ECM-2900	Fuel pressure	Faulty signal
P0090	ECM-290B	Fuel pressure	Signal missing
P0100	ECM-120C	Air mass	Signal too high
P0100	ECM-120D	Air mass	Signal too low
P0101	ECM-1210	Mass air flow sensor	Flow too high
P0101	ECM-121B	Mass air flow sensor	Flow too low
P0102	ECM-121D	Mass air flow sensor	Signal too low
P0103	ECM-121C	Mass air flow sensor	Signal too high
P0110	ECM-132D	Intake air temperature (IAT) sensor inlet	Signal too low
P0111	ECM-1320	Intake air temperature (IAT) sensor inlet	Faulty signal

U0103	ECM-7300	Gear-shift position sensor	Faulty signal
U0167	ECM-710B	Communication Immobilizer	Signal missing
U0401	ECM-A020	Configuration error	Signal missing
U0426	ECM-7100	Communication Immobilizer	Faulty signal

DTC Table (P Codes / U Codes / ECM Codes) Part 9

NOTE: If the diagnostic trouble code is not hyperlinked, then:
- Either the code may not be valid for this vehicle or year.
- Or the information published by the OEM does not include this code for this vehicle or year.

P Code Charts

Conversion Table Standardized Diagnostic Trouble Codes (DTCs)/Volvo Diagnostic Trouble Codes (DTCs)

Information

Background
OBD II is a diagnostics system designed to meet statutory requirements. A standardized instrument for fault-tracing can be plugged in to the data link connector (DLC) (OBD II socket) to read diagnostic trouble codes (DTCs) and system parameters. OBD II contains only emissions related diagnostic trouble codes (DTCs) and parameters. It cannot provide the comprehensive range of information available from the Volvo On-board diagnostics system.

Volvo has its own diagnostic trouble code (DTC) designations that adhere to the in-house Volvo On-board Diagnostics protocol (called DII from model year 1999).

Table explanations
The table below is a conversion table between standardized diagnostic trouble codes (DTCs) (SAE/ISO) and the equivalent Volvo diagnostic trouble codes (DTCs) (DII).

SAE/ISO diagnostic trouble code (DTC): Standardized diagnostic trouble code (DTC) according to SAE J2012/ISO 15031-6. The diagnostic trouble code (DTC) can be read off on vehicles with standardized on-board diagnostic systems for emissions related faults, certified in accordance with OBD II. Reading off is performed with a generic scan tool, an instrument for fault-tracing standardized in accordance with SAE J1978/ISO 15031-4.

Volvo DII diagnostic trouble code (DTC): Volvo-specific diagnostic trouble code (DTC) in accordance with the Volvo On-Board Diagnostic protocol. Can be read off using VIDA on cars from model year 1999.

Diagnostic trouble code (DTC) designation: Volvo diagnostic trouble code (DTC) designation. Used in VIDA.

Fault type: Volvo method for specifying the actual fault. Used in VIDA.

NOTE: An SAE/ISO diagnostic trouble code (DTC) can correspond to several DII diagnostic trouble codes (DTCs). All of these must therefore by rectified in order for the corresponding SAE/ISO diagnostic trouble code (DTC) to disappear.

Several SAE/ISO diagnostic trouble codes (DTCs) may also refer to the same DII diagnostic trouble code (DTC).

There are DII diagnostic trouble codes (DTCs) for non emissions-related faults that do not correspond to any SAE/ISO diagnostic trouble code (DTC).

Engine Control System

VOLVO ECM CODE LIST AND DEFINITIONS

ECM-112C Atmospheric pressure sensor. Signal too high
ECM-112D Atmospheric pressure sensor. Signal too low
ECM-1130 Atmospheric pressure sensor. Faulty signal
ECM-113B Atmospheric pressure sensor. Signal missing
ECM-113C Atmospheric pressure sensor. Signal too high
ECM-113D Atmospheric pressure sensor. Signal too low
ECM-120C Mass air flow. Signal too high
ECM-120D Mass air flow. Signal too low
ECM-1210 Mass air flow (MAF) sensor. Flow too high
ECM-121B Mass air flow (MAF) sensor. Flow too low
ECM-121C Mass air flow (MAF) sensor. Signal too high
ECM-121D Mass air flow (MAF) sensor. Signal too low
ECM-125C Boost pressure sensor. Signal too high
ECM-125D Boost pressure sensor. Signal too low
ECM-1260 Boost pressure sensor. Faulty signal
ECM-126B Boost pressure sensor. Signal missing
ECM-126C Boost pressure sensor. Signal too high
ECM-126D Boost pressure sensor. Signal too low
ECM-131C Intake air temperature (IAT) sensor. Signal too high
ECM-131D Intake air temperature (IAT) sensor. Signal too low
ECM-1320 Intake Air Temperature (IAT) Sensor. Faulty signal
ECM-132C Intake air temperature (IAT) sensor. Signal too high
ECM-132D Intake air temperature (IAT) sensor. Signal too low
ECM-140C Outside temperature sensor. Signal too high
ECM-140D Outside temperature sensor. Signal too low
ECM-1410 Outside temperature sensor. Faulty signal
ECM-141B Outside temperature sensor. Signal missing
ECM-200B Injector cyl 1. Signal missing
ECM-200C Injector cyl 1. Signal too high
ECM-200D Injector cyl 1. Signal too low
ECM-201B Injector cyl 2. Signal missing
ECM-201C Injector cyl 2. Signal too high
ECM-201D Injector cyl 2. Signal too low
ECM-202B Injector cyl 3. Signal missing
ECM-202C Injector cyl 3. Signal too high
ECM-202D Injector cyl 3. Signal too low
ECM-203B Injector cyl 4. Signal missing
ECM-203C Injector cyl 4. Signal too high
ECM-203D Injector cyl 4. Signal too low
ECM-204B Injector cyl 5. Signal missing
ECM-204C Injector cyl 5. Signal too high
ECM-204D Injector cyl 5. Signal too low
ECM-210C Long-term fuel trim, bank 1. Signal too high
ECM-210D Long-term fuel trim, bank 1. Signal too low
ECM-212C Long-term fuel trim, bank 1. Signal too high
ECM-212D Long-term fuel trim, bank 1. Signal too low
ECM-216C Long-term fuel trim, bank 1. Signal too high
ECM-216D Long-term fuel trim, bank 1. Signal too low
ECM-217C Long-term fuel trim, bank 2. Signal too high
ECM-21E0 Long-term fuel trim, bank 1. Faulty signal
ECM-21EB Long-term fuel trim, bank 1. Signal missing
ECM-21EC Long-term fuel trim, bank 1. Signal too high
ECM-21ED Long-term fuel trim, bank 1. Signal too low
ECM-2200 Rear heated oxygen sensor (HO2S), bank 1, heating. Faulty signal

ECM-221B Rear heated oxygen sensor (HO2S), aging, bank 1. Signal missing
ECM-221C Rear heated oxygen sensor (HO2S) aging, bank 1. Signal too high
ECM-221D Rear heated oxygen sensor (HO2S) aging, bank 1. Signal too low
ECM-2220 Rear heated oxygen sensor (HO2S), bank 1. Faulty signal
ECM-222B Rear heated oxygen sensor (HO2S), bank 1. Signal missing
ECM-222C Rear heated oxygen sensor (HO2S), bank 1. Signal too high
ECM-222D Rear heated oxygen sensor (HO2S), bank 1. Signal too low
ECM-223B Rear heated oxygen sensor (HO2S), bank 1. Signal missing
ECM-223C Rear heated oxygen sensor (HO2S), bank 1. Signal too high
ECM-223D Rear heated oxygen sensor (HO2S), bank 1. Signal too low
ECM-2240 Rear heated oxygen sensors (HO2S), switched. Faulty signal
ECM-2400 Front heated oxygen sensor (HO2S), bank 1, heating. Faulty signal
ECM-240B Front heated oxygen sensor (HO2S), bank 1, heating. Signal missing
ECM-240C Front heated oxygen sensor (HO2S), bank 1, heating. Signal too high
ECM-242D Front heated oxygen sensor (HO2S), bank 1. Signal missing
ECM-243B Front heated oxygen sensor (HO2S), bank 1. Signal missing
ECM-244B Front heated oxygen sensor (HO2S), bank 1, heating. Signal missing
ECM-244C Front heated oxygen sensor (HO2S), bank 1, heating. Signal too high
ECM-244D Front heated oxygen sensor (HO2S), bank 1, heating. Signal too low
ECM-2450 Front heated oxygen sensor (HO2S), bank 1. Faulty signal
ECM-245B Front heated oxygen sensor (HO2S), bank 1. Signal missing
ECM-245C Front heated oxygen sensor (HO2S), bank 1. Signal too high
ECM-245D Front heated oxygen sensor (HO2S), bank 1. Signal too low
ECM-246B Front heated oxygen sensor (HO2S), bank 1. Signal missing
ECM-2470 Front heated oxygen sensor (HO2S), bank 1. Faulty signal
ECM-247B Front heated oxygen sensor (HO2S), bank 1. Signal missing
ECM-247C Front heated oxygen sensor (HO2S), bank 1. Signal too high
ECM-248C Front heated oxygen sensor (HO2S), bank 1. Signal too high
ECM-248D Front heated oxygen sensor (HO2S), bank 1. Signal too low
ECM-249B Front heated oxygen sensor (HO2S), bank 1. Signal missing
ECM-24A0 Switched front heated oxygen sensors (HO2S). Faulty signal
ECM-24AB Front heated oxygen sensor (HO2S), bank 1. Signal missing
ECM-24B0 Front heated oxygen sensor (HO2S), bank 1. Faulty signal
ECM-24BB Front heated oxygen sensor (HO2S), bank 1. Signal missing
ECM-24BC Front heated oxygen sensor (HO2S), bank 1. Signal too high
ECM-24BD Front heated oxygen sensor (HO2S), bank 1. Signal too low
ECM-24C0 Front heated oxygen sensor (HO2S), bank 1. Faulty signal
ECM-2720 Engine coolant temperature (ECT) sensor. Faulty signal
ECM-272D Engine coolant temperature (ECT) sensor. Signal too low
ECM-273C Engine coolant temperature (ECT) sensor. Signal too high
ECM-273D Engine coolant temperature (ECT) sensor. Signal too low
ECM-274D Engine coolant temperature (ECT) sensor. Signal too low
ECM-2800 Fuel pressure sensor. Signal too low
ECM-280B Fuel pressure sensor. Signal missing
ECM-280C Fuel pressure sensor. Signal too high
ECM-280D Fuel pressure sensor. Signal too low
ECM-2900 Fuel pressure. Faulty signal
ECM-290B Fuel pressure. Signal missing
ECM-290C Fuel pressure. Signal too high
ECM-290D Fuel pressure. Signal too low
ECM-291B Fuel pump control module. Signal missing
ECM-291C Fuel pump control module. Signal too high
ECM-291D Fuel pump control module. Signal too low
ECM-2A0C Fuel temperature sensor. Signal too high
ECM-2A0D Fuel temperature sensor. Signal too low
ECM-2B00 Thermostat. Faulty signal
ECM-3000 Engine control module (ECM), internal fault. Faulty signal
ECM-3010 Engine control module (ECM), internal fault. Faulty signal
ECM-3020 Engine control module (ECM), internal fault. Faulty signal
ECM-303C Front knock sensor (KS). Signal too high
ECM-303D Front knock sensor (KS). Signal too low
ECM-304C Rear knock sensor (KS). Signal too high
ECM-304D Rear knock sensor (KS). Signal too low
ECM-3100 Misfire, at least one cylinder. Start up
ECM-310C Misfire, at least one cylinder. Catalytic converter damage
ECM-310D Misfire, at least one cylinder. Affects emissions
ECM-3110 Misfire cylinder 1. Start up
ECM-311C Misfire cylinder 1. Catalytic converter damage
ECM-311D Misfire cylinder 1. Emissions impact
ECM-3120 Misfire cylinder 2. Start up

ECM-312C Misfire cylinder 2. Catalytic converter damage
ECM-312D Misfire cylinder 2. Emissions impact
ECM-3130 Misfire cylinder 3. Start up
ECM-313C Misfire cylinder 3. Catalytic converter damage
ECM-313D Misfire cylinder 3. Emissions impact
ECM-3140 Misfire cylinder 4. Start up
ECM-314C Misfire cylinder 4. Catalytic converter damage
ECM-314D Misfire cylinder 4. Emissions impact
ECM-3150 Misfire cylinder 5. Start up
ECM-315C Misfire cylinder 5. Catalytic converter damage
ECM-315D Misfire cylinder 5. Emissions impact
ECM-330B Engine speed (RPM) sensor. Signal missing
ECM-3400 Camshaft position (CMP) sensor, intake. Faulty signal
ECM-340B Camshaft position (CMP) sensor, intake. Signal missing
ECM-340C Camshaft position sensor, intake. Signal too high
ECM-340D Camshaft position sensor, intake. Signal too low
ECM-3410 Camshaft position (CMP) sensor, exhaust. Faulty signal
ECM-341B Camshaft position (CMP) sensor, exhaust. Signal missing
ECM-341C Camshaft position sensor, exhaust. Signal too high
ECM-341D Camshaft position sensor, exhaust. Signal too low
ECM-350B Ignition coil cylinder 1, signal. Signal missing
ECM-350C Ignition coil cylinder 1, signal. Signal too high
ECM-350D Ignition coil cylinder 1, signal. Signal too low
ECM-351B Ignition coil cylinder 2, signal. Signal missing
ECM-351C Ignition coil cylinder 2, signal. Signal too high
ECM-351D Ignition coil cylinder 2, signal. Signal too low
ECM-352B Ignition coil cylinder 3, signal. Signal missing
ECM-352C Ignition coil cylinder 3, signal. Signal too high
ECM-352D Ignition coil cylinder 3, signal. Signal too low
ECM-353B Ignition coil cylinder 4, signal. Signal missing
ECM-353C Ignition coil cylinder 4, signal. Signal too high
ECM-353D Ignition coil cylinder 4, signal. Signal too low
ECM-354B Ignition coil cylinder 5, signal. Signal missing
ECM-354C Ignition coil cylinder 5, signal. Signal too high
ECM-354D Ignition coil cylinder 5, signal. Signal too low
ECM-400C Three-way catalytic converter (TWC) efficiency, bank 1. Signal too high
ECM-401C Three-way catalytic converter (TWC) efficiency, bank 2. Signal too high
ECM-420C Evaporative emission system (EVAP) valve. Open
ECM-420D Evaporative emission system (EVAP). Closed
ECM-421B Canister purge (CP) valve. Signal missing
ECM-421C Evaporative emission system (EVAP) valve. Signal too high
ECM-421D Evaporative emission system (EVAP) valve. Signal too low
ECM-430C Fuel tank system, leakage. Fuel tank filler cap missing
ECM-431B Leak diagnostic unit, preheating. Signal missing
ECM-431C Leak diagnostic unit, preheating. Signal too high
ECM-431D Leak diagnostic unit, preheating. Signal too low
ECM-432B Leak diagnostic unit, valve. Signal missing
ECM-432C Leak diagnostic unit, preheating. Signal too high
ECM-432D Leak diagnostic unit, preheating. Signal too low
ECM-433B Leak diagnostic unit, pump. Signal missing
ECM-433C Leak diagnostic unit, pump. Signal too high
ECM-433D Leak diagnostic unit, pump. Signal too low
ECM-434C Fuel tank system, leakage. Minor leak
ECM-4360 Leak diagnostic unit. Faulty signal
ECM-436B Leak diagnostic unit. Signal missing
ECM-436C Leak diagnostic unit. Signal too high
ECM-436D Leak diagnostic unit. Signal too low
ECM-4380 Fuel tank filler cap. Missing
ECM-439C Fuel tank system, leakage. Major leak
ECM-4400 Fuel level sensor. Faulty signal
ECM-440B Fuel level sensor. Signal missing
ECM-440C Fuel level sensor. Signal too high
ECM-440D Fuel level sensor. Signal too low
ECM-5000 Engine speed (RPM) sensor signal. Faulty signal
ECM-500B Engine speed (RPM) sensor signal. Signal missing
ECM-500C Engine speed (RPM) sensor signal. Signal too high
ECM-500D Engine speed (RPM) sensor signal. Signal too low
ECM-5100 Malfunction indicator lamp (MIL), TCM. Faulty signal
ECM-5110 Malfunction indicator lamp (MIL), CEM. Faulty signal
ECM-512B Malfunction indicator lamp (MIL) communication. Signal missing

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

ECM-5130 Malfunction indicator lamp (MIL), TCM. Faulty signal
ECM-513B Malfunction indicator lamp (MIL), transmission control module (TCM). Signal missing
ECM-5200 Air conditioning (A/C) pressure sensor. Faulty signal
ECM-520B Air conditioning (A/C) pressure sensor. Signal missing
ECM-520C Air conditioning (A/C) pressure sensor. Signal too high
ECM-520D Air conditioning (A/C) pressure sensor. Signal too low
ECM-5300 Vehicle speed signal. Faulty signal
ECM-530B Vehicle speed signal. Signal missing
ECM-530C Speed signal. Signal too high
ECM-530D Speed signal. Signal too low
ECM-540B Oil grade, level and temperature sensor. Faulty signal
ECM-540C Oil grade, level and temperature sensor. Signal too high
ECM-540D Oil grade, level and temperature sensor. Signal too low
ECM-5500 Oil level. Faulty signal
ECM-550D Oil level. Signal too low
ECM-600B Turbocharger (TC) control valve. Signal missing. Intermittent fault
ECM-600B Turbocharger (TC) control valve. Signal missing. Permanent fault
ECM-600C Turbocharger (TC) control valve. Signal too high. Intermittent fault
ECM-600C Turbocharger (TC) control valve. Signal too high. Permanent fault
ECM-600D Turbocharger (TC) control valve. Signal too low. Intermittent fault
ECM-600D Turbocharger (TC) control valve. Signal too low. Permanent fault
ECM-601C Turbocharger (TC) control system, boost pressure fault. Signal too high
ECM-602D Turbocharger (TC) control system, flow fault. Signal too low
ECM-6110 Camshaft position control, intake. Slow
ECM-611B Camshaft control, intake. Faulty
ECM-612B Camshaft reset valve, intake. Signal missing
ECM-612C Camshaft reset valve, intake. Signal too high
ECM-612D Camshaft reset valve, intake. Signal too low
ECM-6140 Camshaft control, exhaust. Slow
ECM-614B Camshaft control, exhaust. Faulty
ECM-616B Camshaft reset valve, exhaust. Signal missing
ECM-616C Camshaft reset valve, exhaust. Signal too high
ECM-616D Camshaft reset valve, exhaust. Signal too low
ECM-6200 Engine cooling fan (FC) control module. Faulty signal
ECM-620B Engine cooling fan control module. Signal too low
ECM-620C Engine cooling fan (FC) control module. Signal too high
ECM-620D Engine cooling fan (FC) control module. Signal too low
ECM-630B A/C relay. Signal missing. Intermittent fault
ECM-630B A/C relay. Signal missing. Permanent fault
ECM-630C A/C relay. Signal too high. Intermittent fault
ECM-630C A/C relay. Signal too high. Permanent fault
ECM-630D A/C relay. Signal too low. Intermittent fault
ECM-630D A/C relay. Signal too low. Permanent fault
ECM-640C Turbocharger (TC) control system. Signal too high
ECM-640D Turbocharger (TC) control system. Signal too low
ECM-650B Engine cooling fan (FC). Signal missing
ECM-650C Engine cooling fan (FC). Signal too high
ECM-650D Engine cooling fan (FC). Signal too low
ECM-660B Malfunction indicator lamp (MIL). Signal missing
ECM-660C Malfunction indicator lamp (MIL). Signal too high
ECM-660D Malfunction indicator lamp (MIL). Signal too low
ECM-670C Camshaft position, intake. High
ECM-670D Camshaft position, intake. Low
ECM-671C Camshaft position, exhaust. High
ECM-671D Camshaft position, exhaust. Low
ECM-680B Engine cooling fan (FC) control modules. Signal missing
ECM-680C Engine cooling fan (FC) control modules. Signal too high
ECM-680D Engine cooling fan (FC) control modules. Signal too low
ECM-700C Engine control module (ECM), internal fault. Signal too high
ECM-700D Engine control module (ECM), internal fault. Signal too low
ECM-7010 Engine control module (ECM), high temperature. Faulty signal
ECM-7020 Engine control module (ECM), high temperature. Faulty signal
ECM-7100 Immobilizer communication. Faulty signal
ECM-710B Immobilizer communication. Signal missing
ECM-720B Engine control module (ECM) internal fault. Signal missing
ECM-7300 Gear position sensor. Faulty signal
ECM-800B System relay. Signal too low
ECM-810C 5 volt power supply. Signal too high
ECM-810D 5 volt power supply. Signal too low
ECM-8200 Battery voltage. Faulty signal

ECM-820C Battery voltage. Signal too high
ECM-820D Battery voltage. Signal too low
ECM-8210 System relay. Faulty signal
ECM-821B System relay. Signal missing
ECM-9000 Brake pedal sensor. Faulty signal
ECM-900B Brake pedal sensor. Signal missing
ECM-900C Brake pedal sensor. Signal too high
ECM-9100 Clutch pedal position sensor. Faulty signal
ECM-910B Clutch pedal sensor. Signal missing
ECM-910C Clutch pedal sensor. Signal too high
ECM-910D Clutch pedal sensor. Signal too low
ECM-9200 Throttle position (TP) sensor. Faulty signal
ECM-9210 Electronic throttle unit, potentiometer 1. Faulty signal
ECM-921C Electronic throttle unit, potentiometer 1. Signal too high
ECM-921D Electronic throttle unit, potentiometer 1. Signal too low
ECM-9220 Electronic throttle unit, potentiometer 2. Faulty signal
ECM-922C Electronic throttle unit, potentiometer 2. Signal too high
ECM-922D Electronic throttle unit, potentiometer 2. Signal too low
ECM-9240 Engine control module (ECM). Faulty signal
ECM-925C Electronic throttle unit. Signal too high
ECM-925D Electronic throttle unit. Signal too low
ECM-926C Electronic throttle unit. Signal too high
ECM-926D Electronic throttle unit. Signal too low
ECM-9270 Throttle unit. Faulty signal
ECM-9280 Throttle unit. Faulty signal
ECM-9290 Engine control module (ECM). Faulty signal
ECM-929C Engine control module (ECM). Signal too high
ECM-929D Engine control module (ECM). Signal too low
ECM-92B0 Electronic throttle unit. Faulty signal
ECM-92CC Electronic throttle unit. Signal too high
ECM-92CD Electronic throttle unit. Signal too low
ECM-92D0 Electronic throttle unit. Faulty signal
ECM-92E0 Engine control module (ECM). Internal fault
ECM-9300 Control module communication problems. Faulty signal
ECM-930B Control module communication problems. Signal missing
ECM-930C Control module, communication problems. Signal too high
ECM-930D Control module communication problems. Signal too low
ECM-9400 Accelerator pedal (AP) position sensor, analog signal. Faulty signal
ECM-940C Accelerator pedal (AP) position sensor, analog signal. Signal too high
ECM-940D Accelerator pedal (AP) position sensor, analog signal. Signal too low
ECM-941C Accelerator pedal (AP) position sensor, digital signal. Signal too high
ECM-941D Accelerator pedal (AP) position sensor, digital signal. Signal too low
ECM-951C Engine control module (ECM), idle air trim. Signal too high
ECM-951D Engine control module (ECM), idle air trim. Signal too low
ECM-960C Engine control module (ECM), torque signal. Internal fault
ECM-9700 Accelerator pedal (AP) position sensor, digital signal. Faulty signal
ECM-970B Accelerator pedal (AP) position sensor, digital signal. Signal missing
ECM-9800 Engine control module (ECM), torque signal. Internal fault
ECM-9810 Engine control module (ECM), engine speed (RPM). Internal fault
ECM-9820 Engine control module (ECM), load signal. Internal fault
ECM-983B Engine control module (ECM). Internal fault
ECM-983C Engine control module (ECM). Internal fault
ECM-983D Engine control module (ECM). Internal fault
ECM-9840 Engine control module (ECM). Internal fault
ECM-984B Engine control module (ECM). Internal fault
ECM-9850 Engine control module (ECM). Internal fault
ECM-9860 Engine control module (ECM). Internal fault
ECM-9970 Memory fault in RAM. Faulty signal
ECM-9980 Memory fault in ROM. Faulty signal
ECM-9990 Engine control module (ECM). Faulty signal
ECM-A12B Speed signal. Signal missing
ECM-A12C Speed signal. Signal too high
ECM-A130 Control module communication
ECM-E000 Control module communication. Internal fault
ECM-E003 Configuration fault. Faulty signal
ECM-XXXX Unknown diagnostic trouble code (DTC) for the current control module version

Brake Control Module (BCM)

BCM CODE CHARTS

BCM-0010 Left front wheel sensor. Signal missing
BCM-0011 Left front wheel sensor. Faulty signal

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

BCM-0012 Left front wheel sensor. Faulty signal
BCM-0020 Right front wheel sensor. Signal missing
BCM-0021 Right front wheel sensor. Faulty signal
BCM-0022 Right front wheel sensor. Faulty signal
BCM-0030 Left rear wheel sensor. Signal missing
BCM-0031 Left rear wheel sensor. Faulty signal
BCM-0032 Left rear wheel sensor. Faulty signal
BCM-0040 Right rear wheel sensor. Signal missing
BCM-0041 Right rear wheel sensor. Faulty signal
BCM-0042 Right rear wheel sensor. Faulty signal
BCM-0050 Control module. Faulty signal
BCM-0052 Control module. Internal fault
BCM-0057 Power supply. Voltage too low
BCM-0058 Power supply. Voltage too high
BCM-0061 Brake discs. Temperature too high
BCM-0065 Stop lamp switch. Faulty signal
BCM-0068 Sensor power supply. Faulty signal
BCM-0070 Power supply for the pump motor. Faulty signal
BCM-0071 Pump motor. Signal missing
BCM-0072 Pump motor. Mechanical fault
BCM-0074 Hydraulic valves. Faulty signal
BCM-0076 Control module. Faulty configuration
BCM-0080 Lateral accelerometer. Incorrect offset value
BCM-0081 Accelerometer. Incorrect offset value
BCM-0082 Yaw rate sensor. Incorrect offset value
BCM-0083 Angle of lean sensor. Incorrect offset value
BCM-0090 Lateral accelerometer. Faulty signal
BCM-0091 Accelerometer. Faulty signal
BCM-0092 Yaw rate sensor. Faulty signal
BCM-0093 Angle of lean sensor. Faulty signal
BCM-0094 Communication between control modules. Communication problems with Active on Demand Coupling
BCM-0095 Communication between control modules. Communication problems with Active on Demand Coupling
BCM-0097 Communication between control modules. Communication problems with the central electronic module (CEM)
BCM-0100 Communication between control modules. Communication problems with the engine control module (ECM)
BCM-0101 Communication between control modules. Communication problems with the engine control module (ECM)
BCM-0103 Pedal position sensor. Faulty signal
BCM-0106 Steering wheel or wheel alignment. Incorrect steering wheel or wheel alignment
BCM-0108 Communication between control modules. Communication with the steering angle sensor. Control module not initiated
BCM-0109 Communication between control modules. Communication with the steering angle sensor. Internal fault
BCM-0111 Communication between control modules. Check of the steering angle sensor tolerances has not been run
BCM-0112 Active yaw control sensor. Sensor not calibrated
BCM-0113 Back-up (reversing) signal. Signal missing
BCM-0114 Communication with the active yaw control sensor. Signal missing
BCM-0115 Communication between control modules. Communication with the steering angle sensor. Signal missing
BCM-0116 Communication with the active yaw control sensor. Communication problems
BCM-0117 Communication with the active yaw control sensor. An incorrect active yaw control sensor had been installed
BCM-0118 Power supply for the active yaw control sensor. Voltage too high
BCM-0119 Power supply for the active yaw control sensor. Voltage too low
BCM-0121 Yaw rate sensor. Signal outside its permitted range
BCM-0123 Active yaw control sensor. Internal fault
BCM-0125 Lateral accelerometer. Signal outside its permitted range
BCM-0127 Angle of lean sensor. Signal outside its permitted range
BCM-0129 Accelerometer. Signal outside its permitted range
BCM-0130 Brake pressure sensor 1. Signal too low
BCM-0133 Brake pressure sensor 2. Signal too low
BCM-0136 Brake pressure sensor 1 and 2. Signal outside its permitted range
BCM-0138 Power supply for the active yaw control sensor. Faulty voltage
BCM-0139 Pressure build-up valve, power brake booster. Signal outside its permitted range
BCM-0140 Pedal pressure sensor. Signal outside its permitted range
BCM-0145 Stability control. Too long stability control
BCM-0146 Factory test, dynamic stability and traction control (DSTC). Test cycle not approved
BCM-0147 Pedal position sensor. Signal outside its permitted range
BCM-0148 Communication between control modules. Faulty configuration ID
BCM-0150 Stop lamp switch. Signal outside its permitted range
BCM-0151 Control module. Internal memory fault
BCM-A030 Communication between control modules. Steering angle sensor. Initialization check not run
BCM-A031 Communication between control modules. Steering angle sensor. Tolerance check not run
BCM-A032 Stability function. Too long stability control
BCM-E000 Control module communication. Faulty communication
BCM-E003 Configuration fault. Faulty configuration

BCM-XXXX Unknown diagnostic trouble code (DTC) for the current control module version

Differential Electronic Module (DEM)

VOLVO DEM CODE LIST AND DEFINITIONS

DEM 0006 Feed pump. Faulty signal
DEM 000B Oil pressure. Incorrect value
DEM-0001 Temperature sensor. Faulty signal
DEM-0002 Pressure sensor. Faulty signal
DEM-0003 System voltage. Faulty voltage
DEM-0005 Control valve. Internal fault
DEM-0007 Hydraulic pressure. Incorrect value
DEM-0008 Control module, calibration fault. Internal fault
DEM-0009 Control module Analog/Digital converter. Internal fault
DEM-000A Power supply. Faulty voltage

TCM-0091 Shift lock solenoid. Signal missing
TCM-0092 Shift lock solenoid. Signal too low
TCM-0093 Gear selector lever control module communication. Signal too high
TCM-0094 Gear selector lever control module communication. Signal missing
TCM-0095 Gear selector lever control module communication Signal too low
TCM-0096 Quickshift sensor. Faulty signal
TCM-0097 Faulty software
TCM-0098 Faulty software
TCM-0099 Control module. Internal fault
TCM-009A Battery voltage. Signal too low
TCM-0100 Poor gear shifting quality
TCM-0101 Shift solenoid S3. Signal too high
TCM-0102 Shift solenoid S3. Signal missing
TCM-0103 Shift solenoid S3. Signal too low
TCM-0107 Shift solenoid S4. Signal too high
TCM-0108 Shift solenoid S4. Signal missing
TCM-0109 Shift solenoid S4. Signal too low

TCM-010A Shift solenoid S5. Signal too high
TCM-010B Shift solenoid S5. Signal missing
TCM-010C Shift solenoid S5. Signal too low
TCM-010D Lock-up solenoid SLU. Signal too high. Intermittent
TCM-010D Lock-up solenoid SLU. Signal too high. Permanent fault
TCM-010F Lock-up solenoid SLU. Signal missing. Intermittent fault
TCM-010F Lock-up solenoid SLU. Signal missing. Permanent fault
TCM-0110 Lock-up solenoid SLU. Signal too low. Intermittent fault
TCM-0110 Lock-up solenoid SLU. Signal too low. Permanent fault
TCM-0112 Line pressure solenoid SLS. Signal too high. Intermittent fault
TCM-0112 Line pressure solenoid SLS. Signal too high. Permanent fault
TCM-0113 Line pressure solenoid SLS. Signal missing. Intermittent fault
TCM-0113 Line pressure solenoid SLS. Signal missing. Permanent fault
TCM-0114 Line pressure solenoid SLS. Signal too low. Intermittent fault
TCM-0114 Line pressure solenoid SLS. Signal too low. Permanent fault
TCM-0115 Shift solenoid S3. Hydraulic fault
TCM-0116 Throttle solenoid SLT. Signal too high. Intermittent fault
TCM-0116 Throttle solenoid SLT. Signal too high. Permanent fault
TCM-0117 Throttle solenoid SLT. Signal missing. Intermittent fault
TCM-0117 Throttle solenoid SLT. Signal missing. Permanent fault
TCM-0118 Throttle solenoid SLT. Signal too low. Intermittent fault
TCM-0118 Throttle solenoid SLT. Signal too low. Permanent fault
TCM-0120 Control unit. Internal fault
TCM-0121 Control unit. Internal fault
TCM-0122 Control unit. Internal fault
TCM-0123 Control unit. Internal fault
TCM-0124 Control unit. Internal fault
TCM-012A Neutral check Faulty connection
TCM-012B Neutral check No neutral check
TCM-012C Neutral check. The engine speed (RPM) oscillates
TCM-E000 Control module communication. Faulty communication
TCM-E003 Configuration fault. Faulty configuration
TCM-XXXX Unknown diagnostic trouble code (DTC) for the current control module version

All Other P Codes

For diagnosis of all P codes - See: Diagnostic Trouble Code Tests and Associated Procedures/P Code Charts

Conversion Table Standardized Diagnostic Trouble Codes (DTCs)/Volvo Diagnostic Trouble Codes

Conversion table standardized diagnostic trouble codes/Volvo diagnostic trouble codes

Information

Background

OBD II is a diagnostics system designed to meet statutory requirements. A standardized instrument for fault-tracing can be plugged in to the data link connector (DLC) (OBD II socket) to read diagnostic trouble codes (DTCs) and system parameters. OBD II contains only emissions related diagnostic trouble codes (DTCs) and parameters. It cannot provide the comprehensive range of information available from the Volvo On-board diagnostics system.
Volvo has its own diagnostic trouble code (DTC) designations that adhere to the in-house Volvo On-board Diagnostics protocol (called DII from model year 1999).

Table explanations

The table below is a conversion table between standardized diagnostic trouble codes (DTCs) (SAE/ISO) and the equivalent Volvo diagnostic trouble codes (DTCs) (DII).
SAE/ISO DTC: Standardized diagnostic trouble code as per SAE J2012/ISO 15031-6. The DTC can be read out from the vehicle using a standardized diagnostics system for emission-related faults certified as per OBD II. The readout is taken with a generic scantool, a fault tracing instrument standardized as per SAE J1978/ISO 15031-4.
Volvo DII DTC: Volvo-specific diagnostic trouble code as per Volvo Onboard Diagnostics protocol. Can be read out from cars from model year 1999 using VIDA.

DTC designation: Volvo DTC designation. Used in VIDA.
Fault type: Volvo's method of specifying the fault. Used in VIDA.

Note! An SAE/ISO diagnostic trouble code can correspond to several DII diagnostic trouble codes. All of these must therefore by rectified in order for the corresponding SAE/ISO diagnostic trouble code to disappear.Several SAE/ISO diagnostic trouble codes may also refer to the same DII diagnostic trouble code.There are DII diagnostic trouble codes for non emission-related malfunctions that do not correspond to any SAE/ISO diagnostic trouble code.

Table

SAE/ISO DTCs	Volvo DII DTCs	Diagnostic trouble code (DTC) designation	Fault type
P0016	ECM-670C	Camshaft position, inlet	High
P0016	ECM-670D	Camshaft position, inlet	Low
P0017	ECM-671C	Camshaft position, exhaust	High
P0017	ECM-671D	Camshaft position, exhaust	Low
P0026	ECM-6110	Camshaft control, inlet	Slow
P0026	ECM-611B	Camshaft control, inlet	Faulty
P0027	ECM-6140	Camshaft control exhaust	Slow
P0027	ECM-614B	Camshaft control exhaust	Faulty
P0030	ECM-244B	Front heated oxygen sensor, bank 1 heating	Signal missing
P0031	ECM-244D	Front heated oxygen sensor, bank 1 heating	Signal too low
P0032	ECM-244C	Front heated oxygen sensor, bank 1 heating	Signal too high
P0036	ECM-223B	Rear heated oxygen sensor, bank 1	Signal missing
P0037	ECM-223D	Rear heated oxygen sensor, bank 1	Signal too low
P0038	ECM-223C	Rear heated oxygen sensor, bank 1	Signal too high
P0040	ECM-24A0	Front heated oxygen sensors mixed up	Faulty signal
P0041	ECM-2240	Rear heated oxygen sensors, mixed up	Faulty signal
P0050	ECM-254B	Front heated oxygen sensor, bank 2 heating	Signal missing
P0051	ECM-254D	Front heated oxygen sensor, bank 2 heating	Signal too low
P0052	ECM-254C	Front heated oxygen sensor, bank 2 heating	Signal too high
P0053	ECM-2400	Front heated oxygen sensor, bank 1 heating	Faulty signal
P0053	ECM-240B	Front heated oxygen sensor, bank 1 heating	Signal missing
P0053	ECM-240C	Front heated oxygen sensor, bank 1 heating	Signal too high
P0053	ECM-240D	Front heated oxygen sensor, bank 1 heating	Signal too low
P0056	ECM-233B	Rear heated oxygen sensor, bank 2	Signal missing
P0057	ECM-233D	Rear heated oxygen sensor, bank 2	Signal too low
P0058	ECM-233C	Rear heated oxygen sensor, bank 2	Signal too high
P0059	ECM-2500	Front heated oxygen sensor, bank 2 heating	Faulty signal
P0059	ECM-250B	Front heated oxygen sensor, bank 2 heating	Signal missing
P0059	ECM-250C	Front heated oxygen sensor, bank 2 heating	Signal too high
P0059	ECM-250D	Front heated oxygen sensor, bank 2 heating	Signal too low
P0071	ECM-1410	Ambient temperature sensor	Faulty signal
P0071	ECM-141B	Ambient temperature sensor	Signal missing
P0072	ECM-140D	Ambient temperature sensor	Signal too low
P0073	ECM-140C	Ambient temperature sensor	Signal too high
P0075	ECM-612B	Intake camshaft reset valve	Signal missing
P0076	ECM-612D	Intake camshaft reset valve	Signal too low
P0077	ECM-612C	Intake camshaft reset valve	Signal too high
P0078	ECM-616B	Exhaust camshaft reset valve	Signal missing
P0079	ECM-616D	Exhaust camshaft reset valve	Signal too low
P0079	ECM-616D	Exhaust camshaft reset valve	Signal too low
P0080	ECM-616C	Exhaust camshaft reset valve	Signal too high
P0087	ECM-290D	Fuel pressure	Signal too low
P0088	ECM-290C	Fuel pressure	Signal too high

DTC Table (P Codes / ECM Codes) Part 1

P0089	ECM-2900	Fuel pressure	Faulty signal
P0090	ECM-290B	Fuel pressure	Signal missing
P0100	ECM-120C	Air mass	Signal too high
P0100	ECM-120D	Air mass	Signal too low
P0101	ECM-1210	Mass air flow sensor	Flow too high
P0101	ECM-121B	Mass air flow sensor	Flow too low
P0102	ECM-121D	Mass air flow sensor	Signal too low
P0103	ECM-121C	Mass air flow sensor	Signal too high
P0110	ECM-132D	Intake air temperature (IAT) sensor inlet	Signal too low
P0111	ECM-1320	Intake air temperature (IAT) sensor inlet	Faulty signal
P0111	ECM-132C	Intake air temperature (IAT) sensor inlet	Signal too high
P0112	ECM-131C	Intake air temperature (IAT) sensor inlet	Signal too high
P0113	ECM-131D	Intake air temperature (IAT) sensor inlet	Signal too low
P0117	ECM-273C	Engine coolant temperature (ECT) sensor	Signal too high
P0118	ECM-273D	Engine coolant temperature (ECT) sensor	Signal too low
P0121	ECM-9210	Electronic throttle unit, potentiometer 1	Faulty signal
P0122	ECM-921D	Electronic throttle unit, potentiometer 1	Signal too low
P0123	ECM-921C	Electronic throttle unit, potentiometer 1	Signal too high
P0125	ECM-270B	Engine coolant temperature (ECT) sensor	Signal missing
P0128	ECM-2B00	Thermostat	Faulty signal
P0131	ECM-248D	Front heated oxygen sensor, bank 1	Signal too low
P0132	ECM-248C	Front heated oxygen sensor, bank 1	Signal too high
P0133	ECM-242D	Front heated oxygen sensor, bank 1	Signal missing
P0136	ECM-222B	Rear heated oxygen sensor, bank 1	Signal missing
P0137	ECM-222D	Rear heated oxygen sensor, bank 1	Signal too low
P0138	ECM-222C	Rear heated oxygen sensor, bank 1	Signal too high
P0140	ECM-221B	Rear heated oxygen sensor aging, bank 1	Signal missing
P0140	ECM-221C	Rear heated oxygen sensor aging, bank 1	Signal too high
P0140	ECM-221D	Rear heated oxygen sensor aging, bank 1	Signal too low
P0141	ECM-2200	Rear heated oxygen sensor bank 1, heating	Faulty signal
P0151	ECM-258D	Front heated oxygen sensor, bank 2	Signal too low
P0152	ECM-258C	Front heated oxygen sensor, bank 2	Signal too high
P0153	ECM-252D	Front heated oxygen sensor, bank 2	Signal missing
P0156	ECM-232B	Rear heated oxygen sensor, bank 2	Signal missing
P0157	ECM-232D	Rear heated oxygen sensor, bank 2	Signal too low
P0158	ECM-232C	Rear heated oxygen sensor, bank 2	Signal too high
P0160	ECM-231B	Rear heated oxygen sensor aging, bank 2	Signal missing
P0160	ECM-231C	Rear heated oxygen sensor aging, bank 2	Signal too high
P0160	ECM-231D	Rear heated oxygen sensor aging, bank 2	Signal too low
P0161	ECM-2300	Rear heated oxygen sensor bank 2, heating	Faulty signal
P0182	ECM-2A0D	Fuel temperature sensor	Signal too low
P0183	ECM-2A0C	Fuel temperature sensor	Signal too high
P0190	ECM-280B	Fuel pressure sensor	Signal too high
P0191	ECM-2800	Fuel pressure sensor	Signal too low

DTC Table (P Codes / ECM Codes) Part 2

P0192	ECM-280D	Fuel pressure sensor	Signal too low

U0426	ECM-7100	Communication Immobilizer	Faulty signal

DTC Table (P Codes / U Codes / ECM Codes) Part 9

NOTE: If the diagnostic trouble code is not hyperlinked, then:
- Either the code may not be valid for this vehicle or year.
- Or the information published by the OEM does not include this code for this vehicle or year.

DTC Conversion Table Notes

Conversion Table Standardized Diagnostic Trouble Codes (DTCs)/Volvo Diagnostic Trouble Codes (DTCs)

Information

Background
OBD II is a diagnostics system designed to meet statutory requirements. A standardized instrument for fault-tracing can be plugged in to the data link connector (DLC) (OBD II socket) to read diagnostic trouble codes (DTCs) and system parameters. OBD II contains only emissions related diagnostic trouble codes (DTCs) and parameters. It cannot provide the comprehensive range of information available from the Volvo On-board diagnostics system.

Volvo has its own diagnostic trouble code (DTC) designations that adhere to the in-house Volvo On-board Diagnostics protocol (called DII from model year 1999).

Table explanations
The table below is a conversion table between standardized diagnostic trouble codes (DTCs) (SAE/ISO) and the equivalent Volvo diagnostic trouble codes (DTCs) (DII).

SAE/ISO diagnostic trouble code (DTC): Standardized diagnostic trouble code (DTC) according to SAE J2012/ISO 15031-6. The diagnostic trouble code (DTC) can be read off on vehicles with standardized on-board diagnostic systems for emissions related faults, certified in accordance with OBD II. Reading off is performed with a generic scan tool, an instrument for fault-tracing standardized in accordance with SAE J1978/ISO 15031-4.

Volvo DII diagnostic trouble code (DTC): Volvo-specific diagnostic trouble code (DTC) in accordance with the Volvo On-Board Diagnostic protocol. Can be read off using VIDA on cars from model year 1999.

Diagnostic trouble code (DTC) designation: Volvo diagnostic trouble code (DTC) designation. Used in VIDA.

Fault type: Volvo method for specifying the actual fault. Used in VIDA.

NOTE: An SAE/ISO diagnostic trouble code (DTC) can correspond to several DII diagnostic trouble codes (DTCs). All of these must therefore by rectified in order for the corresponding SAE/ISO diagnostic trouble code (DTC) to disappear.

Several SAE/ISO diagnostic trouble codes (DTCs) may also refer to the same DII diagnostic trouble code (DTC).

There are DII diagnostic trouble codes (DTCs) for non emissions-related faults that do not correspond to any SAE/ISO diagnostic trouble code (DTC).

U Code Charts

Conversion table standardized diagnostic trouble codes/Volvo diagnostic trouble codes

Information

Background

OBD II is a diagnostics system designed to meet statutory requirements. A standardized instrument for fault-tracing can be plugged in to the data link connector (DLC) (OBD II socket) to read diagnostic trouble codes (DTCs) and system parameters. OBD II contains only emissions related diagnostic trouble codes (DTCs) and parameters. It cannot provide the comprehensive range of information available from the Volvo On-board diagnostics system.
Volvo has its own diagnostic trouble code (DTC) designations that adhere to the in-house Volvo On-board Diagnostics protocol (called DII from model year 1999).

Table explanations

The table below is a conversion table between standardized diagnostic trouble codes (DTCs) (SAE/ISO) and the equivalent Volvo diagnostic trouble codes (DTCs) (DII).
SAE/ISO DTC: Standardized diagnostic trouble code as per SAE J2012/ISO 15031-6. The DTC can be read out from the vehicle using a standardized diagnostics system for emission-related faults certified as per OBD II. The readout is taken with a generic scantool, a fault tracing instrument standardized as per SAE J1978/ISO 15031-4.
Volvo DII DTC: Volvo-specific diagnostic trouble code as per Volvo Onboard Diagnostics protocol. Can be read out from cars from model year 1999 using VIDA.

DTC designation: Volvo DTC designation. Used in VIDA.
Fault type: Volvo's method of specifying the fault. Used in VIDA.

Note! An SAE/ISO diagnostic trouble code can correspond to several DII diagnostic trouble codes. All of these must therefore by rectified in order for the corresponding SAE/ISO diagnostic trouble code to disappear.Several SAE/ISO diagnostic trouble codes may also refer to the same DII diagnostic trouble code.There are DII diagnostic trouble codes for non emission-related malfunctions that do not correspond to any SAE/ISO diagnostic trouble code.

Table

SAE/ISO DTCs	Volvo DII DTCs	Diagnostic trouble code (DTC) designation	Fault type
P0016	ECM-670C	Camshaft position, inlet	High
P0016	ECM-670D	Camshaft position, inlet	Low
P0017	ECM-671C	Camshaft position, exhaust	High
P0017	ECM-671D	Camshaft position, exhaust	Low
P0026	ECM-6110	Camshaft control, inlet	Slow
P0026	ECM-611B	Camshaft control, inlet	Faulty
P0027	ECM-6140	Camshaft control exhaust	Slow
P0027	ECM-614B	Camshaft control exhaust	Faulty
P0030	ECM-244B	Front heated oxygen sensor, bank 1 heating	Signal missing
P0031	ECM-244D	Front heated oxygen sensor, bank 1 heating	Signal too low
P0032	ECM-244C	Front heated oxygen sensor, bank 1 heating	Signal too high
P0036	ECM-223B	Rear heated oxygen sensor, bank 1	Signal missing

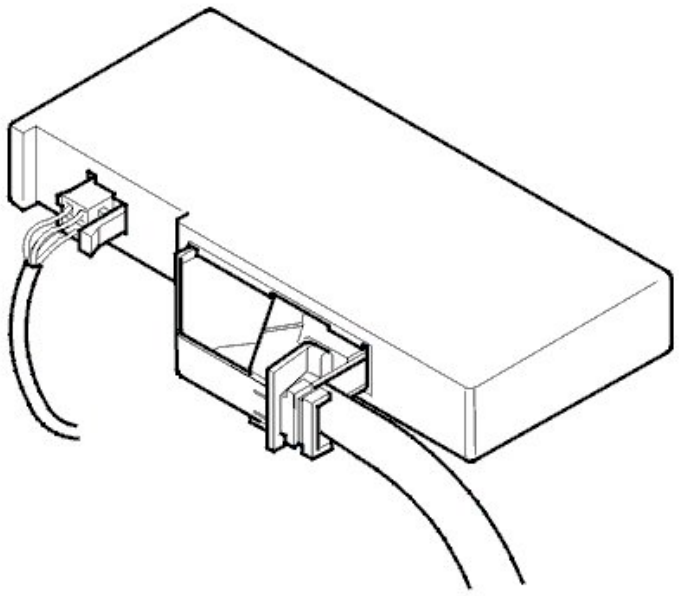
DTC Table (P Codes / U Codes / ECM Codes) Part 9

NOTE: If the diagnostic trouble code is not hyperlinked, then:
- Either the code may not be valid for this vehicle or year.
- Or the information published by the OEM does not include this code for this vehicle or year.

AEM-E001

Diagnostic trouble code (DTC) information AEM-E001

Condition



The control modules transmit and receive information via a standardized serial communication method - CAN (Control Area Network). The diagnostic trouble code (DTC) is stored if the control module registers serious interference (CAN communication blocked).

Note! In the event of system communication problems, it is not possible to communicate with the control module. Therefore it will only be possible to read off the fault if it is intermittent.

Substitute value

- The control module shuts itself off ("bus-off").

  Hint: The control module will remain shut off until the power supply is broken (15, 30, X). When the power supply is connected the control module will make a new attempt to communicate.

Possible source

- Short-circuit between the control area network (CAN) wiring
- Open-circuit in the control area network (CAN) wiring
- Internal fault in the control module
- Internal fault in another control module in the same part of the control area network (CAN).

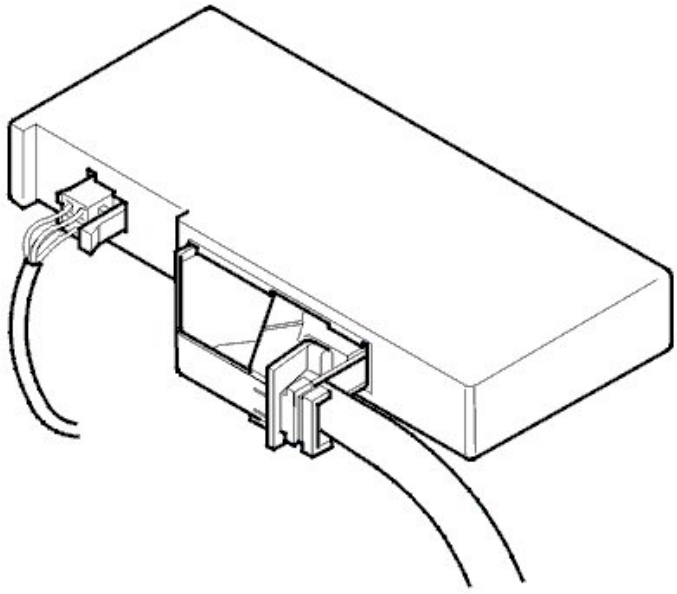
Fault symptom[s]

- Accessories connected to the control module do not function.

AEM-E003

Diagnostic trouble code (DTC) information AEM-E003

Condition



The control module compares its configuration ID with the signal configuration transmitted on the control area network (CAN) by the central electronic module (CEM). If the configuration IDs do not correspond the fault code is stored. The diagnostic trouble code (DTC) is also stored if the communication between the control module and the central electronic module (CEM) is interrupted.

Note! In the event of an open-circuit in both the control area network (CAN) cables, it is not possible to communicate with the control module. Therefore it will only be possible to read off the diagnostic trouble code (DTC) if this type of fault is intermittent. When the diagnostic trouble code (DTC) is stored, the control module responds to the diagnostic command, however normal control area network (CAN) communication does not work. ("Expulsion mode")

Substitute value
- None.

Possible source
- Faulty control area network (CAN) configuration ID. (The node is not intended for this car, for example a used control module with different software/hardware.)
- Open-circuit in the control area network (CAN) wiring between the control module and the central electrical module (CEM).

Fault symptom[s]
- Accessories connected to the control module do not function.

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition

Diagnostic trouble code (DTC) AEM-1A01 is stored if the control module registers that the power supply to the auxiliary electronic module differs by more than two volts from the power supply to the central electronic module.
The diagnostic trouble code (DTC) can be diagnosed when the ignition is on.

Substitute value
- None.

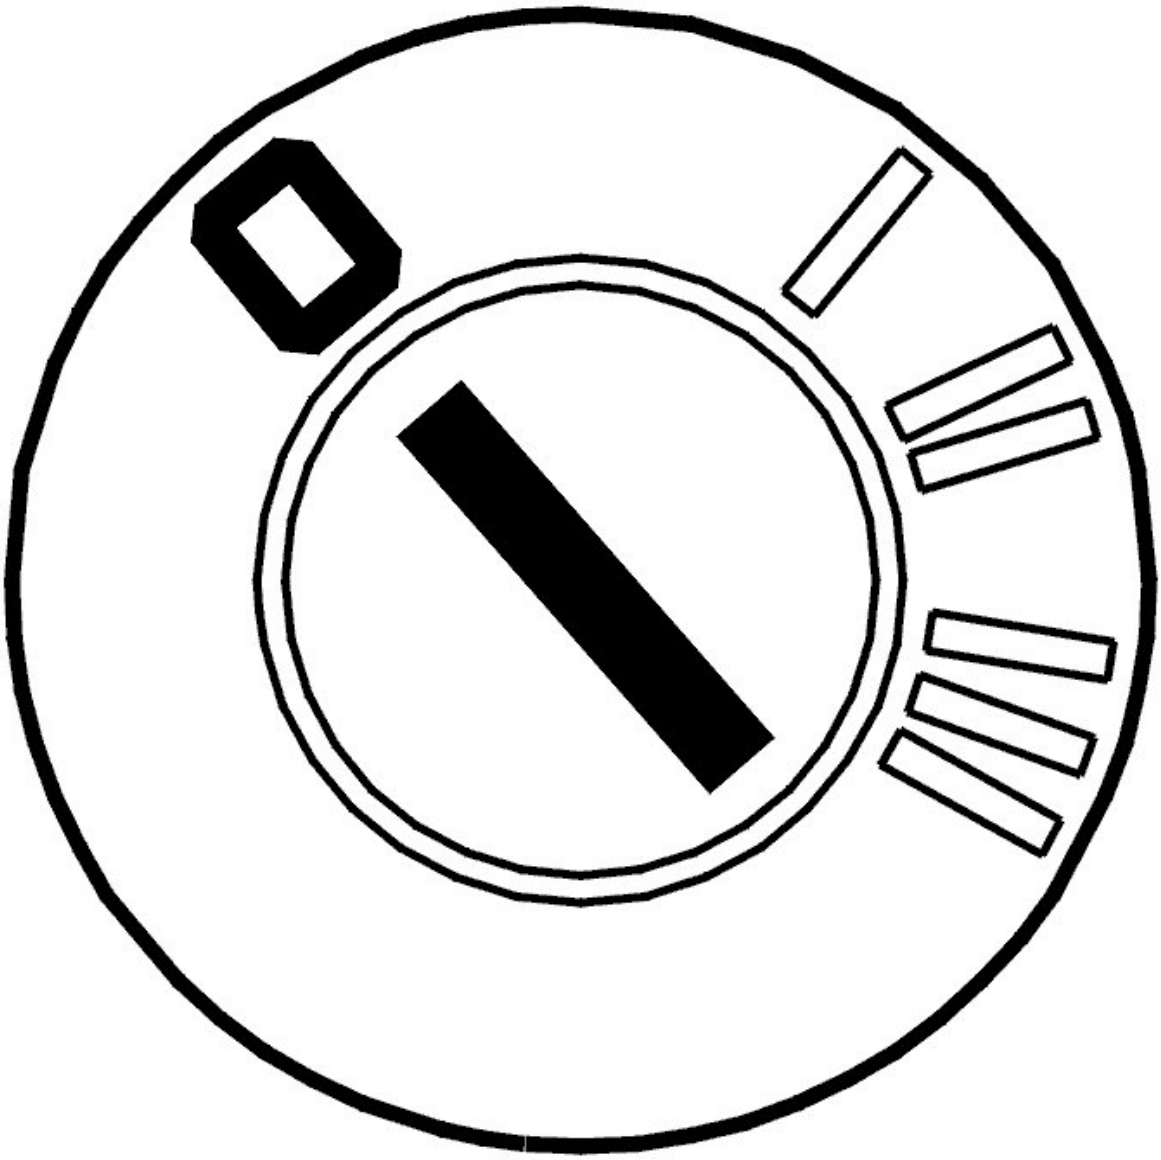
Possible source
- Open-circuit or short-circuit to ground in the 30-supply to the accessory electronic module
- Contact resistance, oxidation or loose connections in the 30-supply to the accessory electronic module.

Fault symptom[s]
- Accessories connected to the control module do not function.

Signal Too Low

Signal too low

Checking the power supply



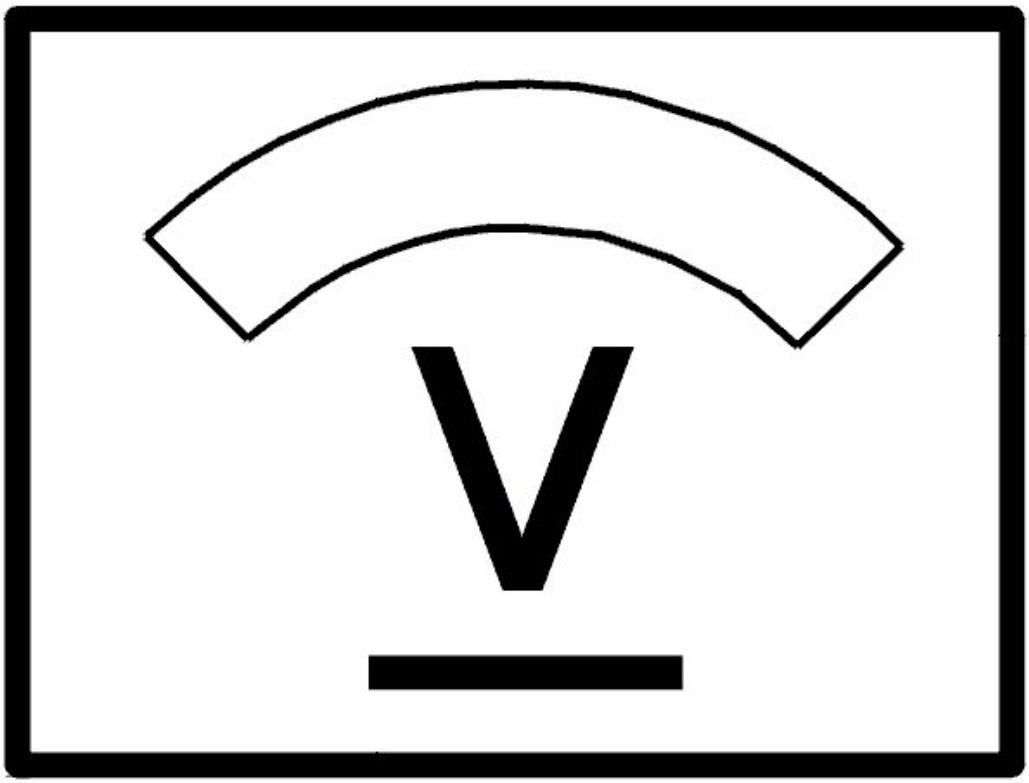
- Ignition off.

Check the voltage to ground at the following points:

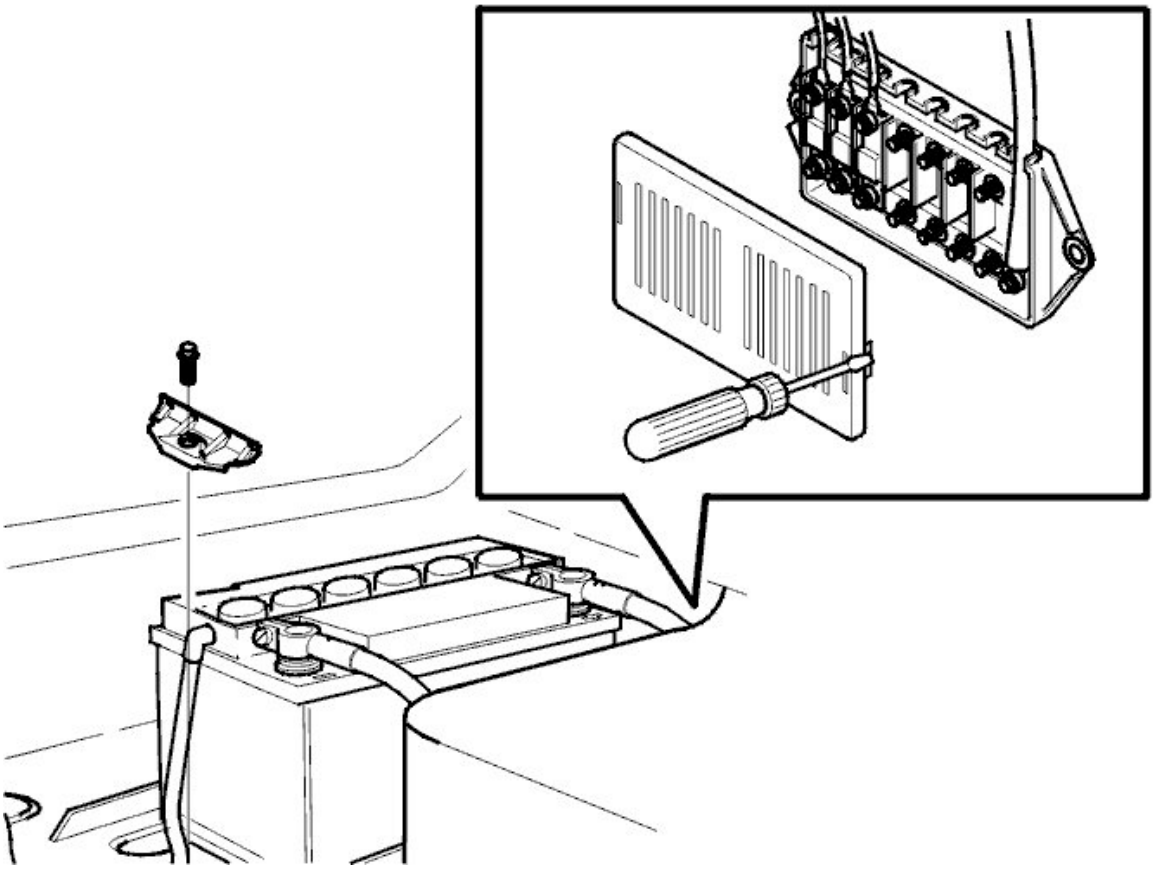
Rear main fuse.
Rear fuse.
The voltage must be at least battery voltage minus 3 V.
Check that the fuses are intact.
Remedy as necessary.

Other information:

- For information about the fuses and ground terminals, see the applicable wiring diagram.



V



Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

Was the fault found?

Yes - Verification

No - Checking the power supply and ground on the Accessory Electronic Module (AEM)

Checking the power supply and ground on the Accessory Electronic Module (AEM)

Check the power supply to the Accessory Electronic Module (AEM). Check between the breakout box terminals for the power supply (#52) and ground (#51). The voltage must be at least battery voltage minus 3 V.
Check the control module connector. Check for contact resistance and oxidation. Check for loose connections. Check for damage carefully.
Check the wiring between the Accessory Electronic Module (AEM) (breakout box for ground terminal #51) and ground. Check for an open-circuit.
Remedy as necessary.

Other information:

- To connect the breakout box, see Connecting the breakout box. Accessory electronic module See: Body and Frame/Body Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box/Connecting the Breakout Box, Accessory Electronic Module (AEM)
- To access or replace the Accessory Electronic Module (AEM) and connector, see Accessory electronic module (AEM), replacing See: Body Control Module/Service and Repair/Replacing the Accessory Electronic Module
- For information about signals, see Signal description. Accessory electronic module (AEM) See: Body and Frame/Body Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Description / Specification/Signal Description, Accessory Electronic Module (AEM)
- To fault-trace wiring and terminals see Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals
- For information about the fuses and ground terminals, see the applicable wiring diagram.

Diagnostic Trouble Code (DTC) Information

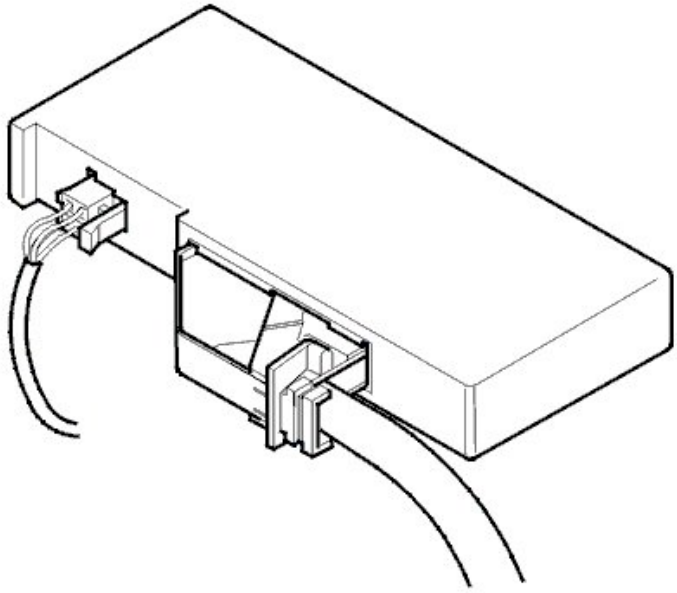
Diagnostic trouble code (DTC) information AEM-6C53

Condition



The diagnostic trouble code (DTC) is stored if the control module registers that the signal is too high on the signal cable for alarm output P1.
The diagnostic trouble code (DTC) can be diagnosed when the ignition is on and alarm output P1 is activated.

Substitute value
- None.

Possible source
- Short-circuit to supply voltage in the signal cable for alarm output P1
- Damaged alarm.

Fault symptom[s]
- The alarm does not function at all.

Signal Too High

Signal too high

Checking components and wiring

Check the signal cable for alarm output P1. Check between accessory control module terminal #B16 and the alarm unit connector. Check for a short-circuit to supply voltage.
Remedy as necessary.

Other information:
- To connect the breakout box, see Connecting the breakout box. Accessory electronic module See: Body and Frame/Body Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box/Connecting the Breakout Box, Accessory Electronic Module (AEM)

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information AUM-36E1

Condition

Audio module (AUM) checks the signal on the leads from the satellite antenna. The diagnostic trouble code (DTC) is stored if the control module registers that the signal is too low.
The diagnostic trouble code can be diagnosed upon start-up of the control module.

Substitute value
- Nothing.

Possible source

- The signal cable is short-circuited to ground.

Fault symptom[s]
- Poor radio reception

Fault-tracing

Fault-tracing

Checking satellite antenna

Check the cables for open circuit and short circuit to ground.

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition

Diagnostic trouble code (DTC) AUM-40FF is stored if the head unit/audio control module registers that there is an open-circuit in the power supply to the main antenna or a faulty installation.

Possible source
- Open-circuit in the power supply from the head unit/audio control module to the main antenna.
- Main antenna not installed.
- Defective antenna amplifier.

Fault symptom[s]
- Poor radio reception (AM).

Signal Missing. Intermittent Fault

Signal missing. Intermittent fault

Checking contact resistance, oxidation and wiring

Check the antenna amplifier and the head unit / audio control module connectors for contact resistance and oxidation according to Checking wiring and terminals. Intermittent faults See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Intermittent Faults. Remedy if necessary.
Check the cables between the antenna amplifier terminal #C1 and head unit / audio control module terminal #A9 for an open-circuit according to Checking wiring and terminals. Intermittent faults See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Intermittent Faults.
Remedy as necessary.

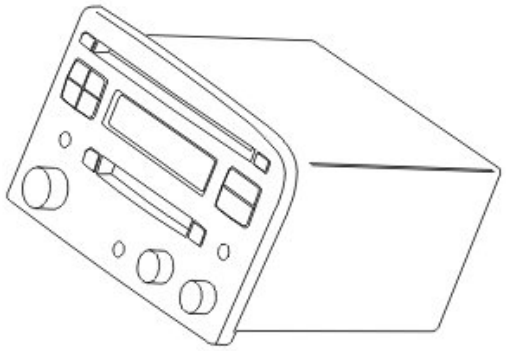
AUM-E001

Diagnostic trouble code (DTC) information AUM-E001

Condition



The control modules transmit and receive information via a standardized serial communication method - CAN (Controller Area Network). The diagnostic trouble code (DTC) is stored if the control module registers serious interference (CAN communication blocked).

Note! In the event of system communication problems, it is not possible to communicate with the control module. Therefore it will only be possible to read off the fault if it is intermittent.

Substitute value
- The control module shuts itself off ("bus-off").

  Hint: The control module will remain shut off until the power supply is broken (15, 30, X). When the power supply is connected the control module will make a new attempt to communicate.

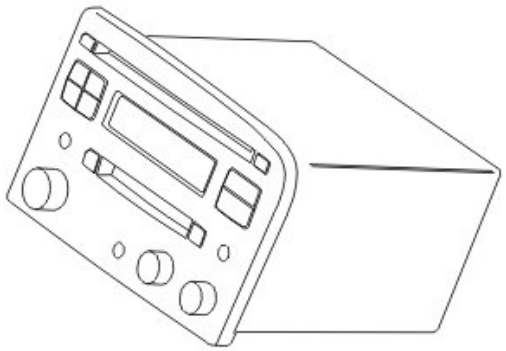
Possible source
- Short-circuit between Control area network (CAN) wiring
- Open-circuit in the control area network (CAN) wiring
- Internal fault in the control module
- Internal fault in another control module in the same part of the Control area network (CAN).

Fault symptom[s]
- The rheostat function on the audio system is not working
- The radio buttons on the steering wheel do not function
- Carphone mute on the radio does not function.

AUM-E003

Diagnostic trouble code (DTC) information AUM-E003

Condition



The control module compares its configuration ID with the signal configuration transmitted on the control area network (CAN) by the central electronic module (CEM). If the configuration IDs do not correspond the fault code is stored. The diagnostic trouble code (DTC) is also stored if the communication between the control module and the central electronic module (CEM) is interrupted.

Note! In the event of open-circuit in both the control area network (CAN) cables, it is not possible to communicate with the control module. Therefore it will only be possible to read off the diagnostic trouble code (DTC) if this type of fault is intermittent. When the diagnostic trouble code (DTC) is stored, the control module responds to the diagnostic command, however normal control area network (CAN) communication does not work. ("Expulsion mode")

Substitute value
- None.

Possible source
- Faulty control area network (CAN) configuration ID. (The node is not intended for this car, for example a used control module with different software/hardware.)
- Open-circuit in the control area network (CAN) wiring between the control module and the central electrical module (CEM).

Fault symptom[s]
- The rheostat function on the audio system is not working
- The radio buttons on the steering wheel do not function
- Carphone mute on the radio does not function.

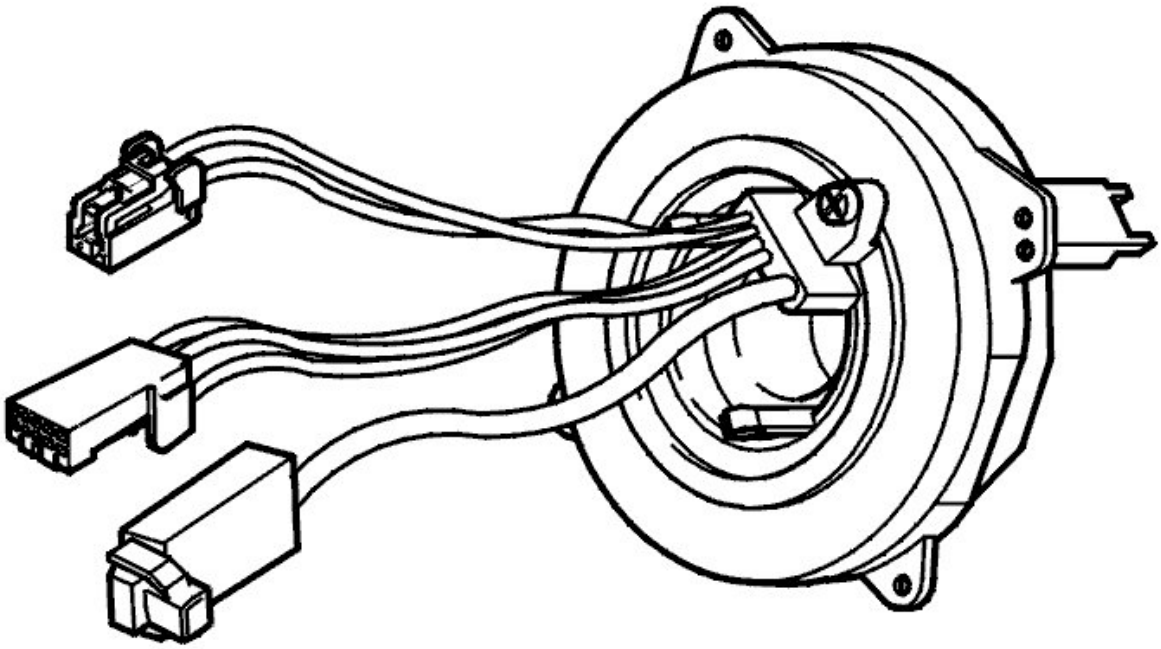
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition



The steering wheel angle sensor is initialized when the steering wheel is moved at least ±5° within a certain amount of time of the ignition being switched on.
Diagnostic trouble code (DTC) BCM-A030 is stored if the steering angle is not initialized after 2 minutes driving at a speed above 10 km/h.
The initialization can be run before the ignition is switched off even after diagnostic trouble code (DTC) BCM-A030 has been stored. The anti spin warning lamp then goes out. Diagnostic trouble code (DTC) BCM-0108 is also stored if the initialization is not completed before the ignition is switched off.

Substitute value
- Active yaw control is blocked.

Possible source
- The steering wheel angle sensor is uninitiated after two minutes driving above 10 km/h.

Note! This diagnostic trouble code (DTC) is not due to an internal hardware fault in the Brake control module (BCM) and must not be remedied by replacing the control module.

Fault symptom[s]
- The anti-spin warning lamp is lit (up to and including 2002 model year)
- General yellow warning lamp lit (from model year 2003 inclusive)
- The traction control system does not function.

The Initialization Check Has Not Been Run

The initialization check has not been run

Checking diagnostic trouble codes (DTCs)

If diagnostic trouble code (DTC) BCM-A030 is stored on its own it must be erased.
If diagnostic trouble code (DTC) BCM-0108 is stored at the same time as BCM-A030, read off the diagnostic trouble codes (DTCs) from the control module for the steering angle sensor. Fault-trace the system.
Select an option:

1. Diagnostic trouble code (DTC) BCM-A030 is stored on its own
2. Diagnostic trouble codes (DTCs) BCM-0108 and BCM-A030 are stored at the same time.

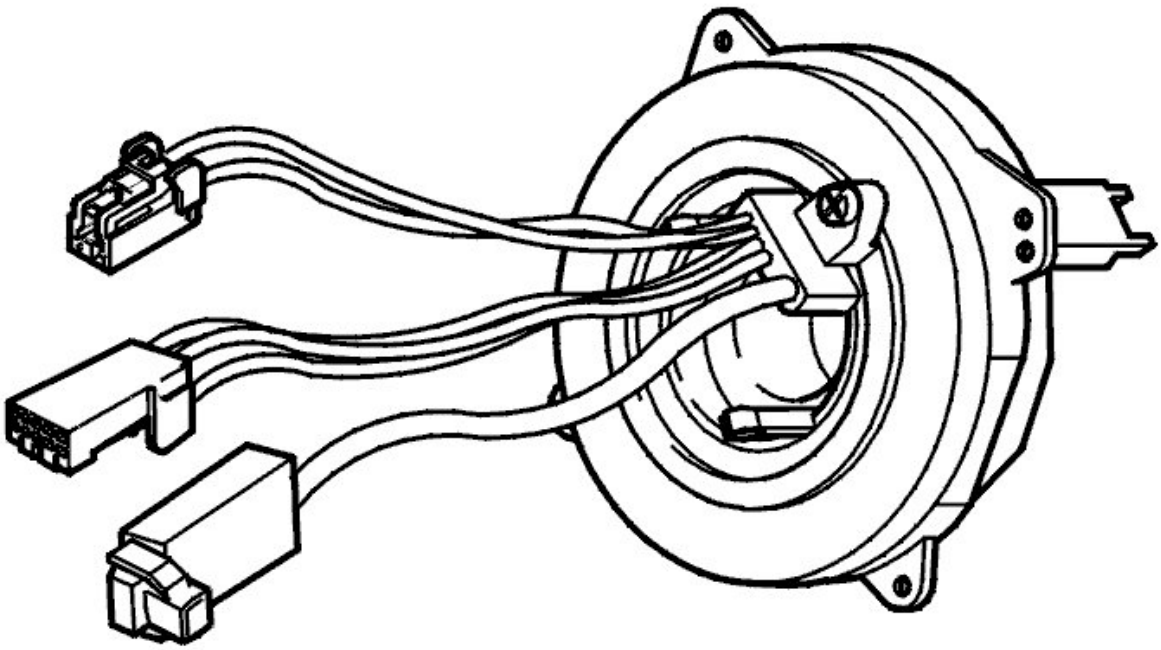
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information BCM-A031

Condition



After the steering wheel angle sensor has been initialized, a check of the plausibility of the steering wheel angle is run.
The diagnostic trouble code (DTC) is stored if the check is not approved and speed exceeds 50 km/h.
The feasibility check can be performed after the relevant diagnostic trouble code is generated, but before the ignition is switched off. If the check is not complete within one minute, BCM-0111 is also generated.

Substitute value
- Active yaw control is blocked.

Possible source
- The plausibility check of the steering wheel angle is not approved.

Note! This diagnostic trouble code (DTC) is not due to an internal hardware fault in the Brake control module (BCM) and must not be remedied by replacing the control module.

Fault symptom[s]
- -2002Anti-spin warning lamp lit
- 2003-General warning lamp lit
- Anti skid function is not working

Condition

The control modules transmit and receive information via a standardized serial communication method - CAN (Control Area Network). The diagnostic trouble code (DTC) is stored if the control module registers serious interference (CAN communication blocked).

Note! In the event of system communication problems, it is not possible to communicate with the control module. Therefore it will only be possible to read off the fault if it is intermittent.

Substitute value
- The control module shuts itself off ("bus-off")

  Hint: The control module will remain shut off until the power supply is broken (15, 30, X). When the power supply is connected the control module will make a new attempt to communicate.

Possible source
- Short-circuit between the control area network (CAN) wiring
- Open-circuit in the control area network (CAN) wiring
- Internal fault in the control module
- Internal fault in another control module in the same part of the control area network (CAN).

Fault symptom[s]
- The ABS warning lamp is lit
- No ABS function
- Message in the display.

Signal Missing

Signal missing

General information

Note! Figures shown are only examples.

Hint: For general information about CAN-troubleshooting, see:
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

General about CAN-related diagnostic trouble codes.
CEM-DF01 - DF17can only be stored in Central electronic module (CEM). These diagnostic trouble codes are stored when an electric fault is detected in CAN-lines. Start with these diagnostic trouble codes first.
CEM-1AXX only stored in Central electronic module (CEM). One diagnostic trouble code for every control module on the CAN-net. These diagnostic trouble codes indicate that Central electronic module (CEM) does not receive any reply from other control modules.
XXX-E000 (HS-CAN)/E001 (LS-CAN) can be stored in all CAN-connected control modules. These diagnostic trouble codes indicate that the control module has detected interference on the CAN-net.
XXX-E003 can be stored in all CAN-connected control modules except in Central electronic module (CEM). The control modules on the CAN-net listen for a message (identity number) that is sent out at regular intervals from Central electronic module (CEM). This diagnostic trouble code indicates that the control module has not received any identity number, or that the expected number is not correct. Interference on the CAN-net can also store this diagnostic trouble code.

Note! In case of CAN-related faults, it is likely that a combination of above diagnostic trouble codes occur.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

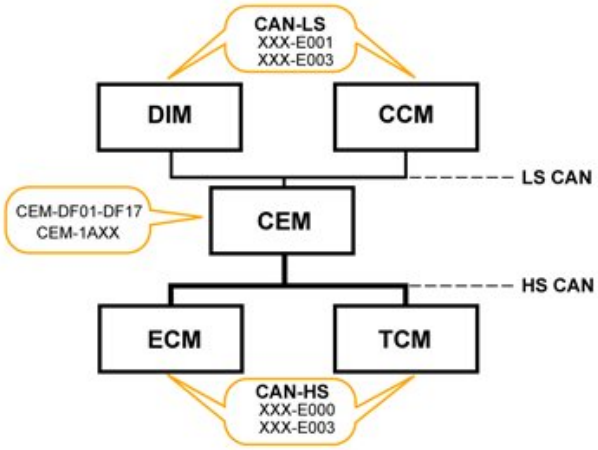
If a communication diagnostic trouble code can be read from the control module, the malfunction is probably intermittent.

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

Intermittent fault in the voltage supply and ground to a control module on the CAN network results in the Central electronic module (CEM) storing a diagnostic trouble code (DTC) for an open-circuit in communication with the control module where the voltage supply does not work. There will probably not be a diagnostic trouble code (DTC) in the control module where the open-circuit in the voltage supply occurred as the control module cannot store a diagnostic trouble code (DTC) when it is not supplied with power.

Note! Central electronic module (CEM) should not be replaced in case of CAN-fault, unless troubleshooting reveals that Central electronic module (CEM) has an internal fault.

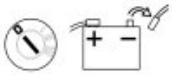
Caution! During this fault-tracing use the wiring diagram to provide support when taking readings.



Select "Continue".

Continue - Checking resistance in CAN-net

Checking resistance in CAN-net



- Ignition off
- Disconnect the battery negative lead
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #6 and #14. The resistance should be approx. 55 - 65 ohms.
- If resistance is approx. 120 ohms, this indicates open circuit in the circuit so that only one terminating resistor (120 ohms) has been measured.
- If resistance is above 1 kohms this indicates open circuit/high contact resistance somewhere in the circuit.
- If resistance is below 55 ohms this indicates short-circuiting/contact resistance between the CAN-lines somewhere in the circuit.

Hint: For HS-CAN (High Speed) the terminating resistors are located in Brake control module (BCM) and in Engine control module (ECM).

Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

Note! Resistance measurement measures only main lines in the CAN-net (in circuit where both terminating resistors are found), not branches to certain control modules. See wiring diagram for vehicle model in question.Open circuit on branching without a terminating resistor cannot be detected with this measurement. However, short-circuiting on a branch can be detected. To measure resistance in the CAN-net to control modules located in a branching of their own, the measurement shall be done against the CAN-net at that control module. The values shall be as above.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they

work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy wiring as necessary.

- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Faults in the CAN network may be due to a control module sending faulty messages that disrupt normal communication. When messages are sent incorrectly, this results in a considerable increase in the amount of traffic on the CAN network. Check the load by measuring the average voltage value on the CAN cables in relation to ground.
For further information, see the wiring diagram.
Measure voltage between the following connections on the OBDII-box/diagnostics socket.
- #6 and #4 (ground). The voltage should be approx: 2,8 - 3,2 V.
- #14 and #4 (ground). The voltage should be approx: 1,8 - 2,2 V.
- #6 and #14. The voltage shall be between approx. 0.55-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Hint: DiCE Error Frame Finder can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools: **951 3010** (memory card) as well as associated TJ 20402.

- Ignition on.
- Connect DiCE Error Frame Finder to the diagnostics socket.
- Note the blue LED-indicator. The indicator flashes to show detection of fault messages.

Note! Certain interference may occur without any real fault!

Cable fault

- Shake the cables lightly and pull lightly on the connections during the check to locate any fault. Note the blue LED-indicator.

"Chatting" control modules

- "Chatting" control modules may be difficult to find and troubleshooting may take time. Let the vehicle stand with DiCE connected for an extended time period. Afterwards, activate functions to provoke a malfunction. It may take up to several hours before the fault messages are sent. When the indicator starts to flash, remove the fuse for one control module at a time until the indicator stops flashing. When the indicator stops flashing, restore the fuse for the relevant control module and check that the indicator starts to flash again. Then it is likely that the problem is identified.

Remedy wiring as necessary.

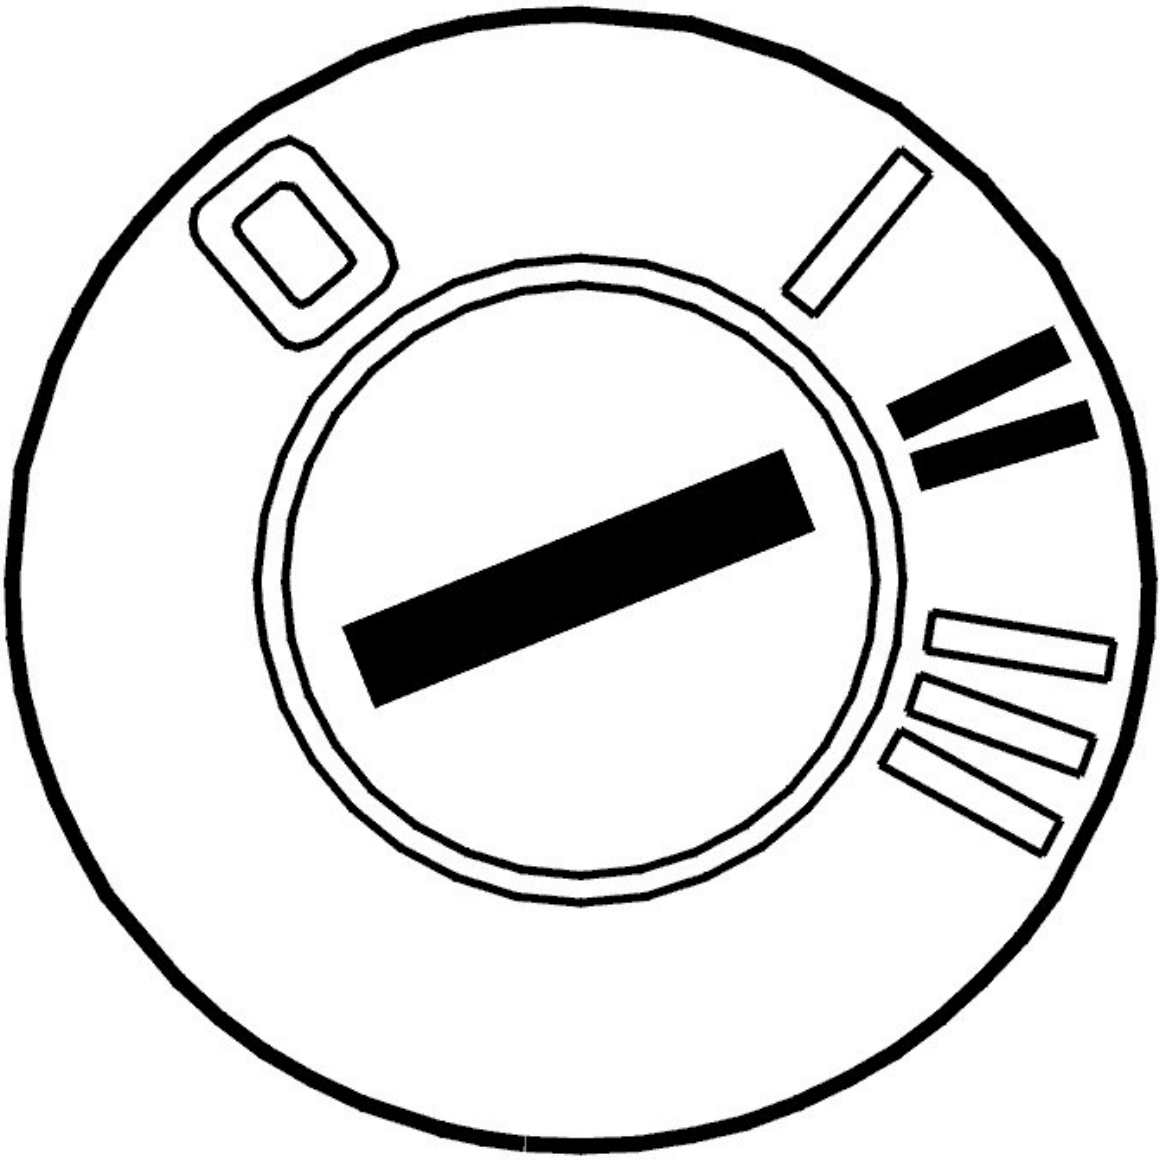
Was a fault detected?

Yes - Identifying a control module in the CAN network

No - respectively

Identifying a control module in the CAN network



Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:

- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Hint: DiCE Error Frame Finder can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools: **951 3010** (memory card) as well as associated TJ 20402.

If the load on the CAN network is too high, this may be due to a control module sending faulty messages on the CAN network (known as a disruptive control module). The fault may also be due to an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The faults can occur without a diagnostic trouble code (DTC) being stored by the control modules. The voltage can be measured between the CAN cables in order to check the load on the CAN network.

Note! It is not necessarily the control module(s) that stored the diagnostic trouble code (DTC) that is communicating faultily. Faulty messages can come from any control module in the same section of the CAN network. However, faulty communication in one network cannot affect the communication on the other network. In other words, faulty communication on the LS-CAN cannot disrupt communication on the HS-CAN and vice versa.

- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Check communication/load on CAN-net by measuring voltage between CAN-L and CAN-H. Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #6 and #14. The average value of the voltage must be approximately 0.6-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

In order to identify which control module has faulty communication, cut the power supply to one control module at a time. Check the voltage in the

CAN cables again. The easiest way to cut the power supply is to remove the fuse(s) for the relevant control module. Repeat until the voltage between the CAN wiring drops to the normal level.

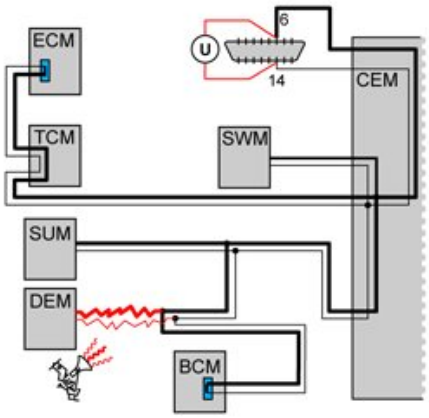
Note! When connecting and disconnecting individual control modules, other diagnostic trouble codes (DTCs) may be stored in certain control modules.

Hint: When the suspected defective control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the malfunction appears and disappears. Switch off the ignition between each check.

Note! Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.

A control module that is communicating incorrectly must be replaced. See Repairing and installing/Removing, replacing and installing.

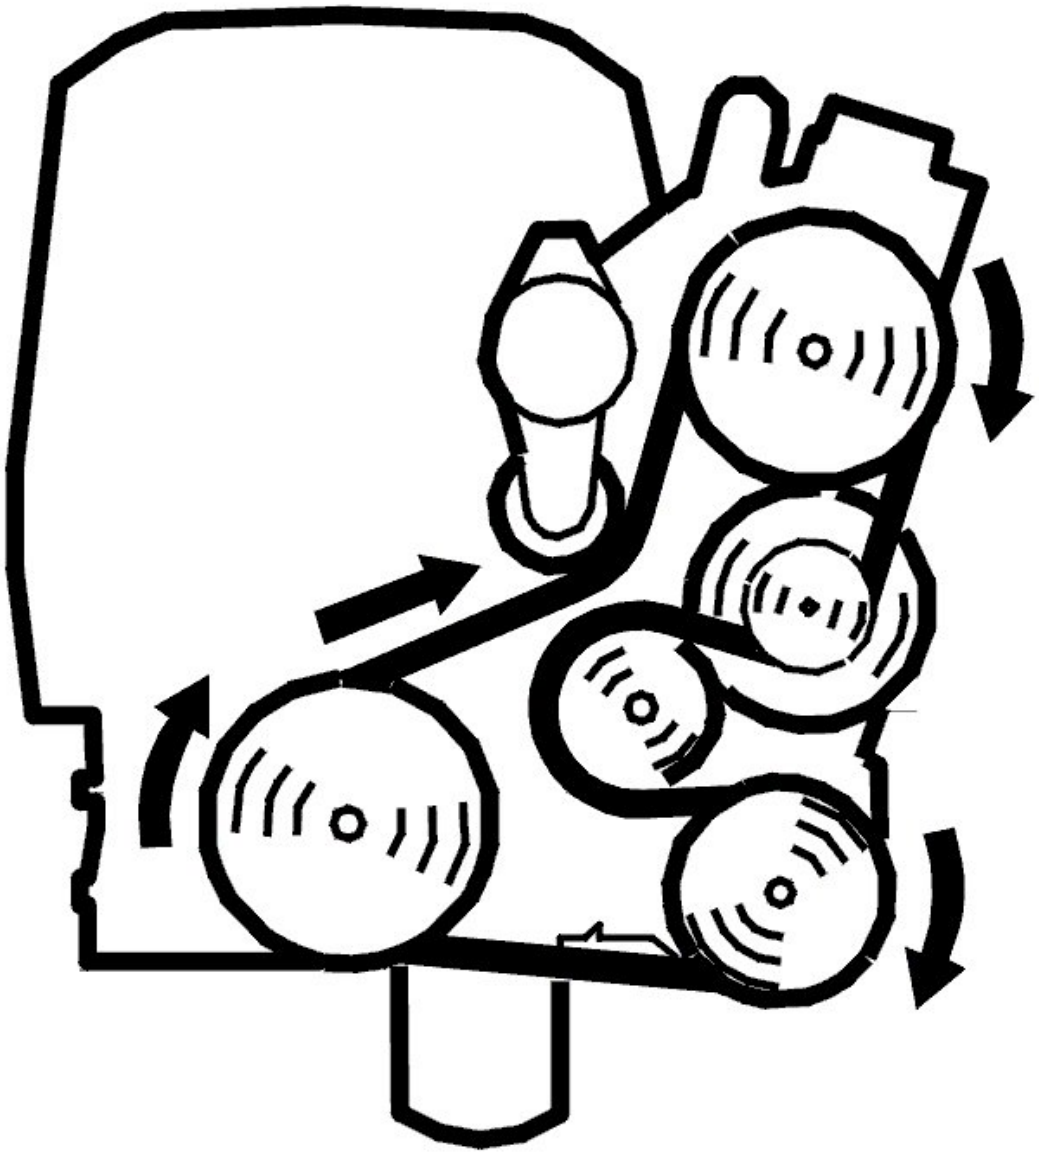
Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

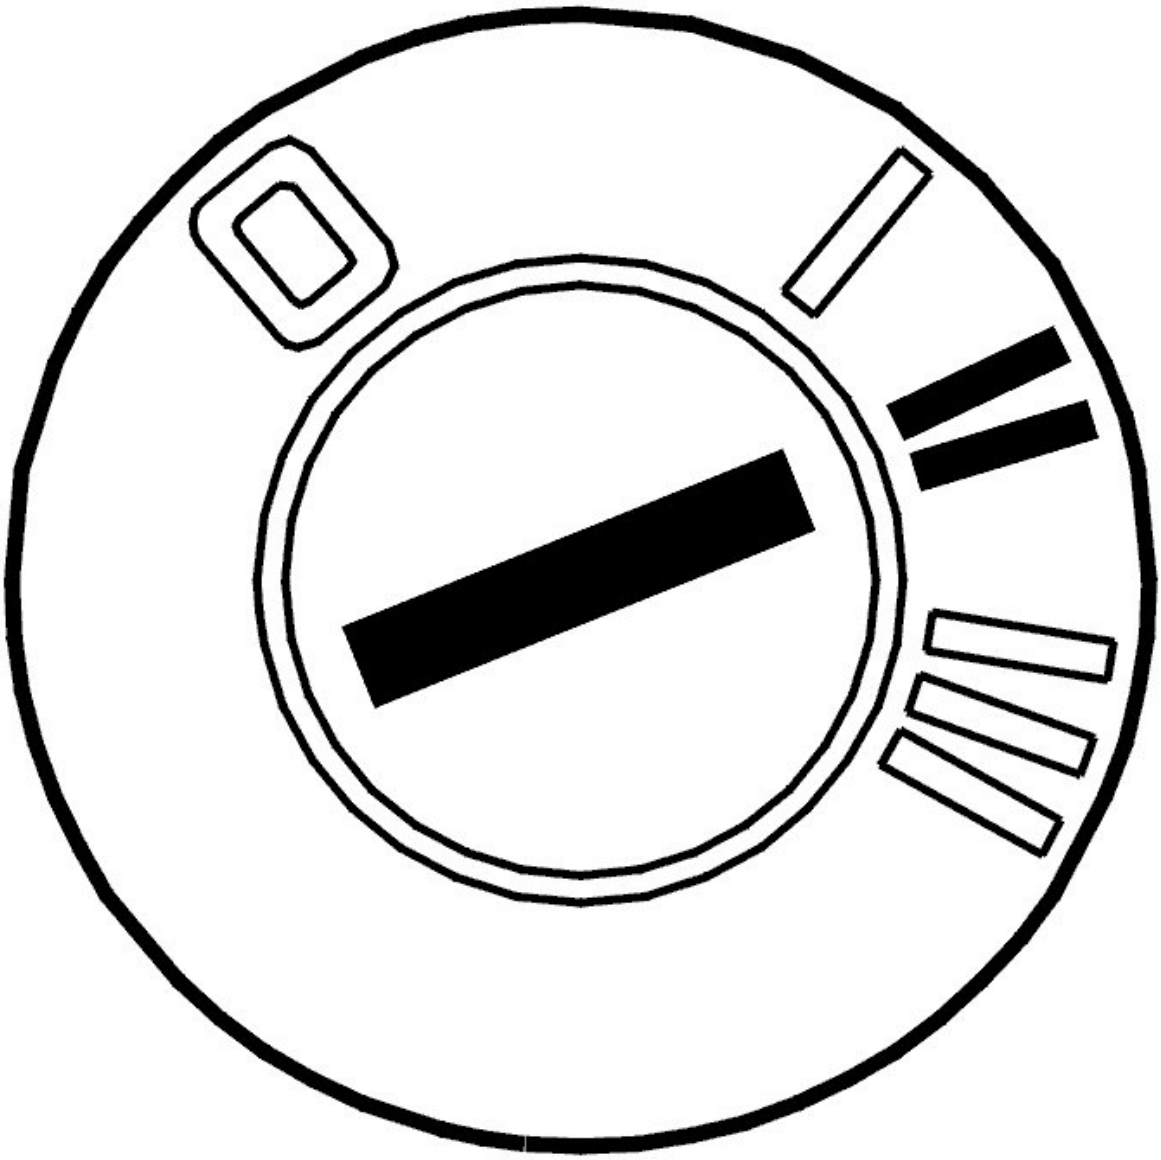


Continue - Verification

Verification

Hint: After rectifying a fault, a verification should be carried out.





- Reinstall the connectors, components etc.
- Ignition on.

Note! For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

- Erase diagnostic trouble codes (DTCs) in all control modules.
- Ignition off.
- Ignition on.
- Start the vehicle. Allow the vehicle to run for 10 minutes.
- Read out the diagnostic trouble codes in the vehicle via the DIAGNOSTICS tab.

Does the diagnostic trouble code (DTC) for faulty communication return?

Yes - Fault-tracing information

No - Fault Found

Fault-tracing information

Information

Fault-tracing information

The fault should have been detected and remedied. As this is not the case fault-tracing has failed.
Exit fault-tracing for this diagnostic trouble code (DTC) or make another attempt.

Do you want to exit fault-tracing?

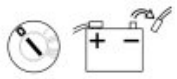
Yes - FAULT-TRACING FAILED

No - Attempt New Test

FAULT-TRACING FAILED - FAULT-TRACING FAILED

Attempt New Test - General information

Checking short-circuiting to ground/voltage in CAN-net



- Ignition off.
- Disconnect the battery negative lead.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Checking for a short-circuit to ground

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #6 and #4 (ground). Measurement is shown in the figure. The resistance should be above 1 kohms.
- #14 and #4 (ground). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and ground.

Checking for a short-circuit to voltage

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #6 and #16 (voltage). Measurement is shown in the figure. The resistance should be above 1 kohms.
- #14 and #16 (voltage). The resistance should be above 1 kohms.

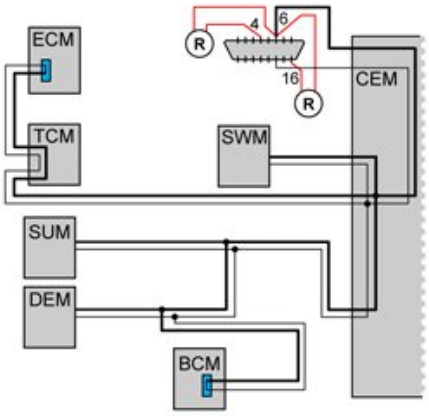
If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and voltage cable.
Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

Hint: Part the CAN-net at suitable points to decide where a short-circuit may be found.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy wiring as necessary.

Other information
- Battery, disconnecting See: Starting and Charging/Battery/Service and Repair/Procedures/Battery, Disconnecting
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

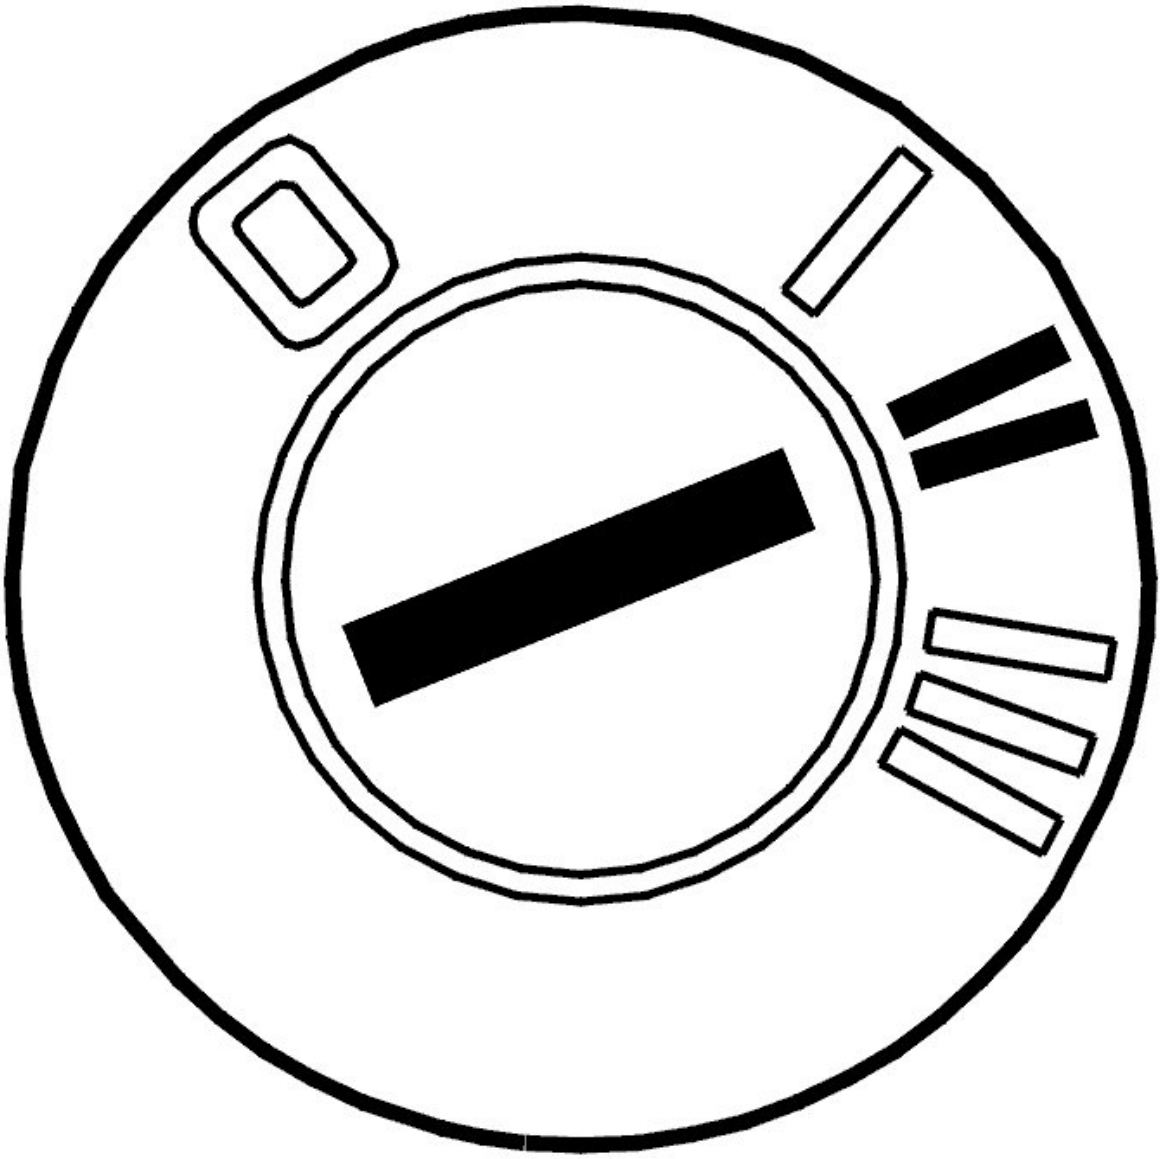


Was a fault detected?

Yes - Verification

No - Checking the traffic load on the CAN cables

Checking voltage-drop in cable for CAN-H and CAN-L, respectively



- Connect the battery.
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

In principle, the voltage measured in each cable in the CAN-net shall be the same at each control module in the network. This means that the voltage-drop in the cable for CAN-H and CAN-L, respectively, between the control modules should be very low. If there is a voltage-difference in the CAN-lines between the diagnostics socket/Central electronic module (CEM) and a control module due to, e.g., contact resistance in a connector or branching, communication may be lost/interfered with.
Check if there is voltage-drop in the cable for CAN-H and CAN-L between the diagnostics socket/Central electronic module (CEM) and the control module where there is problem with communication.
Carry out the following:
Measure voltage between the following connections on the OBDII-box/diagnostics socket.
- #6 and corresponding connection on relevant control module for CAN-H. The voltage shall be lower than 50 mV.
- #14 and corresponding connection on relevant control module for CAN-L. The voltage shall be lower than 50 mV.

If voltage is too high, this indicates too high contact resistance in cable, connector, or branching. Check the circuit between the diagnostics socket and control module in question for contact resistance and oxidation.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy wiring as necessary.

Other information

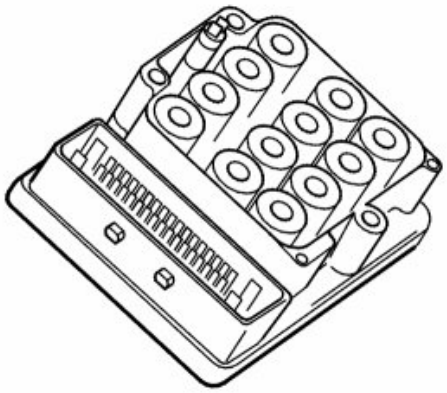
Continue - Verification

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information BCM-E003

Condition



The control module compares its configuration ID with the signal configuration transmitted on the control area network (CAN) by the central electronic module (CEM). If the configuration IDs do not correspond the fault code is stored. The diagnostic trouble code (DTC) is also stored if the communication between the control module and the central electronic module (CEM) is interrupted.

Note! In the event of an open-circuit in both the control area network (CAN) cables, it is not possible to communicate with the control module. Therefore it will only be possible to read off the diagnostic trouble code (DTC) if this type of fault is intermittent. When the diagnostic trouble code (DTC) is stored, the control module responds to the diagnostic command, however normal control area network (CAN) communication does not work. ("Expulsion mode")

Substitute value
- None.

Possible source
- Faulty control area network (CAN) configuration ID. (The node is not intended for this car, for example a used control module with different software/hardware.)
- Open-circuit in the control area network (CAN) wiring between the control module and the central electrical module (CEM).

Note! This diagnostic trouble code (DTC) is not due to an internal hardware fault in the Brake control module (BCM) and must not be remedied by replacing the control module.

Fault symptom[s]
- The ABS warning lamp is lit
- No ABS function
- Message in the display.

Signal Missing

Signal missing

General information

Note! Figures shown are only examples.

Hint: For general information about CAN-troubleshooting, see:
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

General about CAN-related diagnostic trouble codes.
CEM-DF01 - DF17can only be stored in Central electronic module (CEM). These diagnostic trouble codes are stored when an electric fault is detected in CAN-lines. Start with these diagnostic trouble codes first.
CEM-1AXX only stored in Central electronic module (CEM). One diagnostic trouble code for every control module on the CAN-net. These diagnostic trouble codes indicate that Central electronic module (CEM) does not receive any reply from other control modules.
XXX-E000 (HS-CAN)/E001 (LS-CAN) can be stored in all CAN-connected control modules. These diagnostic trouble codes indicate that the control module has detected interference on the CAN-net.
XXX-E003 can be stored in all CAN-connected control modules except in Central electronic module (CEM). The control modules on the CAN-net listen for a message (identity number) that is sent out at regular intervals from Central electronic module (CEM). This diagnostic trouble code indicates that the control module has not received any identity number, or that the expected number is not correct. Interference on the CAN-net can also store this diagnostic trouble code.

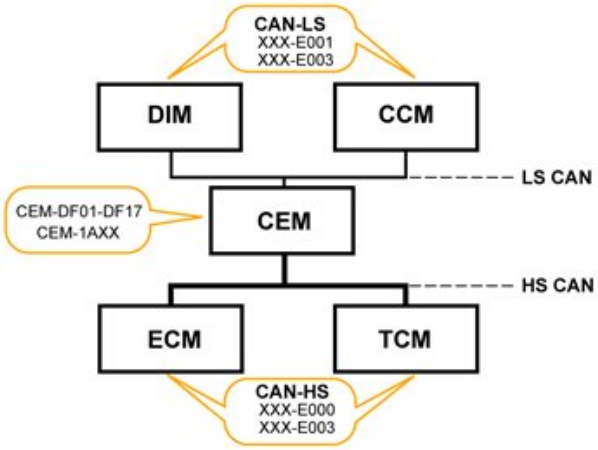
Note! In case of CAN-related faults, it is likely that a combination of above diagnostic trouble codes occur.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

If a communication diagnostic trouble code can be read from the control module, the malfunction is probably intermittent.
Intermittent fault in the voltage supply and ground to a control module on the CAN network results in the Central electronic module (CEM) storing a diagnostic trouble code (DTC) for an open-circuit in communication with the control module where the voltage supply does not work. There will probably not be a diagnostic trouble code (DTC) in the control module where the open-circuit in the voltage supply occurred as the control module cannot store a diagnostic trouble code (DTC) when it is not supplied with power.

Note! Central electronic module (CEM) should not be replaced in case of CAN-fault, unless troubleshooting reveals that Central electronic module (CEM) has an internal fault.

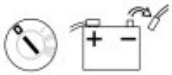
Caution! During this fault-tracing use the wiring diagram to provide support when taking readings.



Select "Continue".

Continue - Checking resistance in CAN-net

Checking resistance in CAN-net



- Ignition off
- Disconnect the battery negative lead
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #6 and #14. The resistance should be approx. 55 - 65 ohms.
- If resistance is approx. 120 ohms, this indicates open circuit in the circuit so that only one terminating resistor (120 ohms) has been measured.
- If resistance is above 1 kohms this indicates open circuit/high contact resistance somewhere in the circuit.
- If resistance is below 55 ohms this indicates short-circuiting/contact resistance between the CAN-lines somewhere in the circuit.

Hint: For HS-CAN (High Speed) the terminating resistors are located in Brake control module (BCM) and in Engine control module (ECM).

Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

Note! Resistance measurement measures only main lines in the CAN-net (in circuit where both terminating resistors are found), not branches to certain control modules. See wiring diagram for vehicle model in question.Open circuit on branching without a terminating resistor cannot be detected with this measurement. However, short-circuiting on a branch can be detected. To measure resistance in the CAN-net to control modules located in a branching of their own, the measurement shall be done against the CAN-net at that control module. The values shall be as above.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy wiring as necessary.

Other information

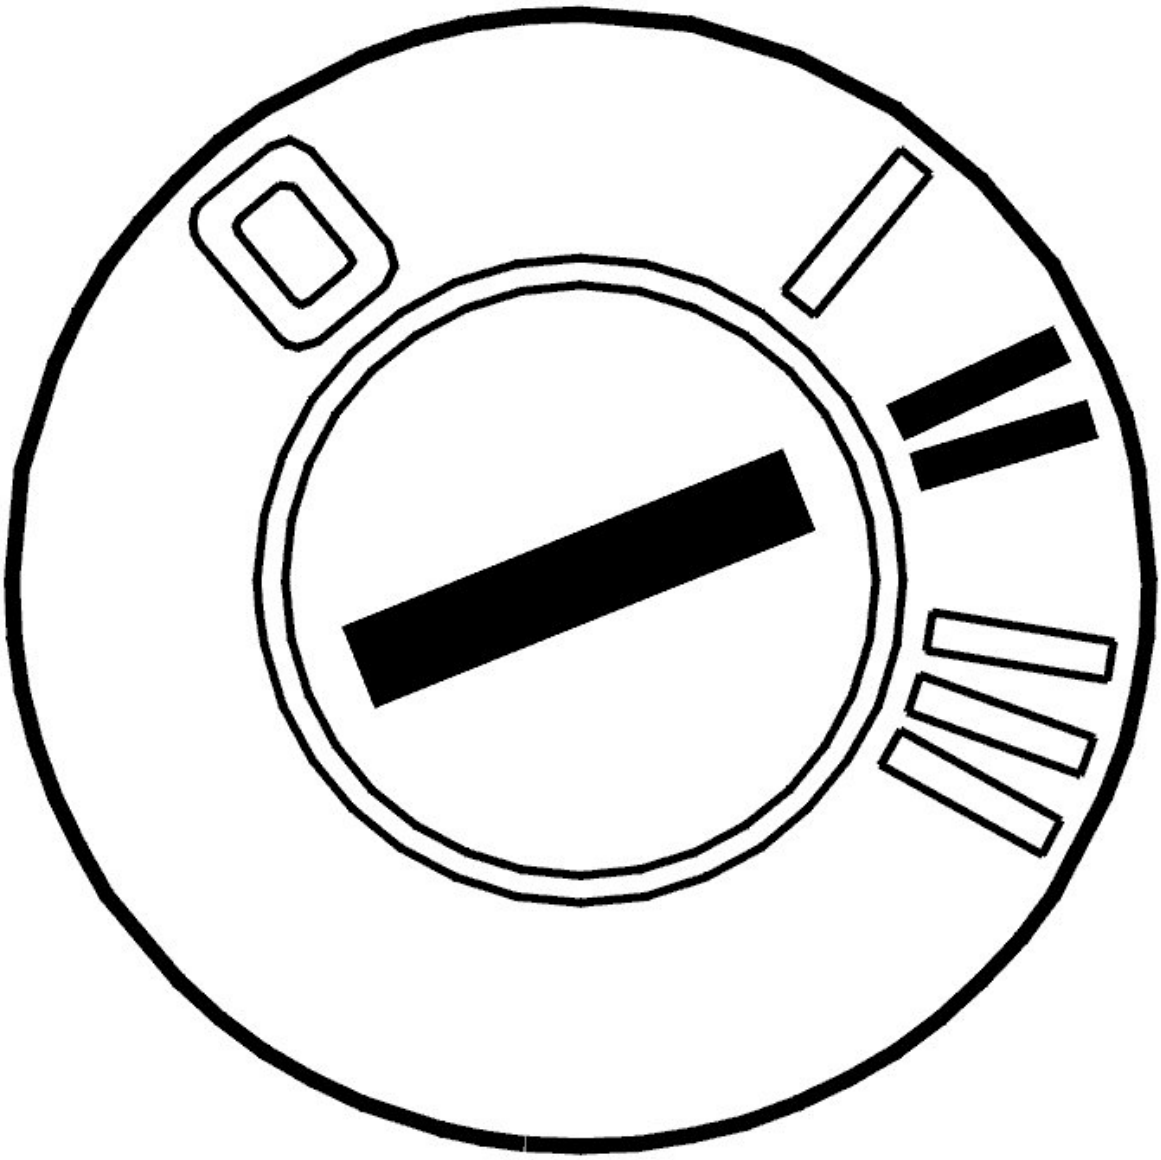
Was a fault detected?

Yes - Verification

No - Checking short-circuiting to ground/voltage in CAN-net

Checking the traffic load on the CAN cables



- Connect the battery
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Faults in the CAN network may be due to a control module sending faulty messages that disrupt normal communication. When messages are sent incorrectly, this results in a considerable increase in the amount of traffic on the CAN network. Check the load by measuring the average voltage value on the CAN cables in relation to ground.
For further information, see the wiring diagram.
Measure voltage between the following connections on the OBDII-box/diagnostics socket.
- #6 and #4 (ground). The voltage should be approx: 2,8 - 3,2 V.
- #14 and #4 (ground). The voltage should be approx: 1,8 - 2,2 V.
- #6 and #14. The voltage shall be between approx. 0.55-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Hint: DiCE Error Frame Finder can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools: **951 3010** (memory card) as well as associated TJ 20402.

- Ignition on.
- Connect DiCE Error Frame Finder to the diagnostics socket.
- Note the blue LED-indicator. The indicator flashes to show detection of fault messages.

Note! Certain interference may occur without any real fault!

Cable fault

- Shake the cables lightly and pull lightly on the connections during the check to locate any fault. Note the blue LED-indicator.

"Chatting" control modules

- "Chatting" control modules may be difficult to find and troubleshooting may take time. Let the vehicle stand with DiCE connected for an extended time period. Afterwards, activate functions to provoke a malfunction. It may take up to several hours before the fault messages are sent. When the indicator starts to flash, remove the fuse for one control module at a time until the indicator stops flashing. When the indicator stops flashing, restore the fuse for the relevant control module and check that the indicator starts to flash again. Then it is likely that the problem is identified.

Remedy wiring as necessary.

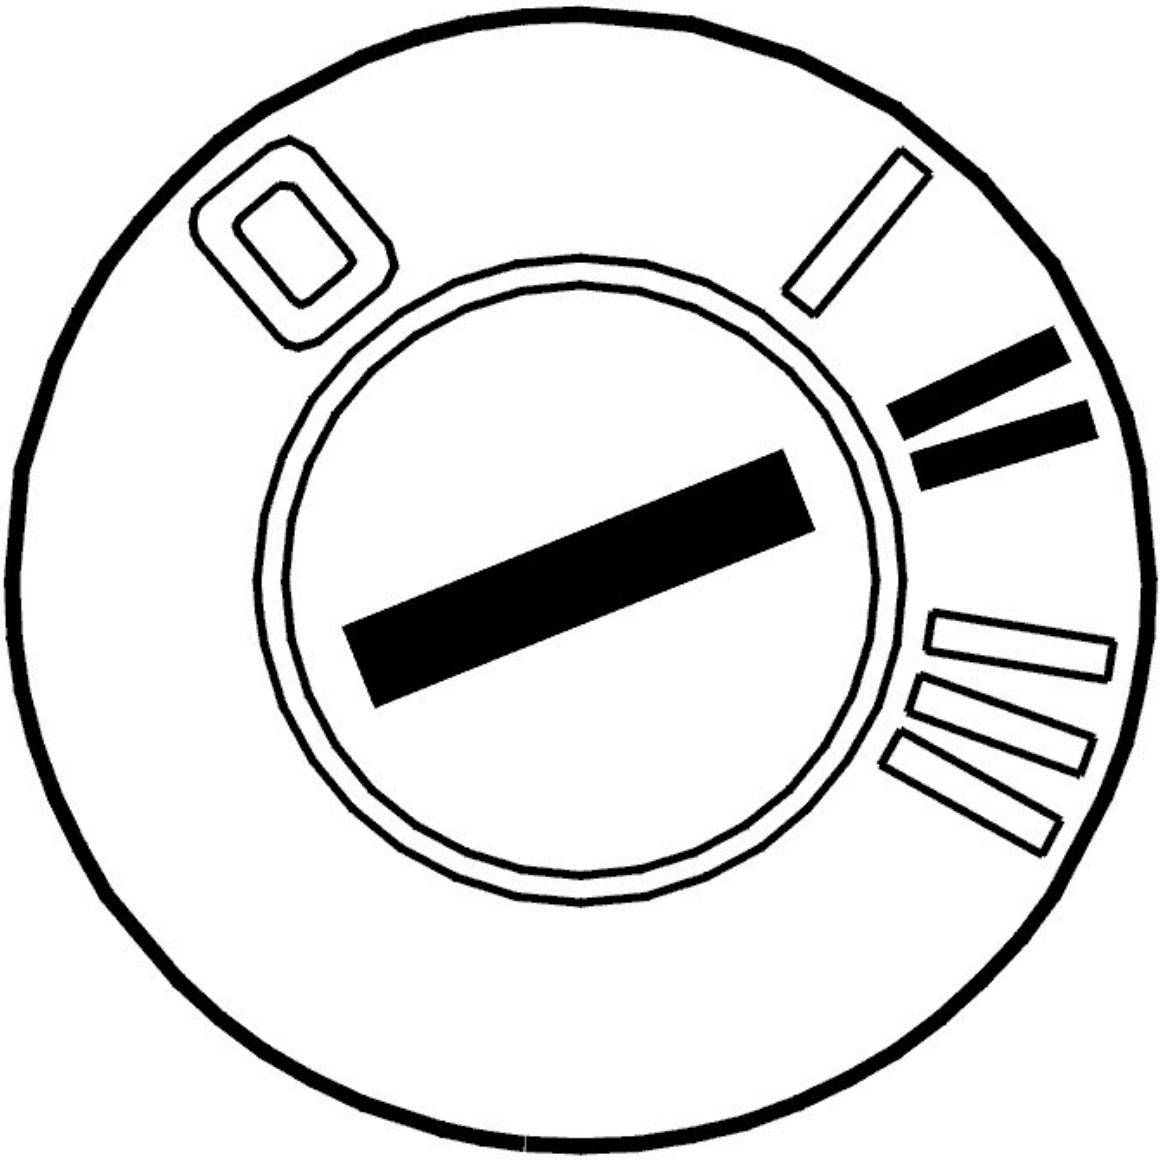
No - respectively

Identifying a control module in the CAN network



Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:

- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Hint: DiCE Error Frame Finder can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools: **951 3010** (memory card) as well as associated TJ 20402.

If the load on the CAN network is too high, this may be due to a control module sending faulty messages on the CAN network (known as a disruptive control module). The fault may also be due to an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The faults can occur without a diagnostic trouble code (DTC) being stored by the control modules. The voltage can be measured between the CAN cables in order to check the load on the CAN network.

Note! It is not necessarily the control module(s) that stored the diagnostic trouble code (DTC) that is communicating faultily. Faulty messages can come from any control module in the same section of the CAN network. However, faulty communication in one network cannot affect the communication on the other network. In other words, faulty communication on the LS-CAN cannot disrupt communication on the HS-CAN and vice versa.

- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Check communication/load on CAN-net by measuring voltage between CAN-L and CAN-H. Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #6 and #14. The average value of the voltage must be approximately 0.6-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

In order to identify which control module has faulty communication, cut the power supply to one control module at a time. Check the voltage in the

CAN cables again. The easiest way to cut the power supply is to remove the fuse(s) for the relevant control module. Repeat until the voltage between the CAN wiring drops to the normal level.

Note! When connecting and disconnecting individual control modules, other diagnostic trouble codes (DTCs) may be stored in certain control modules.

Hint: When the suspected defective control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the malfunction appears and disappears. Switch off the ignition between each check.

Note! Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.

A control module that is communicating incorrectly must be replaced. See Repairing and installing/Removing, replacing and installing.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

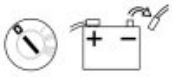
Checking short-circuiting to ground/voltage in CAN-net



- Ignition off.
- Disconnect the battery negative lead.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Checking for a short-circuit to ground

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #6 and #4 (ground). Measurement is shown in the figure. The resistance should be above 1 kohms.
- #14 and #4 (ground). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and ground.

Checking for a short-circuit to voltage

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #6 and #16 (voltage). Measurement is shown in the figure. The resistance should be above 1 kohms.
- #14 and #16 (voltage). The resistance should be above 1 kohms.

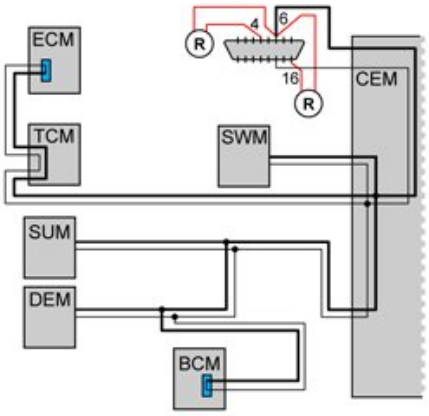
If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and voltage cable.
Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

Hint: Part the CAN-net at suitable points to decide where a short-circuit may be found.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy wiring as necessary.

Other information
- Battery, disconnecting See: Starting and Charging/Battery/Service and Repair/Procedures/Battery, Disconnecting
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

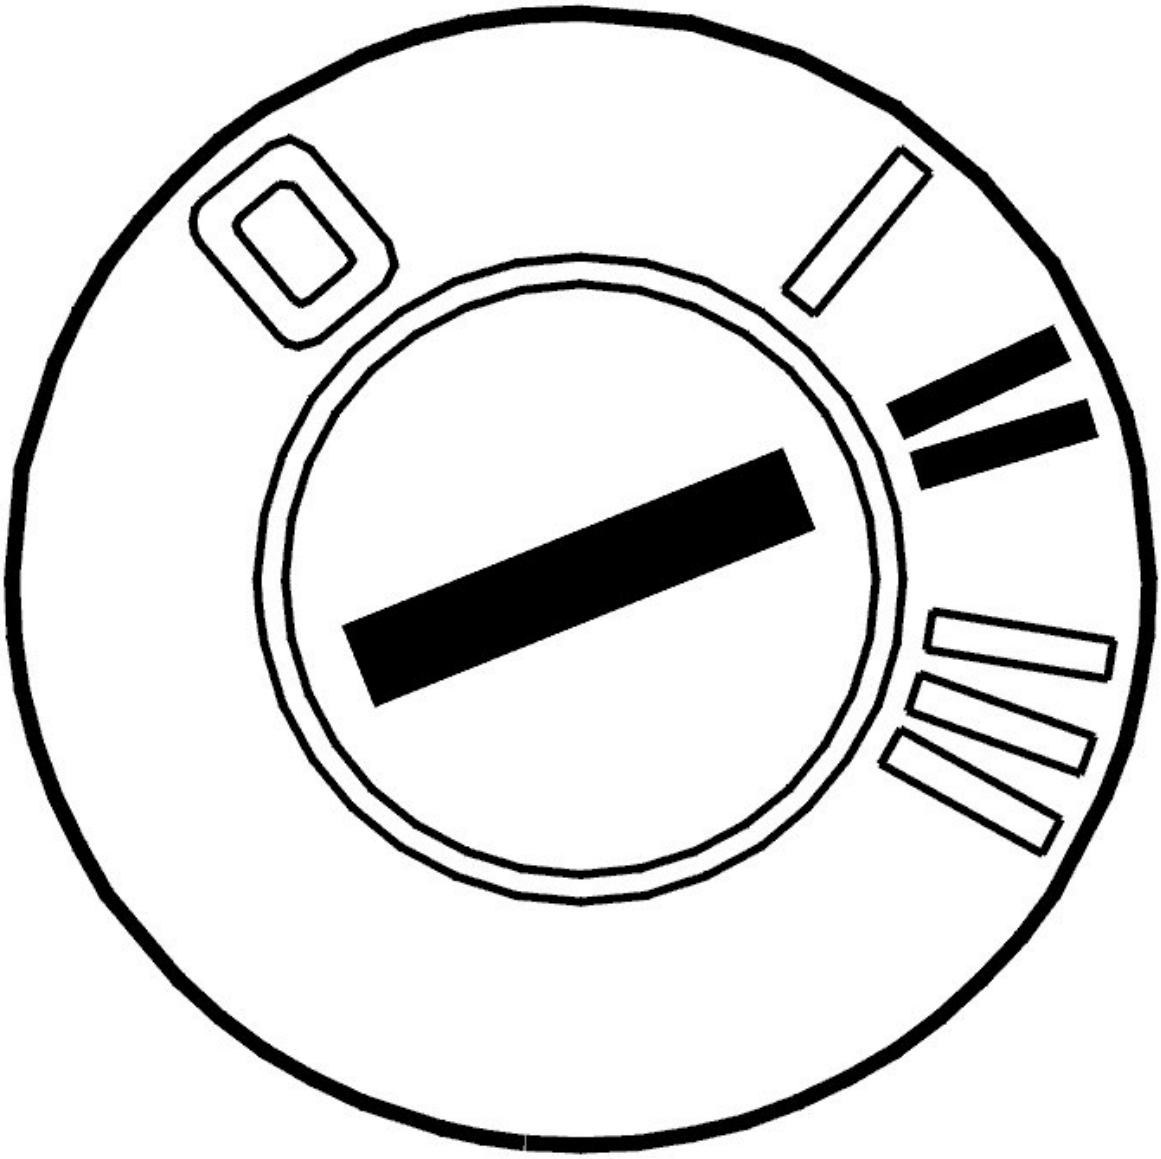


Was a fault detected?

Yes - Verification

No - Checking the traffic load on the CAN cables

Checking voltage-drop in cable for CAN-H and CAN-L, respectively



- Connect the battery.
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

In principle, the voltage measured in each cable in the CAN-net shall be the same at each control module in the network. This means that the voltage-drop in the cable for CAN-H and CAN-L, respectively, between the control modules should be very low. If there is a voltage-difference in the CAN-lines between the diagnostics socket/Central electronic module (CEM) and a control module due to, e.g., contact resistance in a connector or branching, communication may be lost/interfered with.
Check if there is voltage-drop in the cable for CAN-H and CAN-L between the diagnostics socket/Central electronic module (CEM) and the control module where there is problem with communication.
Carry out the following:
Measure voltage between the following connections on the OBDII-box/diagnostics socket.
- #6 and corresponding connection on relevant control module for CAN-H. The voltage shall be lower than 50 mV.
- #14 and corresponding connection on relevant control module for CAN-L. The voltage shall be lower than 50 mV.

If voltage is too high, this indicates too high contact resistance in cable, connector, or branching. Check the circuit between the diagnostics socket and control module in question for contact resistance and oxidation.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy wiring as necessary.

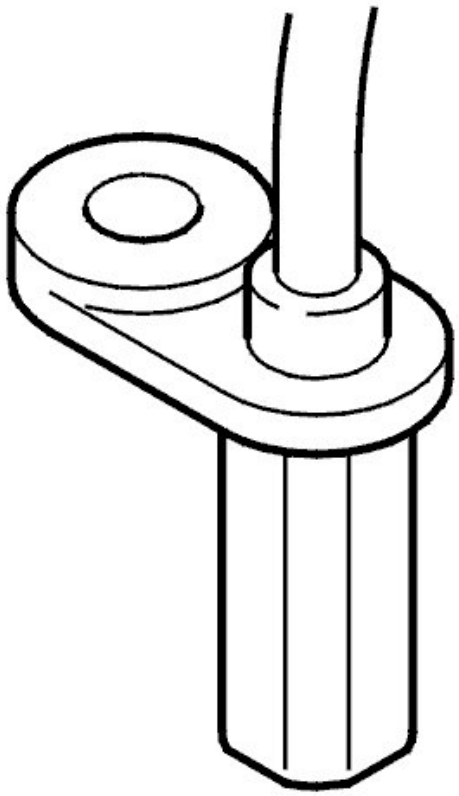
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition



The brake control module (BCM) receives information about wheel speed from the wheel sensors. The wheel sensors, which are on the wheel mounting, read off a pulse wheel on the wheel spindle. Diagnostic trouble code (DTC) BCM-0010, BCM-0020, BCM-0030 or BCM-0040 is stored, depending on the wheel sensor, if the control module registers that the signal from any of the wheel sensors is distorted or missing too many times.

- BCM-0010: Wheel sensor, left front
- BCM-0020: Wheel sensor, right front
- BCM-0030: Wheel sensor, left rear
- BCM-0040: Wheel sensor, right rear.

The diagnostic trouble code (DTC) can be diagnosed at speeds above 10 km/h.

Substitute value

- The ABS is blocked
- Electronic Brake force Distribution is blocked if two or more wheel sensors are not working
- Traction control is blocked
- Stability control is blocked
- Active yaw control is blocked
- Brake assistance is blocked.

Hint: For information about brake system abbreviations, see Brake system, abbreviations See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Description and Operation/Brake System, Abbreviations.

Possible source

- Contact resistance in the terminals
- Open-circuit, short-circuit to ground or supply voltage in the power supply to the wheel sensor
- The signal cables are short-circuited to each other
- Short-circuit to supply voltage or ground in the signal cable
- Open-circuit in the signal cable
- Defective wheel sensor
- Internal fault in the control module.

Fault symptom[s]

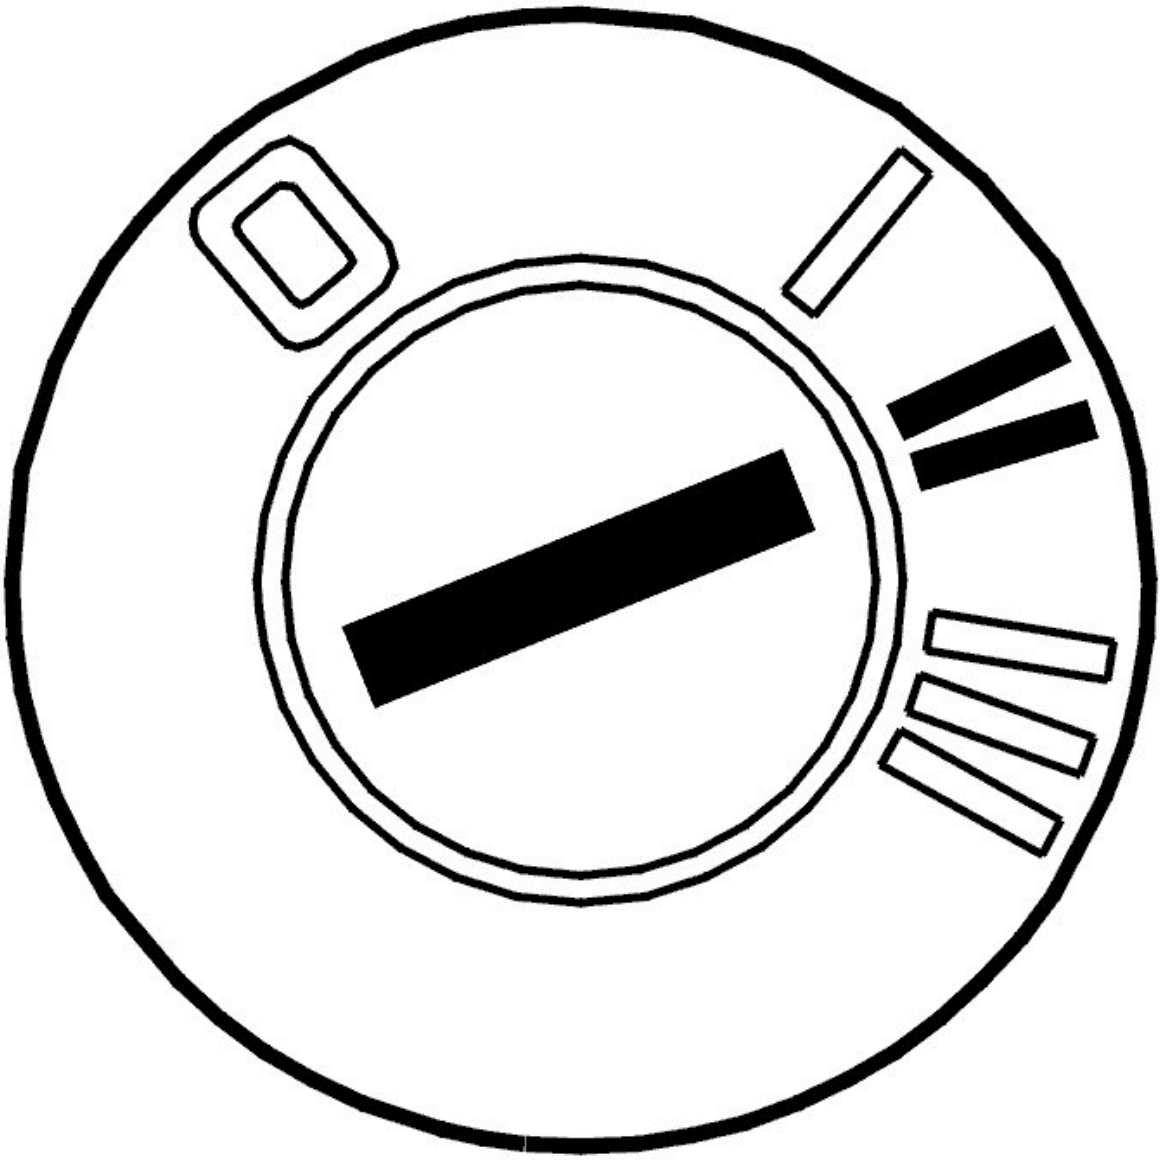
- General warning lamp lit
- The ABS warning lamp is lit
- The anti-spin warning lamp is lit (up to and including 2002 model year)
- The warning lamp for brake circuit not functioning is lit
- The ABS system does not function
- Anti-spin does not function
- The stability control system does not function
- The traction control system does not function.

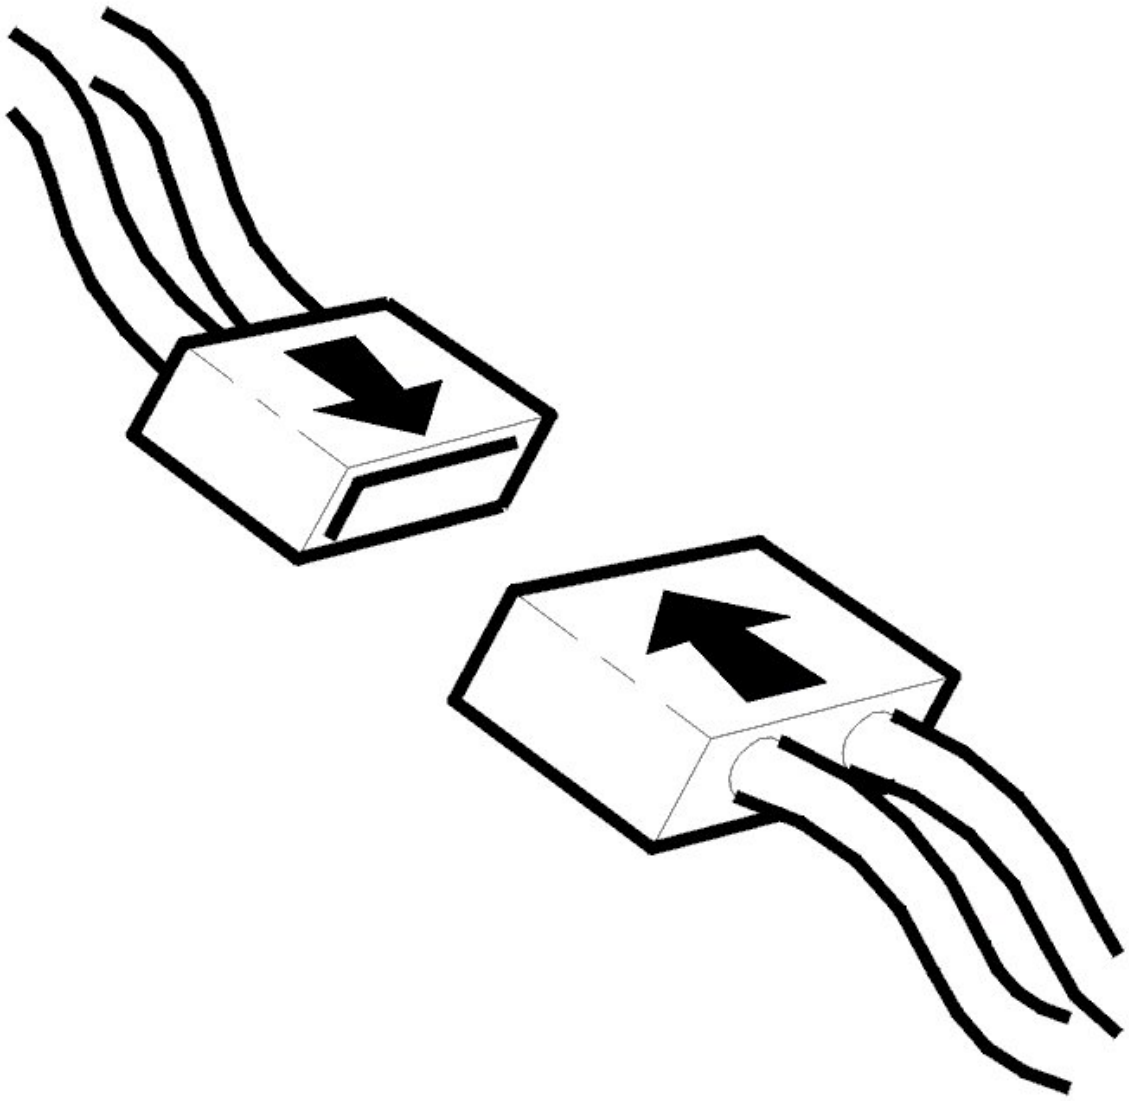
Note! If the fault is intermittent the ABS warning lamp will not go out until the vehicle speed exceeds 10 km/h in the next operating cycle.

Signal Missing

Signal missing

Checking the connectors for the control module and wheel sensor





- Ignition off
- Check the wheel sensor and control module connectors. Check for contact resistance and oxidation
- Reinstall the components, reconnect the connectors etc.
- Raise the car so that the relevant wheel is clear of the ground
- Ignition on
- Read off the wheel speed for the relevant wheel.

Spin the relevant wheel and check that the wheel speed is updated.
If the wheel speed is updated, the cause of the fault was loose connections in the connectors for the control module or wheel sensor.

Note! The speed signal will only be active for approximately 20 seconds. Activate the function again if necessary.

Other information

- To disconnect the wheel sensor connector, see Wheel sensor front, replacing See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Wheel Speed Sensor/Service and Repair/Wheel Sensor Front, Replacing
- To disconnect the connector for the brake control module (BCM), see Connecting the breakout box, brake control module (BCM) See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box/Connecting the Breakout Box, Brake Control Module (BCM)
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

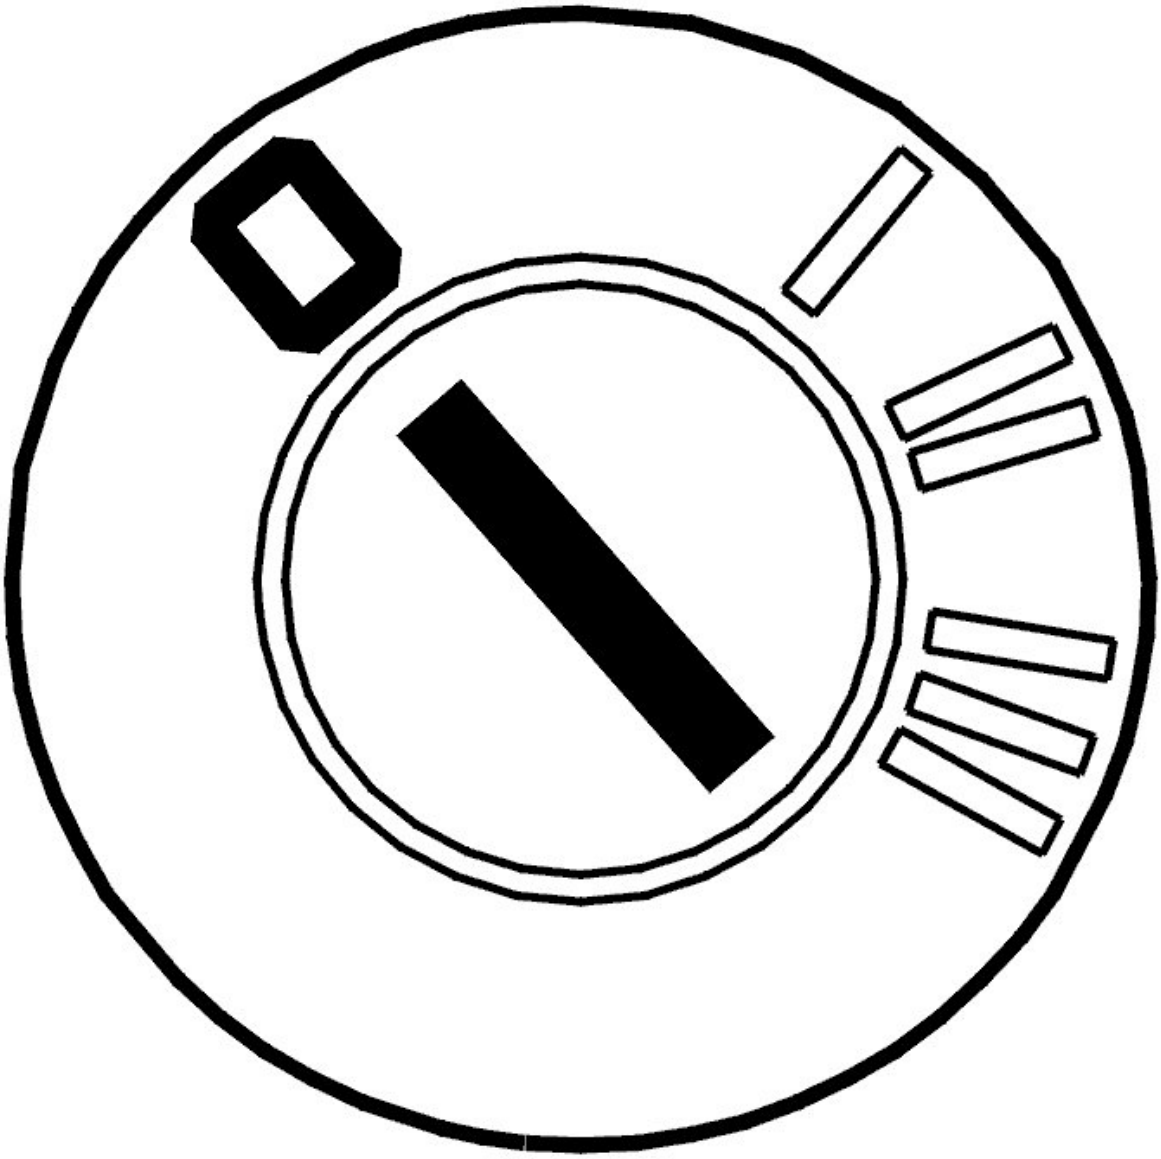
Is the wheel speed updated?

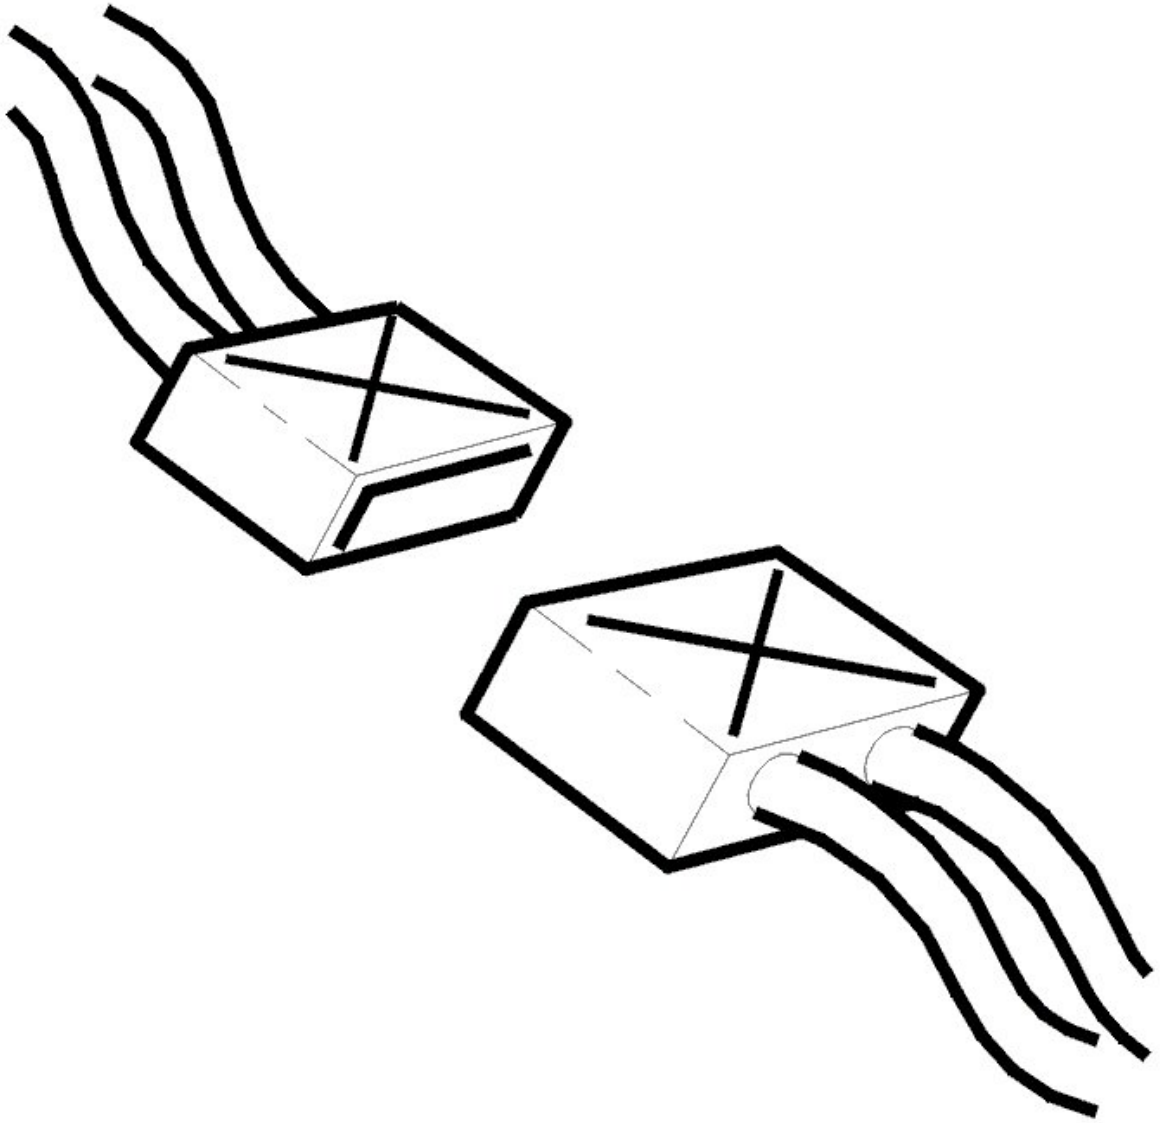
Yes - Fault Found

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

No - Checking wiring and sensors

Checking wiring and sensors





Checking the power supply

Check the signal cable between control module
- terminal #45 (#A45) (left front)
- #34 (#A34) (right front).

and terminal #1 on the relevant sensor. Check for an open-circuit. Check for a short-circuit to ground. Check for a short-circuit to supply voltage.

Checking the signal cable

Check the signal cable between control module
- terminal #46 (#A46) (left front)
- #33 (#A33) (right front).

and terminal #2 on the relevant sensor. Check for an open-circuit. Check for a short-circuit to ground. Check for a short-circuit to supply voltage.

Checking the function of the sensor

Check the sensor. Ensure that the breakout box is connected, the sensor is connected and the ignition is on. Measure the signal from the sensor. Connect a voltmeter between:
- terminals #45 (#A45) and #46 (#A46) (left front)
- terminals #34 (#A34) and #33 (#A33) (right front).

on the breakout box. The voltage should vary by approximately 1 V when the pulse wheel is rotating. Replace the wheel sensor if the voltage is faulty.

Hint: Particularly check the wiring at the steering shaft.

Remedy as necessary.

Other information:
- To connect the breakout box, see Connecting the breakout box, brake control module (BCM) See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box/Connecting the Breakout Box, Brake Control Module (BCM)

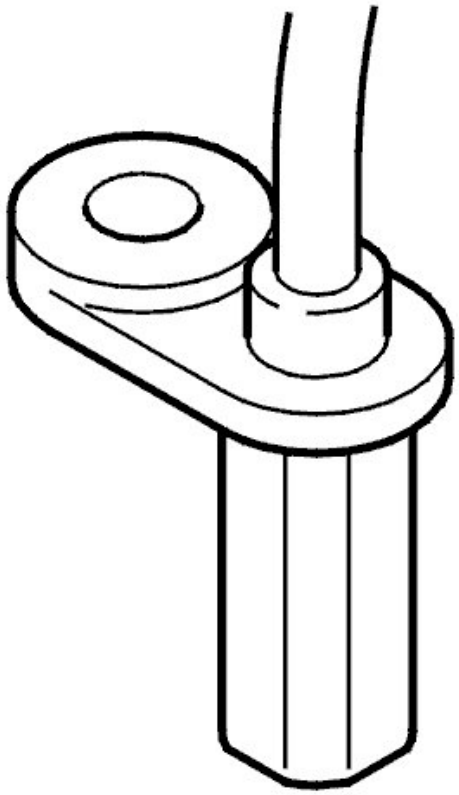
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition



The brake control module (BCM) can register this diagnostic trouble code (DTC) for a number of different fault causes.

1. The diagnostic trouble code is generated if the Brake control module (BCM) registers that the wheel stops or rotates too slowly in relation to the vehicle's reference speed while driving or ABS-control when speed is above 20 km/h.
2. Brake control module (BCM) has a counter, extrapolation counter, which counts the number of times that the speed change on the wheel is too big compared to that which is allowed (calculated). The diagnostic trouble code (DTC) is stored if wheel acceleration on one of the wheel sensors is greater than on other wheel sensors.
3. The diagnostic trouble code (DTC) is stored if the slowest wheel rotates at a speed that is less than 40-60 % of the fastest wheel (depending on the vehicle's speed) but finds that the wheel sensor circuit is unbroken.

The diagnostic trouble code (DTC) can be diagnosed at speeds above 10 km/h.

Substitute value
- The ABS is blocked
- Electronic Brake force Distribution (EBD) is blocked if two or more wheel sensors are not working
- Traction control is blocked
- Stability control is blocked
- Active yaw control is blocked
- Brake assistance is blocked.

Hint: For information about brake system abbreviations, see Brake system, abbreviations See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Description and Operation/Brake System, Abbreviations.

Possible source
- One of the wheels has been blocked while the car has being driven
- Loose wheel sensor
- The gap between the wheel sensor and the pulse wheel is too large or too small
- Hub vibrations or play in the wheel bearings
- Defective pulse wheel
- Defective wheel sensor.
- Dirt between wheel sensor and pulse wheel.

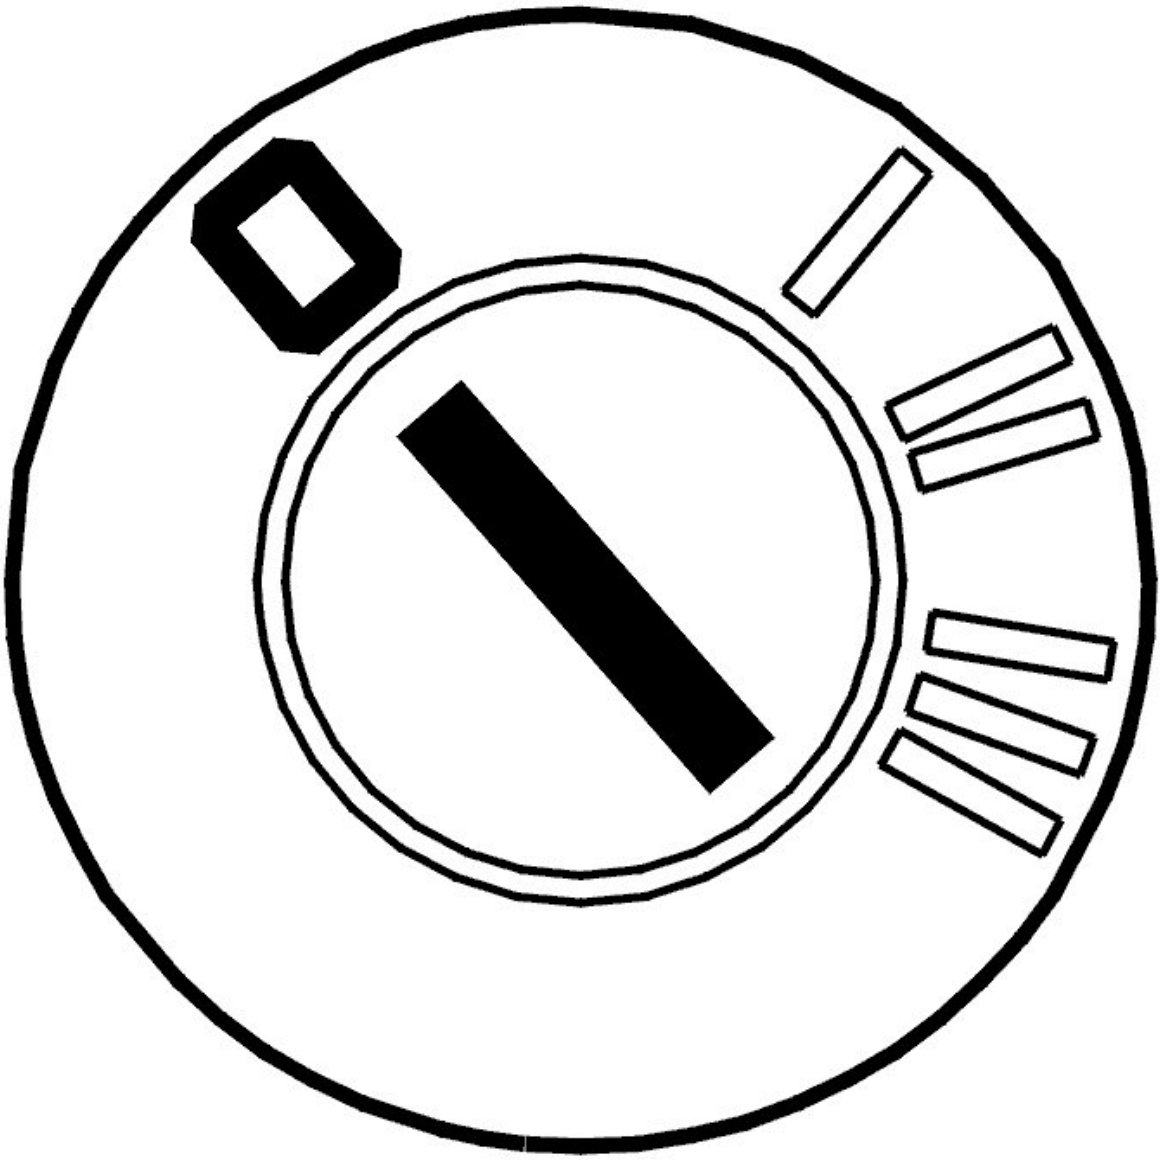
Note! This diagnostic trouble code (DTC) is not due to an internal hardware fault in the Brake control module (BCM) and must not be remedied by replacing the control module.

Fault symptom[s]
- General warning lamp lit
- The ABS warning lamp is lit
- The anti-spin warning lamp is lit (up to and including 2002 model year)
- The ABS system does not function
- Anti-spin does not function
- The stability control system does not function
- The traction control system does not function.

Faulty Signal

Faulty signal

Checking the wheel sensor and pulse wheel



- Ignition off.
- Remove the wheel for better access.

Check that the relevant wheel sensor is mounted tightly against the shaft/hub. Check that there is no dirt between the sensor and mating surface.
Check that the toothed wheel is properly mounted and is free from damage (all teeth intact, no scratches or deformity, etc.)
Remedy as necessary.

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition

The brake control module (BCM) receives information about wheel speed from the wheel sensors. The wheel sensors, which are on the wheel mounting, read off a pulse wheel on the wheel spindle. Diagnostic trouble code (DTC) BCM-0010, BCM-0020, BCM-0030 or BCM-0040 is stored, depending on the wheel sensor, if the control module registers that the signal from any of the wheel sensors is distorted or missing too many times.

- BCM-0010: Wheel sensor, left front
- BCM-0020: Wheel sensor, right front
- BCM-0030: Wheel sensor, left rear
- BCM-0040: Wheel sensor, right rear.

The diagnostic trouble code (DTC) can be diagnosed at speeds above 10 km/h.

Substitute value

- The ABS is blocked
- Electronic Brake force Distribution is blocked if two or more wheel sensors are not working
- Traction control is blocked
- Stability control is blocked
- Active yaw control is blocked

- Brake assistance is blocked.

Hint: For information about brake system abbreviations, see Brake system, abbreviations See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Description and Operation/Brake System, Abbreviations.

Possible source
- Contact resistance in the terminals
- Open-circuit, short-circuit to ground or supply voltage in the power supply to the wheel sensor
- The signal cables are short-circuited to each other
- Short-circuit to supply voltage or ground in the signal cable
- Open-circuit in the signal cable
- Defective wheel sensor
- Internal fault in the control module.

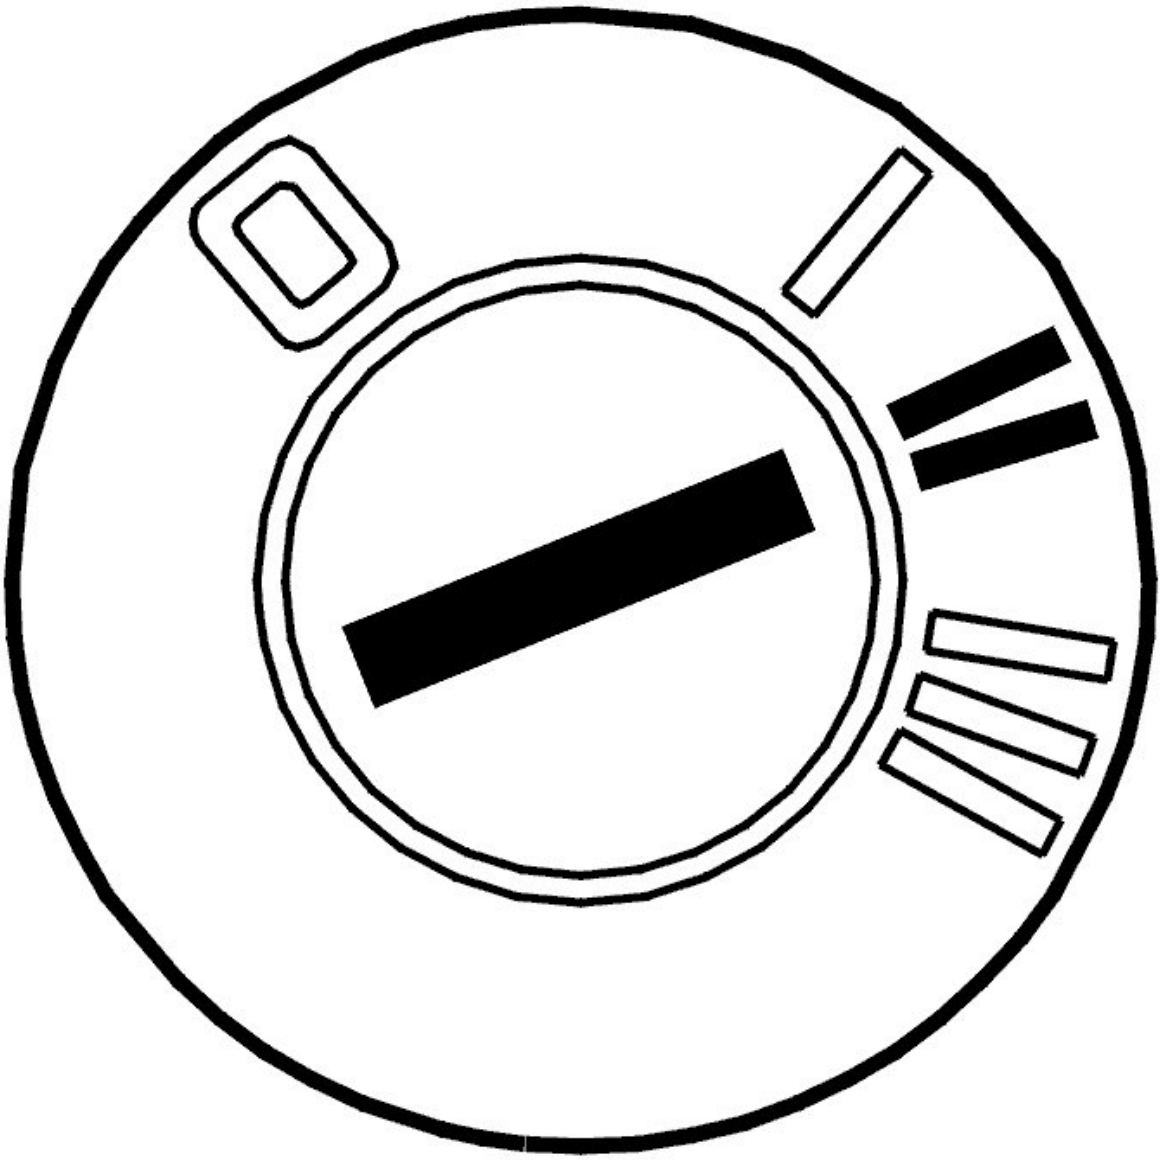
Fault symptom[s]
- General warning lamp lit
- The ABS warning lamp is lit
- The anti-spin warning lamp is lit (up to and including 2002 model year)
- The warning lamp for brake circuit not functioning is lit
- The ABS system does not function
- Anti-spin does not function
- The stability control system does not function
- The traction control system does not function.

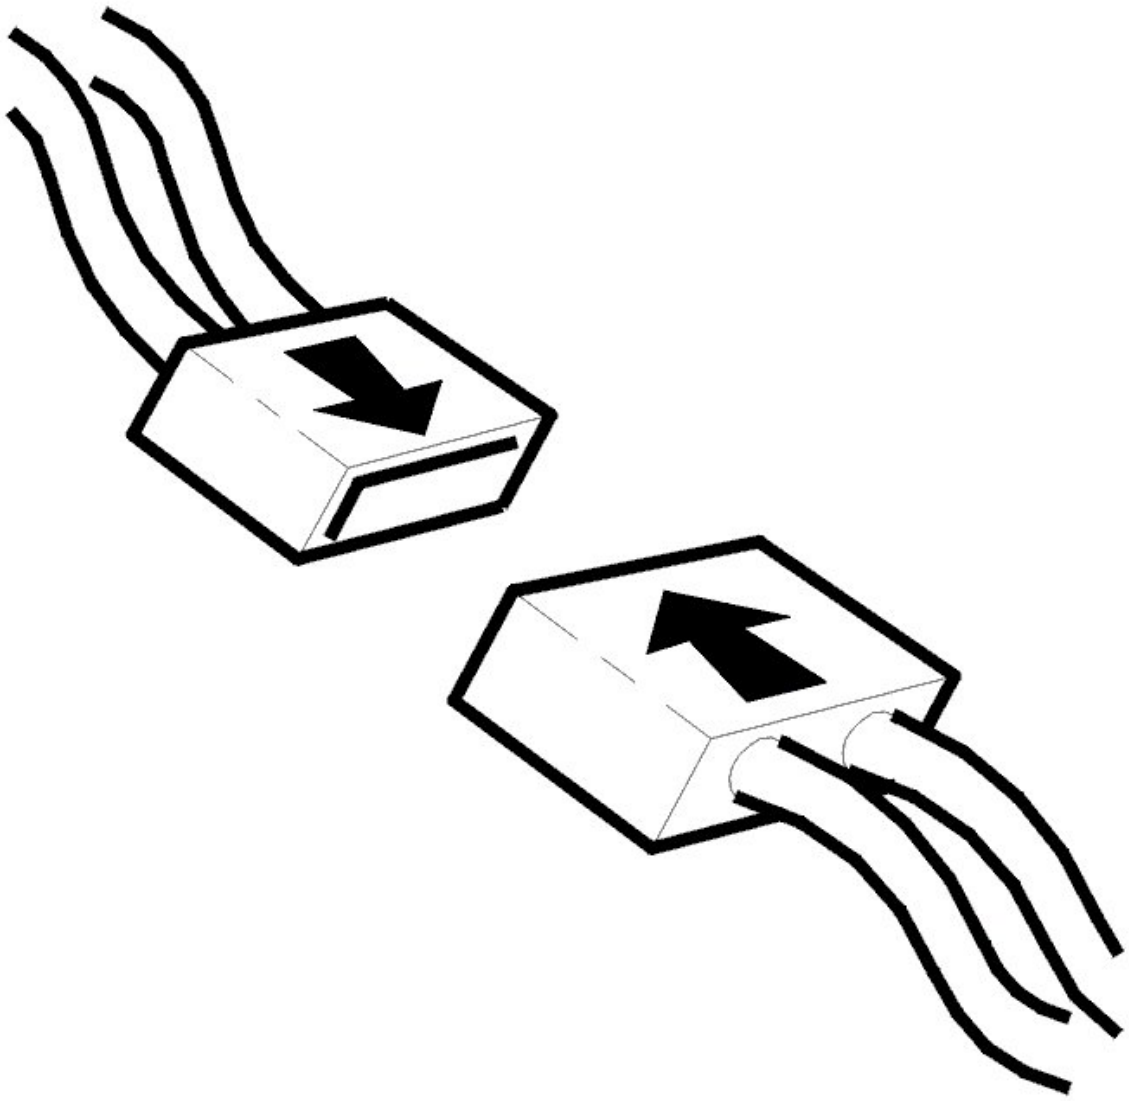
Note! If the fault is intermittent the ABS warning lamp will not go out until the vehicle speed exceeds 10 km/h in the next operating cycle.

Signal Missing

Signal missing

Checking the connectors for the control module and wheel sensor





- Ignition off
- Check the wheel sensor and brake control module (BCM) connectors. Check for contact resistance and oxidation
- Reinstall the components, reconnect the connectors etc.
- Raise the car so that the relevant wheel is clear of the ground
- Ignition on
- Read off the wheel speed for the relevant wheel.

Spin the relevant wheel and check that the wheel speed is updated.
If the wheel speed is updated, the cause of the fault was loose connections in the connectors for the control module or wheel sensor.

Note! The speed signal will only be active for approximately 20 seconds. Activate the function again if necessary.

Other information

- To disconnect the wheel sensor connector, see Wheel sensor rear, replacing See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Wheel Speed Sensor/Service and Repair/Wheel Sensor Rear, Replacing
- To disconnect the control module connector, see Connecting the breakout box, brake control module (BCM) See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box/Connecting the Breakout Box, Brake Control Module (BCM)
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

Is the wheel speed updated?

Yes - Fault Found

No - Checking wiring and sensors

Checking wiring and sensors
Checking the power supply

Check the power supply cable between the control module
- terminal #36 (#A36) (left rear)
- terminal #43 (#A43) (right rear).

and terminal #1 on the relevant sensor. Check for an open-circuit. Check for a short-circuit to ground. Check for a short-circuit to supply voltage.

Hint: With the ignition on, the voltage should be approximately 1 V under Ubat measured at the ground terminal.

Checking the signal cable

Check the power supply cable between the control module
- terminal #37 (#A37) (left rear)
- terminal #42 (#A42) (right rear).

and terminal #2 on the relevant sensor. Check for an open-circuit. Check for a short-circuit to ground. Check for a short-circuit to supply voltage.
Checking the function of the sensor

Check the sensor. Ensure that the breakout box is connected, the sensor is connected and the ignition is on. Measure the signal from the sensor. Connect a voltmeter between:
- terminals #36 (#A36) and #37 (#A37) (left front)
- terminals #43 (#A43) and #42 (#A42) (right front).

on the breakout box. The voltage should vary by approximately 1 V when the pulse wheel is rotating. Replace the wheel sensor if the voltage is faulty.
Remedy as necessary.

Other information
- To connect the breakout box, see Connecting the breakout box, brake control module (BCM) See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box/Connecting the Breakout Box, Brake Control Module (BCM)
- To replace the wheel sensor, see Wheel sensor rear, replacing See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Wheel Speed Sensor/Service and Repair/Wheel Sensor Rear, Replacing
- For information about signals, see Signal specification, brake control module (BCM) with STC/ TRACS See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Specification and Signal specification, brake control module (BCM) with DSTC (dynamic stability and traction control) See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Specification
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

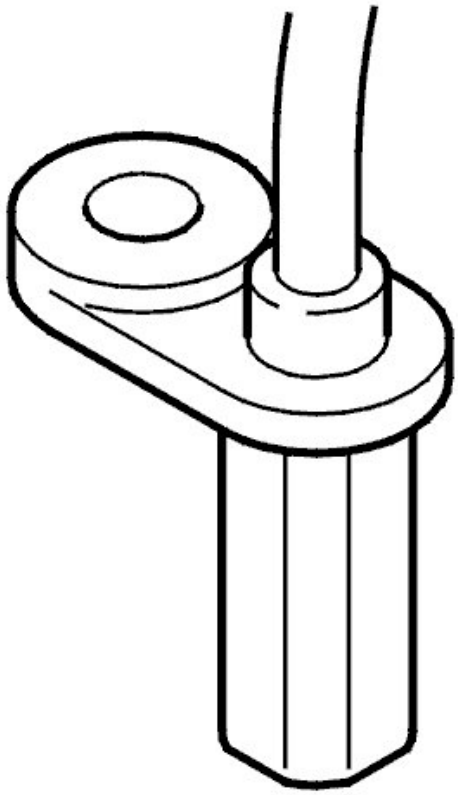
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition



The brake control module (BCM) can register this diagnostic trouble code (DTC) for a number of different fault causes.

1. The diagnostic trouble code is generated if the Brake control module (BCM) registers that the wheel stops or rotates too slowly in relation to the vehicle's reference speed while driving or ABS-control when speed is above 20 km/h.
2. Brake control module (BCM) has a counter, extrapolation counter, which counts the number of times that the speed change on the wheel is too big compared to that which is allowed (calculated). The diagnostic trouble code (DTC) is stored if wheel acceleration on one of the wheel sensors is greater than on other wheel sensors.
3. The diagnostic trouble code (DTC) is stored if the slowest wheel rotates at a speed that is less than 40-60 % of the fastest wheel (depending on the vehicle's speed) but finds that the wheel sensor circuit is unbroken.

The diagnostic trouble code (DTC) can be diagnosed at speeds above 10 km/h.

Substitute value
- The ABS is blocked
- Electronic Brake force Distribution (EBD) is blocked if two or more wheel sensors are not working
- Traction control is blocked
- Stability control is blocked
- Active yaw control is blocked
- Brake assistance is blocked.

Hint: For information about brake system abbreviations, see Brake system, abbreviations See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Description and Operation/Brake System, Abbreviations.

Possible source
- One of the wheels has been blocked while the car has being driven
- Loose wheel sensor
- The gap between the wheel sensor and the pulse wheel is too large or too small
- Hub vibrations or play in the wheel bearings
- Defective pulse wheel
- Defective wheel sensor.
- Dirt between wheel sensor and pulse wheel.

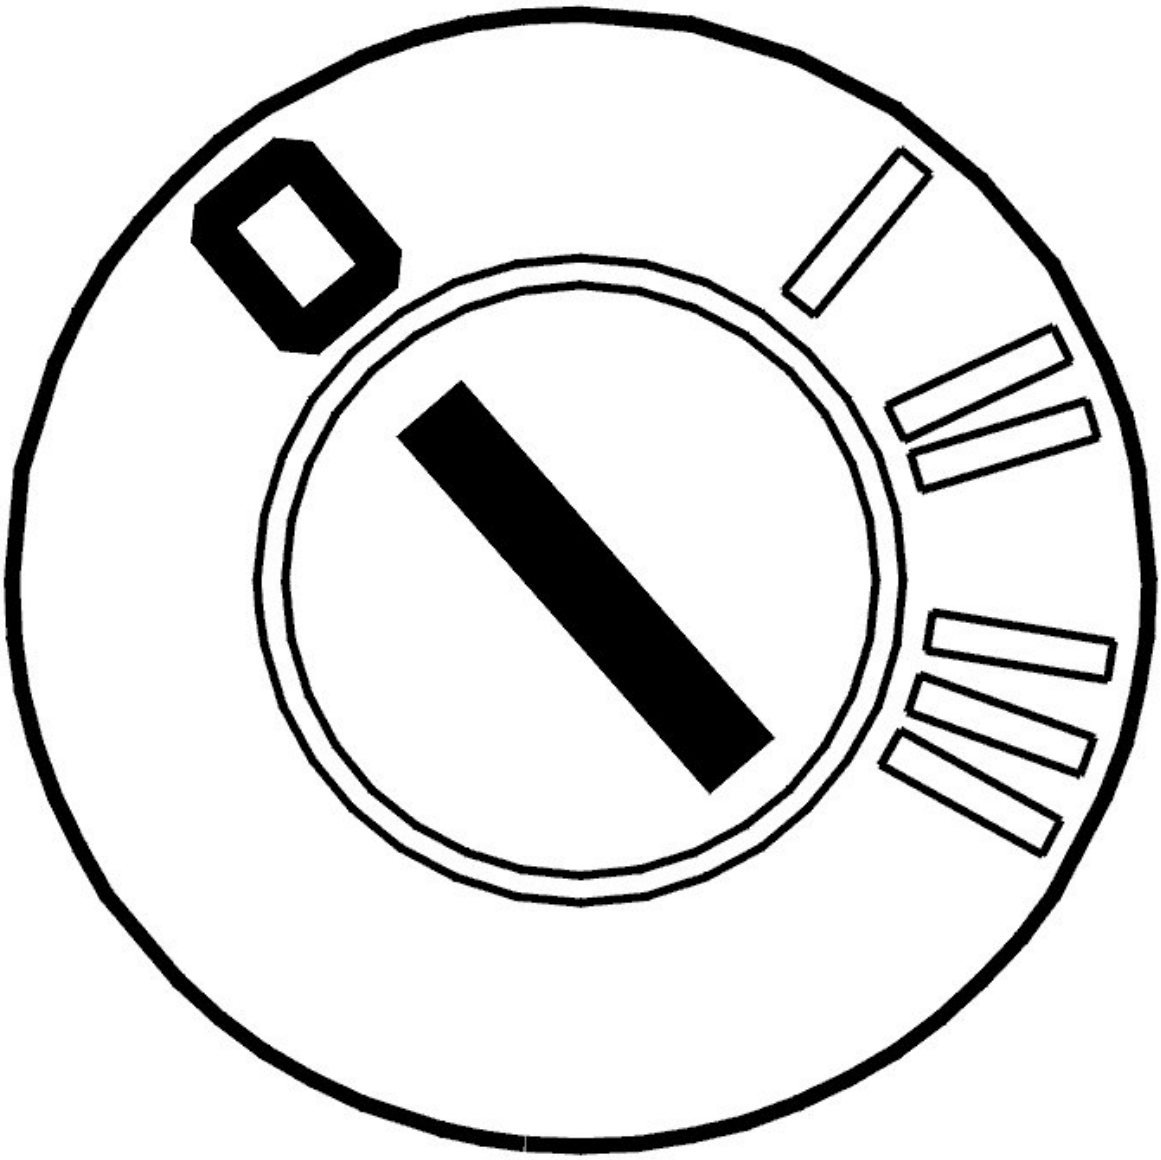
Note! This diagnostic trouble code (DTC) is not due to an internal hardware fault in the Brake control module (BCM) and must not be remedied by replacing the control module.

Fault symptom[s]
- General warning lamp lit
- The ABS warning lamp is lit
- The anti-spin warning lamp is lit (up to and including 2002 model year)
- The ABS system does not function
- Anti-spin does not function
- The stability control system does not function
- The traction control system does not function.

Faulty Signal

Faulty signal

Checking the wheel sensor and pulse wheel



- Ignition off.
- Remove the wheel for better access.

Check that the relevant wheel sensor is mounted tightly against the shaft/hub. Check that there is no dirt between the sensor and mating surface.
Check that the toothed wheel is properly mounted and is free from damage (all teeth intact, no scratches or deformity, etc.)
Remedy as necessary.

Other information

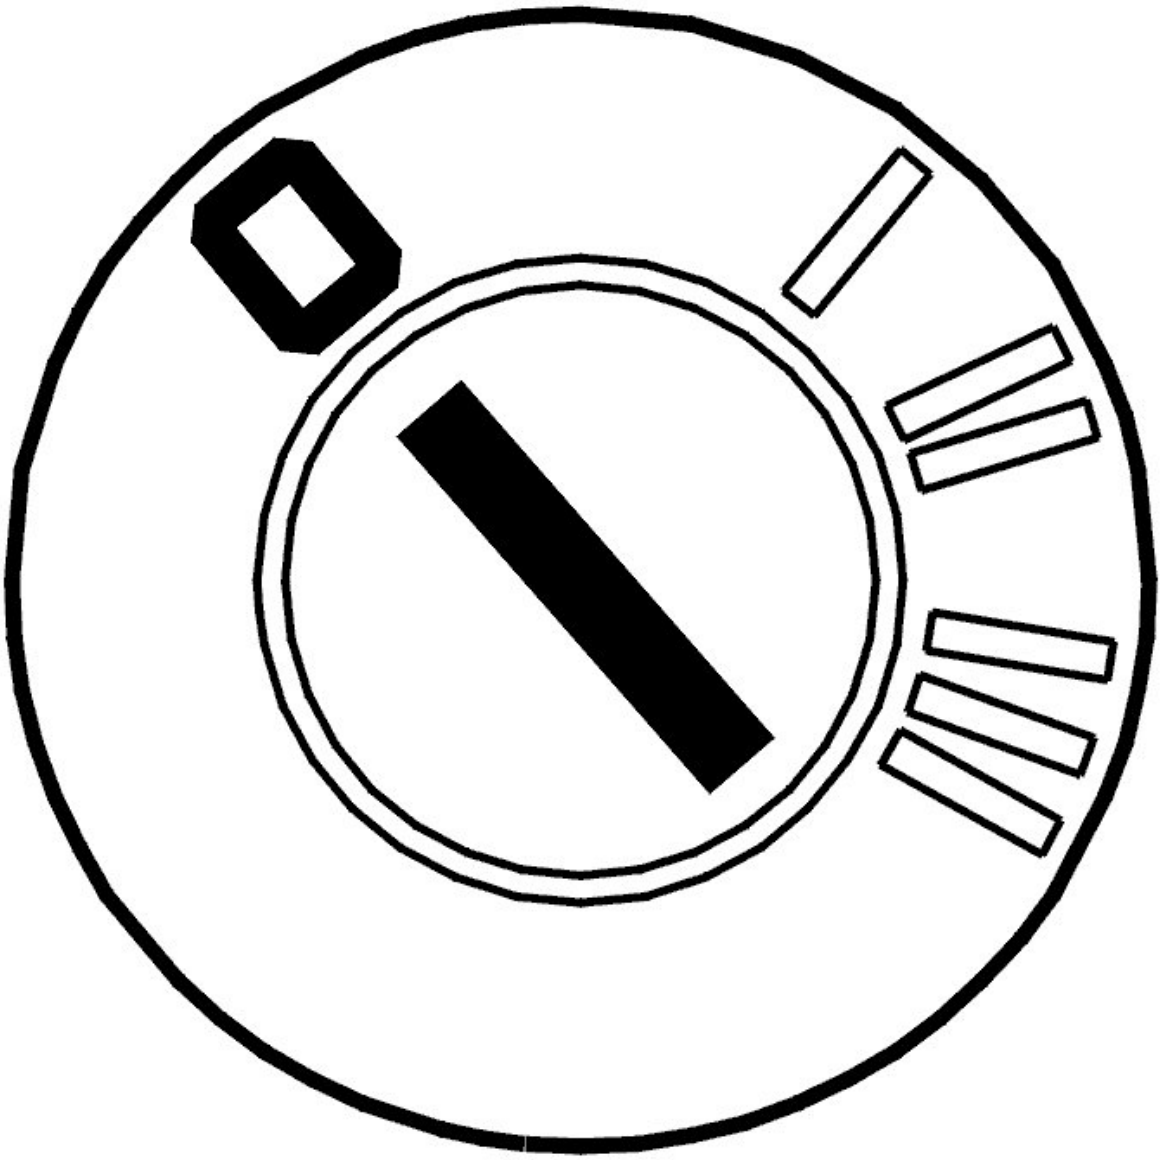
- General warning lamp lit
- No ABS function
- Anti-spin does not function
- The traction control system does not function.

Note! If the fault becomes intermittent, the ABS warning lamp will not go out until the vehicle speed exceeds 10 km/h in the next operating cycle.

Faulty Signal

Faulty signal

Checking the wheel sensor and pulse wheel

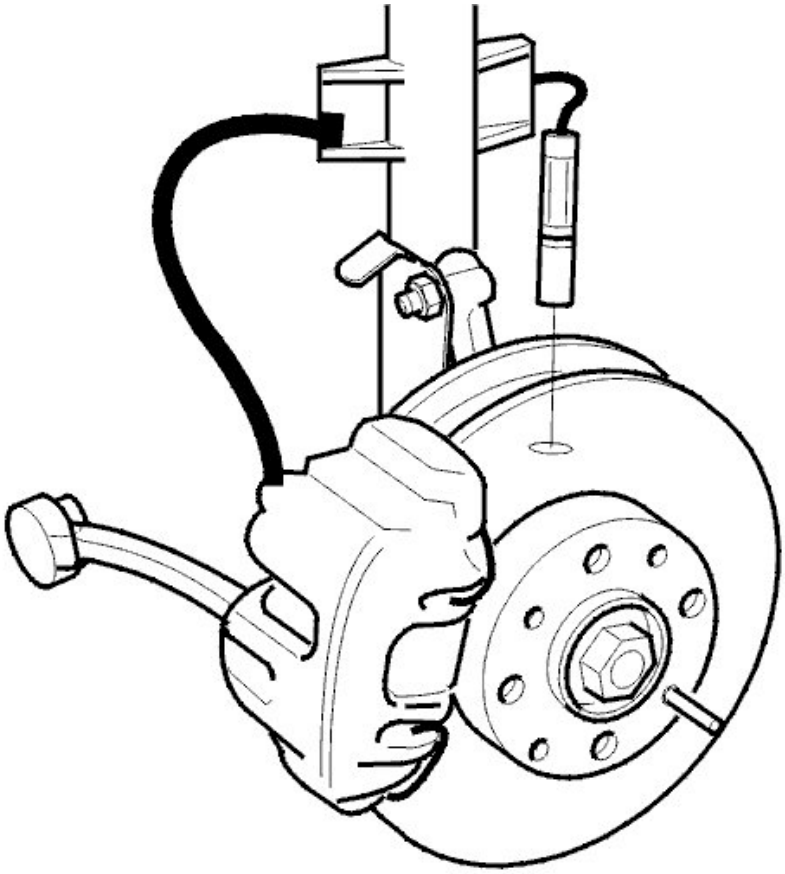


- Ignition off.
- Remove the wheel for better access.

Check that the relevant wheel sensor is mounted tightly against the shaft/hub. Check that there is no dirt between the sensor and mating surface.
Check that the toothed wheel is properly mounted and is free from damage (all teeth intact, no scratches or deformity, etc.)
Remedy as necessary.

Other information

- Wheel sensor front, replacing See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Wheel Speed Sensor/Service and Repair/Wheel Sensor Front, Replacing
- Wheel sensor rear, replacing See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Wheel Speed Sensor/Service and Repair/Wheel Sensor Rear, Replacing



Was a fault detected?

Yes - Verification

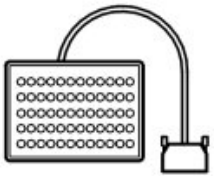
No - Checking the connectors and cables

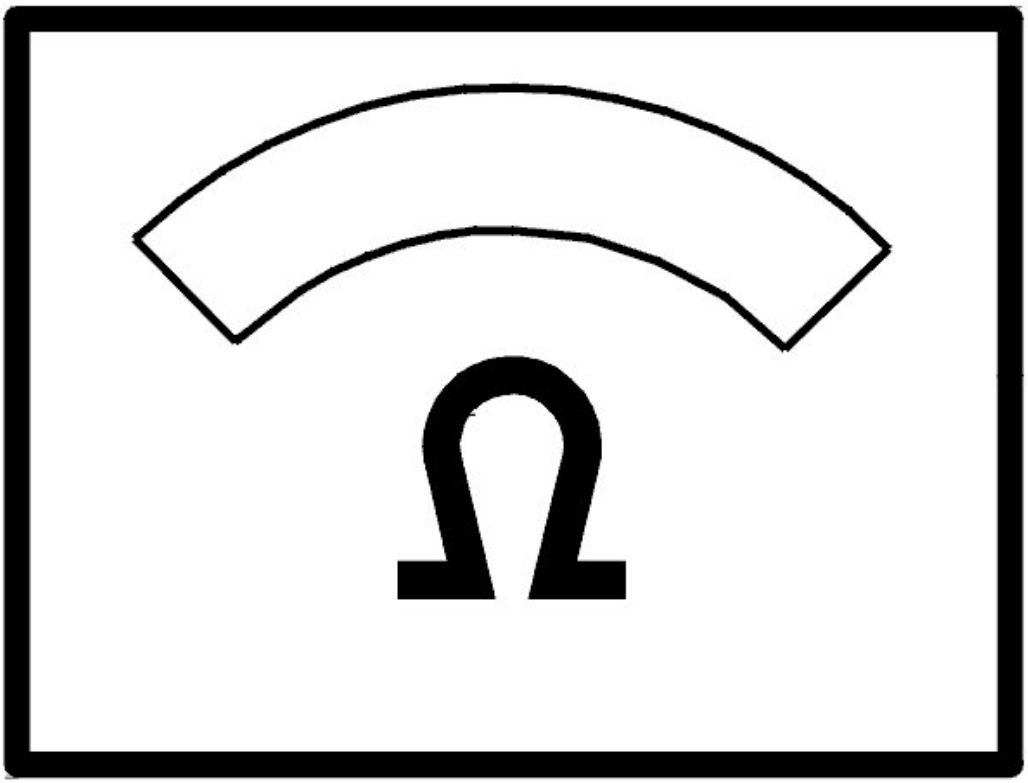
Checking the connectors and cables

Check the connectors of the brake control module (BCM) and the relevant wheel sensors for contact resistance and oxidation.
Check the connectors and cable insulation for damage.
Check that the wheel sensor cables are not too close to sources of interference.
Remedy as necessary.

Other information

- Connecting the breakout box, brake control module (BCM) See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box/Connecting the Breakout Box, Brake Control Module (BCM)
- Wheel sensor front, replacing See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Wheel Speed Sensor/Service and Repair/Wheel Sensor Front, Replacing
- Wheel sensor rear, replacing See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Wheel Speed Sensor/Service and Repair/Wheel Sensor Rear, Replacing
- Signal specification, brake control module (BCM) with STC/ TRACS See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Specification
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals





Was a fault detected?

Yes - Verification

No - No Fault Found

Verification

Verification

Verification

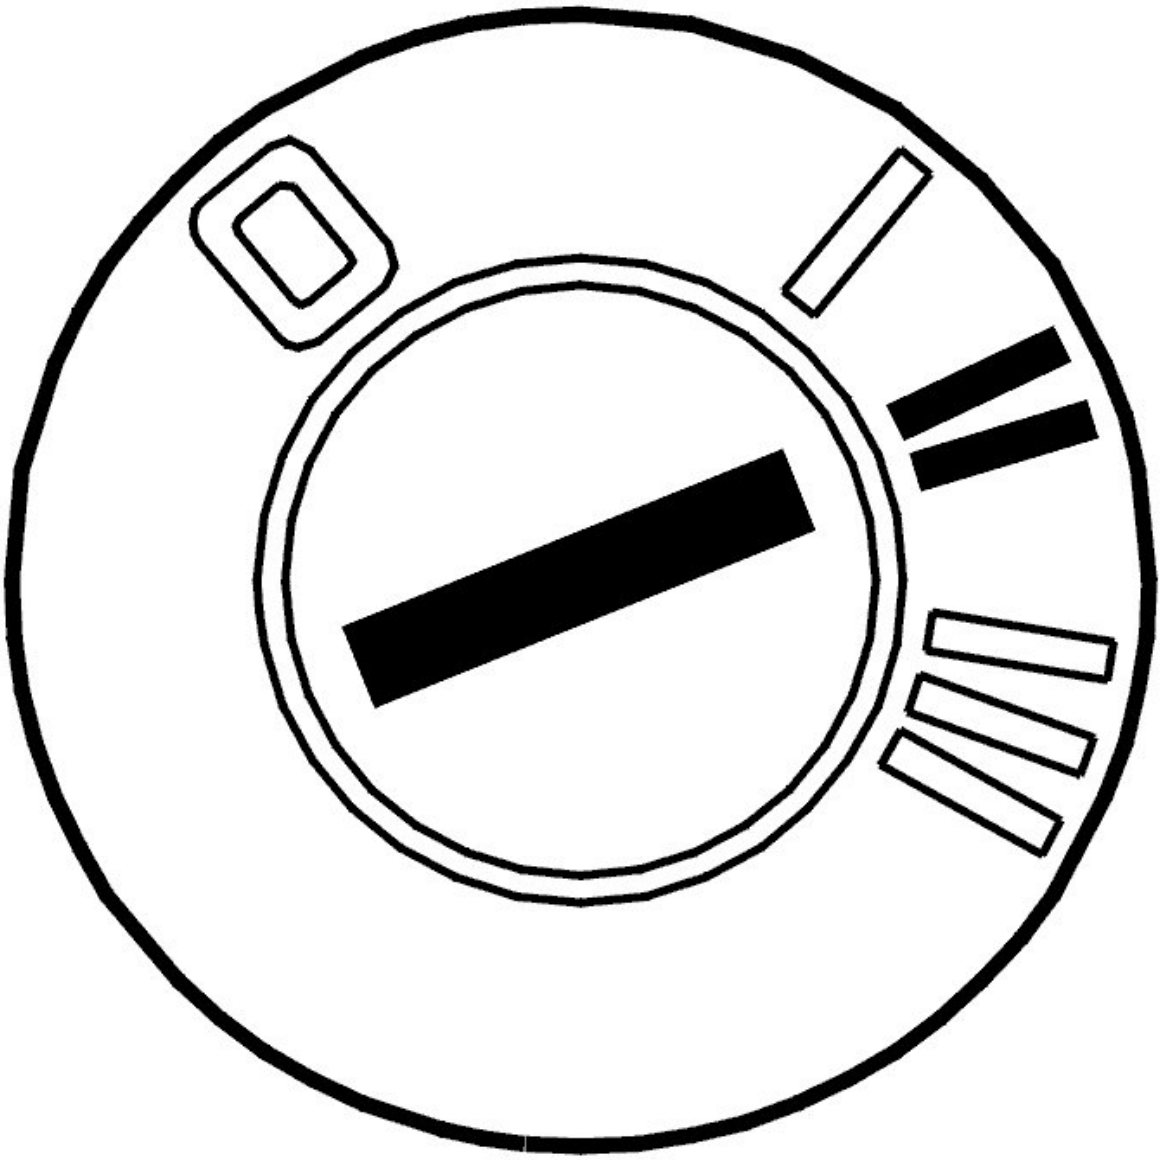
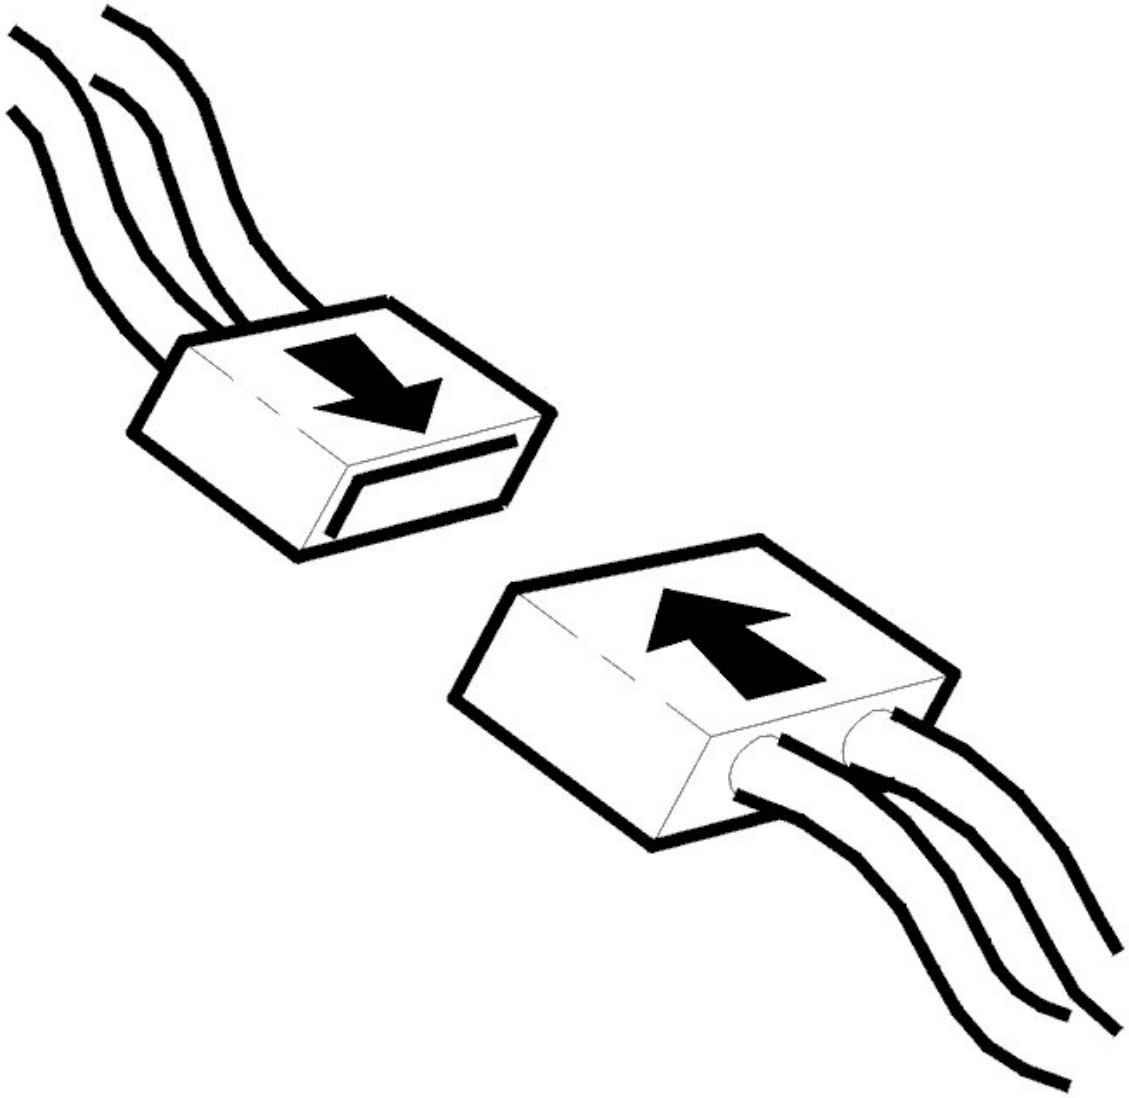
Hint: After carrying out the repair, check that the fault has been remedied.





- Ignition off
- Reinstall the components, reconnect the connectors etc.
- Ignition on
- Test drive the car. See Test Drive Form (DSTC (dynamic stability and traction control) /brake control module), description See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Testing and Inspection/Initial Inspection and Diagnostic Overview/Test Drive Form (DSTC (Dynamic Stability And Traction Control) /Brake Control Module), Description.

Check the ABS warning lamp during the test drive.
If the fault has been remedied the lamp will go out when the speed exceeds 20 km/h.
If the warning lamp does not go out, return to the workshop and read off the diagnostic trouble codes (DTCs).

Does the ABS warning lamp go out and remain unlit?

Yes - VERIFIED

No - VERIFICATION FAILED

VERIFIED - Fault Found

VERIFICATION FAILED - Fault-tracing information

Fault-tracing information

Do you want to exit fault-tracing?

Yes - FAULT-TRACING FAILED

No - Attempt New Test

FAULT-TRACING FAILED - FAULT-TRACING FAILED

Attempt New Test - Checking the wheel sensor and pulse wheel

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition

Diagnostic trouble code (DTC) BCM-0050 is stored if the brake control module (BCM) registers an internal fault, such as distortion or an open-circuit in the circuit for the hydraulic valves.

Substitute value
- The ABS is blocked
- Electronic Brake force Distribution is blocked
- Stability control is blocked
- Traction control is blocked
- Active yaw control is blocked
- Brake assistance is blocked.

Hint: For information about brake system abbreviations, see Brake system, abbreviations See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Description and Operation/Brake System, Abbreviations.

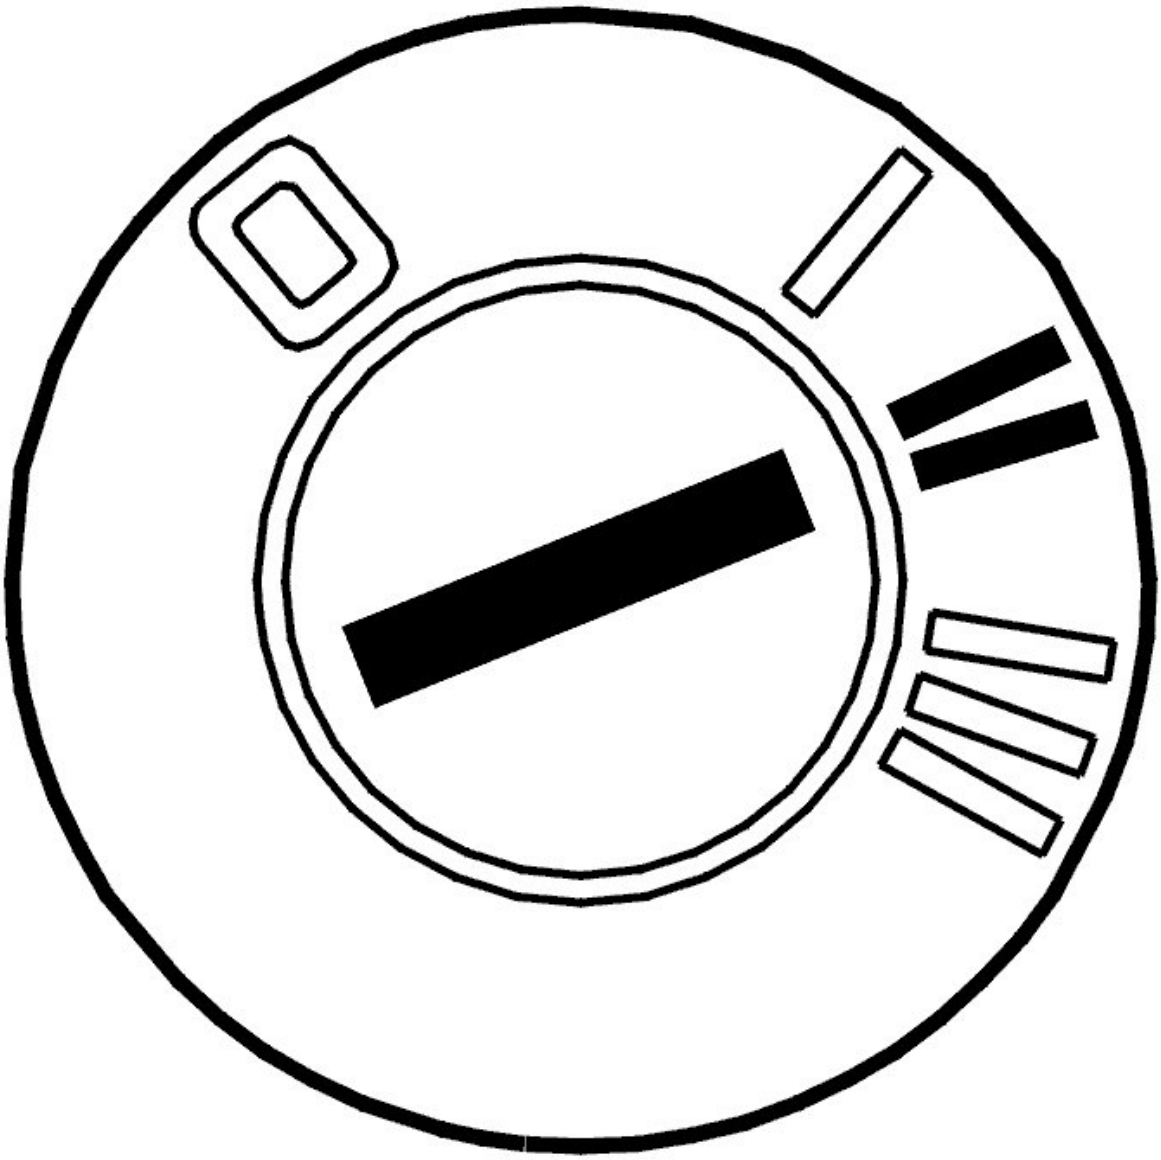
Possible source
- Interference that has affected control module calculations
- Internal fault in the control module.

Fault symptom[s]
- General warning lamp lit
- The ABS warning lamp is lit
- The warning lamp for brake circuit not functioning is lit
- The anti-spin warning lamp is lit (up to and including 2002 model year)
- The ABS system does not function
- Anti-spin does not function
- The stability control system does not function
- The traction control system does not function.

Internal Fault

Internal fault

Reading off diagnostic trouble codes (DTCs)



- Ignition on
- Read off diagnostic trouble codes (DTCs).

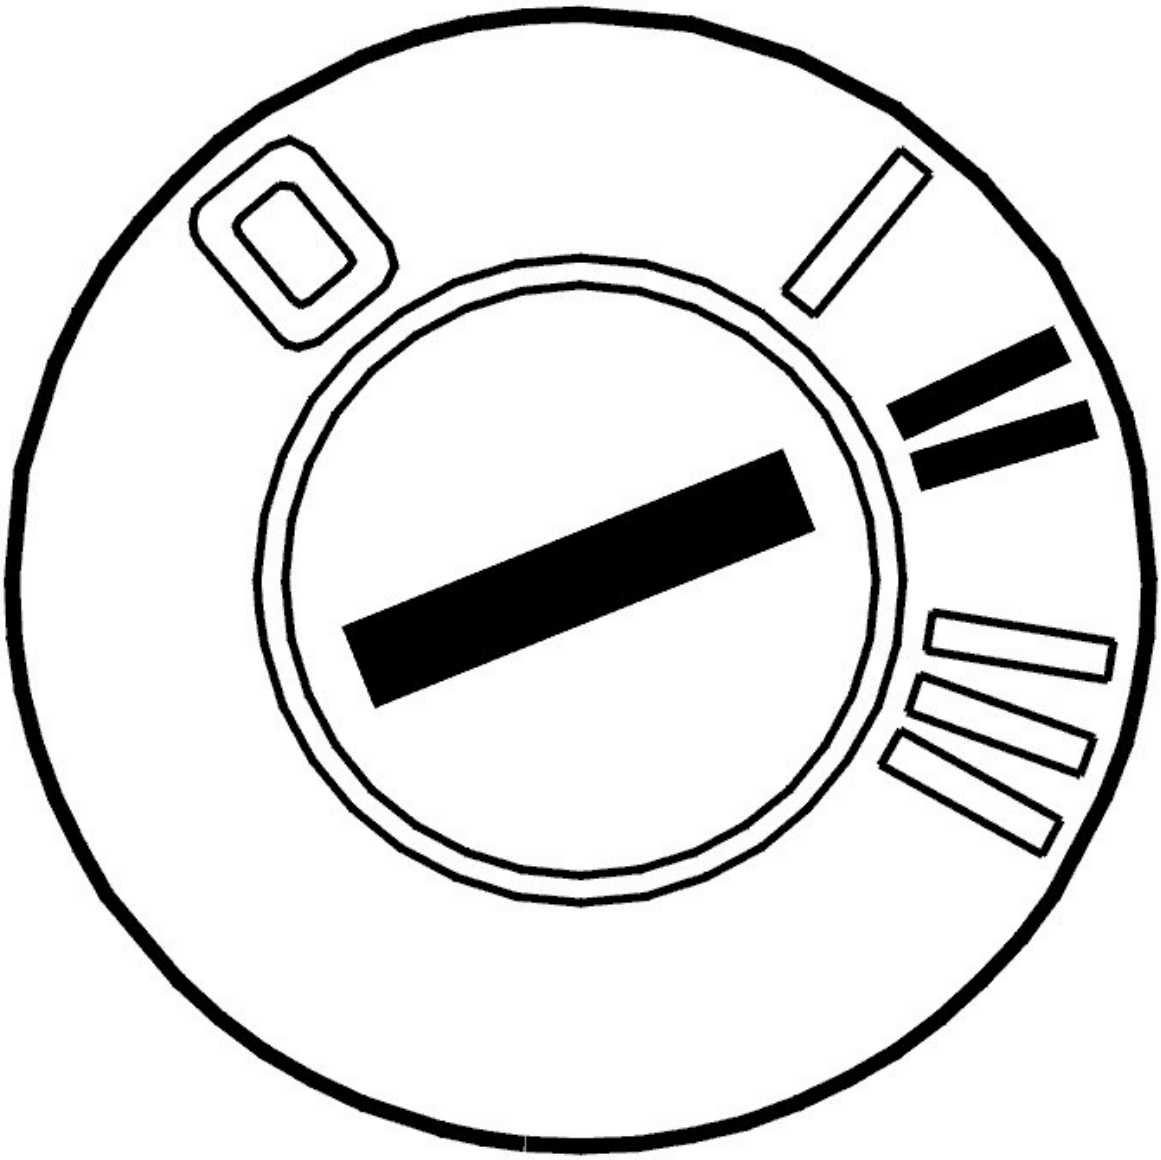
If any other codes than BCM-0050 are stored, these must be fault-traced first.

Were any diagnostic trouble codes (DTCs) other than BCM-0050 stored?

Yes - DONE

No - Erasing diagnostic trouble code (DTC)

Erasing diagnostic trouble code (DTC)

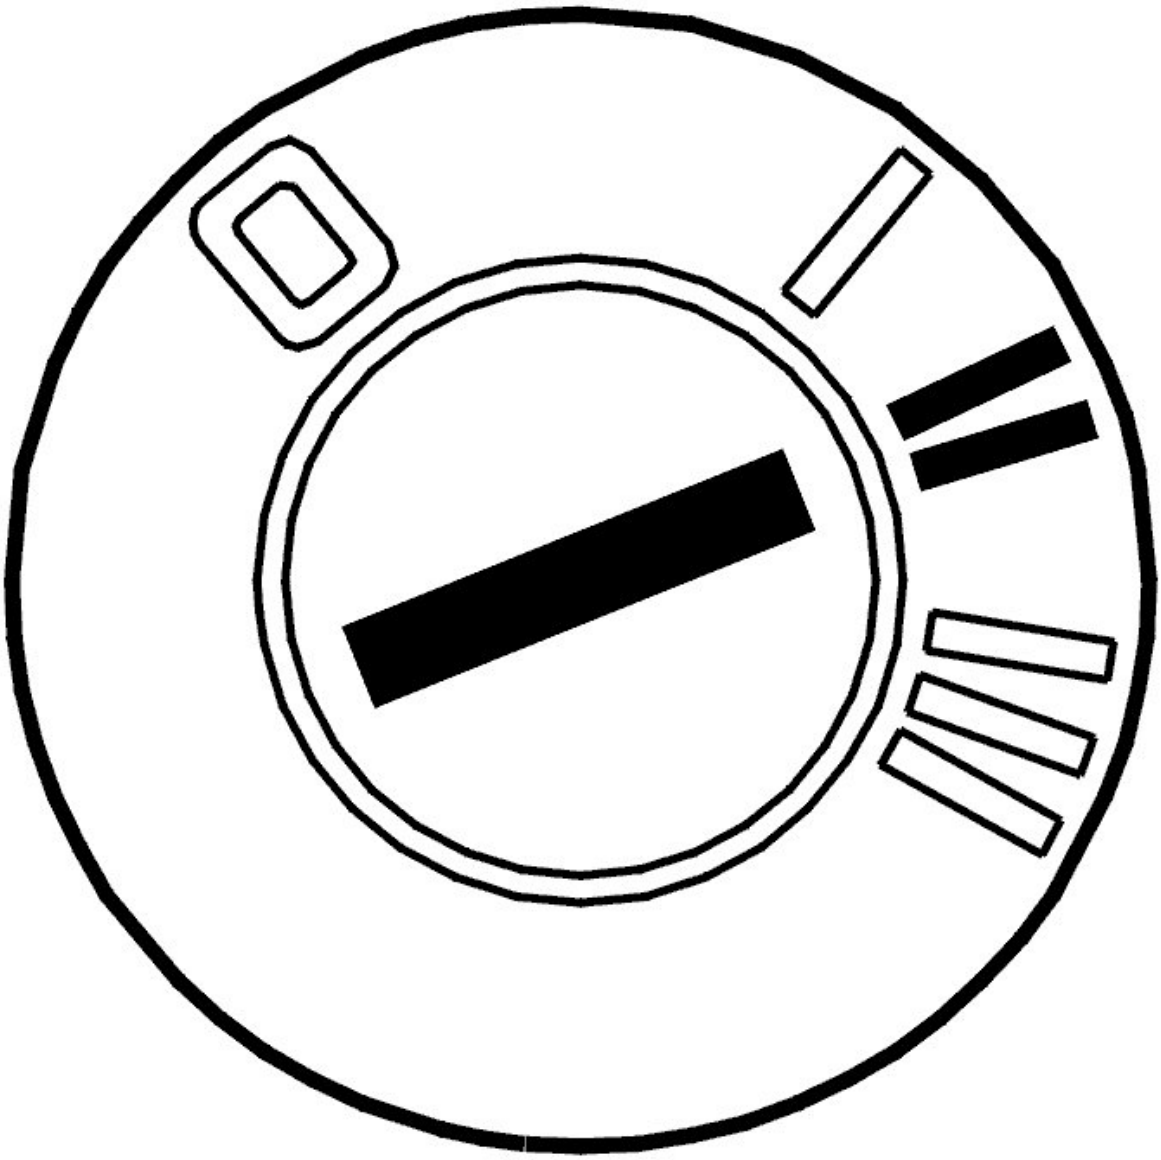


- Ignition on.

Erase the diagnostic trouble codes (DTC).

Continue - Checking diagnostic trouble codes (DTCs)

Checking diagnostic trouble codes (DTCs)



- Ignition off
- Check the brake control module (BCM) connector. Check for contact resistance and oxidation
- Wait a couple of seconds
- Ignition on
- Read off diagnostic trouble codes (DTCs).

Replace the brake control module (BCM) if diagnostic trouble code (DTC) BCM-0050 is still stored as a permanent fault.

Other information

- To replace the control module, see Brake Control Module (BCM), replacing See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Electronic Brake Control Module/Service and Repair/Brake Control Module (BCM), Replacing
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

Was diagnostic trouble code (DTC) BCM-0050 stored as a permanent fault?

Yes - Fault Found

No - Fault-tracing information

Fault-tracing information

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

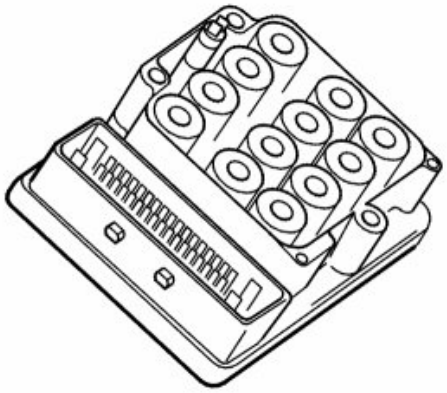
The control module has previously registered a fault but the fault is no longer active. Check that the wiring is not too close to a source of interference such as a carphone etc.

Yes - No Fault Found

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition



Diagnostic trouble code (DTC) BCM-0052 is stored if the brake control module (BCM) detects an internal fault.

Substitute value
- The ABS is blocked
- Electronic Brake force Distribution is blocked
- Traction control is blocked
- Stability control is blocked
- Active yaw control is blocked
- Brake assistance is blocked.

Hint: For information about brake system abbreviations, see Brake system, abbreviations See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Description and Operation/Brake System, Abbreviations.

Possible source
- Interference that has affected control module calculations
- Internal fault in the control module.

Fault symptom[s]
- General warning lamp lit
- The ABS warning lamp is lit
- The warning lamp for brake circuit not functioning is lit
- The anti-spin warning lamp is lit (up to and including 2002 model year)
- The ABS system does not function
- Anti-spin does not function
- The stability control system does not function
- The traction control system does not function.

Continue - DONE

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition

Diagnostic trouble code (DTC) BCM-0057 is stored if the brake control module (BCM) registers that the battery voltage is less than 9.5 V and the speed of the quickest rotating wheel is over 20 km/h.
The diagnostic trouble code (DTC) can be diagnosed when the speed is above 20 km/h and too low voltage has been detected for longer than approximately 0.5 ms.

Substitute value
- The ABS is blocked
- Electronic Brake force Distribution is blocked if the voltage is below 8 V
- Traction control is blocked
- Stability control is blocked
- Active yaw control is blocked
- Brake assistance is blocked.

Hint: For information about brake system abbreviations, see Brake system, abbreviations See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Description and Operation/Brake System, Abbreviations.

Possible source
- Contact resistance in the terminals
- Battery voltage too low
- Fault in the charging system
- Open-circuit or short-circuit to ground in the cable for the power supply
- Defective fuse in the circuit
- Interference in the wiring
- Defective control module.

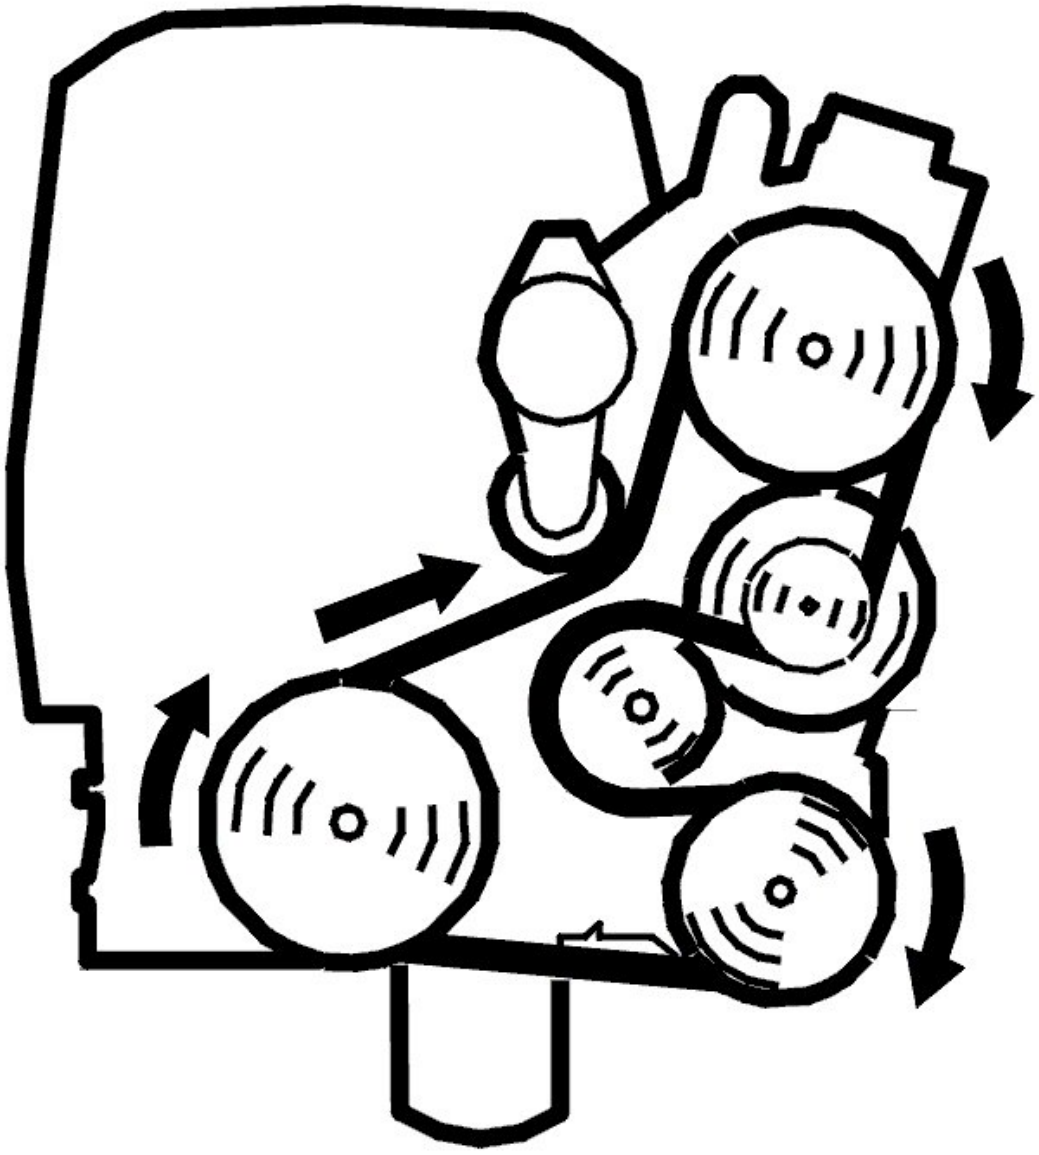
Fault symptom[s]
- General warning lamp lit

- The ABS warning lamp is lit
- The warning lamp for brake circuit not functioning is lit
- The anti-spin warning lamp is lit (up to and including 2002 model year)
- The ABS system does not function
- Anti-spin does not function
- The stability control system does not function
- The traction control system does not function.

Voltage Too Low

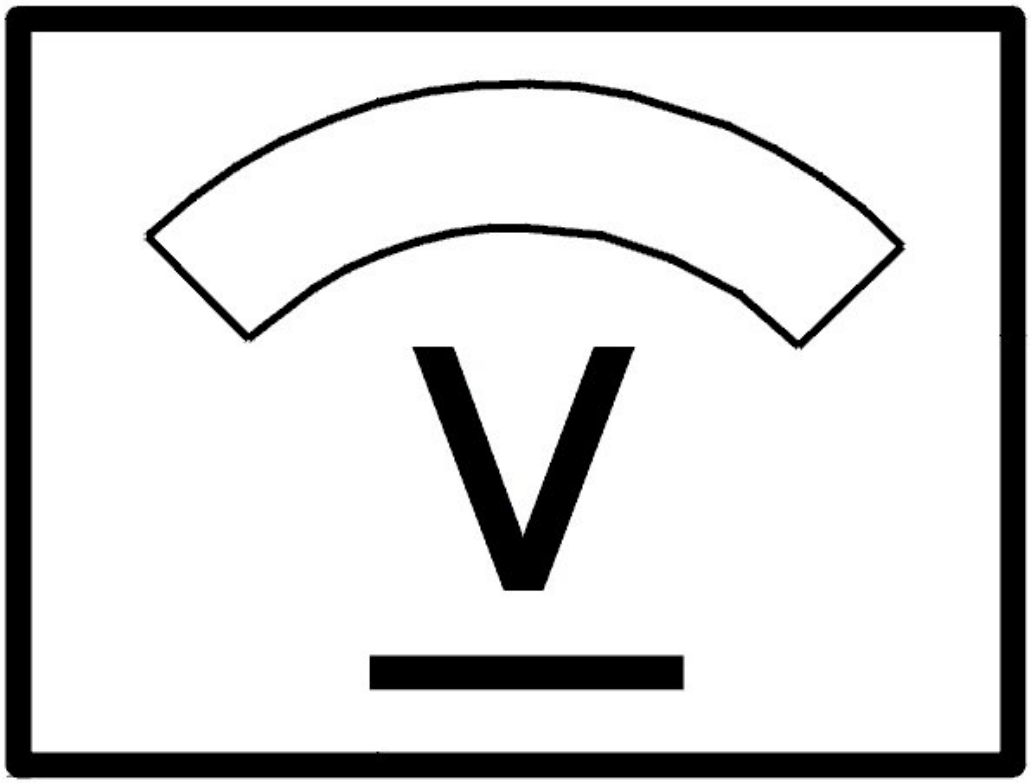
Voltage too low

Checking the battery voltage



- Start the engine and let it run at idle speed
- Connect a voltmeter between the battery positive and negative terminals.

The voltage must be normal system voltage.
If the voltage is too low, check the charging system according to the relevant information.

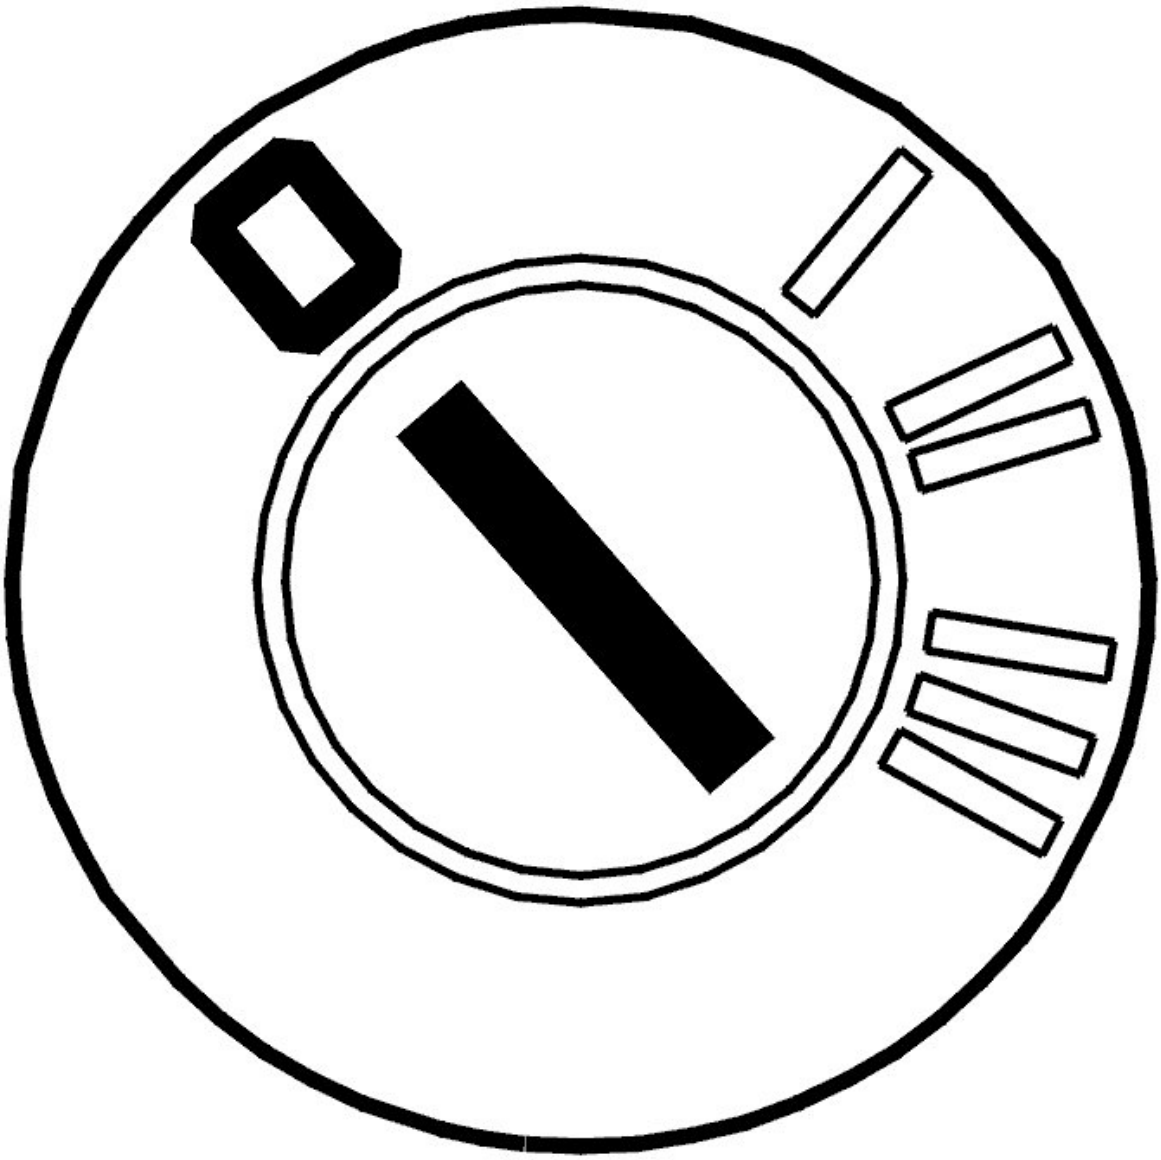


Was the voltage too low?

Yes - DONE

No - Checking the power supply

Checking the power supply



- Ignition off.

Check the brake control module connector. Check for contact resistance and oxidation.
Check the cable for power supply between the fuse for the brake control module in the integrated relay/fusebox in the engine compartment and terminal #A32 (#32) in the connector for the brake control module. Check for a short-circuit to ground.

Hint: With the ignition on and the voltmeter connected between terminals #A32 (#32) and #A47 (#A47) on the breakout box, the voltmeter should read battery voltage.

Other information

- To connect the breakout box, see Connecting the breakout box, brake control module (BCM) See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box/Connecting the Breakout Box, Brake Control Module (BCM)

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition

Diagnostic trouble code (DTC) BCM-0058 is stored if the control module registers that the battery voltage is above 18 V.
The diagnostic trouble code (DTC) can be diagnosed when the ignition is switched on.

Substitute value
- The ABS is blocked
- Electronic Brake force Distribution is blocked
- Traction control is blocked
- Stability control is blocked
- Active yaw control is blocked
- Brake assistance is blocked.

Hint: For information about brake system abbreviations, see Brake system, abbreviations See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Description and Operation/Brake System, Abbreviations.

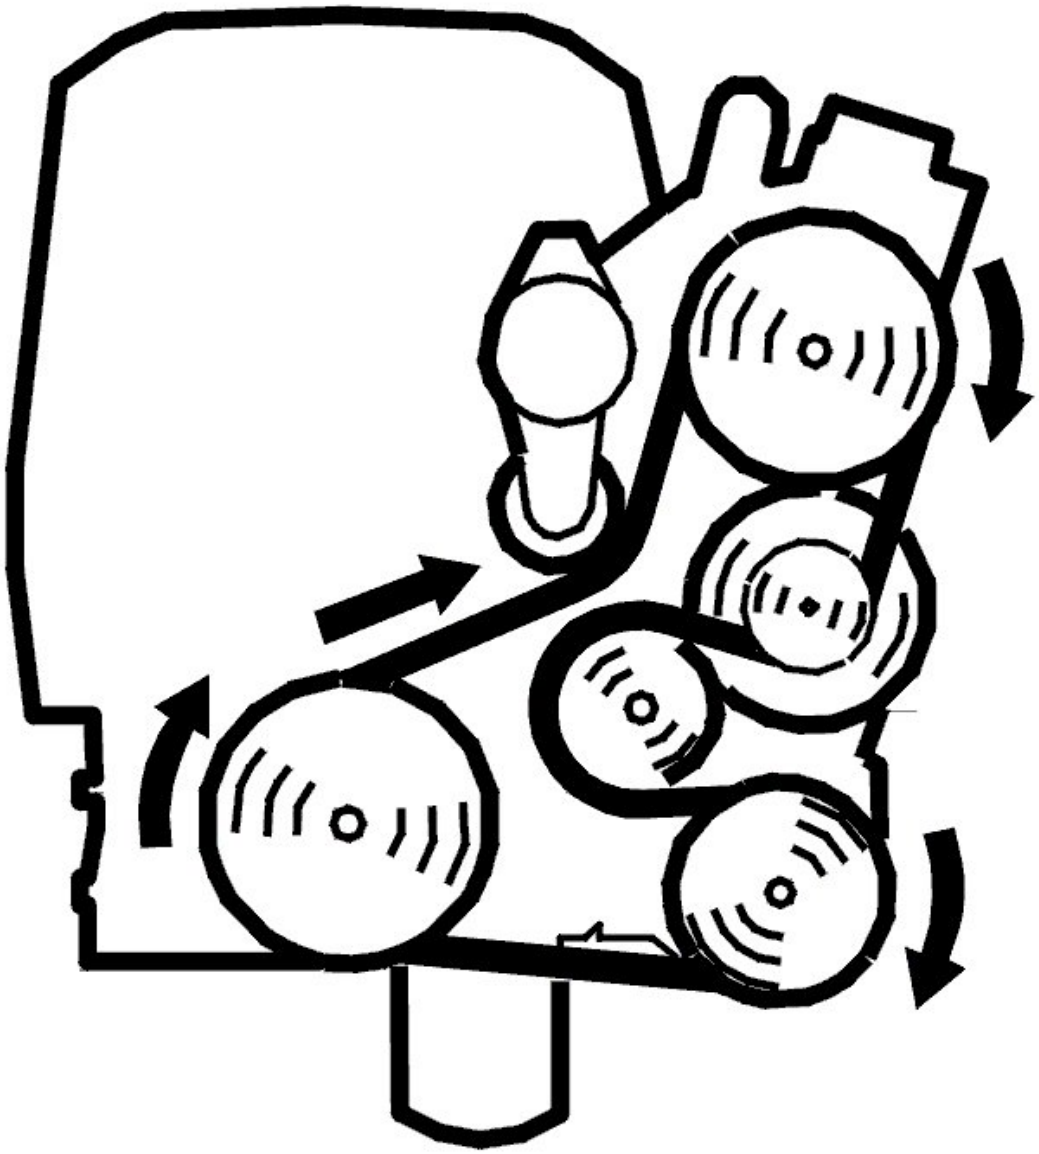
Possible source
- Fault in the charging system.

Fault symptom[s]
- General warning lamp lit
- The ABS warning lamp is lit
- The warning lamp for brake circuit not functioning is lit
- The anti-spin warning lamp is lit (up to and including 2002 model year)
- The ABS system does not function
- Anti-spin does not function
- The stability control system does not function
- The traction control system does not function.

Voltage Too High

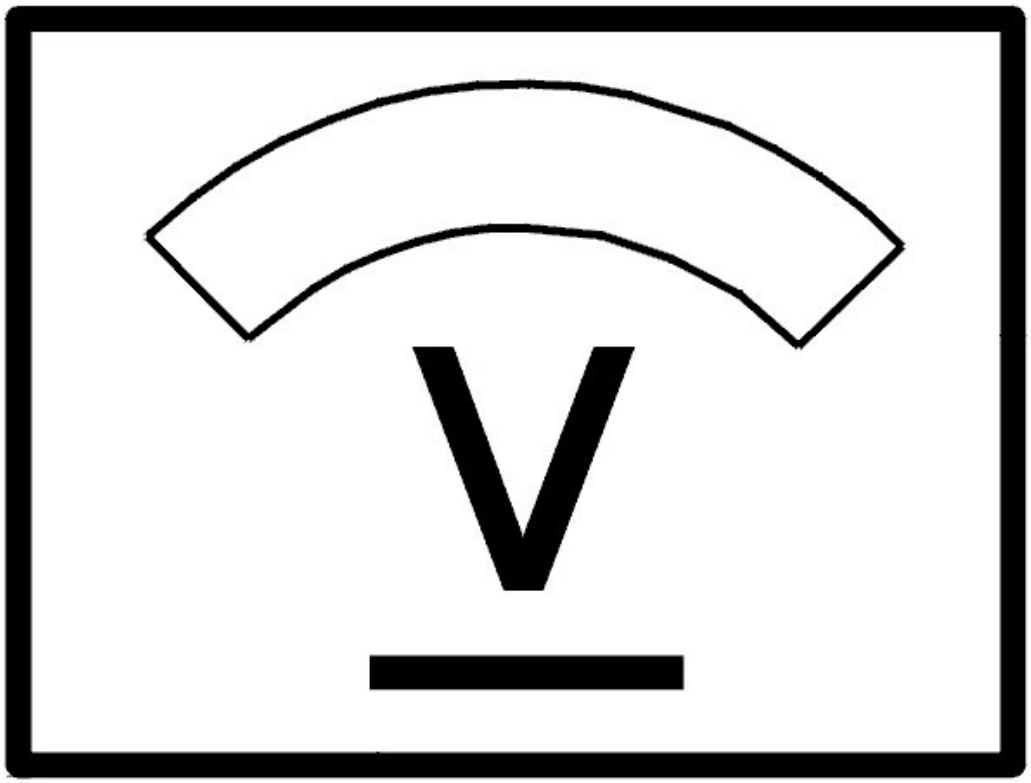
Voltage too high

Checking the battery voltage



- Start the engine and let it run at idle speed
- Connect a voltmeter between the battery positive and negative terminals.

The voltage must be normal system voltage.
If the voltage is too high, check the charging system according to the relevant information.



Was the voltage too high?

Yes - Fault Found

No - Fault-tracing information

Fault-tracing information

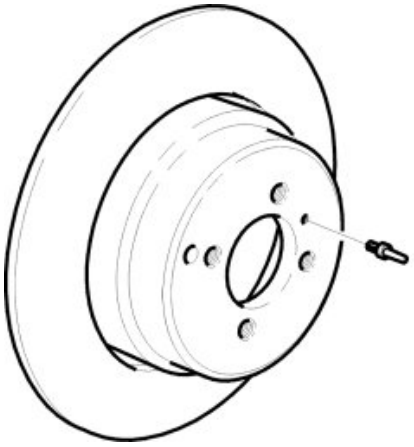
The fault-tracing indicates that the control module has previously registered a fault but that the fault is no longer active.

Continue - No Fault Found

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition



In cars with traction control (STC/DSTC/TRACS), the brake control module registers how much the brakes are used and then calculates the temperature of all brake discs. Diagnostic trouble code (DTC) BCM-0061 is stored if the calculated temperature exceeds 450°C.
The diagnostic trouble code (DTC) can be diagnosed while the ignition is switched on.

Substitute value
- Traction control is blocked.

Hint: For information about brake system abbreviations, see Brake system, abbreviations See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Description and Operation/Brake System, Abbreviations.

Possible source
- Excessive anti-spin control
- Brakes applied too long (brakes have been used so much that brake disc temperature has become too high).

Note! This diagnostic trouble code (DTC) is not due to an internal hardware fault in the Brake control module (BCM) and must not be remedied by replacing the control module.

Fault symptom[s]
- Anti-spin does not function.

Note! The anti-spin function is deactivated until the temperature of the brake discs is below 300°C.

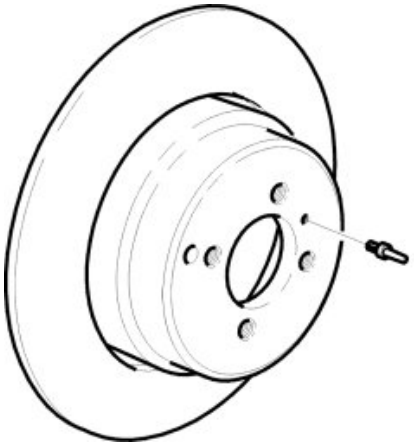
Temperature Too High

Temperature too high

Visual inspection of brakes
- Remove the front wheels.

Check the brakes for the front wheel visually.
Check there is no overheating damage to brake caliper, brake pads or brake disc. Replace damaged components.
Tell the customer why the anti-spin function was temporarily blocked and why the ABS warning lamp was lit.
Remedy as necessary.

Other information
- To remove or replace brake calipers, see Brake calipers front, replacing See: Brakes and Traction Control/Disc Brake System/Brake Caliper/Service and Repair/Removal and Replacement
- To remove or replace brake pads, see Brake pads front, replacing See: Brakes and Traction Control/Disc Brake System/Brake Pad/Service and Repair
- To remove or replace brake discs, see Brake disc front, replacing See: Brakes and Traction Control/Disc Brake System/Brake Rotor/Disc/Service and Repair.

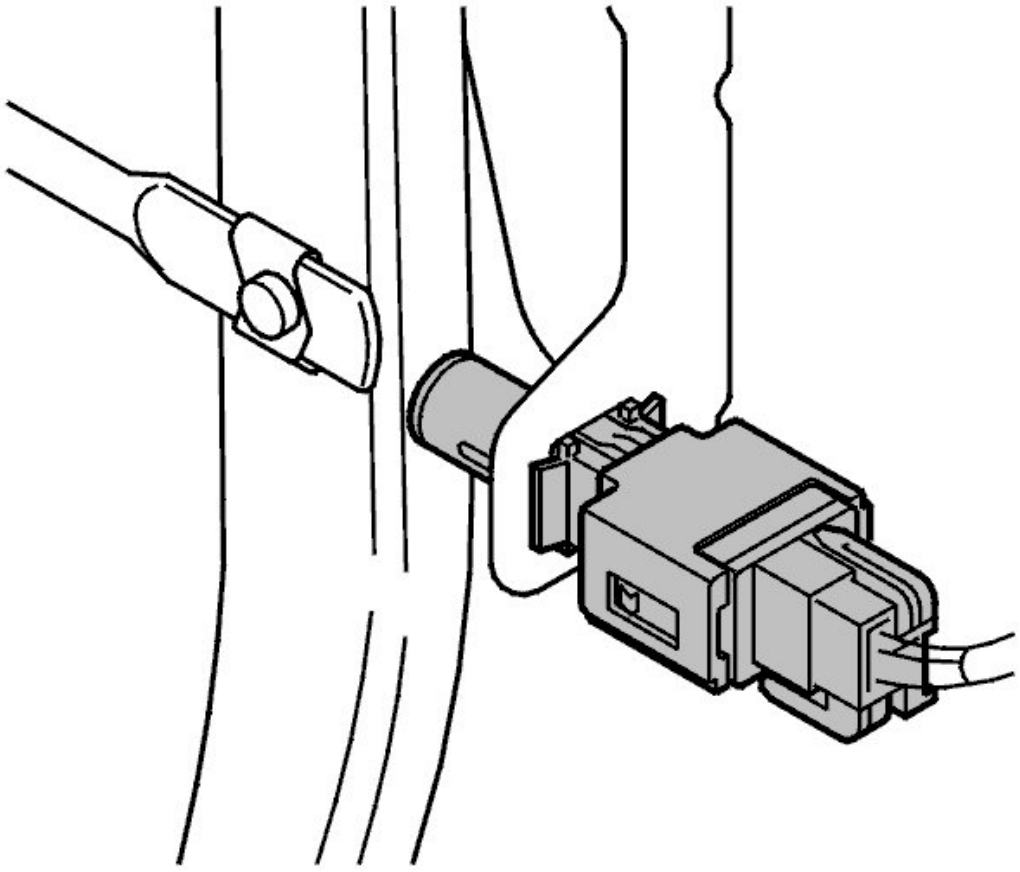


Continue - Fault Found

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition



Note! Only applies to four wheel drive cars with TRACS (traction control system).

The brake control module compares the signals with each other in order to detect a faulty signal from the stop lamp switch or the pedal position sensor. Diagnostic trouble code (DTC) BCM-0065 is stored if the control module registers a faulty signal from the stop lamp switch or the pedal position sensor.

Substitute value

- Traction control is blocked.

Hint: For information about brake system abbreviations, see Brake system, abbreviations See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Description and Operation/Brake System, Abbreviations.

Possible source

- Short-circuit to ground or supply voltage in the signal cable for the stop lamp switch

- Defective stop lamp switch
- Defective pedal position sensor.

Fault symptom[s]
- Anti-spin does not function.

Faulty Signal

Faulty signal

Checking diagnostic trouble codes in the central electronic module (CEM) and the engine control module (ECM)

If there are diagnostic trouble codes (DTCs) for the brake pedal position sensor or stop lamp switch stored in the engine control module (ECM) or central electronic module (CEM), these must be fault traced first.

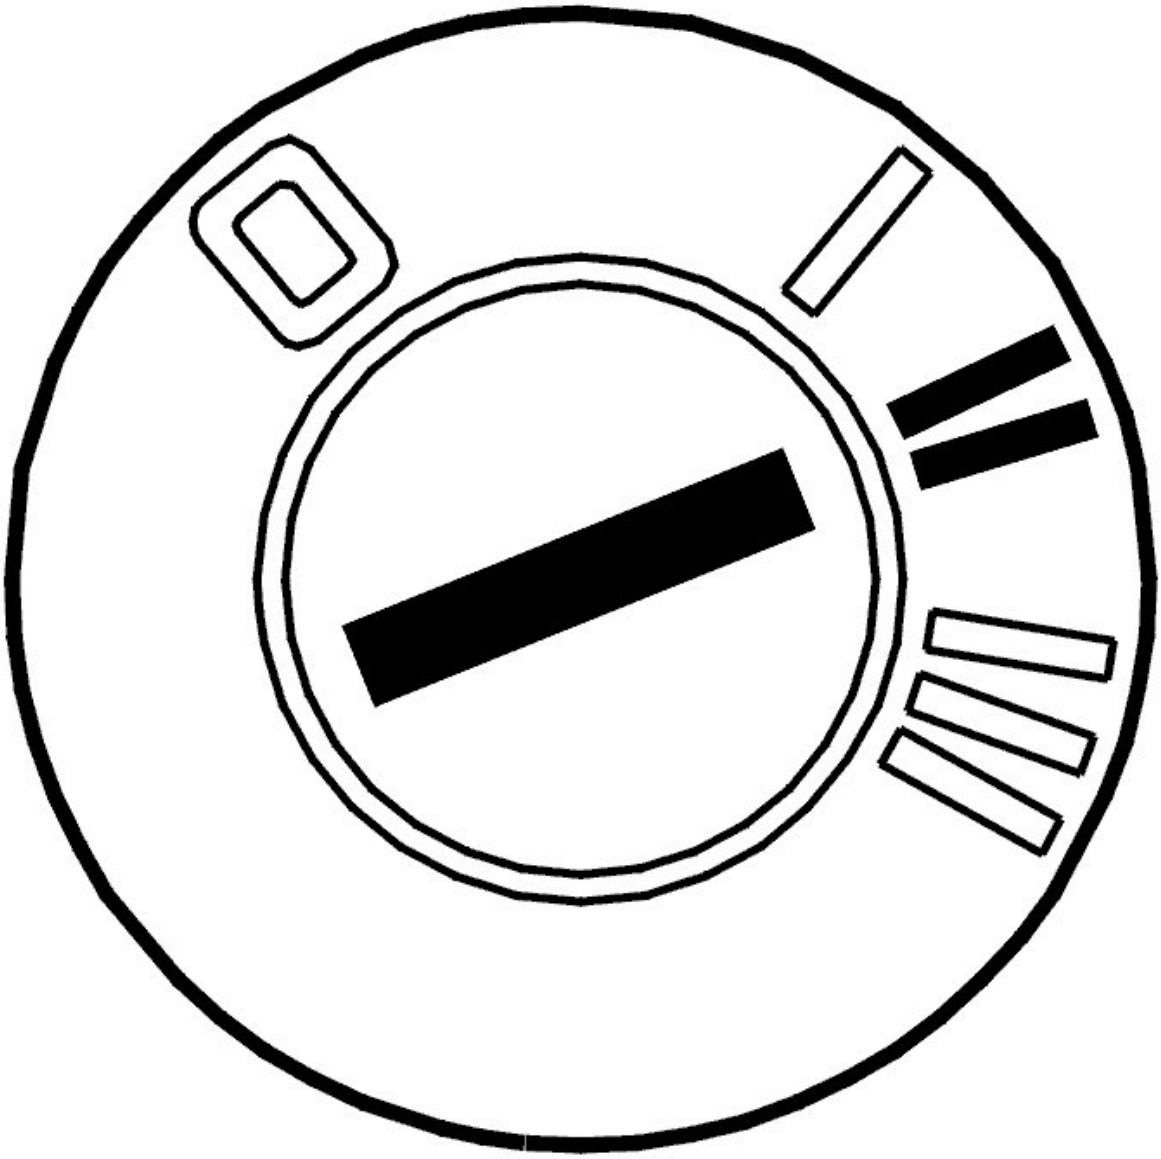
Were diagnostic trouble codes (DTCs) stored for the pedal position sensor or the stop lamp switch?

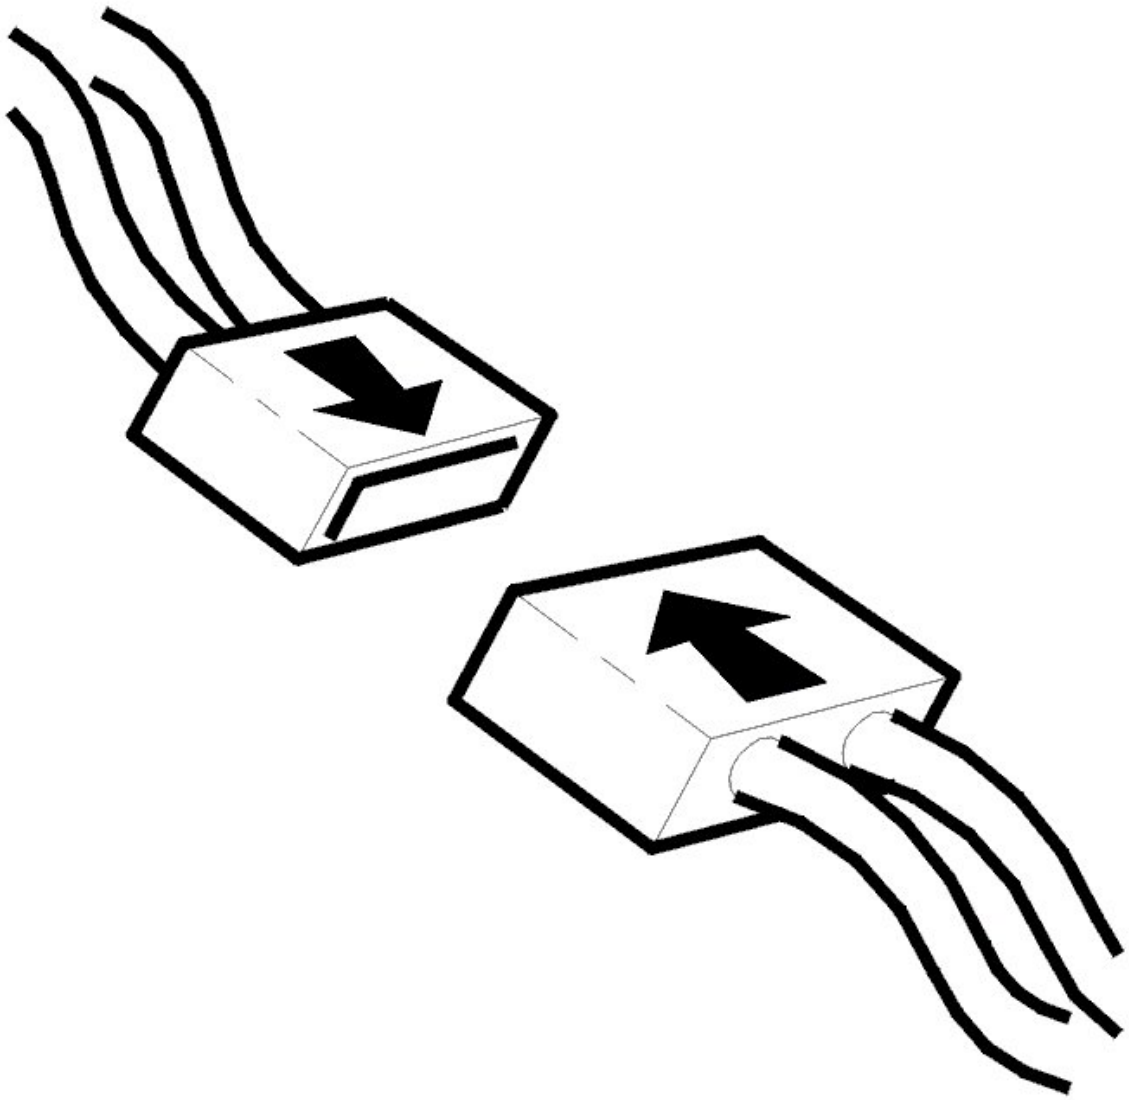
Yes - DONE

No - Checking the control module and sensor connectors

Checking the control module and sensor connectors

Hint: The cause of the diagnostic trouble code (DTC) may be in the circuit for the stop lamp switch or for the pedal position sensor.





- Ignition off
- Check the connectors for the brake control module (BCM), the stop lamp switch and the pedal position sensor. Check for contact resistance and oxidation
- Reinstall the components, reconnect the connectors etc.
- Ignition on
- Read off the status of the stop lamp switch and the position of the pedal position sensor.

Depress and release the brake pedal. The value must change between OFF and ON and the position of the pedal position sensor must be updated.

Other information

- To disconnect the connector for the brake control module (BCM), see Connecting the breakout box, brake control module (BCM) See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box/Connecting the Breakout Box, Brake Control Module (BCM)
- To access the stop lamp switch, see Stop lamp switch, replacing See: Lighting and Horns/Brake Light Switch/Service and Repair
- To access the pedal position sensor, see Pedal sensor power brake booster, replacing See: Brakes and Traction Control/Power Brake Assist/Brake Booster Vacuum Sensor/Service and Repair
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

Select an option:

1. The value for the stop lamp switch does not change
2. The value for the pedal position sensor is not updated
3. These values are OK.

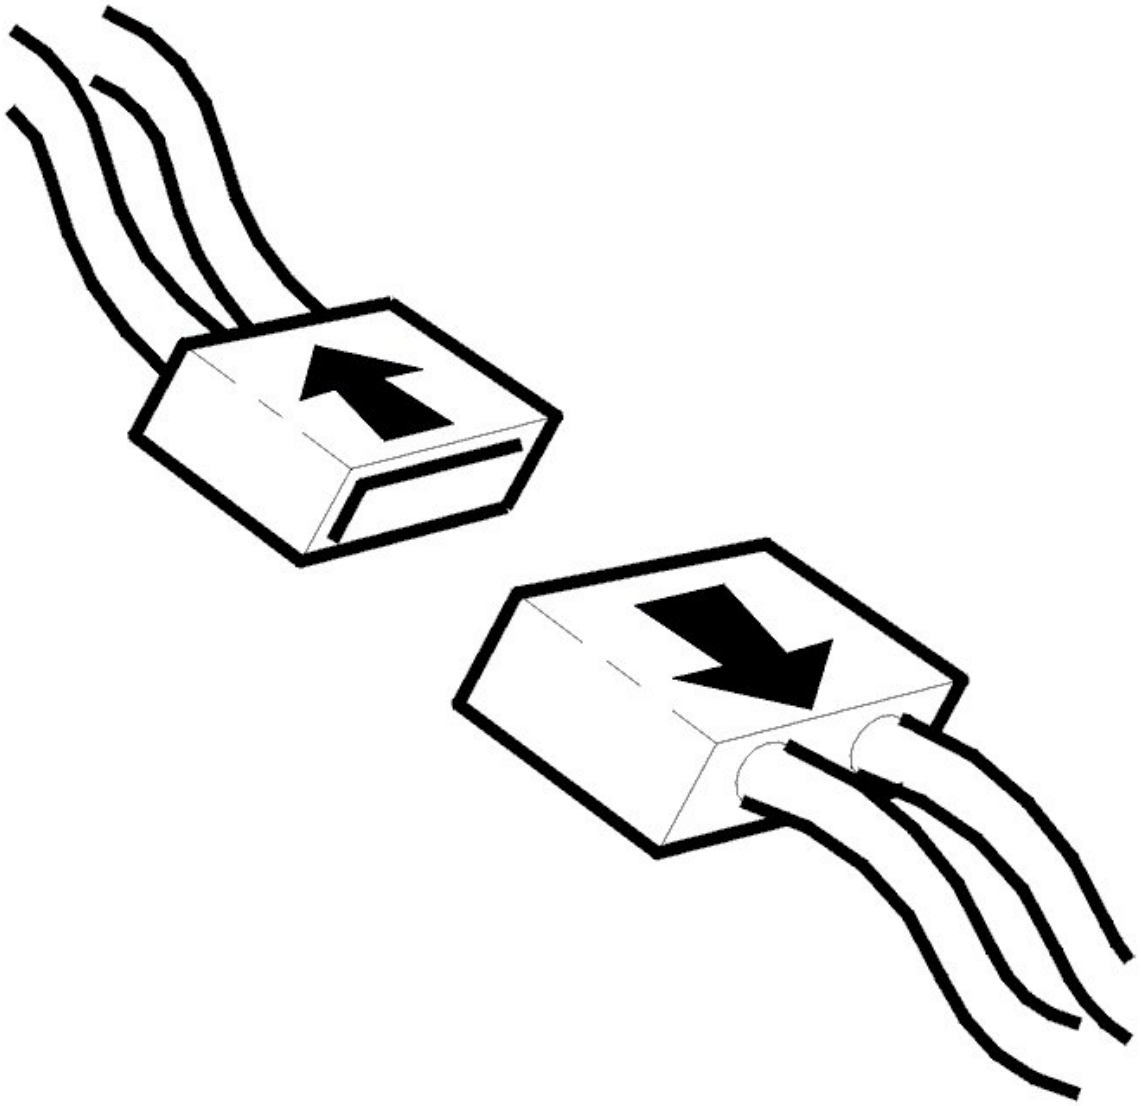
Does the value change?

1 - Checking the fuse, wiring and sensors

2 - Signal outside its permitted range

3 - **No Fault Found**

Checking the fuse, wiring and sensors



Check that the fuse for the stop lamp circuit is intact. If the fuse is blown, first check the circuit for the stop lamp switch before replacing the fuse. Check for a short-circuit to supply.
If the fuse is intact, check the circuit for the stop lamp switch. Check for an open-circuit and a short-circuit to ground.
Remedy as necessary.

Other information

- To connect the breakout box to the brake control module (BCM), see Connecting the breakout box, brake control module (BCM) See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box/Connecting the Breakout Box, Brake Control Module (BCM)
- To connect the breakout box to the Engine control module (ECM), see: Connecting the breakout box, B5244T5, B5254T2 See: Pinout Values and Diagnostic Parameters/Connecting the Breakout Box

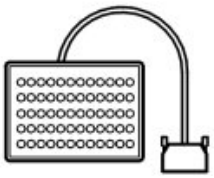
- To replace the stop lamp switch, see Stop lamp switch, replacing See: Lighting and Horns/Brake Light Switch/Service and Repair
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals



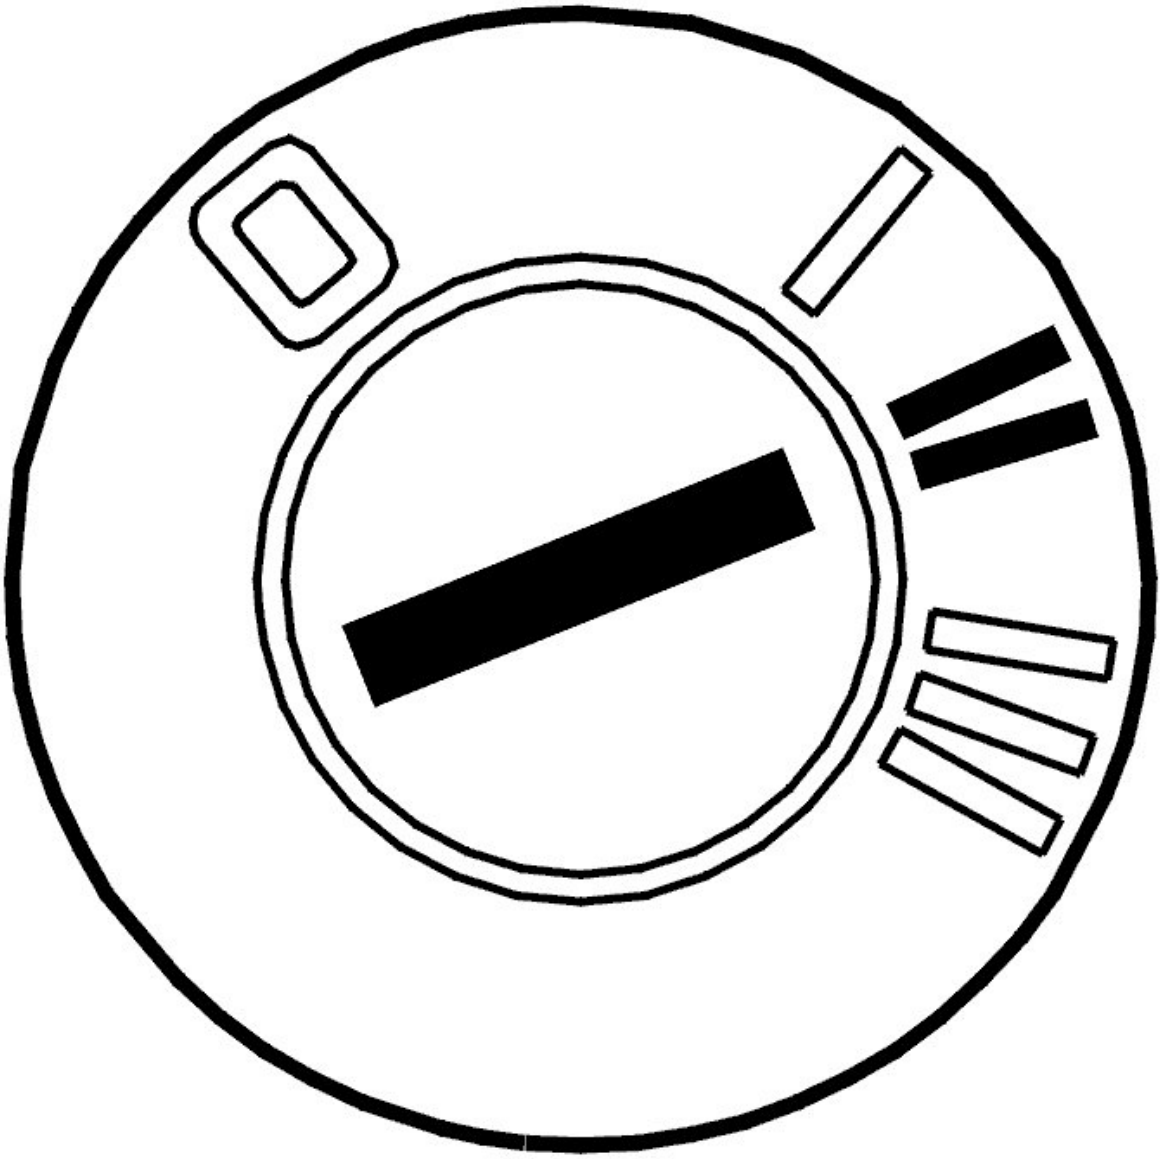
Was a fault detected?

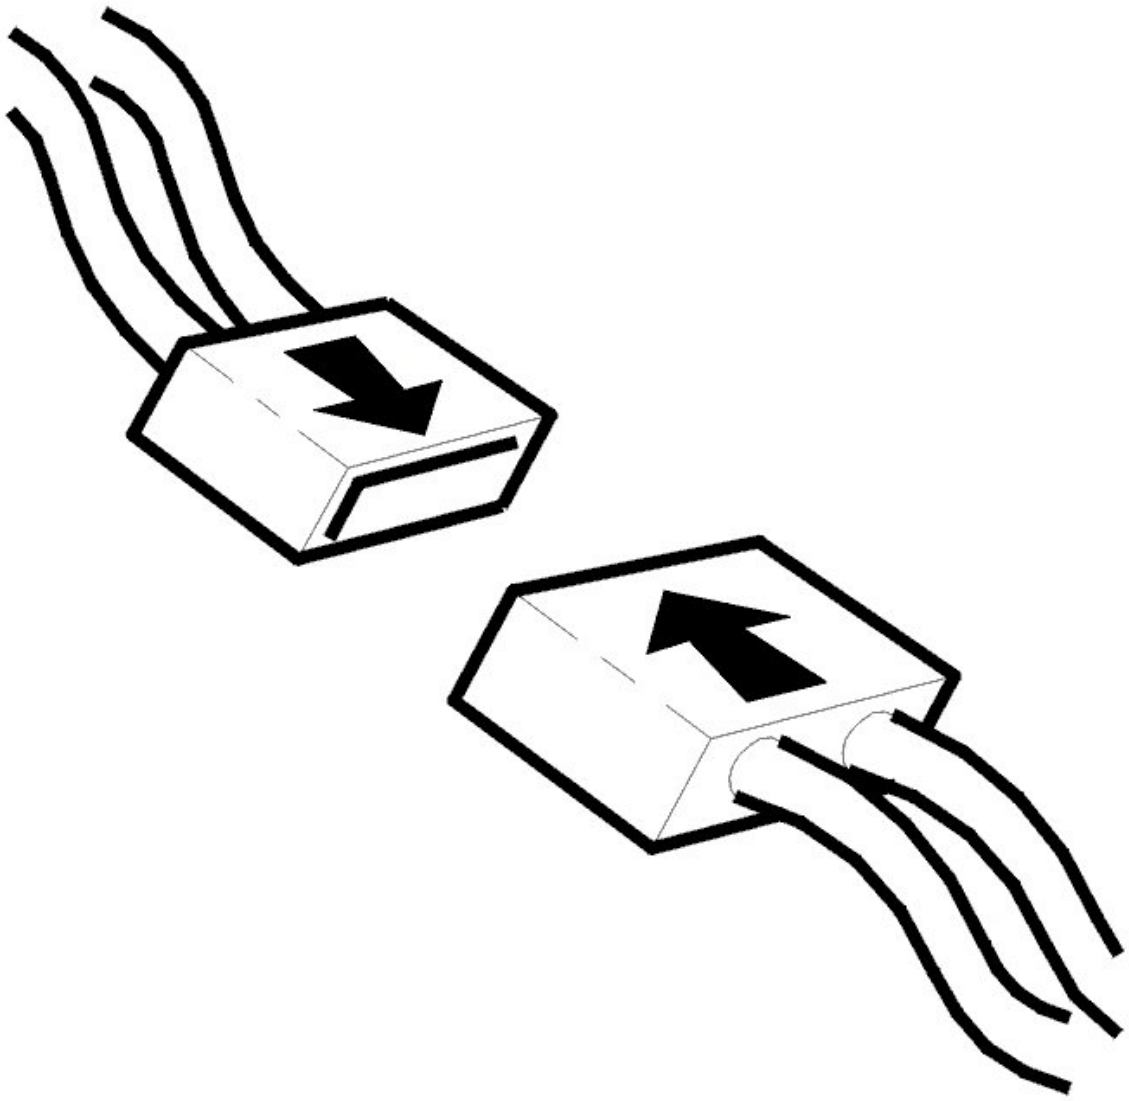
Yes - Verification

No - No Fault Found

Signal outside its permitted range

Checking the connectors



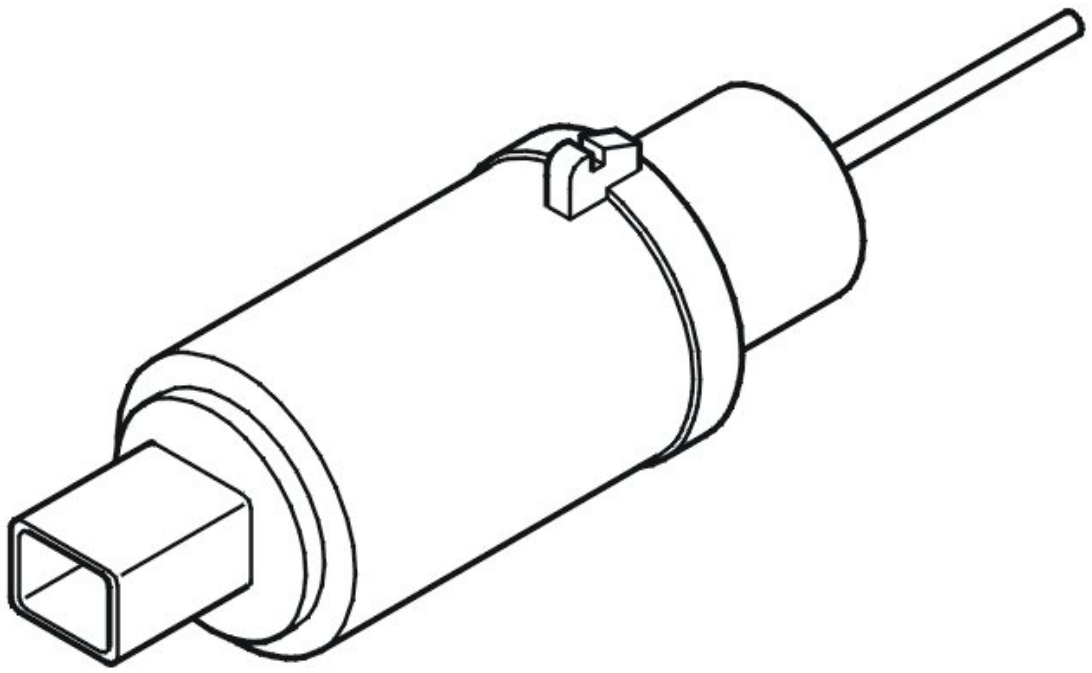


- Ignition off
- Check the brake control module (BCM) and pedal position sensor connectors. Check for contact resistance and oxidation
- Reinstall the components, reconnect the connectors etc.
- Connect the breakout box
- Ignition on
- Read off the signal from the pedal position sensor.

Depress the brake pedal. Check that the pedal signal is updated.

Other information

- To connect the breakout box, see Connecting the breakout box, brake control module (BCM) See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box/Connecting the Breakout Box, Brake Control Module (BCM)
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals.



Was the signal updated?

Yes - Fault Found

No - Checking wiring and sensors

Checking wiring and sensors

Check the wiring between the pedal position sensor:
- terminal #1 and control module terminal #7 (#A7)
- terminal #2 and control module terminal #5 (#A5)
- terminal #3 and control module terminal #3 (#A3).

check for an open-circuit, a short-circuit to ground and a short-circuit to supply voltage.

Hint: Connect an ohmmeter between terminals #2 and #3 on the pedal position sensor connector.
The resistance must be approximately 0.5 kohms with the brake pedal unaffected and approximately 2.5-3 kohms when the brake pedal is depressed.

Connect an ohmmeter between terminals #1 and #3 on the pedal position sensor connector.
The resistance must be approximately 2.5-3 kohms with the brake pedal unaffected and approximately 0.5 kohms with depressed brake pedal.

Replace the pedal position sensor if the resistance is incorrect.

Replace the pedal position sensor if no fault is found.

Other information
- To connect the breakout box, see Connecting the breakout box, brake control module (BCM) See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box/Connecting the Breakout Box, Brake Control Module (BCM)

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition

Note! The diagnostic trouble code (DTC) applies only to cars with dynamic stability and traction control (DSTC).

The brake pressure sensors and pedal position sensor have a common internal power supply in the control module.
Diagnostic trouble code (DTC) BCM-0068 is stored if the brake control module (BCM) detects that the voltage to the sensors is incorrect.
The diagnostic trouble code (DTC) can be diagnosed while the ignition is switched on.

Substitute value
- Stability control is blocked
- Traction control is blocked
- Active yaw control is blocked
- TRACS (traction control system) is blocked
- Brake assistance is blocked.

Hint: For information about brake system abbreviations, see Brake system, abbreviations See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Description and Operation/Brake System, Abbreviations.

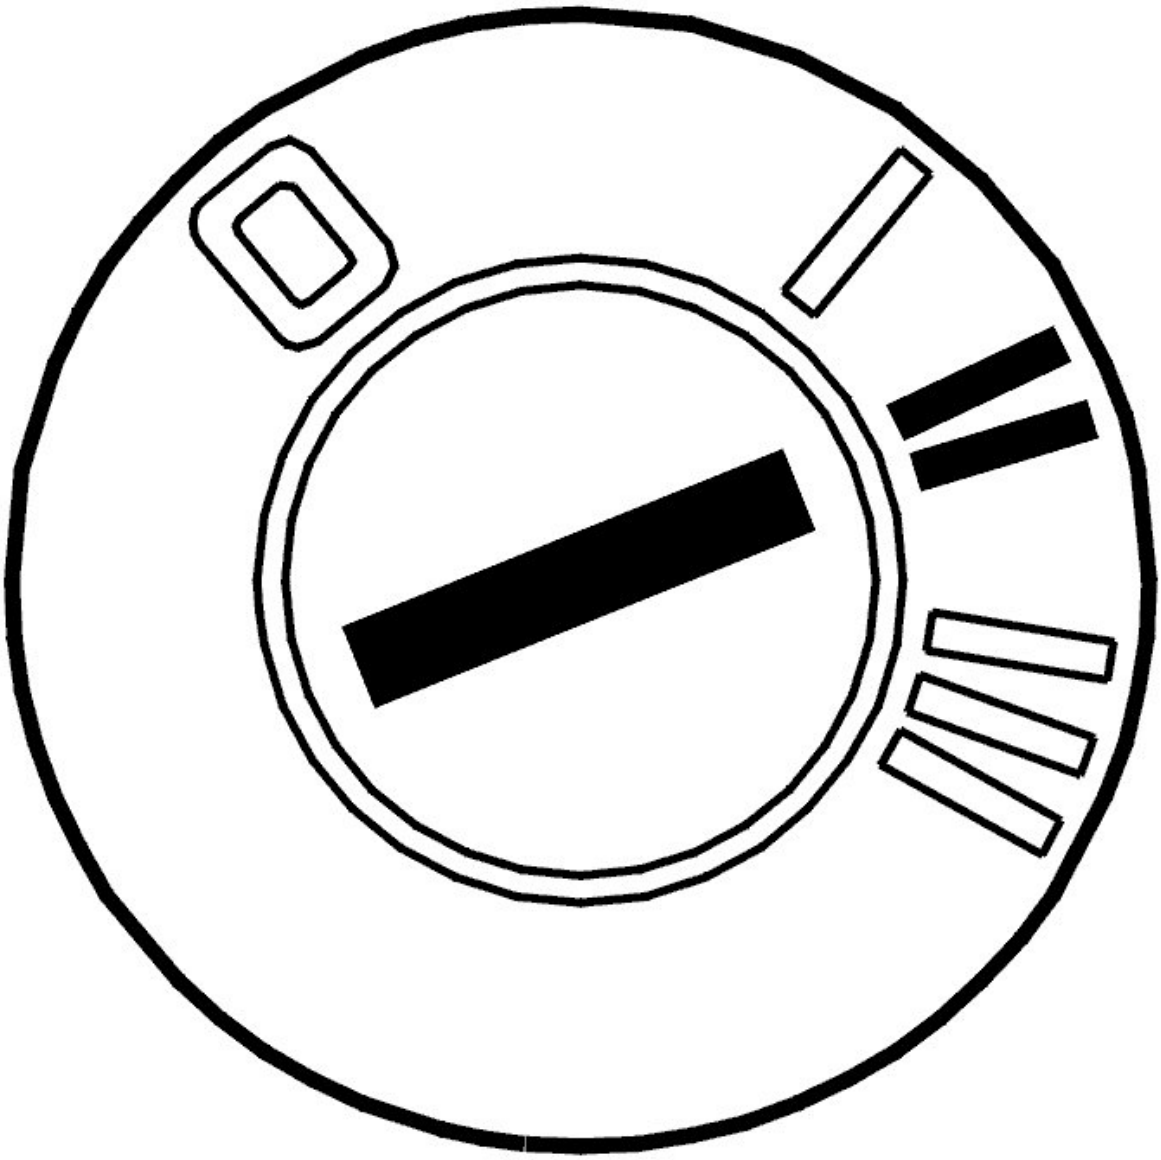
Possible source
- Short-circuit to ground or supply voltage in the wiring
- Defective sensor
- Defective brake control module (BCM).

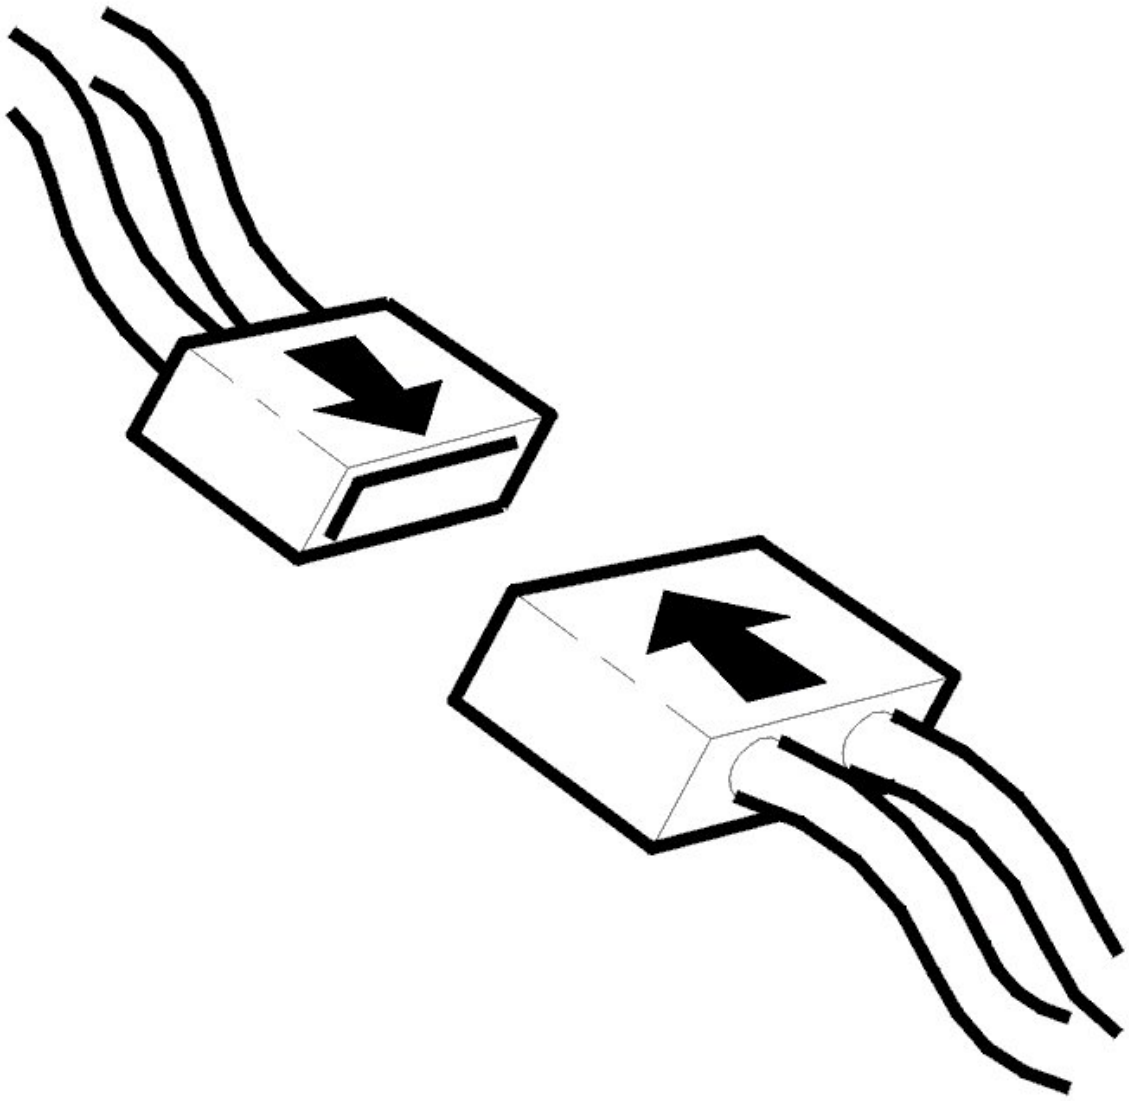
Fault symptom[s]
- General warning lamp lit
- The anti-spin warning lamp is lit (up to and including 2002 model year)
- Anti-spin does not function
- The stability control system does not function
- The traction control system does not function.

Faulty Signal

Faulty signal

Checking the connectors





- Ignition off
- Check the connectors for the brake control module (BCM), pedal position sensor and brake pressure sensor. Check for contact resistance and oxidation
- Reinstall the components, reconnect the connectors etc.
- Ignition on.

Test drive the car. See Test Drive Form (DSTC (dynamic stability and traction control) /brake control module), description See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Testing and Inspection/Initial Inspection and Diagnostic Overview/Test Drive Form (DSTC (Dynamic Stability And Traction Control) /Brake Control Module), Description.
Read off the status of the diagnostic trouble code (DTC).

Other information

- To connect the breakout box, see Connecting the breakout box, brake control module (BCM) See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box/Connecting the Breakout Box, Brake Control Module (BCM)

- To disconnect the connectors for the brake pressure sensors, see Pressure sensor, master cylinder, replacing See: Brakes and Traction Control/Hydraulic System/Brake Fluid Pressure Sensor/Switch/Service and Repair
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

Is the status of the diagnostic trouble code (DTC) intermittent?

Yes - Fault Found

No - Checking the wiring and component

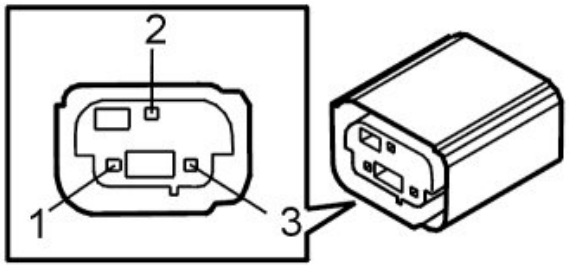
Checking the wiring and component

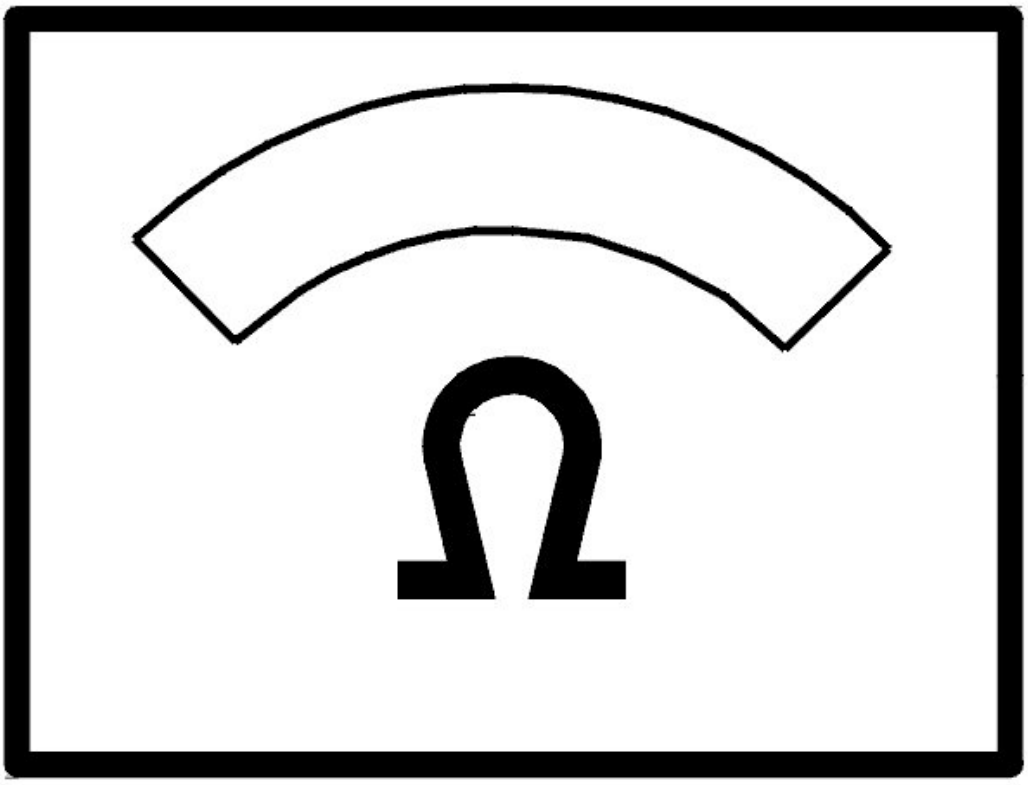
Check the wiring between pedal position sensor
- terminal #1 and brake control module (BCM) terminal #7 (#A7)
- terminal #2 and brake control module (BCM) terminal #5 (#A5)
- terminal #3 and brake control module (BCM) terminal #3 (#A3).

check for an open-circuit, a short-circuit to ground and a short-circuit to supply voltage.
Check the pedal position sensor as follows
- ignition off
- connect the breakout box to the wiring
- the control module disconnected.

measure the resistance at the pedal position sensor.
The resistance between terminals #3 (#A3) and #5 (#A5) must be approximately 0.5 kohms when the brake pedal is unaffected. The resistance must increase when the brake pedal is pressed.
The resistance between terminals #3 (#A3) and #7 (#A7) must be approximately 2.5 kohms when the brake pedal is unaffected. The resistance must decrease when the brake pedal is pressed.
Replace the pedal position sensor if the resistance is incorrect.
Remedy as necessary.

Other information
- To connect the breakout box, see Connecting the breakout box, brake control module (BCM) See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box/Connecting the Breakout Box, Brake Control Module (BCM)
- To replace the pedal position sensor, see Pedal sensor power brake booster, replacing See: Brakes and Traction Control/Power Brake Assist/Brake Booster Vacuum Sensor/Service and Repair
- For information about signals, see Signal specification, brake control module (BCM) with DSTC (dynamic stability and traction control) See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Specification.





Was a fault detected?

Yes - Verification

No - Checking wiring and sensors

Checking wiring and sensors

Check the wiring between the control module and the connectors for the brake pressure sensors.

For brake pressure sensor 1:
- terminal #1 and control module terminal #19 (terminal #A19)
- terminal #2 and control module terminal #20 (#A20)
- terminal #3 and control module terminal #18 (#A18).

For brake pressure sensor 2:
- terminal #1 and control module terminal #21 (#A21)
- terminal #2 and control module terminal #23 (terminal #A23)
- terminal #3 and control module terminal #22 (terminal #A22).

check for an open-circuit, a short-circuit to ground and a short-circuit to supply voltage.

Hint: Check the brake pressure sensors. First connect the breakout box and the connectors for the sensors. Switch on the ignition. Measure the signal from the sensor:

Brake pressure sensor 1:
- terminal #A19 and terminal #A20 on the breakout box. The voltage must be between approximately 0.25- 4.75 V, depending on the brake pressure
- terminal #A18 and terminal #A19 on the breakout box. The voltage must be approximately 5 V.

Brake pressure sensor 2:

- terminal #A21 and terminal #A23 on the breakout box. The voltage must be between approximately 0.25- 4.75 V, depending on the brake pressure
- terminal #A21 and terminal #A22 on the breakout box. The voltage must be approximately 5 V.

Remedy as necessary.

Other information

Fault-tracing information

The fault should be diagnosed and remedied. Since this is not the case the fault-tracing process has failed.
Complete the fault-tracing for those fault or try again.

Do you want to terminate fault-tracing at this time?

Yes - FAULT-TRACING FAILED

No - Attempt New Test

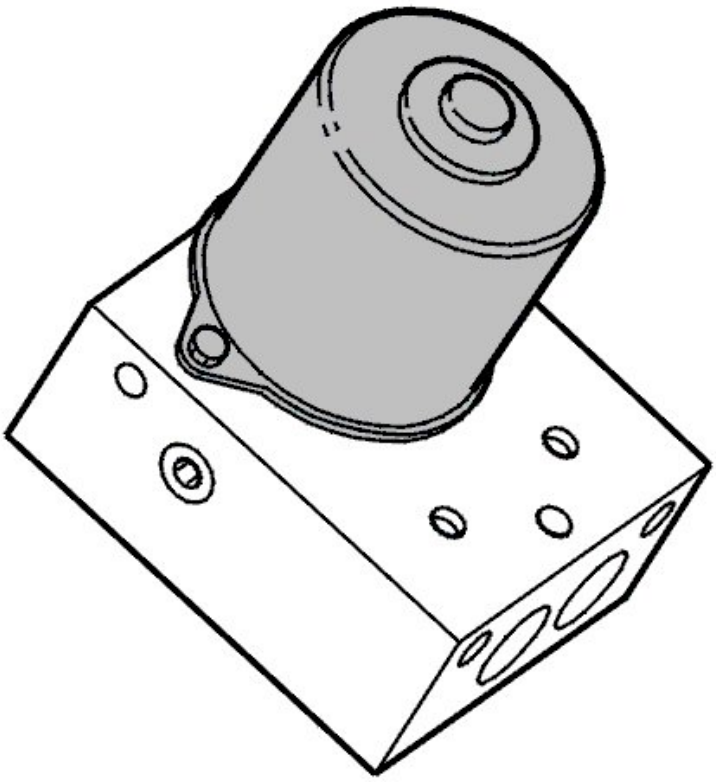
FAULT-TRACING FAILED - FAULT-TRACING FAILED

Attempt New Test - Checking the connectors

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition



Diagnostic trouble code (DTC) BCM-0070 is stored if the brake control module (BCM) detects that the voltage to the pump motor is incorrect. The diagnostic trouble code (DTC) can be diagnosed while the ignition is switched on.

Substitute value
- The ABS is blocked
- Traction control is blocked
- Stability control is blocked
- Active yaw control is blocked
- Brake assistance is blocked.

Hint: For information about brake system abbreviations, see Brake system, abbreviations See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Description and Operation/Brake System, Abbreviations.

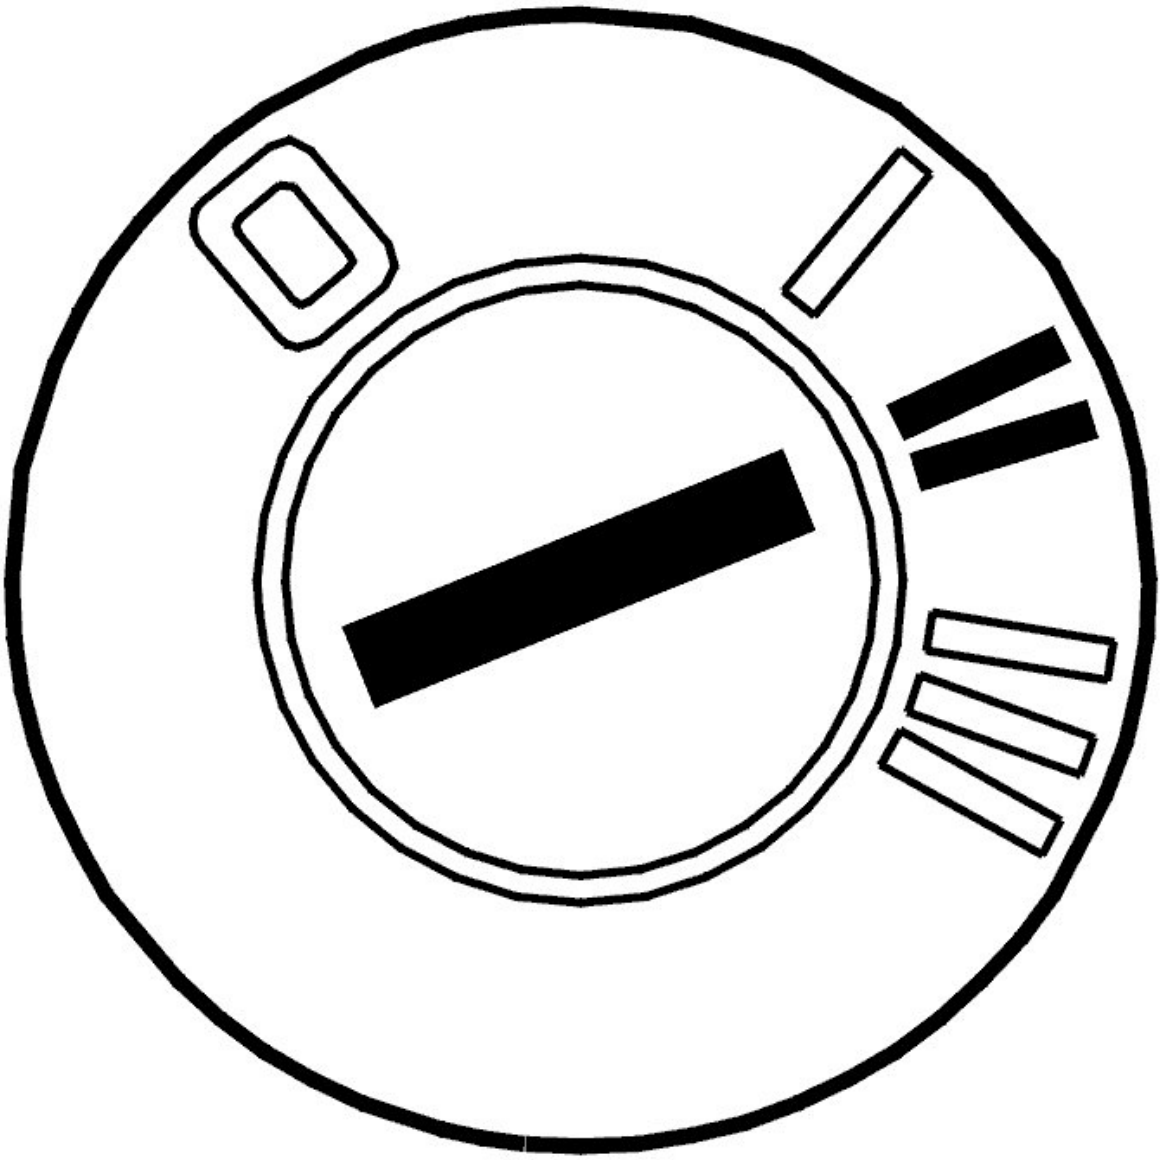
Possible source
- Contact resistance in the terminals
- The fuse for the pump motor is defective
- Open-circuit in the power supply to the pump motor
- Open-circuit in the ground lead for the pump motor
- Open-circuit in the power supply (30-supply) to the control module for the pump motor
- Defective pump motor
- Defective control module.

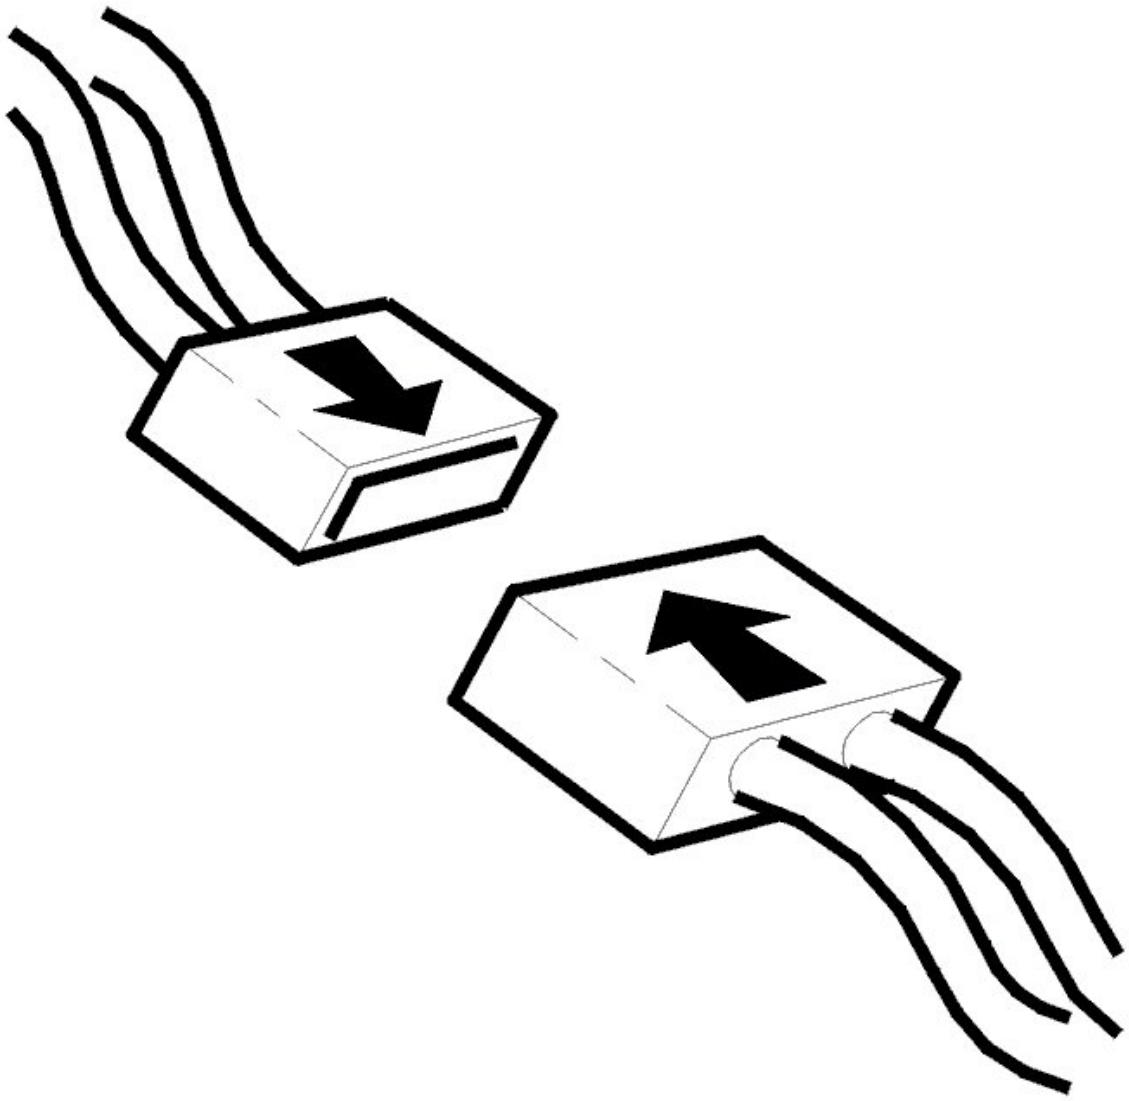
Fault symptom[s]
- General warning lamp lit
- The ABS warning lamp is lit
- The anti-spin warning lamp is lit (up to and including 2002 model year)
- The ABS system does not function
- Anti-spin does not function
- The stability control system does not function
- The traction control system does not function.

Faulty Signal

Faulty signal

Checking the operation of the pump motor





- Ignition off
- Check the brake control module (BCM) and pump motor connectors. Check for contact resistance and oxidation
- Reconnect the components, connectors etc.
- Ignition on
- Activate the pump motor.

Check that the pump motor starts and operates normally.
If the pump motor starts and seems to operate normally, the cause of the fault was probably contact resistance and oxidation in the control module or pump motor connectors.

Other information

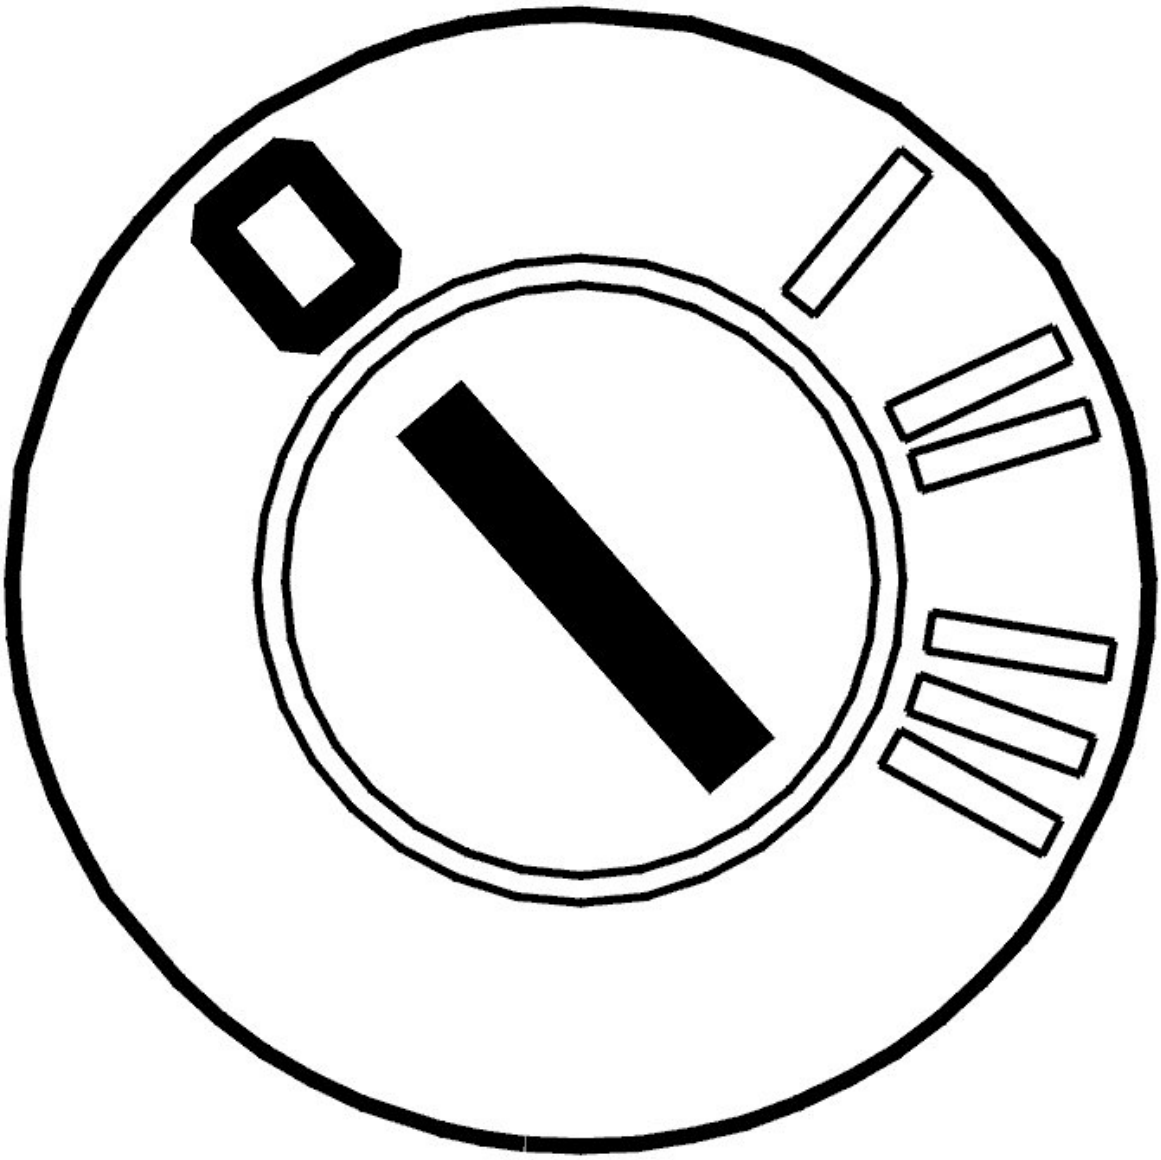
- To disconnect the control module and pump motor, see Connecting the breakout box, brake control module (BCM) See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box/Connecting the Breakout Box, Brake Control Module (BCM)
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

Is the pump OK?

Yes - Fault Found

No - Checking the wiring and component

Checking the wiring and component

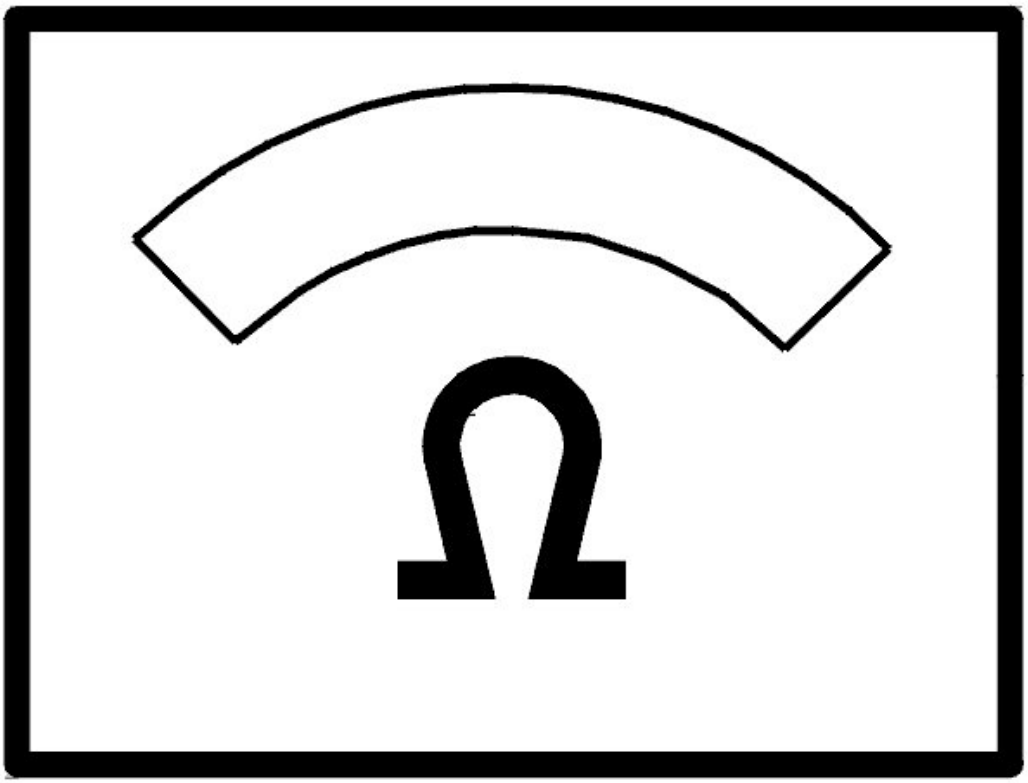


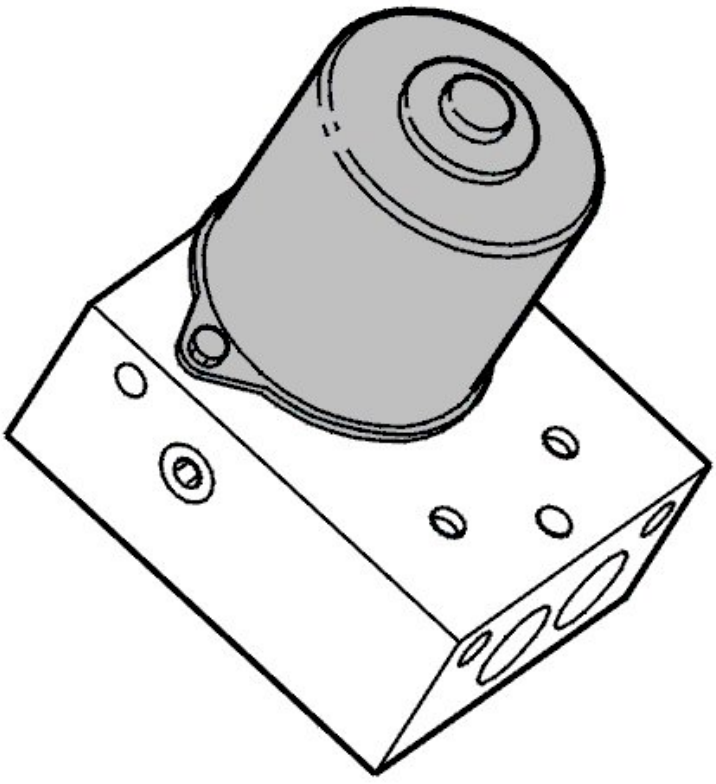
- Ignition off.

Check the circuit for the pump motor between brake control module (BCM) terminal #1 (#A1) and the fuse in the integrated relay/fusebox in the engine compartment. Check for an open-circuit. Check for a short-circuit to ground.
Check the fuse for the brake system in the integrated relay / fusebox in the engine compartment. If the fuse is blown, check the cable between the fuse and control module terminal #1 (#A1). Check for a short-circuit to ground. Then replace the fuse.
Remedy as necessary.

Other information

- To connect the breakout box, see Connecting the breakout box, brake control module (BCM) See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box/Connecting the Breakout Box, Brake Control Module (BCM)
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals
- For further information about the fuses and relays, see the Wiring Diagram.



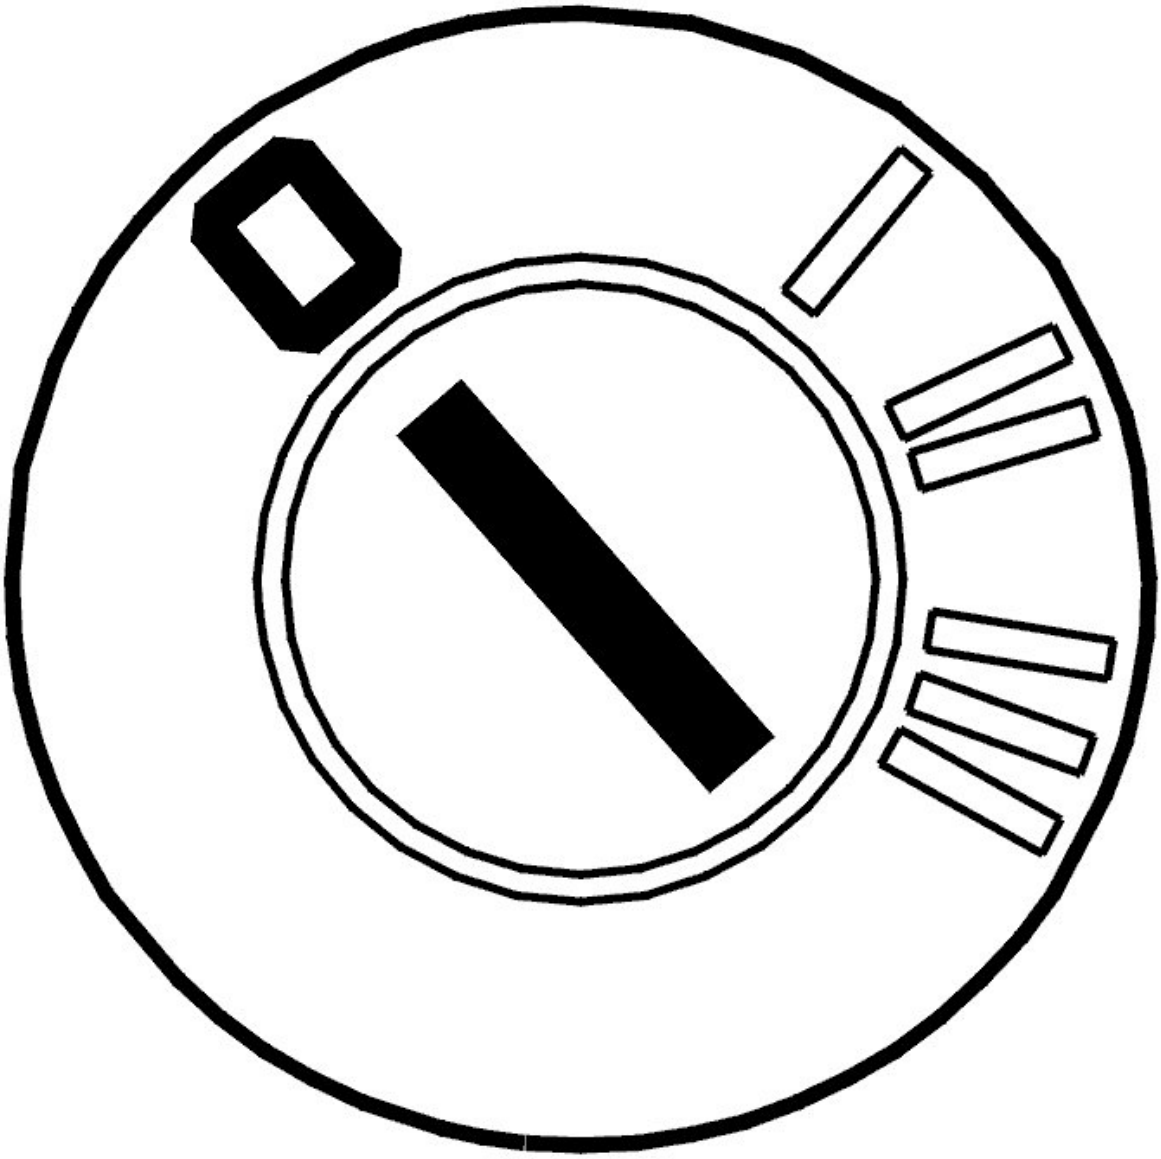


Was a fault detected?

Yes - Verification

No - Checking the pump motor circuit

Checking the pump motor circuit



- Ignition off
- Remove the brake control module (BCM)
- Connect adapter 951 2856 Test cable See: Tools and Equipment/951 2856 Test Cable to the power supply terminal on the pump motor
- Connect the red fused cable to battery voltage. The black cable must be connected to ground.

The pump motor must start when the cable is connected. Run for a maximum of 10 seconds.
Replace the control module if the pump motor starts and seems to run normally.
Replace the hydraulic unit if the pump motor does not start.

Other information

- To replace the control module, see Brake Control Module (BCM), replacing See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Electronic Brake Control Module/Service and Repair/Brake Control Module (BCM), Replacing
- To replace the hydraulic unit, see Hydraulic unit, replacing See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Hydraulic Control Assembly - Antilock Brakes/Service and Repair.

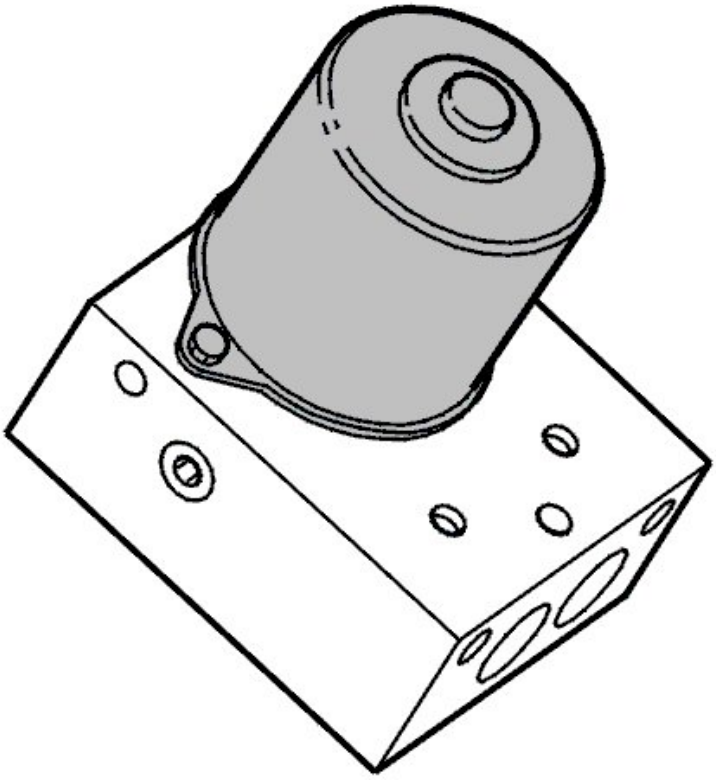
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition



Diagnostic trouble code (DTC) BCM-0071 is stored if the brake control module (BCM) registers that the pump motor does not start or that the signal from the pump motor is missing.
The diagnostic trouble code (DTC) can be diagnosed while the ignition is switched on.

Substitute value

- The ABS is blocked
- Traction control is blocked
- Stability control is blocked
- Active yaw control is blocked
- Brake assistance is blocked.

Hint: For information about brake system abbreviations, see Brake system, abbreviations See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Description and Operation/Brake System, Abbreviations.

Possible source

- Contact resistance in the terminals
- The fuse for the pump motor is defective
- Open-circuit in the power supply to the pump motor
- Open-circuit in the ground lead for the pump motor
- Defective pump motor
- Defective control module.

Fault symptom[s]

- General warning lamp lit
- The ABS warning lamp is lit
- The anti-spin warning lamp is lit (up to and including 2002 model year)
- The ABS system does not function
- Anti-spin does not function
- The stability control system does not function
- The traction control system does not function.

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition

The brake control module (BCM) can register diagnostic trouble code (DTC) BCM-0074 for a number of different fault causes. Diagnostic trouble code (DTC) BCM-0074 is stored:

- if there is a short-circuit to ground or open-circuit in the control module inlet or outlet valve circuits
- if the control module is subject to interference so that its calculations are incorrect
- if the control module registers a fault in its internal inlet and outlet valve circuits
- if there is a short-circuit to ground, short-circuit to supply voltage or an open-circuit in the inlet valve in the anti-spin circuit
- if the control module registers an open-circuit or short-circuit in one of its internal circuits.

Substitute value

- The ABS is blocked
- Traction control is blocked
- Stability control is blocked
- Active yaw control is blocked
- Electronic Brake force Distribution is blocked
- Brake assistance is blocked.

Hint: For information about abbreviations, see Brake system, abbreviations See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Description and Operation/Brake System, Abbreviations.

Possible source

- Internal fault in the control module.

Fault symptom[s]

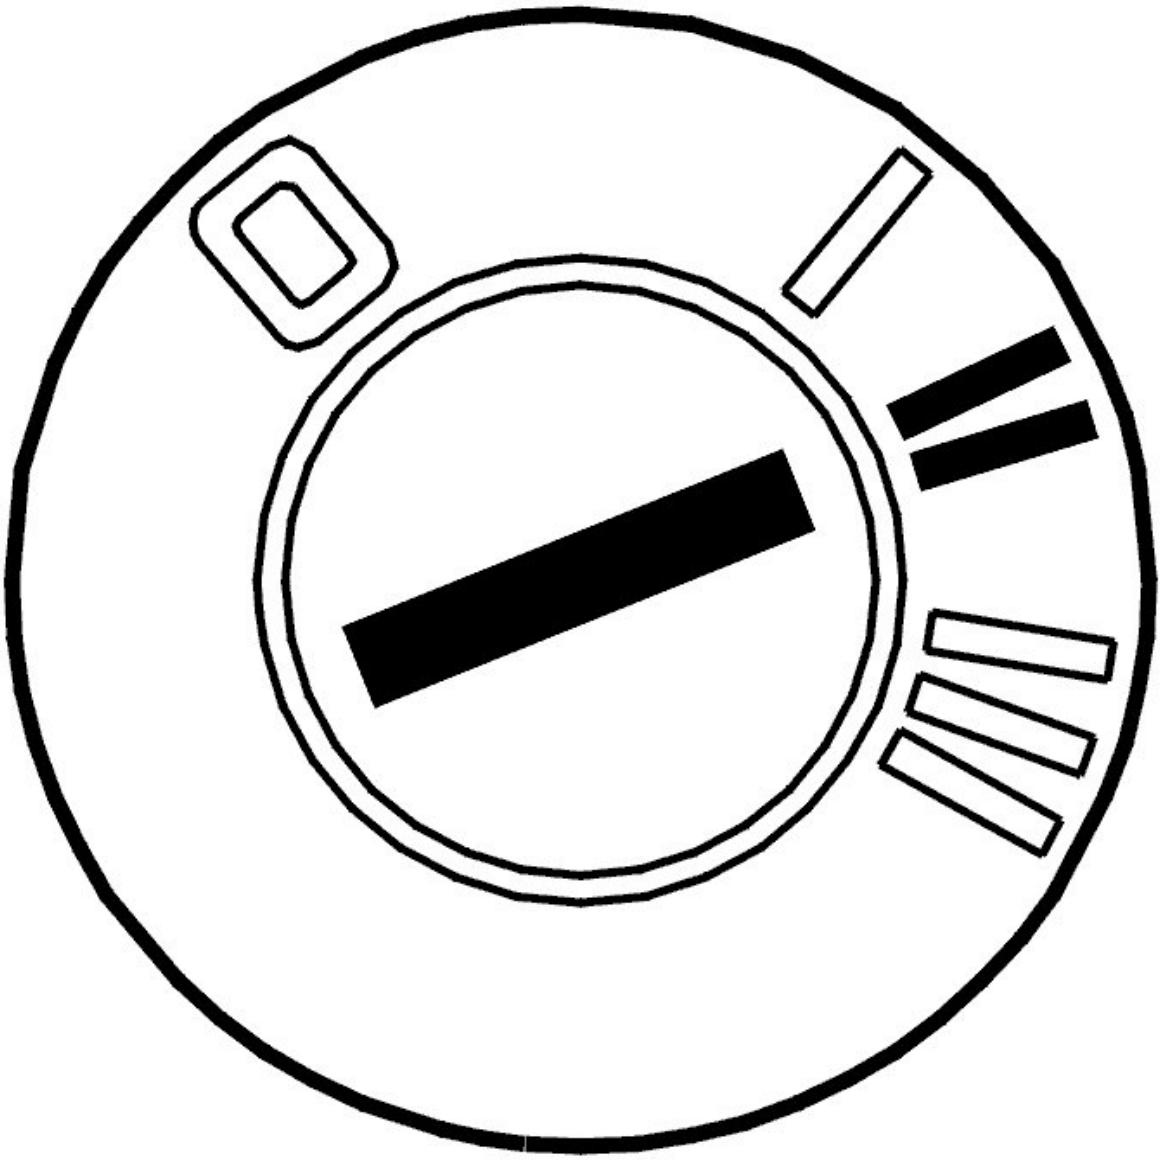
- The ABS warning lamp is lit
- The warning lamp for brake circuit not functioning is lit
- The anti-spin warning lamp is lit (up to and including 2002 model year)
- The ABS system does not function
- Anti-spin does not function

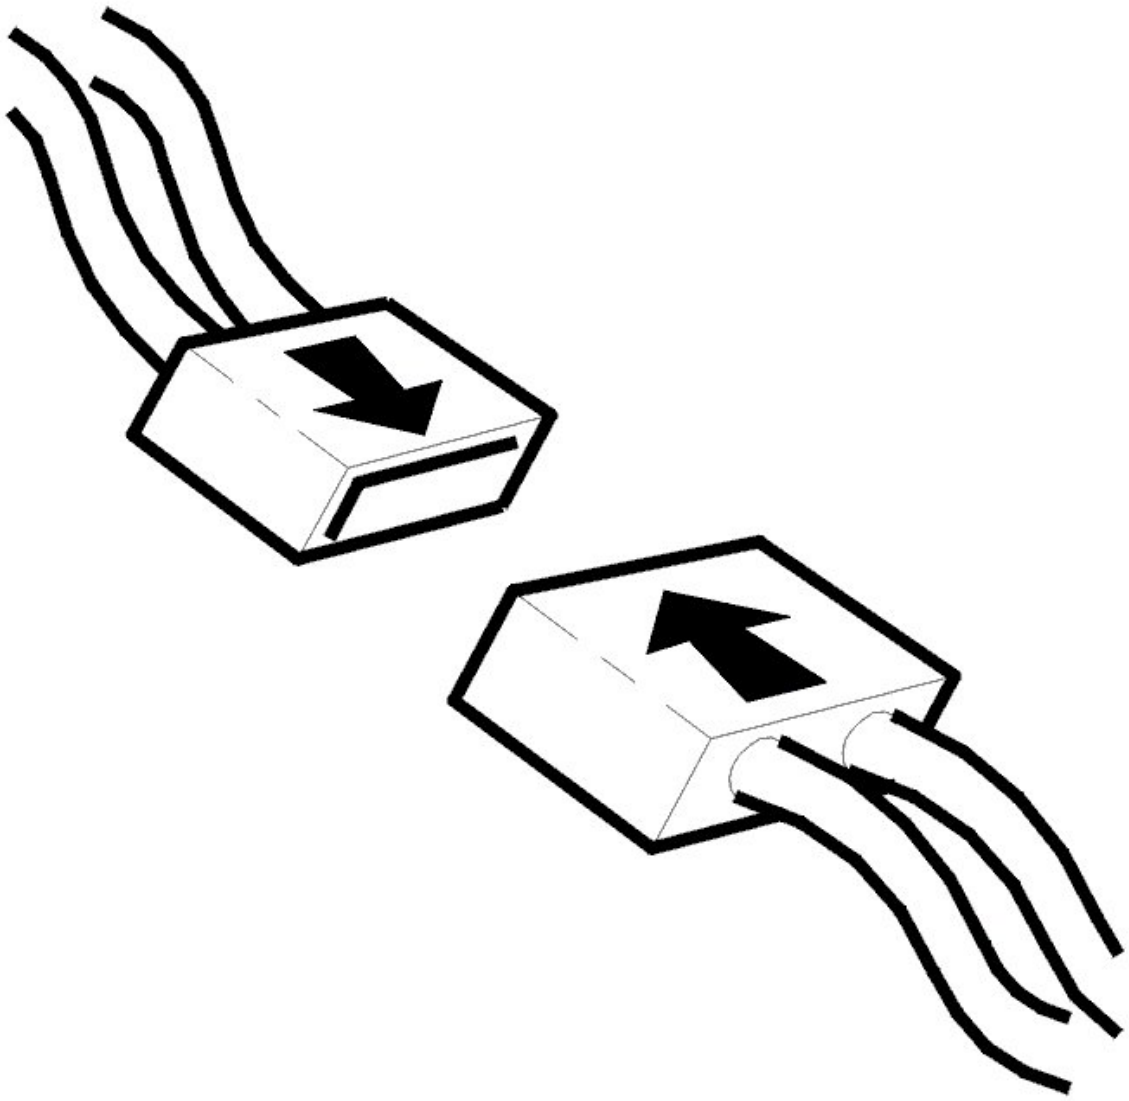
- The stability control system does not function
- The traction control system does not function.

Faulty Signal

Faulty signal

Checking the function of the hydraulic valves





- Ignition off
- Check the brake control module (BCM) connector. Check for contact resistance and oxidation
- Reconnect the components, connectors etc.
- Ignition on.

Try to activate the hydraulic valves.
There should be a "ticking" noise.

Other information

- To disconnect the control module, see Connecting the breakout box, brake control module (BCM) See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box/Connecting the Breakout Box, Brake Control Module (BCM)

Can the valves be activated?

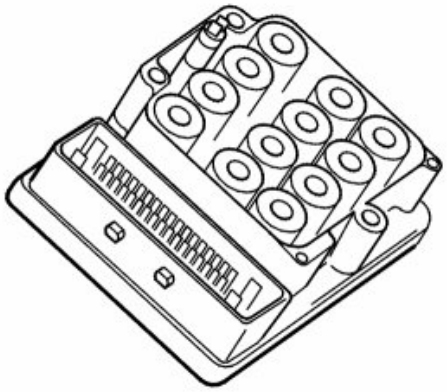
Yes - Fault Found

No - Replacing the control module and programming

Replacing the control module and programming

Caution! A new control module is delivered without software. The control module must be programmed in order to function after replacement.

For further information about programming and replacing the control module, see Brake Control Module (BCM), replacing See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Electronic Brake Control Module/Service and Repair/Brake Control Module (BCM), Replacing.

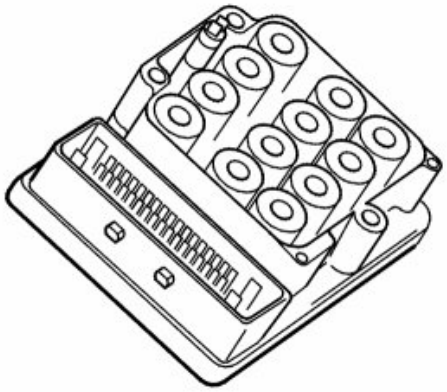


Continue - Fault Found

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition



The brake control module (BCM) is programmed at the factory with software for several car models. During the first ignition cycle, the control module reads the vehicle configuration data from the central electronic module (CEM). The brake control module (BCM) then configures itself according to the car model and equipment.
Diagnostic trouble code (DTC) BCM-0076 may be stored if

- a brake control module (BCM) is installed that has previously been used in another car
- a central electronic module (CEM) is installed that has previously been used in another car
- software for another car is downloaded into the brake control module (BCM).

Substitute value

- Traction control is blocked
- Stability control is blocked
- Active yaw control is blocked.

Hint: For information about abbreviations, see Brake system, abbreviations See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Description and Operation/Brake System, Abbreviations.

Possible source

- A brake control module (BCM) from another model has been installed
- A central electronic module (CEM) from another model has been installed
- Software for another car is downloaded into the brake control module (BCM).

Note! This diagnostic trouble code (DTC) is not due to an internal hardware fault in the Brake control module (BCM) and must not be remedied by replacing the control module.

Fault symptom[s]

- The anti-spin warning lamp is lit (up to and including 2002 model year)
- General yellow warning lamp lit (from model year 2003 inclusive)
- Anti-spin does not function
- The stability control system does not function
- The traction control system does not function.

Faulty Configuration

Faulty configuration

Fault-tracing information
The diagnostic trouble code (DTC) can be generated in some cases after the brake control module (BCM) has been reprogrammed. If this is the case, the brake control module (BCM) must be configured.

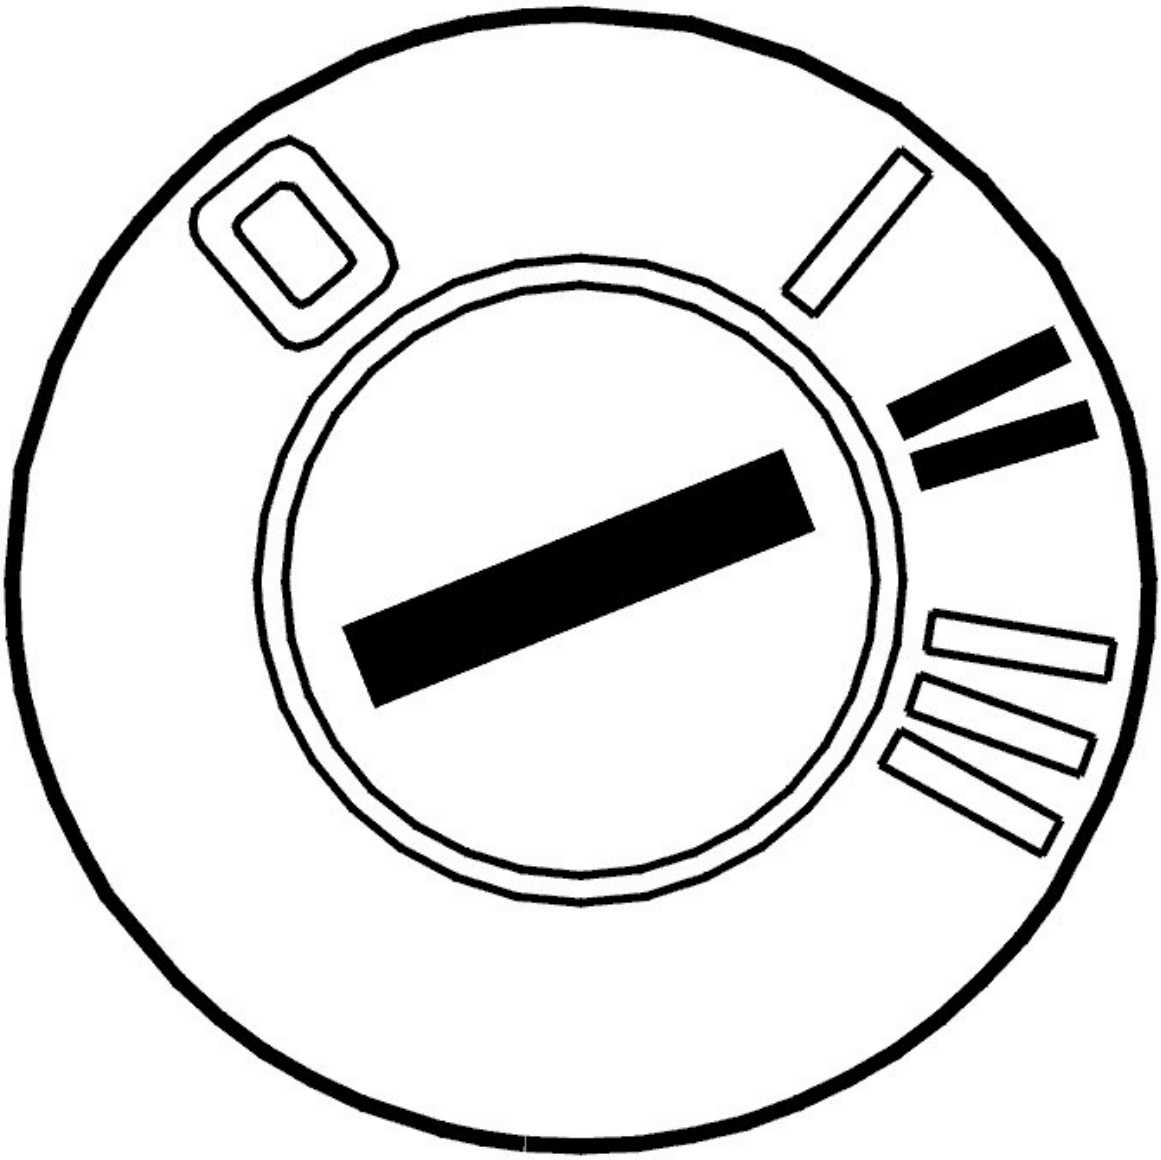
Was the diagnostic trouble code (DTC) generated after the brake control module (BCM) was reprogrammed?

Yes - Checking the car configuration

No - Checking diagnostic trouble codes (DTCs) in the central electronic module (CEM)

Checking diagnostic trouble codes (DTCs) in the central electronic module (CEM)

Note! If the central electronic module (CEM) is incorrectly configured it may affect the brake control module (BCM). Fault-trace the central electronic module (CEM) first if there are diagnostic trouble codes (DTCs) stored in both the control modules.



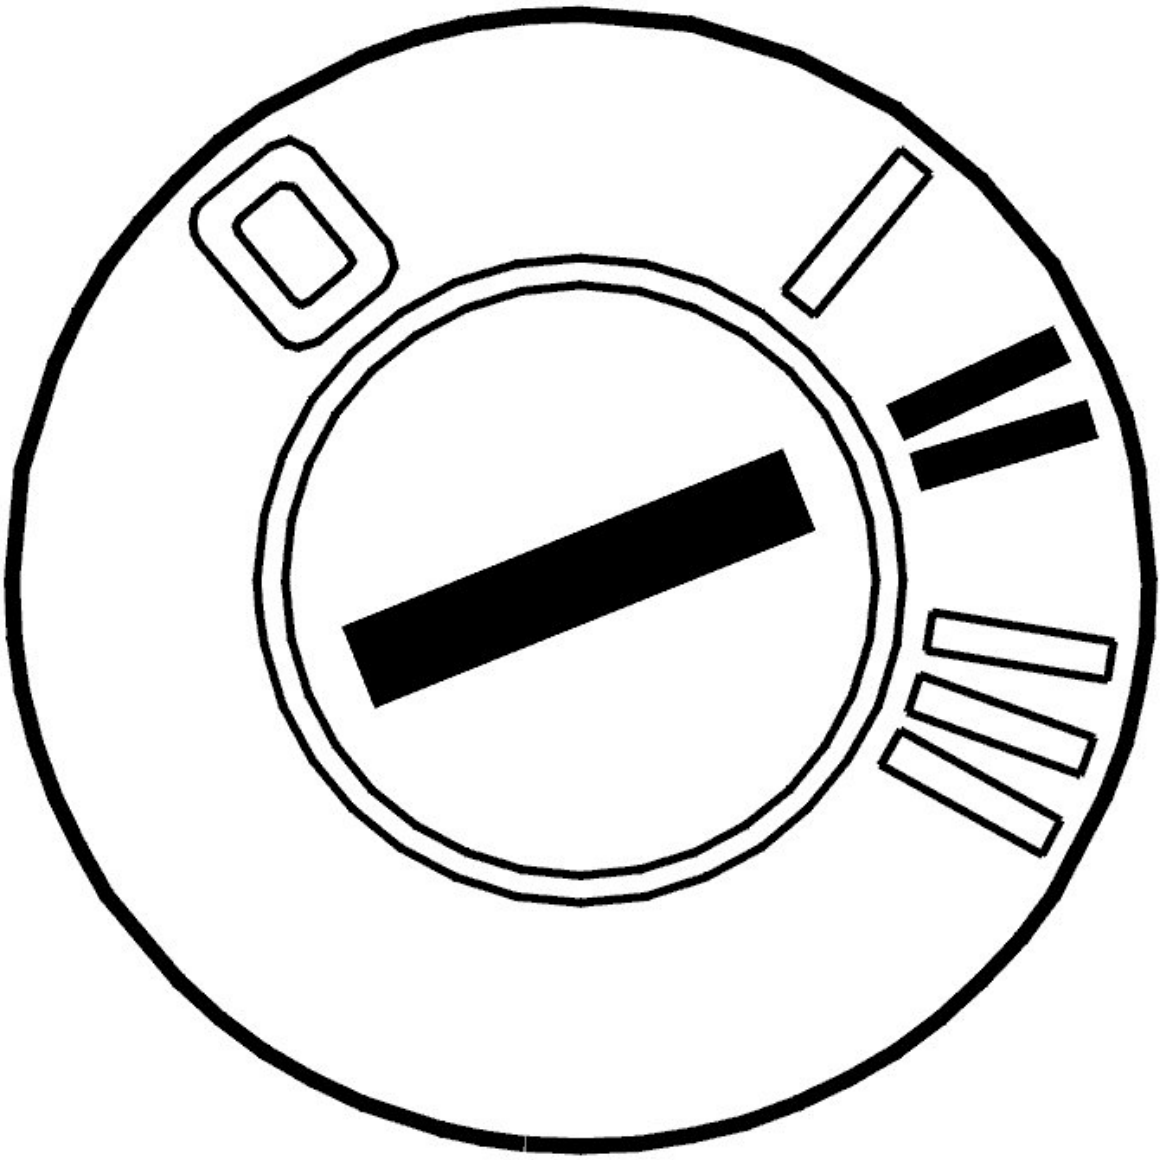
- Ignition on
- Read off diagnostic trouble codes (DTCs).

Are diagnostic trouble codes (DTCs) stored in the central electronic module (CEM)?

Yes - DONE

No - Checking the software

Checking the software



- Ignition on
- Read off the software version from the brake control module (BCM).

Check that the diagnostic number corresponds to the car configuration. If the software does not correspond to the car configuration, make a bookmark and cancel the fault-tracing. Then go to the software manager and download the correct software. Then resume the fault-tracing.

Was the control module programmed with the correct software?

Yes - Checking the car configuration

No - Erasing diagnostic trouble codes (DTCs)

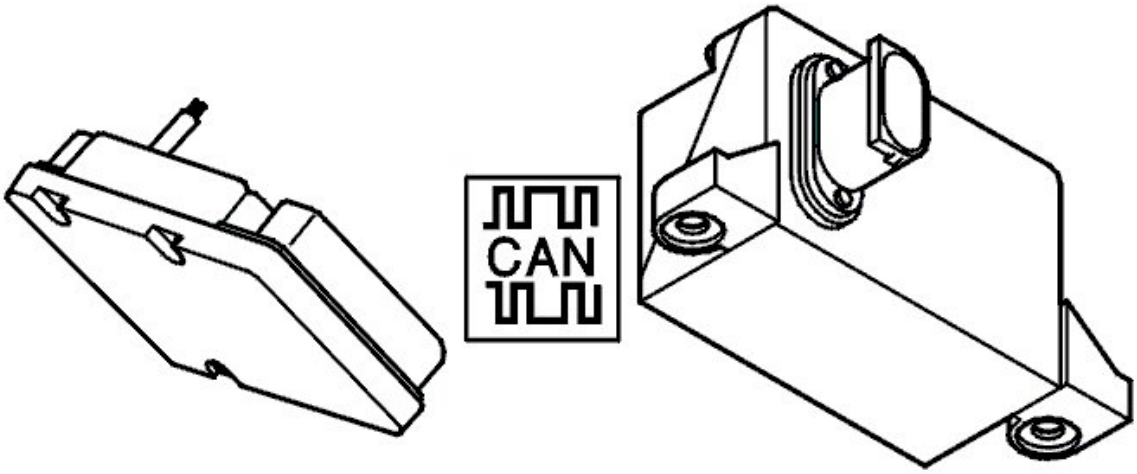
FAULT FOUND - Fault Found

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition



Note! The diagnostic trouble code (DTC) applies only to cars with dynamic stability and traction control (DSTC).

The yaw rate sensor, lateral accelerometer, accelerometer (only AWD) and angle of lean sensor (only RSC) are integrated in the active yaw control sensor for DSTC. The sensors transmit information to the brake control module (BCM) indicating the size of the yaw angle, the lateral acceleration of the car, the forward acceleration and the lateral angle of lean via its own internal Control area network (CAN). Each sensor has an offset value, correction value, for the individual sensor offset.
Diagnostic trouble code (DTC) BCM-0080, BCM-0081, BCM-0082 or BCM-0083 is stored, depending on the sensor, if the control module registers an incorrect offset value from any of the sensors.

- BCM-0080: Lateral accelerometer
- BCM-0081: Accelerometer
- BCM-0082: Yaw rate sensor
- BCM-0083: Angle of lean sensor.

The diagnostic trouble code (DTC) can be diagnosed while the ignition is switched on.

Substitute value

- Traction control is blocked
- Stability control is blocked
- Active yaw control is blocked
- RSC system is blocked (cars equipped with RSC only).

Hint: For information about brake system abbreviations, see Brake system, abbreviations See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Description and Operation/Brake System, Abbreviations.

Possible source

- Active yaw control sensor incorrectly installed
- The active yaw control sensor is loose
- The bracket for the active yaw control sensor is bent
- Internal fault in the active yaw control sensor.

Note! This diagnostic trouble code (DTC) is not due to an internal hardware fault in the Brake control module (BCM) and must not be remedied by replacing the control module.

Fault symptom[s]

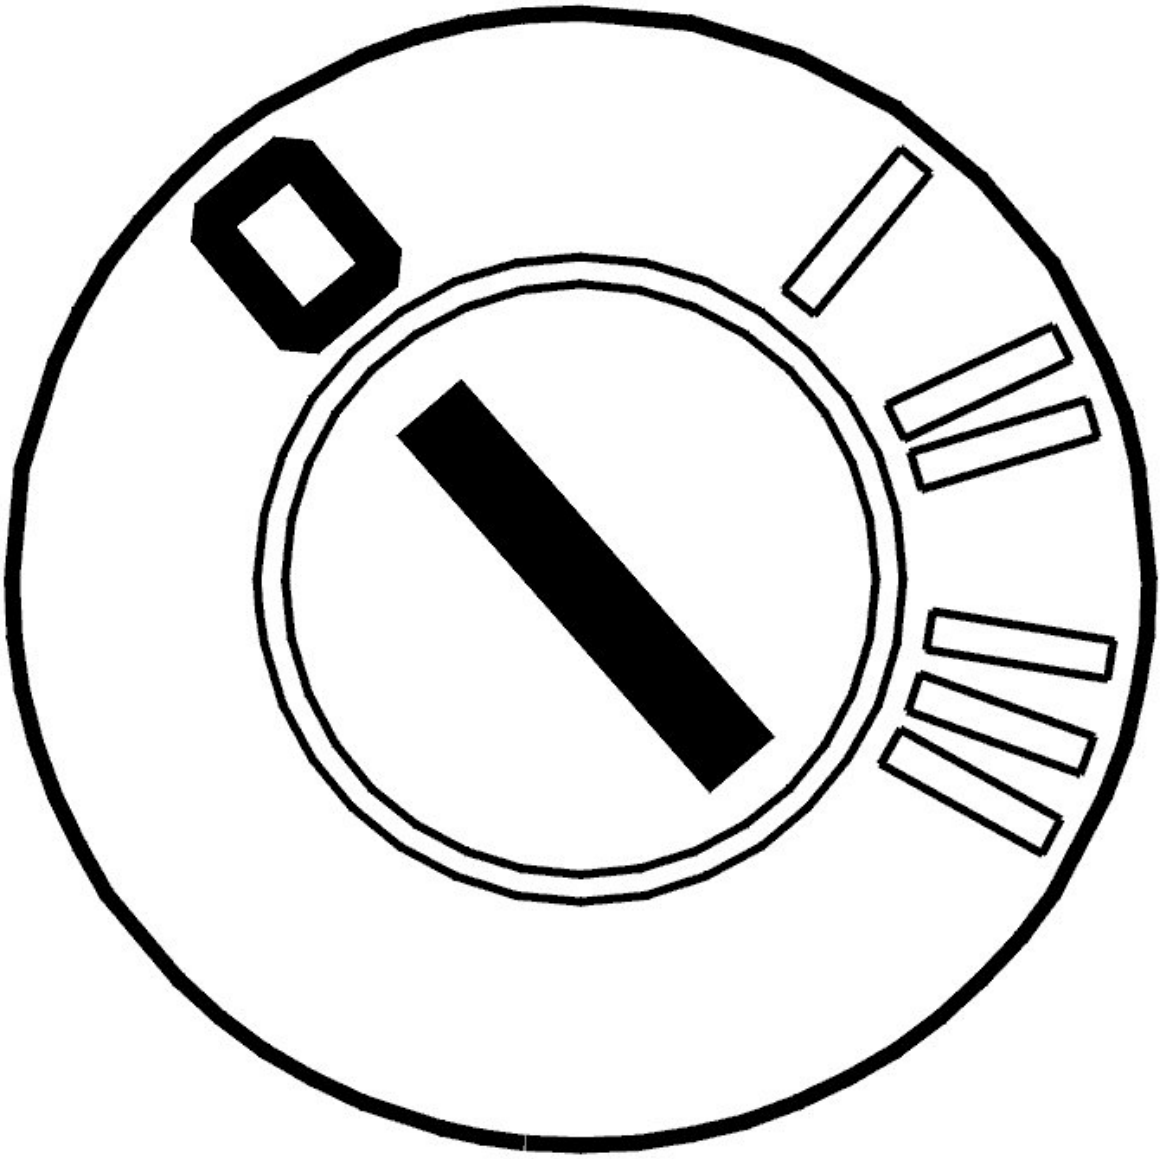
- The anti-spin warning lamp is lit (up to and including 2002 model year)

- General yellow warning lamp lit (from model year 2003)
- Text window and warning symbol/Red symbol and text message
- Anti-spin does not function
- The stability control system does not function
- The traction control system does not function.

Incorrect offset value

Incorrect offset value

Checking the component



- Ignition off.

Check that the active yaw control sensor is securely installed on the bracket under the passenger seat.
Check that the bracket is not bent or damaged in any other way.
Remedy as necessary.

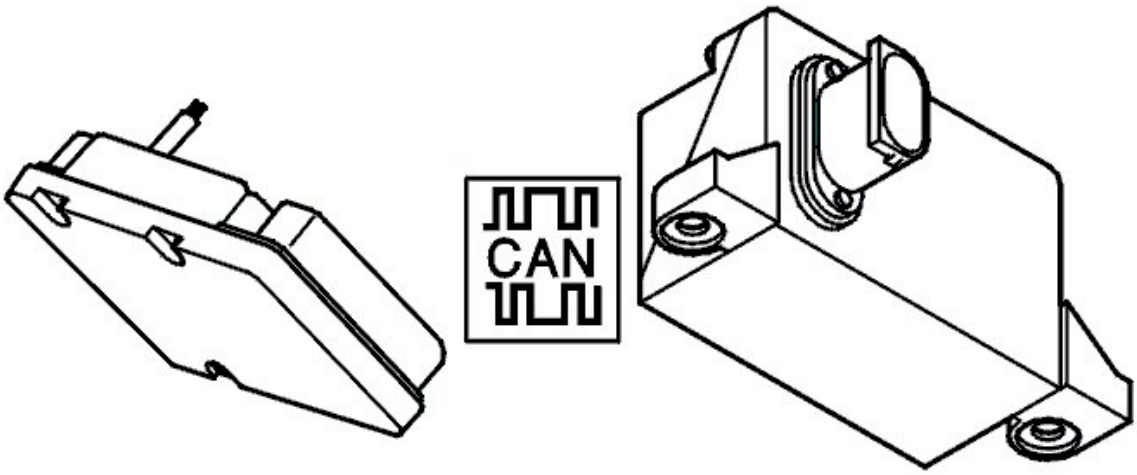
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition



Note! The diagnostic trouble code (DTC) applies only to cars with dynamic stability and traction control (DSTC).

The yaw rate sensor, lateral accelerometer, accelerometer (only AWD) and angle of lean sensor (only RSC) are integrated in the active yaw control sensor for DSTC. The sensors transmit information to the brake control module (BCM) indicating the size of the yaw angle, the lateral acceleration of the car, the forward acceleration and the lateral angle of lean via its own internal Control area network (CAN). Each sensor has an offset value, correction value, for the individual sensor offset.
Diagnostic trouble code (DTC) BCM-0080, BCM-0081, BCM-0082 or BCM-0083 is stored, depending on the sensor, if the control module registers an incorrect offset value from any of the sensors.

- BCM-0080: Lateral accelerometer
- BCM-0081: Accelerometer
- BCM-0082: Yaw rate sensor
- BCM-0083: Angle of lean sensor.

The diagnostic trouble code (DTC) can be diagnosed while the ignition is switched on.

Substitute value

- Traction control is blocked
- Stability control is blocked
- Active yaw control is blocked
- RSC system is blocked (cars equipped with RSC only).

Hint: For information about brake system abbreviations, see Brake system, abbreviations See: Brakes and Traction Control/Antilock Brakes /

Traction Control Systems/Description and Operation/Brake System, Abbreviations.

Possible source
- Active yaw control sensor incorrectly installed
- The active yaw control sensor is loose
- The bracket for the active yaw control sensor is bent
- Internal fault in the active yaw control sensor.

Note! This diagnostic trouble code (DTC) is not due to an internal hardware fault in the Brake control module (BCM) and must not be remedied by replacing the control module.

Fault symptom[s]
- The anti-spin warning lamp is lit (up to and including 2002 model year)

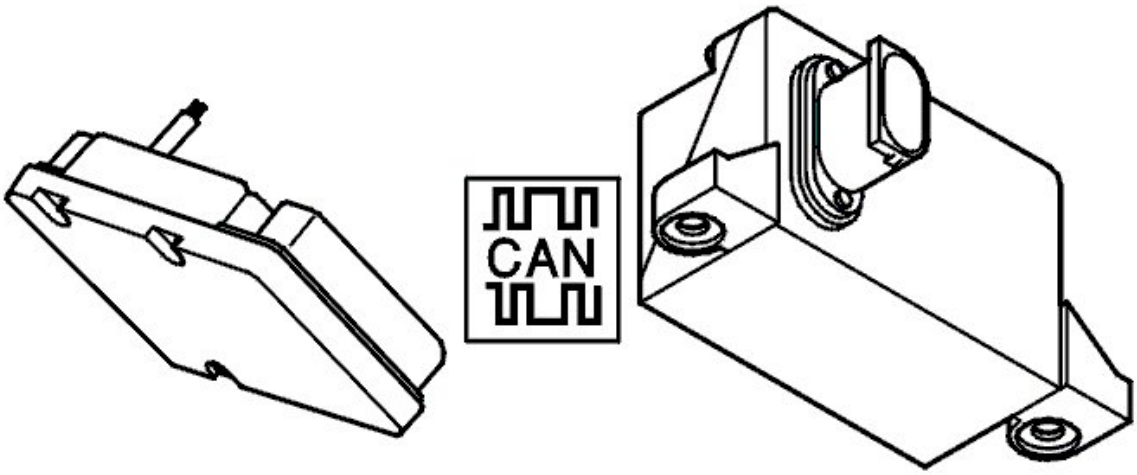
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition



Note! The diagnostic trouble code (DTC) applies only to cars with dynamic stability and traction control (DSTC).

The yaw rate sensor, lateral accelerometer, accelerometer and angle of lean sensor (only RSC) are integrated in the active yaw control sensor for DSTC (dynamic stability and traction control). The sensors transmit information to the brake control module (BCM) indicating the size of the yaw angle, the lateral acceleration of the car, the forward acceleration and the lateral angle of lean via the Control area network (CAN).
Diagnostic trouble code (DTC) BCM-0090, BCM-0091, BCM-0092 or BCM-0093 is stored, depending on the sensor, if the control module registers a faulty signal from any of the sensors.

- BCM-0090: Lateral accelerometer
- BCM-0091: Accelerometer
- BCM-0092: Yaw rate sensor
- BCM-0093: Angle of lean sensor.

The diagnostic trouble code (DTC) can be diagnosed while the ignition is switched on.

Substitute value

- Traction control is blocked
- Stability control is blocked
- Active yaw control is blocked
- RSC system is blocked (cars equipped with RSC only).

Hint: For information about brake system abbreviations, see Brake system, abbreviations See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Description and Operation/Brake System, Abbreviations.

Possible source

- Open-circuit or short-circuit to ground in the wiring for the active yaw control sensor
- Internal fault in the active yaw control sensor.

Note! This diagnostic trouble code (DTC) is not due to an internal hardware fault in the Brake control module (BCM) and must not be remedied by replacing the control module.

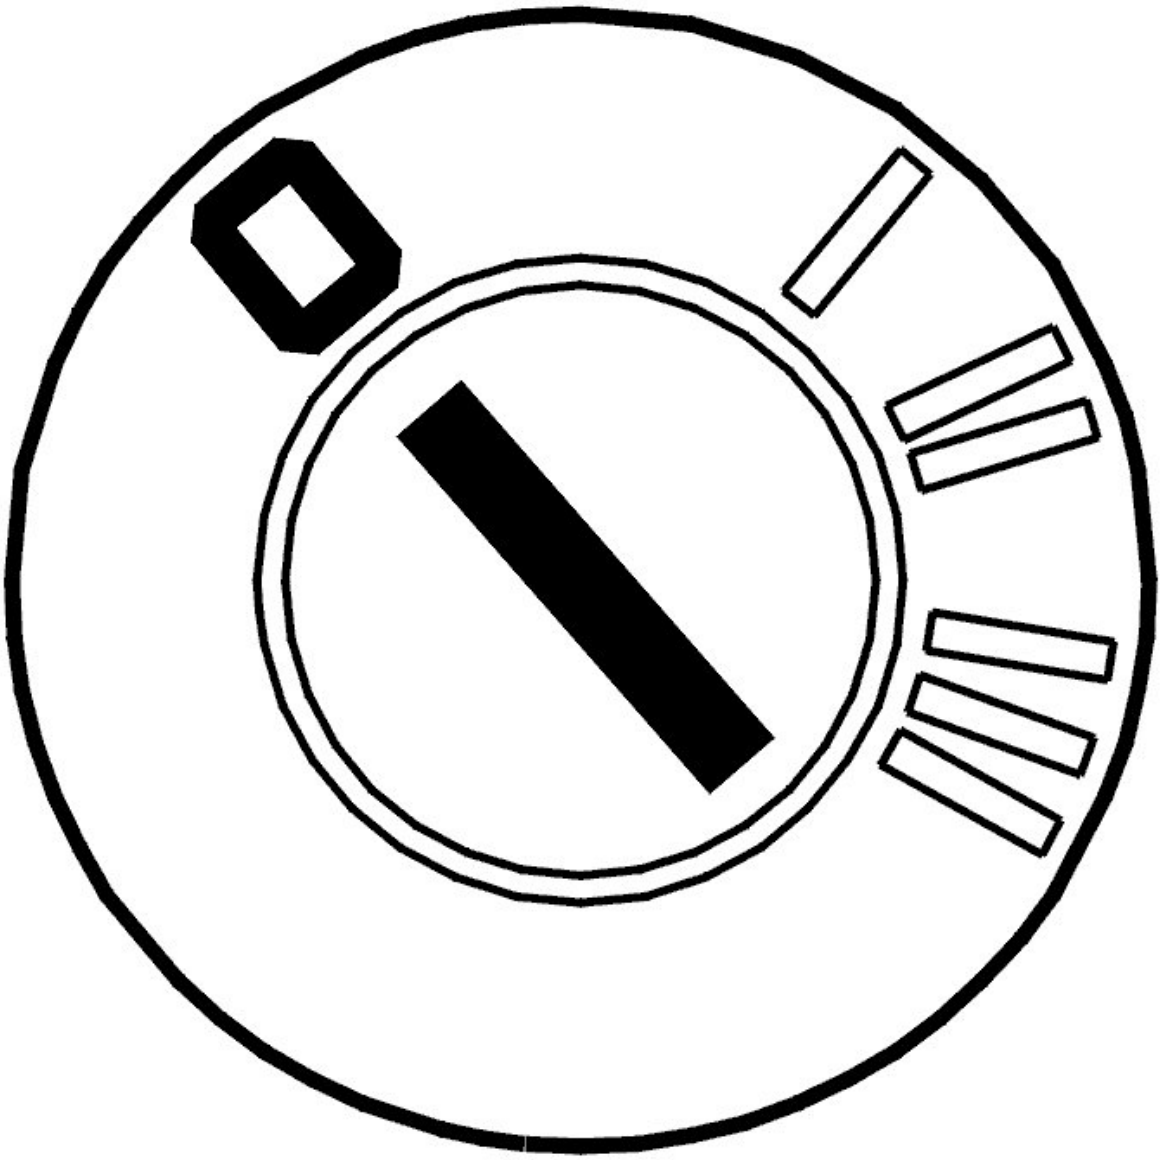
Fault symptom[s]

- The anti-spin warning lamp is lit (up to and including 2002 model year)
- General yellow warning lamp lit (from model year 2003)
- Anti-spin does not function
- The stability control system does not function
- The traction control system does not function.

Faulty Signal

Faulty signal

Checking the wiring



- Ignition off.

Check the wiring between the active yaw control sensor:

- terminal #1 and control module terminal #A25 (#A25)
- terminal #2 and control module terminal #A29 (#A29)
- terminal #3 and control module terminal #A6 (#A6)
- terminal #5 and control module terminal #A39 (#A39).

check for an open-circuit.

Hint: Read off the relevant signal for the diagnostic trouble code (DTC). Check that the value is within its permitted range.

- Steering wheel angle sensor, offset value. The value must be 0° ±17 °/s.
- Yaw rate sensor, offset value. The value must be 0° ±6.0 °/s.
- Lateral accelerometer, offset value. The value must be 0° ±1.7 m/s.
- Accelerometer, offset value. The value must be 0° ±1.7 m/s.

If the value is incorrect, this can mean a damaged AYC sensor.
Remedy as necessary.

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition

Note! The diagnostic trouble code (DTC) applies only to cars with all-wheel drive (AWD) and dynamic stability and traction control (DSTC).

The differential electronic module (DEM) indicates to the brake control module (BCM) when four wheel drive is activated. During four wheel drive the brake control module (BCM) must not activate the stability function due to the risk of disrupting the differential electronic module (DEM). A DTC is stored if the Brake control module (BCM) registers that the signal from the Differential electronic module (DEM) is missing, or if the signal indicates that four wheel drive is not working.
The diagnostic trouble code (DTC) can be diagnosed when the ignition is switched on.

Substitute value
- Stability control is blocked
- Traction control is blocked (All-wheel drive (AWD) TRACS (Traction Control System) is blocked without a warning lamp lighting)
- Active yaw control is blocked.

Hint: Brake system, abbreviations See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Description and Operation/Brake System, Abbreviations

Possible source
- Open-circuit or short-circuit in the wiring for the control area network (CAN)
- Damaged Differential Electronic Module (DEM).

Fault symptom[s]
- The anti-spin warning lamp is lit (up to and including 2002 model year)
- General yellow warning lamp lit (from model year 2003 inclusive)
- Anti-spin does not function
- The stability control system does not function
- The traction control system does not function.

Communication Problems With the Differential Electronic Module (DEM)

Communication problems with the differential electronic module (DEM)

Checking diagnostic trouble codes (DTCs) in the central electronic module

Checking diagnostic trouble codes (DTCs) in the central electronic module

Checking other diagnostic trouble codes (DTCs)

In the event of communication problems, the fault may exist in other parts of the communications network.
The role of the central electronic module is to generally control the communications network and to store diagnostic trouble codes (DTCs) in the event of communication problems between control modules.

If there are diagnostic trouble codes (DTCs) stored for communication problems in the central electronic module, stop the fault tracing and fault trace the central electronic module.

Were diagnostic trouble codes (DTCs) for communication problems stored in the central electronic module?

Yes - DONE

No - No Fault Found

DONE - DONE

No Fault Found - Checking diagnostic trouble codes (DTCs)

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition

Note! The diagnostic trouble code (DTC) applies only to cars with dynamic stability and traction control (DSTC).

The control modules in the car continually transmit and receive information over the data network (Controller Area Network).
Diagnostic trouble code (DTC) BCM-0097 is stored if the brake control module (BCM) registers that the signal from the central electronic module (CEM), which contains information about the vehicle type, has been absent for more than 27 seconds after the ignition is switched on.
The diagnostic trouble code (DTC) can be diagnosed when the ignition is switched on.

Substitute value
- Traction control is blocked
- Stability control is blocked
- Active yaw control is blocked.

Hint: For information about abbreviations, see Brake system, abbreviations See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Description and Operation/Brake System, Abbreviations.

Possible source
- A brake control module (BCM) from another model has been installed
- A central electronic module (CEM) from another model has been installed.

Fault symptom[s]

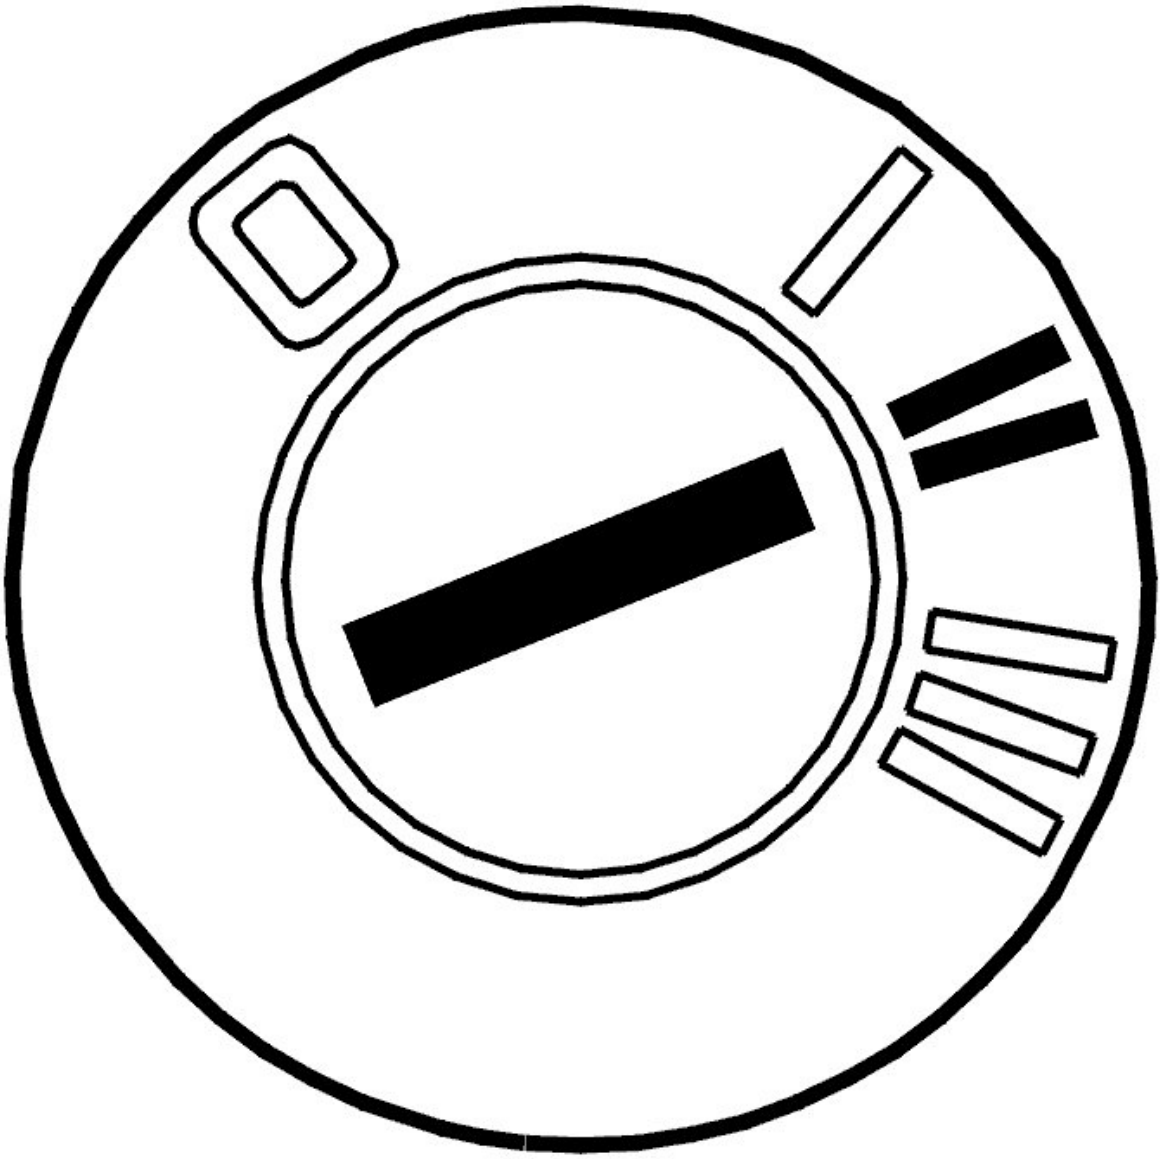
- The anti-spin warning lamp is lit (up to and including 2002 model year)
- General yellow warning lamp lit (from model year 2003 inclusive)
- Anti-spin does not function
- The stability control system does not function
- The traction control system does not function.

Communication Problems With the Central Electronic Module

Communication problems with the central electronic module

Checking other diagnostic trouble codes (DTCs)

Hint: In the event of communication problems, the fault may exist in other parts of the communications network. The role of the central electronic module is to generally control the communications network and to store diagnostic trouble codes (DTCs) in the event of communication problems between control modules.
If there are diagnostic trouble codes (DTC) stored in the central electronic module these must be fault traced accordingly.



- Ignition on
- Wait approximately 60 seconds
- Read off diagnostic trouble codes (DTCs).

If there are diagnostic trouble codes (DTCs) for communication problems stored for the brake control module in the central electronic module, these must be fault traced first.

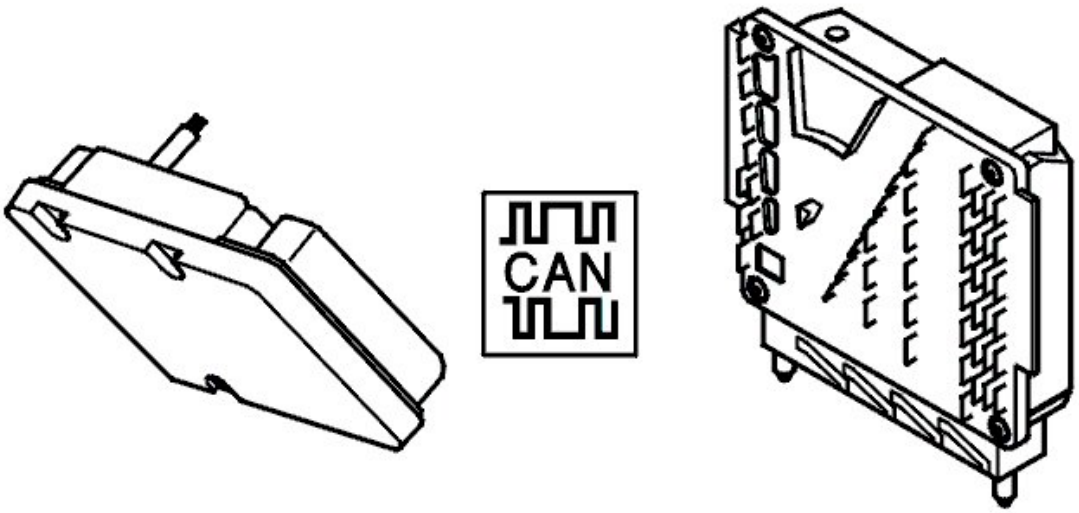
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition



Note! The diagnostic trouble code (DTC) applies only to cars with stability and traction control (STC) / dynamic stability and traction control (DSTC).

The engine control module (ECM) transmits a signal via the Control area network (CAN) which indicates whether the engine speed signal to the brake control module (BCM) is correct or not. The brake control module (BCM) uses the engine speed (RPM) signal during control of the stability function.
Diagnostic trouble code (DTC) BCM-0101 is stored if the brake control module (BCM) registers that the engine control module (ECM) has transmitted a signal indicating that the engine speed (RPM) signal is implausible.
The diagnostic trouble code (DTC) can be diagnosed after the engine has been started.

Substitute value
- Traction control is blocked
- Stability control is blocked
- Active yaw control is blocked.

Hint: For information about abbreviations, see Brake system, abbreviations See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Description and Operation/Brake System, Abbreviations.

Possible source
- Fault in the engine management system.

Note! This diagnostic trouble code (DTC) is not due to an internal hardware fault in the Brake control module (BCM) and must not be remedied by replacing the control module.

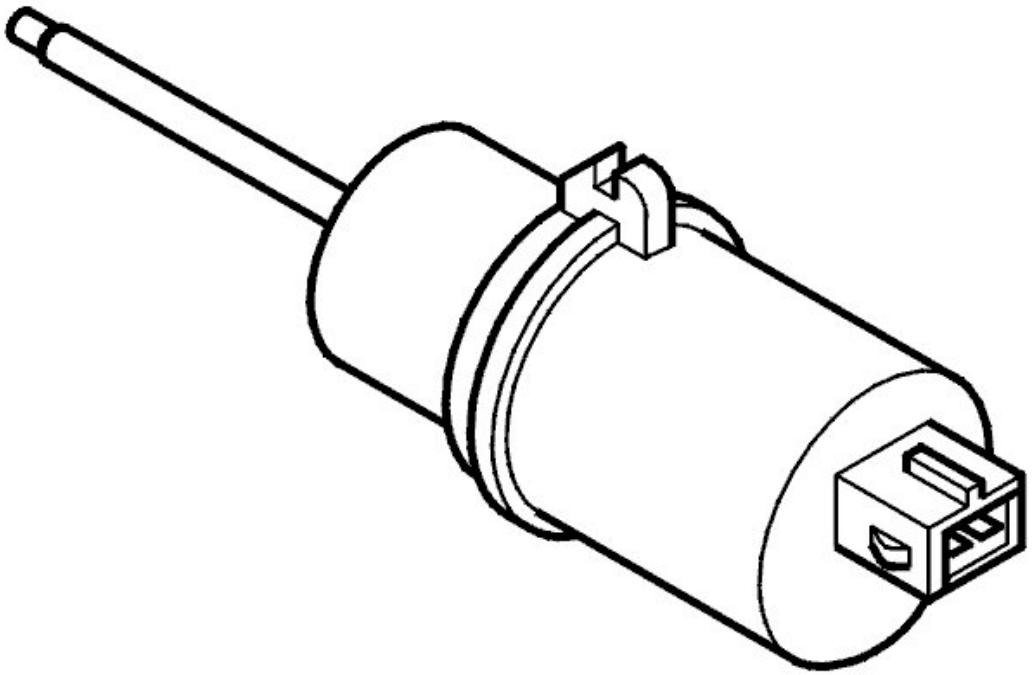
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition



The brake pedal position sensor transmits a signal to the brake control module about the position of the brake pedal and the speed at which it is pressed. The brake control module uses the signal to activate the brake assistance function during emergency braking.
Diagnostic trouble code (DTC) BCM-0103 is stored if the control module registers a faulty signal from the pedal position sensor.
The diagnostic trouble code (DTC) can be diagnosed when the ignition is switch on and if the signal from the pedal position sensor is more than 4.85 V or less than 0.15 V for too long.

Substitute value
- Brake assistance is blocked.

Hint: For information about abbreviations, see Brake system, abbreviations See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Description and Operation/Brake System, Abbreviations.

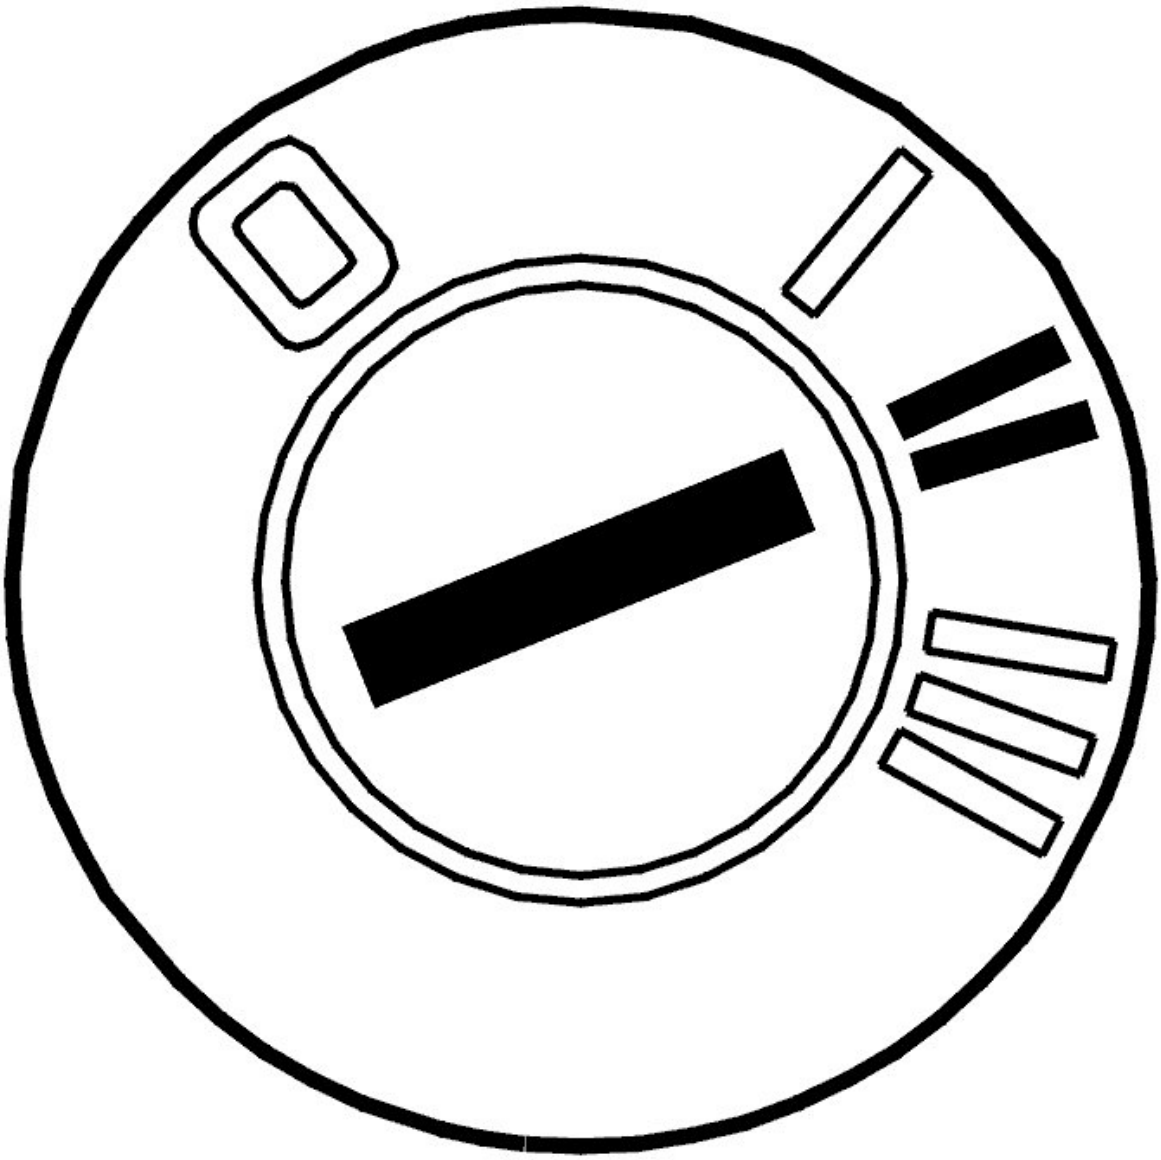
Possible source
- Open-circuit in the signal cable
- Short-circuit to ground or supply voltage in the wiring
- Incorrectly installed sensor
- Defective sensor
- Internal fault in the control module.

Fault symptom[s]
- General warning lamp lit.

Faulty Signal

Faulty signal

Checking the connectors



- Ignition off
- Check the brake control module (BCM) and pedal position sensor connectors. Check for contact resistance and oxidation
- Reinstall the components, reconnect the connectors etc.
- Connect the breakout box to the brake control module (BCM)
- Ignition on
- Read off the position and speed of the pedal position sensor.

Depress the brake pedal. Check that the signals are updated.
The signal for the pedal position sensor must increase as the brake pedal is pressed further.
Press the brake pedal at different speeds. Check that the speed signal is updated.

Other information

- To connect the breakout box, see Connecting the breakout box, brake control module (BCM) See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box/Connecting the Breakout Box, Brake Control Module (BCM)
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

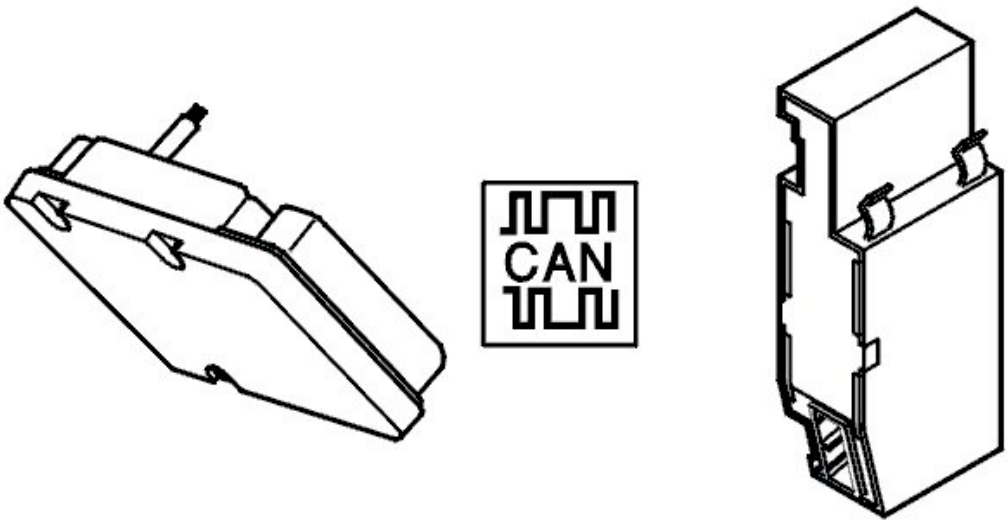
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition



Note! The diagnostic trouble code (DTC) applies only to cars with dynamic stability and traction control (DSTC).

The control module for the steering angle sensor transmits signals from the steering wheel angle sensor on the Control area network (CAN) from where it is retrieved by the brake control module (BCM). A reference signal is calculated using the signals from the wheel sensors, the yaw rate sensor and the lateral accelerometer. Diagnostic trouble code (DTC) BCM-0106 is stored if the brake control module (BCM) registers that the reference signal is outside its permitted range.

Substitute value
- Stability control is blocked
- Active yaw control is blocked
- Traction control is blocked.

Hint: For information about abbreviations, see Brake system, abbreviations See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Description and Operation/Brake System, Abbreviations.

Possible source
- Incorrect front wheel alignment
- Incorrectly installed steering wheel angle sensor
- Defective steering wheel angle sensor.

Note! This diagnostic trouble code (DTC) is not due to an internal hardware fault in the Brake control module (BCM) and must not be remedied by replacing the control module.

Fault symptom[s]
- The anti-spin warning lamp is lit (up to and including 2002 model year)
- Anti-spin does not function
- The stability control does not function
- The traction control system does not function.

Incorrect Steering Wheel or Wheel Alignment

Incorrect steering wheel or wheel alignment

Checking diagnostic trouble codes (DTCs)

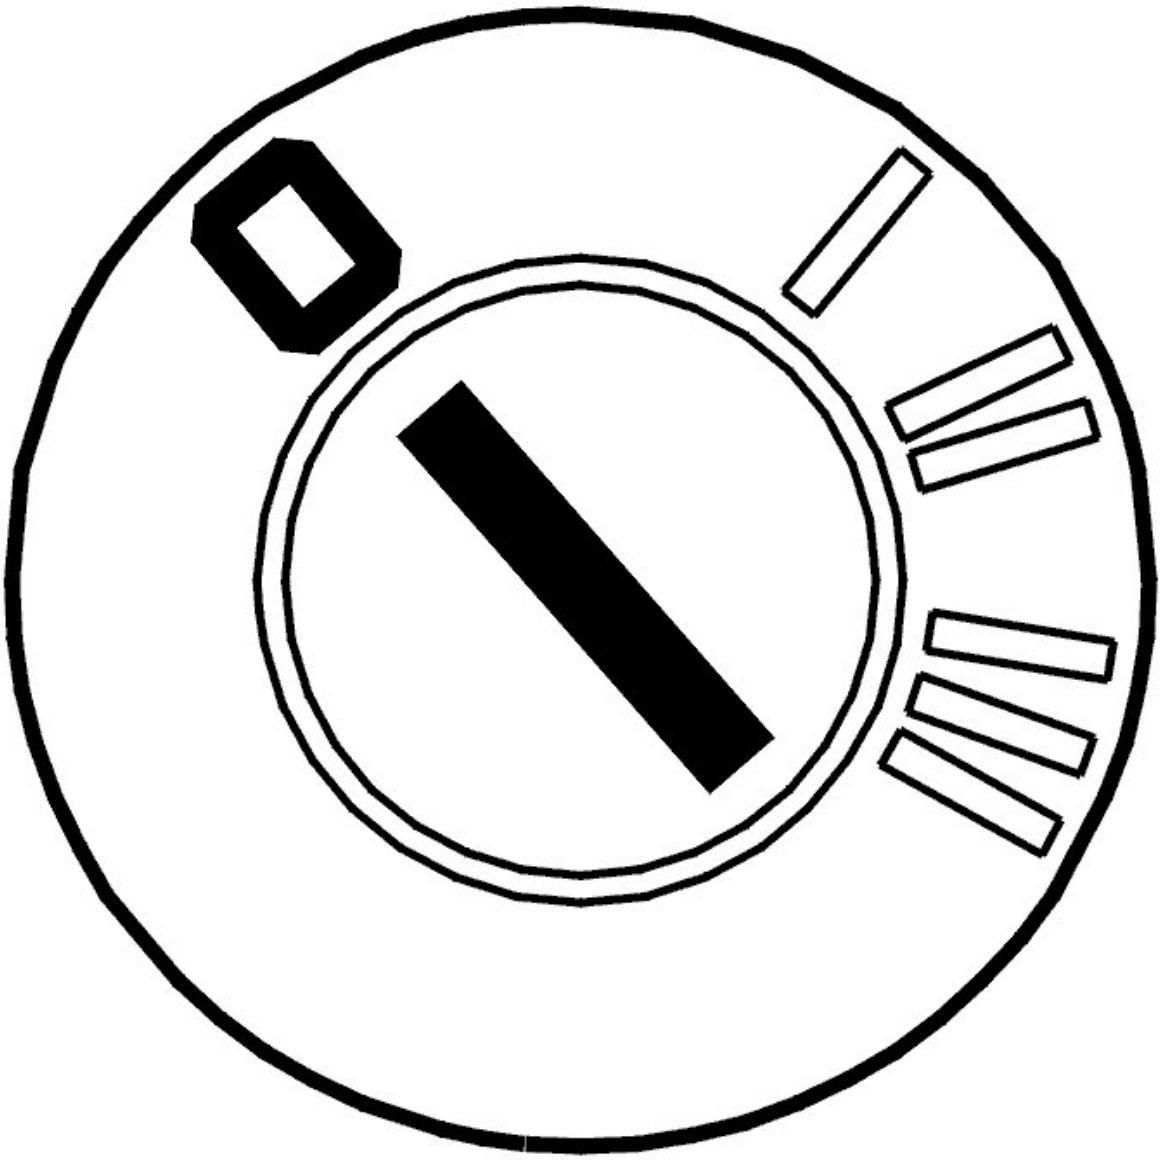
Note! If diagnostic trouble codes (DTCs) are stored for the control module for the steering angle sensor, wheel sensors or active yaw control sensor (including the yaw sensor and lateral accelerometer), these must be fault traced first.

Are diagnostic trouble codes (DTCs) stored for the steering angle sensor, wheel sensors or active yaw control sensor?

Yes - DONE

No - Checking diagnostic trouble codes (DTCs)

Checking diagnostic trouble codes (DTCs)



- Ignition off.

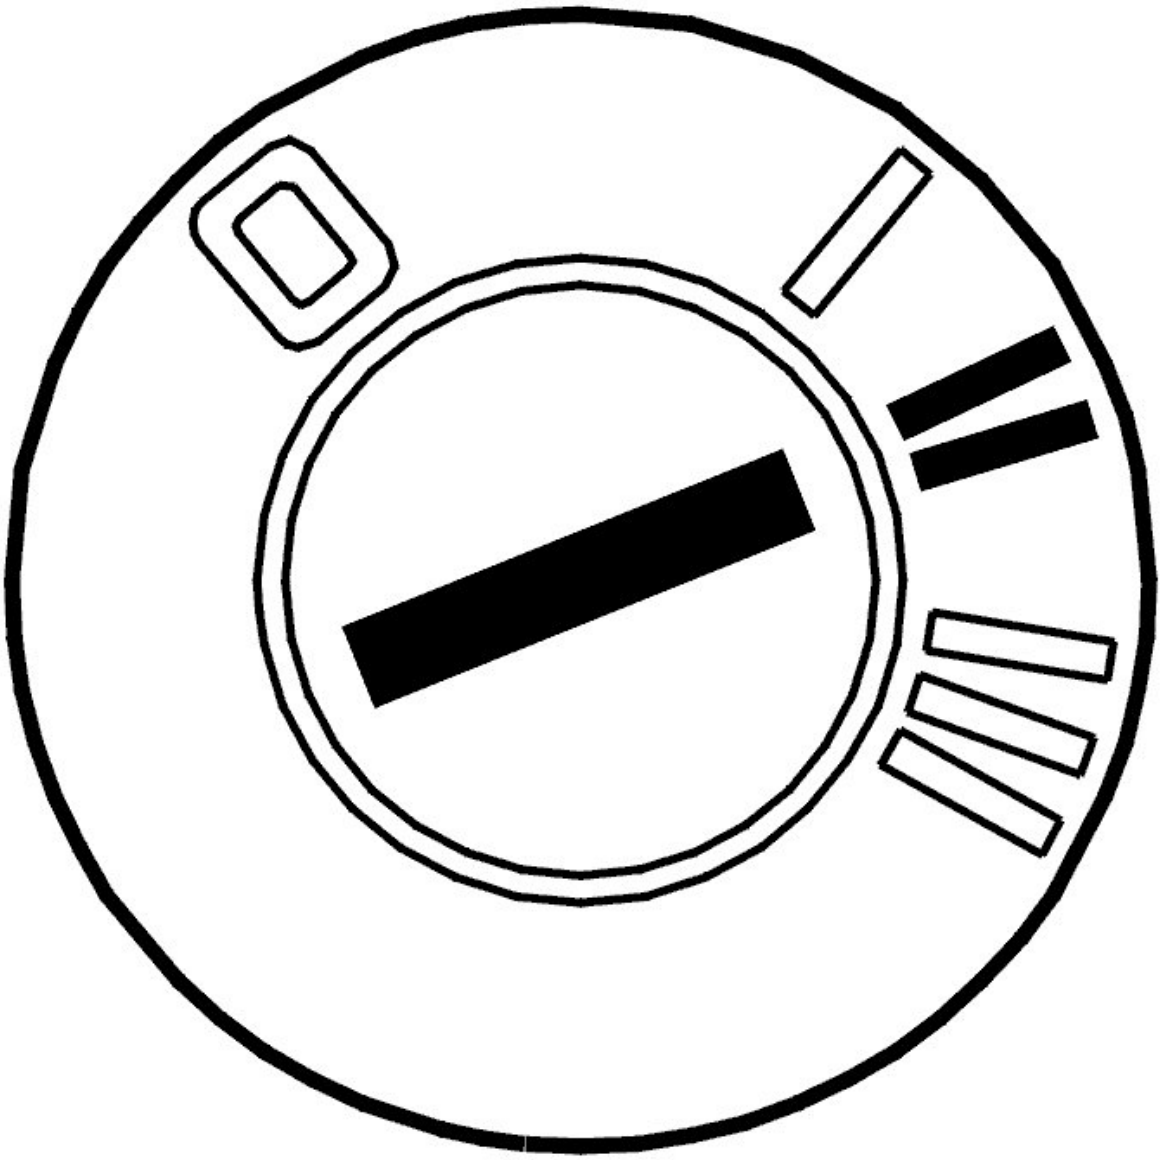
Check whether the active yaw control sensor is loose or incorrectly installed. See Active yaw control sensor, replacing See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Yaw Rate Sensor/Service and Repair/Active Yaw Control Sensor, Replacing.

Is the active yaw control sensor secure?

Yes - Checking the connectors

No - Verification

Checking the connectors



- Ignition on
- Set the steering wheel to the straight forward position
- Read off the steering wheel angle.

With the steering wheel and the front wheels in the straight ahead position, the value for the steering wheel angle must be approximately 0°.
If the steering wheel angle does not correspond to the position of the steering wheel, reset the steering wheel angle and calibrate the dynamic stability and traction control (DSTC) system.
If the front wheel alignment does not correspond to the position of the steering wheel, adjust the front end and calibrate the dynamic stability and traction control (DSTC) system.

Other information

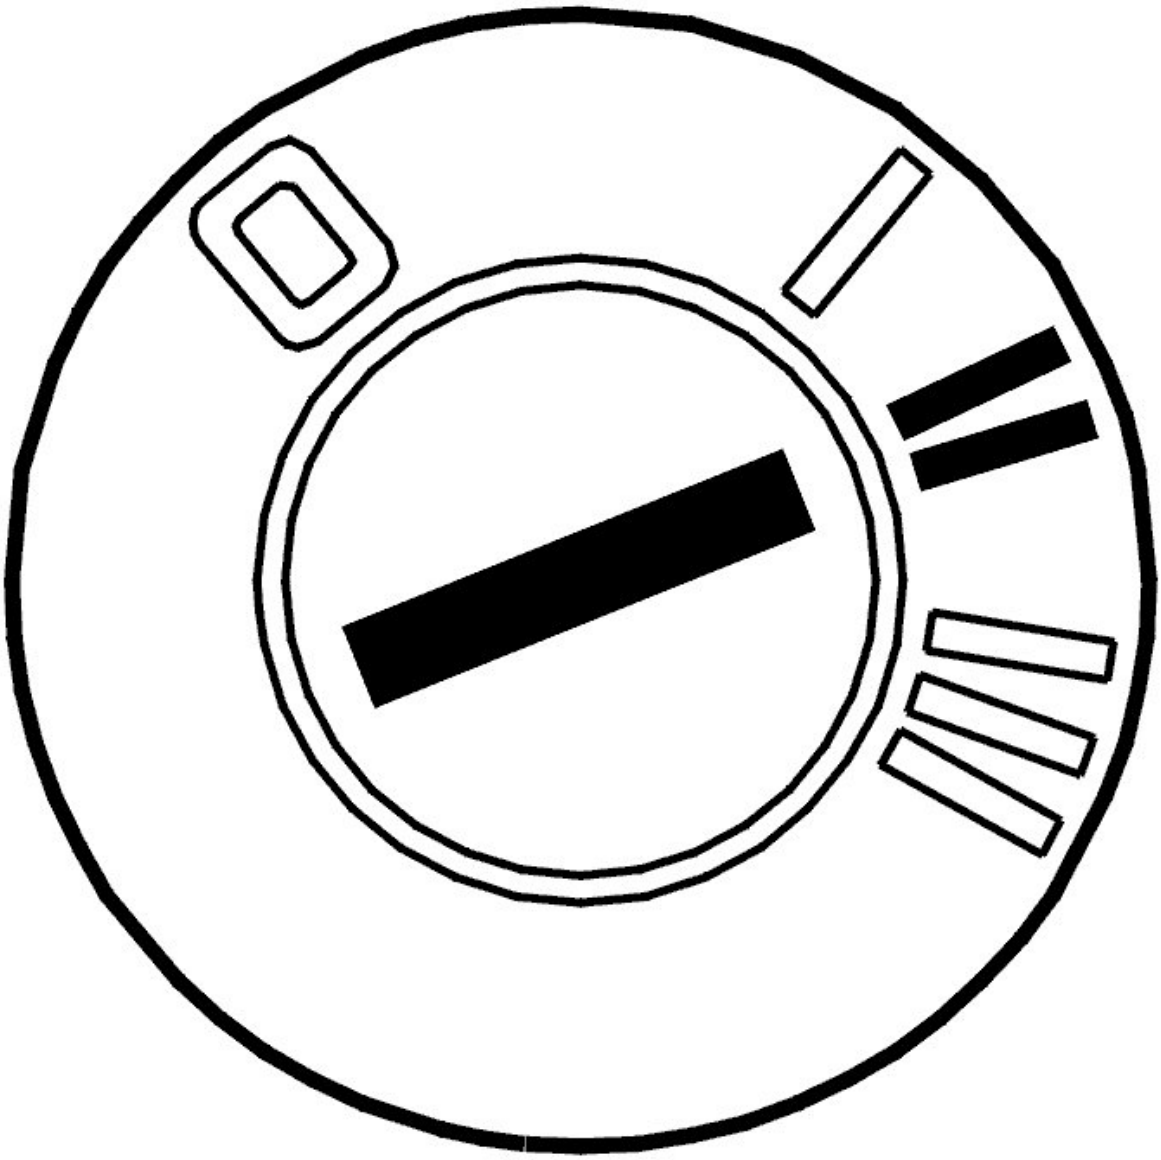
- To reset the steering wheel angle sensor, see Contact reel / steering wheel angle sensor, replacing See: Restraint Systems/Air Bag Systems/Clockspring Assembly / Spiral Cable/Service and Repair/Removal and Replacement/Contact Reel / Steering Wheel Angle Sensor, Replacing
- To adjust the front end, see Wheel alignment, checking / adjusting See: Maintenance/Alignment/Service and Repair.

Were the steering wheel and front wheel alignment OK?

Yes - Intermittent fault

No - Calibration

Calibration



- Ignition on.

Calibrate the brake control module (BCM).

Continue - Verification

Intermittent fault

Hint: The status of the diagnostic trouble code (DTC) indicates that the brake control module (BCM) has previously registered a fault but that the fault is not active.

Check the connectors for the brake control module (BCM) and the control module for the steering wheel angle sensor. Check for contact resistance and oxidation.
Also check that the wiring for CAN communication is not too close to a source of interference such as a carphone etc.
Remedy as necessary.

Other information

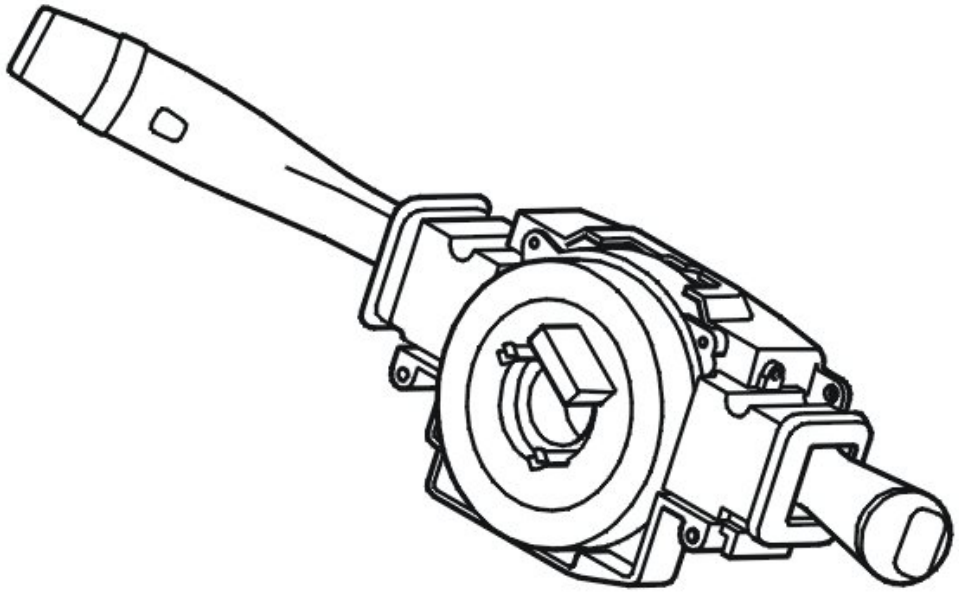
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition



Note! The diagnostic trouble code (DTC) applies only to cars with dynamic stability and traction control (DSTC).

The control module for the steering angle sensor is initiated by turning the steering wheel in either direction within 120 seconds of the car being started. The brake control module (BCM) retrieves the signals from the steering wheel angle sensor on the Control area network (CAN). Diagnostic trouble code (DTC) BCM-0108 is stored if the brake control module (BCM) registers that the control module for the steering wheel angle sensor has not be initialized within 120 seconds of start and the vehicle speed exceeds 10 km/h.

Substitute value
- Active yaw control is blocked.

Hint: For information about abbreviations, see Brake system, abbreviations See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Description and Operation/Brake System, Abbreviations.

Possible source
- After starting the driver has driven straight ahead for more than two minutes and then switched off the ignition which has led to the steering wheel angle sensor not being initiated
- Internal fault in the steering angle sensor.

Note! This diagnostic trouble code (DTC) is not due to an internal hardware fault in the Brake control module (BCM) and must not be remedied by replacing the control module.

Fault symptom[s]
- The anti-spin warning lamp is lit (up to and including 2002 model year)
- General yellow warning lamp lit (from model year 2003 inclusive)
- The traction control system does not function.

Communication With the Steering Angle Sensor

Communication with the steering angle sensor. Control module not initiated

Fault-tracing information

The control module for the steering angle sensor is initiated when the steering wheel is turned more than 5° in any direction. Diagnostic trouble code (DTC) BCM-0108 may be stored if the car has been turned for more than 2 minutes without turning the steering wheel. Ask the customer whether this is the case.
If this is not the case, read off diagnostic trouble codes (DTCs) from the steering angle sensor and fault trace according to the information for this system.

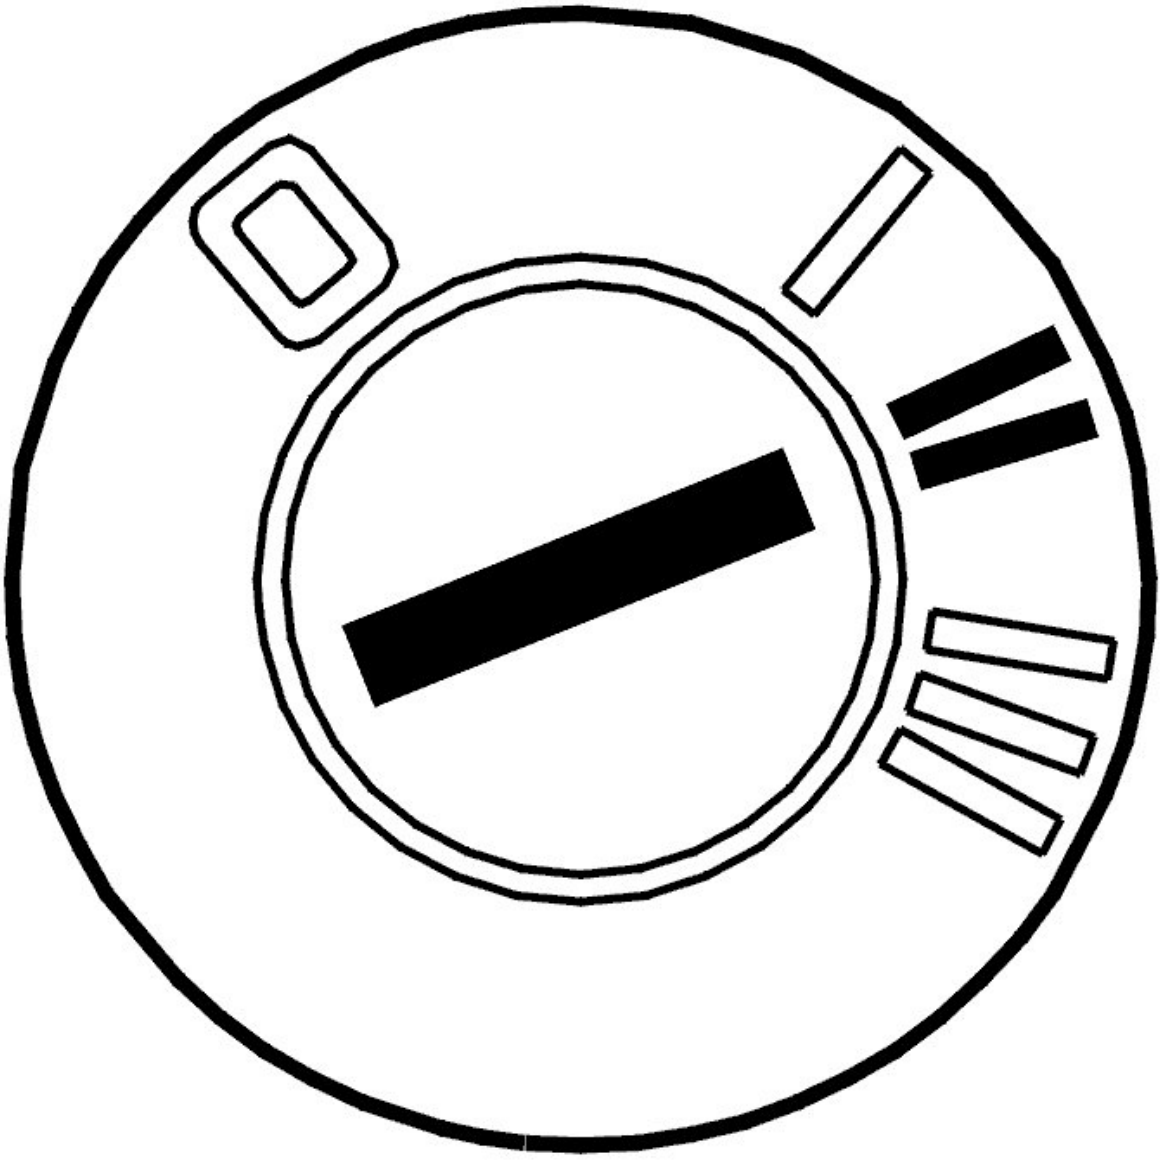
Sensor not calibrated

Fault-tracing information

Hint: The diagnostic trouble code (DTC) may be stored when downloading software, in which case it only needs to be erased.

Note! Only erase the diagnostic trouble code (DTC) if it was stored when downloading software.

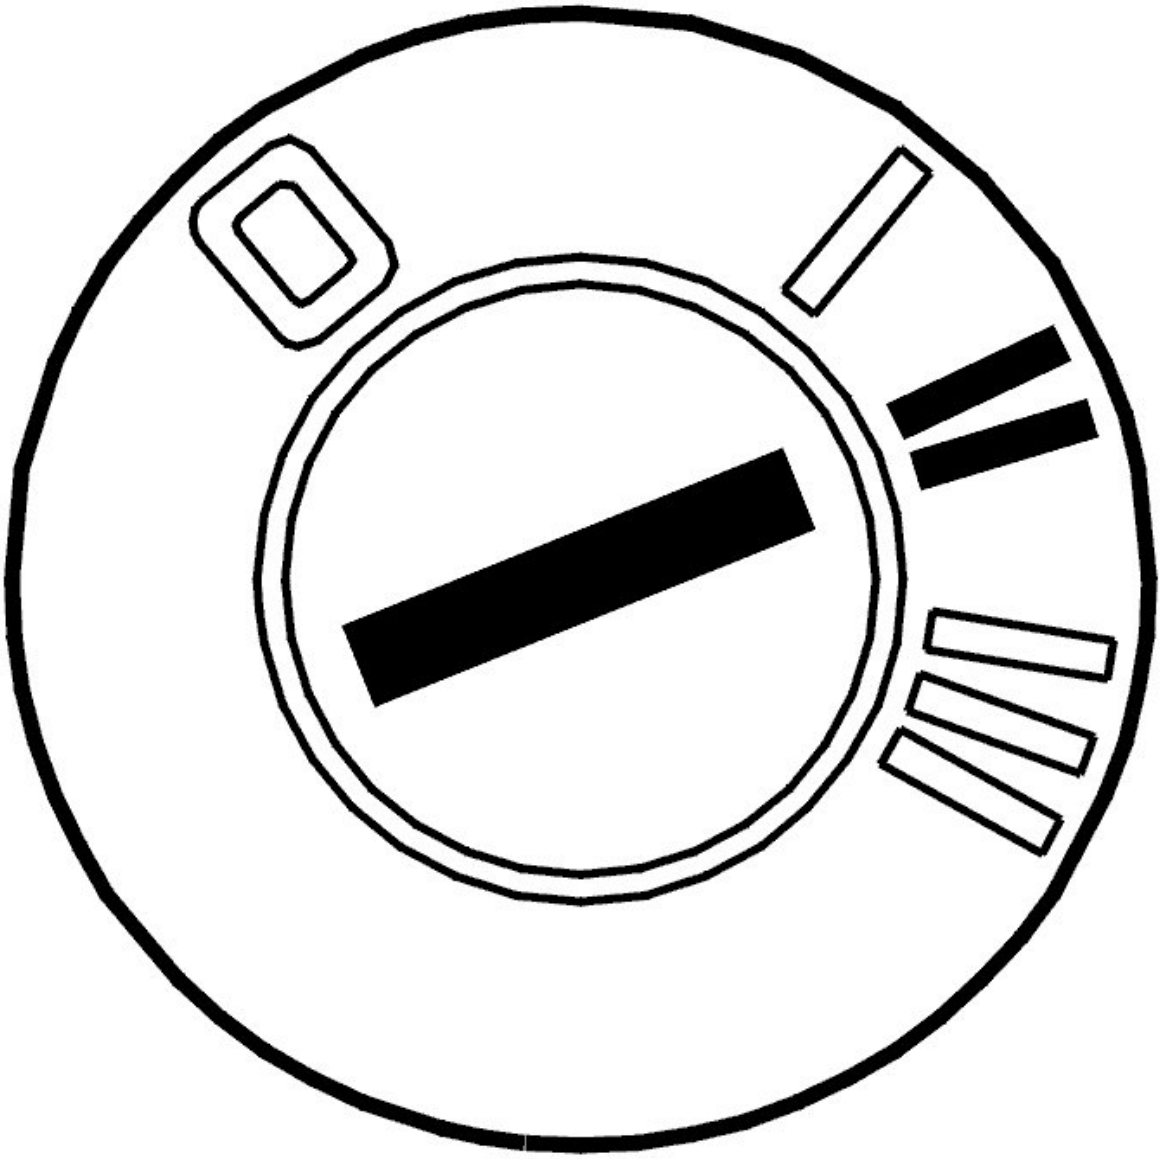


- Ignition on.

Erase diagnostic trouble codes (DTCs).

Continue - Calibrating the sensor

Calibrating the sensor



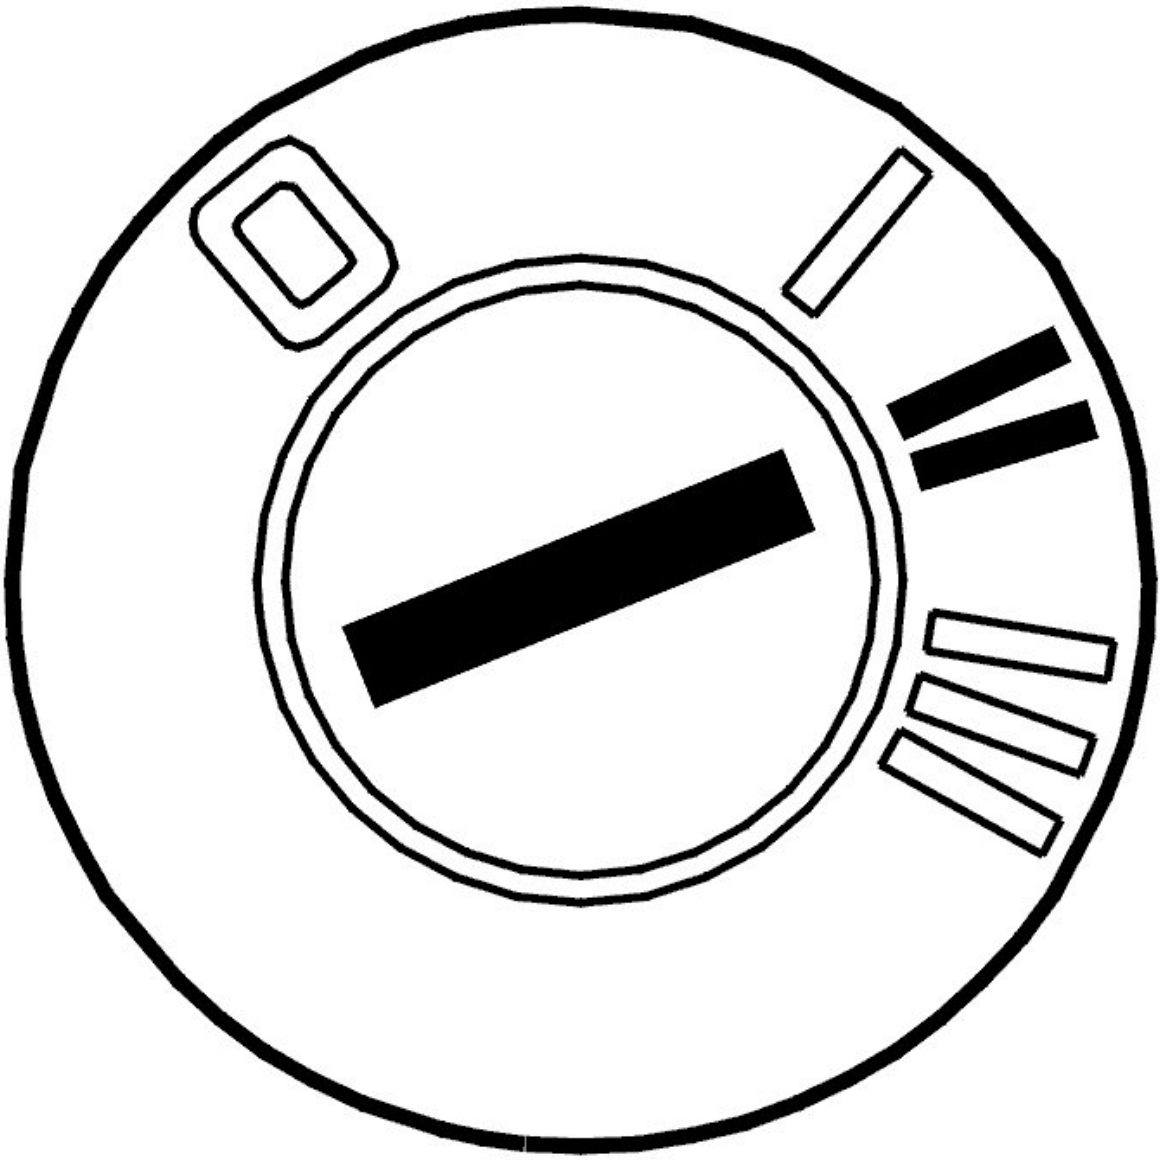
- Ignition on
- Calibrate the brake system.

Note! When calibrating, the car must be on a level surface. Do not touch the brake pedal.The accelerometer can only be calibrated on cars with All-wheel drive (AWD).

Caution! For the XC90, the yaw rate sensor and tilt sensor must also be calibrated.

Continue - Reading off the status of the diagnostic trouble code (DTC)

Reading off the status of the diagnostic trouble code (DTC)



- Ignition on
- Wait approximately 60 seconds
- Read off diagnostic trouble codes (DTCs).

If the status of the diagnostic trouble code (DTC) has changed from permanent to intermittent the fault is no longer active.
Try a new active yaw control sensor if the status of the diagnostic trouble code (DTC) is permanent.

Other information

- To replace the active yaw control sensor, see Active yaw control sensor, replacing See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Yaw Rate Sensor/Service and Repair/Active Yaw Control Sensor, Replacing.

Is the status of the diagnostic trouble code (DTC) intermittent?

Yes - **Fault Found**

No - Verification

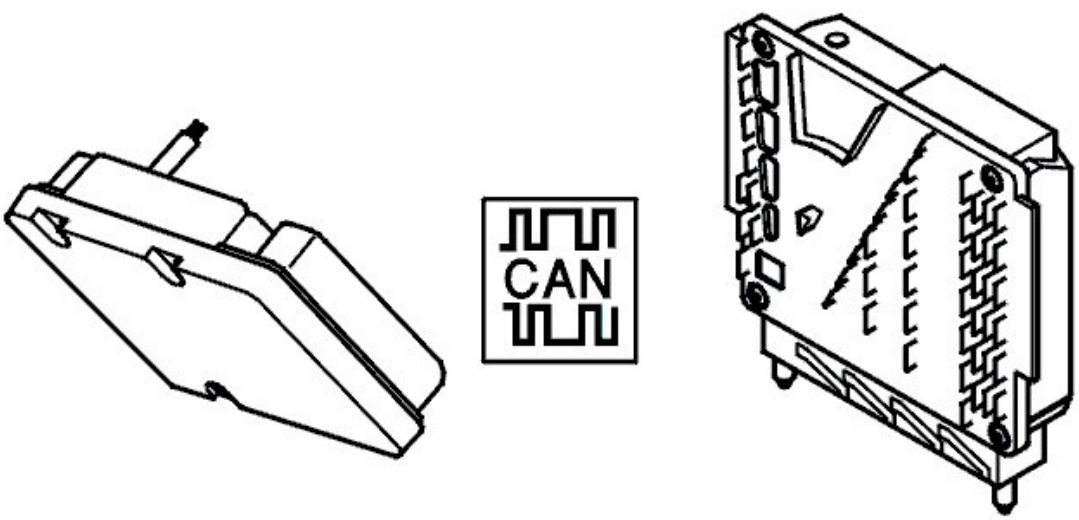
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition



Note! The diagnostic trouble code (DTC) applies only to cars with dynamic stability and traction control (DSTC).

The brake control module receives a signal from the central electronic module (manual transmissions) or from the transmission control module (TCM) (automatic transmission) with information about the selected gear. If back-up (reverse) gear is selected, the stability function cannot be activated.
Diagnostic trouble code (DTC) BCM-0113 is stored if the brake control module registers that the signal is distorted, missing or receives a signal indicating that back-up (reverse) gear is selected when the car is being driven forward for more than one second.
The diagnostic trouble code (DTC) can be diagnosed when speed exceeds 40 km/h and the vehicle is driven straight ahead followed by a turn.

Substitute value
- None.

Possible source
- Open-circuit or short-circuit in the circuit for the back-up (reversing) lamp switch (manual transmission)
- Interference in the Control area network (CAN)
- Short-circuit or open-circuit on the Control area network (CAN).

Note! This diagnostic trouble code (DTC) is not due to an internal hardware fault in the Brake control module (BCM) and must not be remedied by replacing the control module.

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

Fault symptom[s]

- None.

Signal Missing

Signal missing

Checking diagnostic trouble codes (DTCs) in the central electronic module

If there are diagnostic trouble codes (DTCs) stored in the central electronic module for communication problems or for the back-up (reversing) lamp, these must be fault traced first.

Were diagnostic trouble codes (DTCs) stored for communication problems or for the back-up (reversing) lamp in the central electronic module?

Yes - **Troubleshooting completed.**

No - Checking the transmission

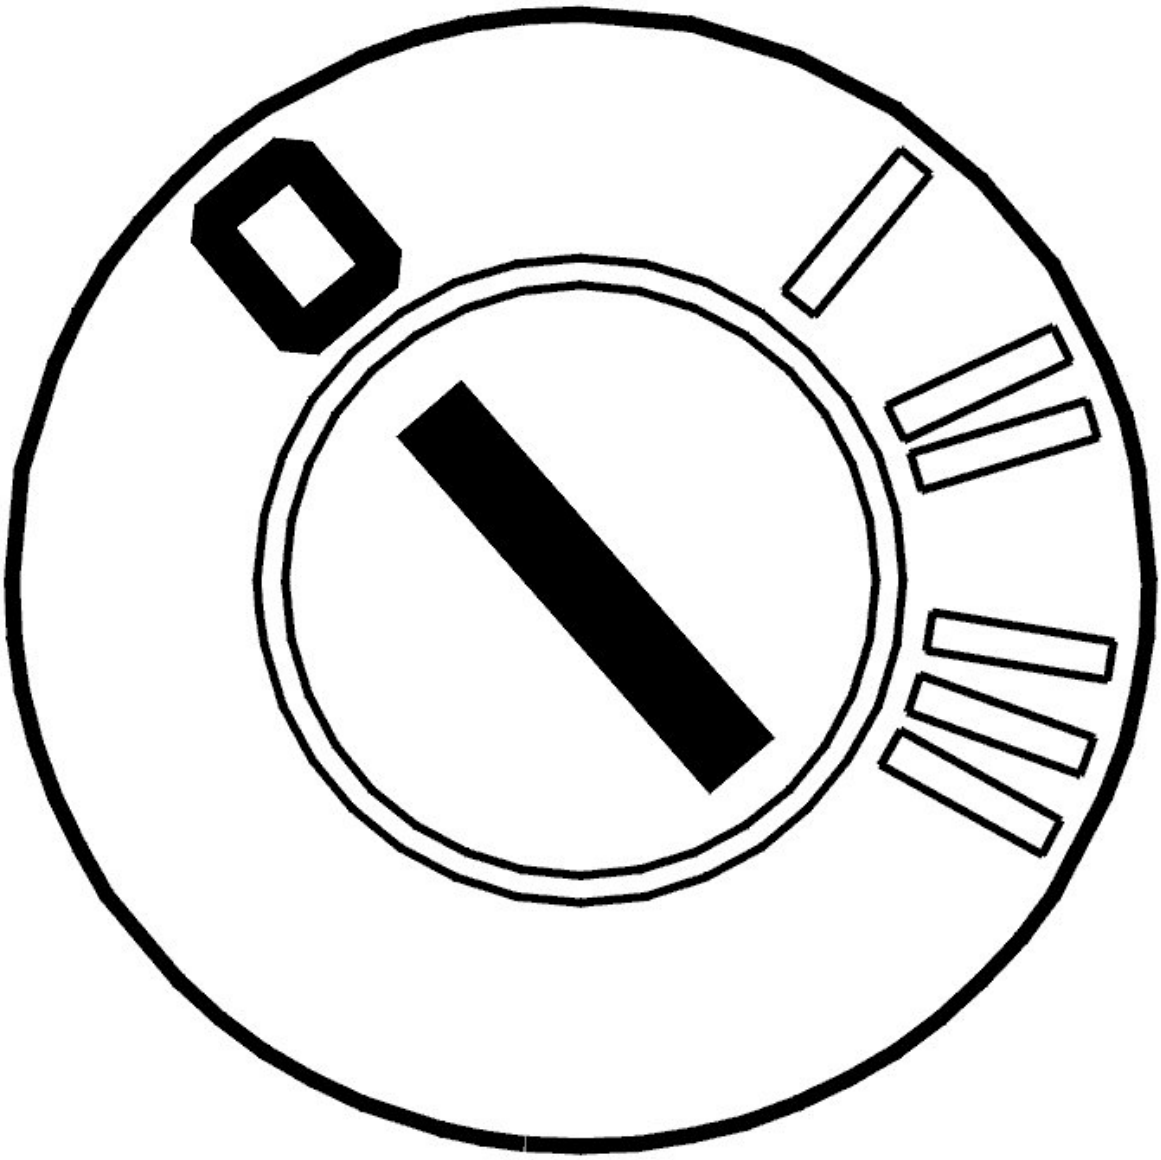
Checking the transmission

Is the car equipped with automatic transmission?

Yes - Checking wiring and terminals (automatic transmissions)

No - Checking back-up (reversing) lamp switch

Checking wiring and terminals (automatic transmissions)



- Ignition off.

Check the brake control module and transmission control module (TCM) connectors. Check for damaged or bent terminal pins. Check for contact resistance and oxidation.
Check the wiring for CAN communication between brake control module terminal #11 (#A11) and terminal #2 (#B12) on the transmission control module (TCM) and between brake control module terminal #15 (#A15) and terminal #14 (#B24) on the transmission control module (TCM). Check for an open-circuit. Check for a short-circuit to ground. Check for a short-circuit to supply voltage.
Remedy as necessary.

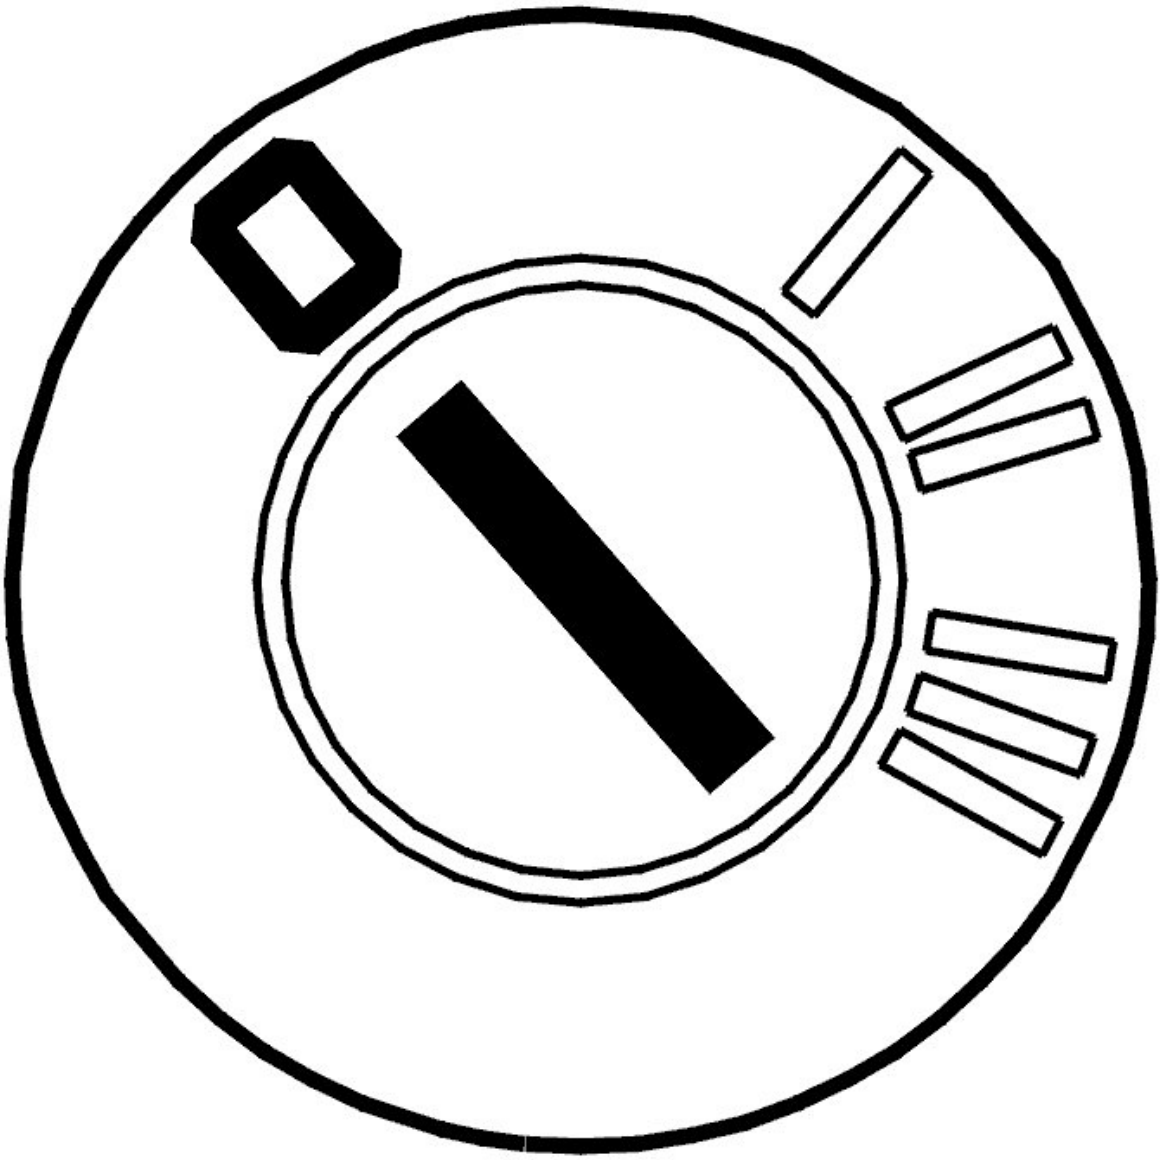
Other information

- To connect the breakout box to the brake control module, see Connecting the breakout box, brake control module (BCM) See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box/Connecting the Breakout Box, Brake Control Module (BCM)
- To fault-trace the wiring and connections, see Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals.

Continue - Verification

Signal too low. Permanent fault

Checking back-up (reversing) lamp switch



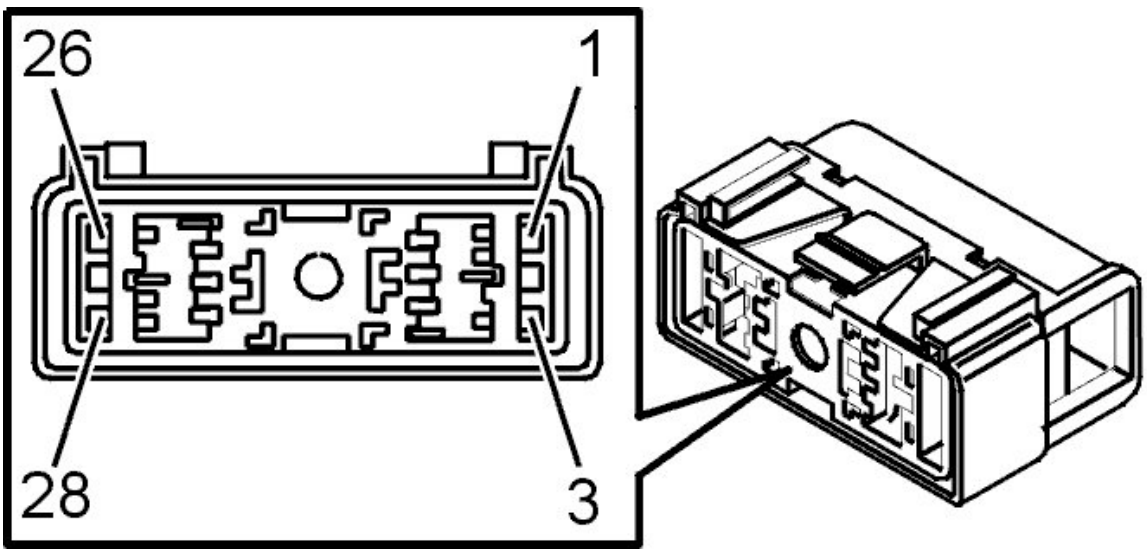
- Ignition off.

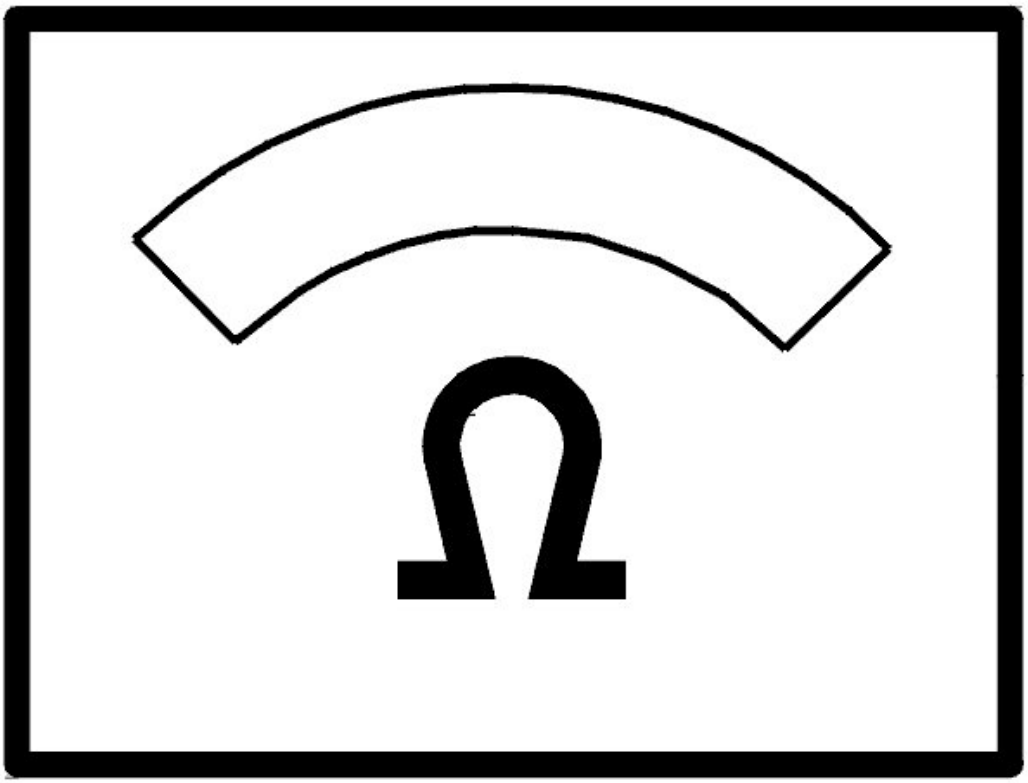
Hint: Check the back-up (reversing) light switch resistance between connector 54/1 terminal #24 and ground with gears 1 to 5 engaged. Resistance should be high.

The back-up gear switch should be open in all gear positions except back-up gear.
Remedy as necessary.

Other information:

- To access the back-up (reversing) lamp switch, see Back-up lamp switch, replacing See: Lighting and Horns/Backup Lamp/Backup Lamp Switch/Service and Repair.





Was a fault detected?

Yes - Verification

No - Checking the cable

Checking the cable

Check the cable between the central electronic module (CEM) terminal #1A and the back-up (reversing) lamp switch terminal #2 (3/10). Check for

a short-circuit to ground.
Remedy as necessary.

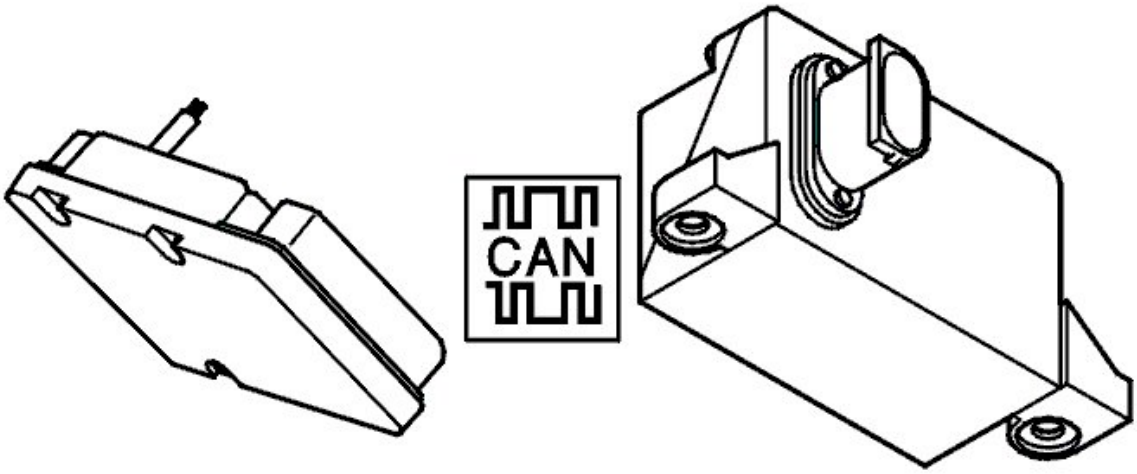
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition



Note! The diagnostic trouble code (DTC) applies only to cars with dynamic stability and traction control (DSTC).

Diagnostic trouble code (DTC) BCM-0114 is stored if the brake control module (BCM) registers that the signal from the active yaw control sensor is missing or faulty.

Substitute value
- Traction control is blocked
- Stability control is blocked
- Active yaw control is blocked.

Hint: For information about abbreviations, see Brake system, abbreviations See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Description and Operation/Brake System, Abbreviations.

Possible source
- Contact resistance in the terminals
- Open-circuit in the wiring between the brake control module (BCM) and the active yaw control sensor
- The active yaw control sensor is not connected
- Internal fault in the active yaw control sensor.

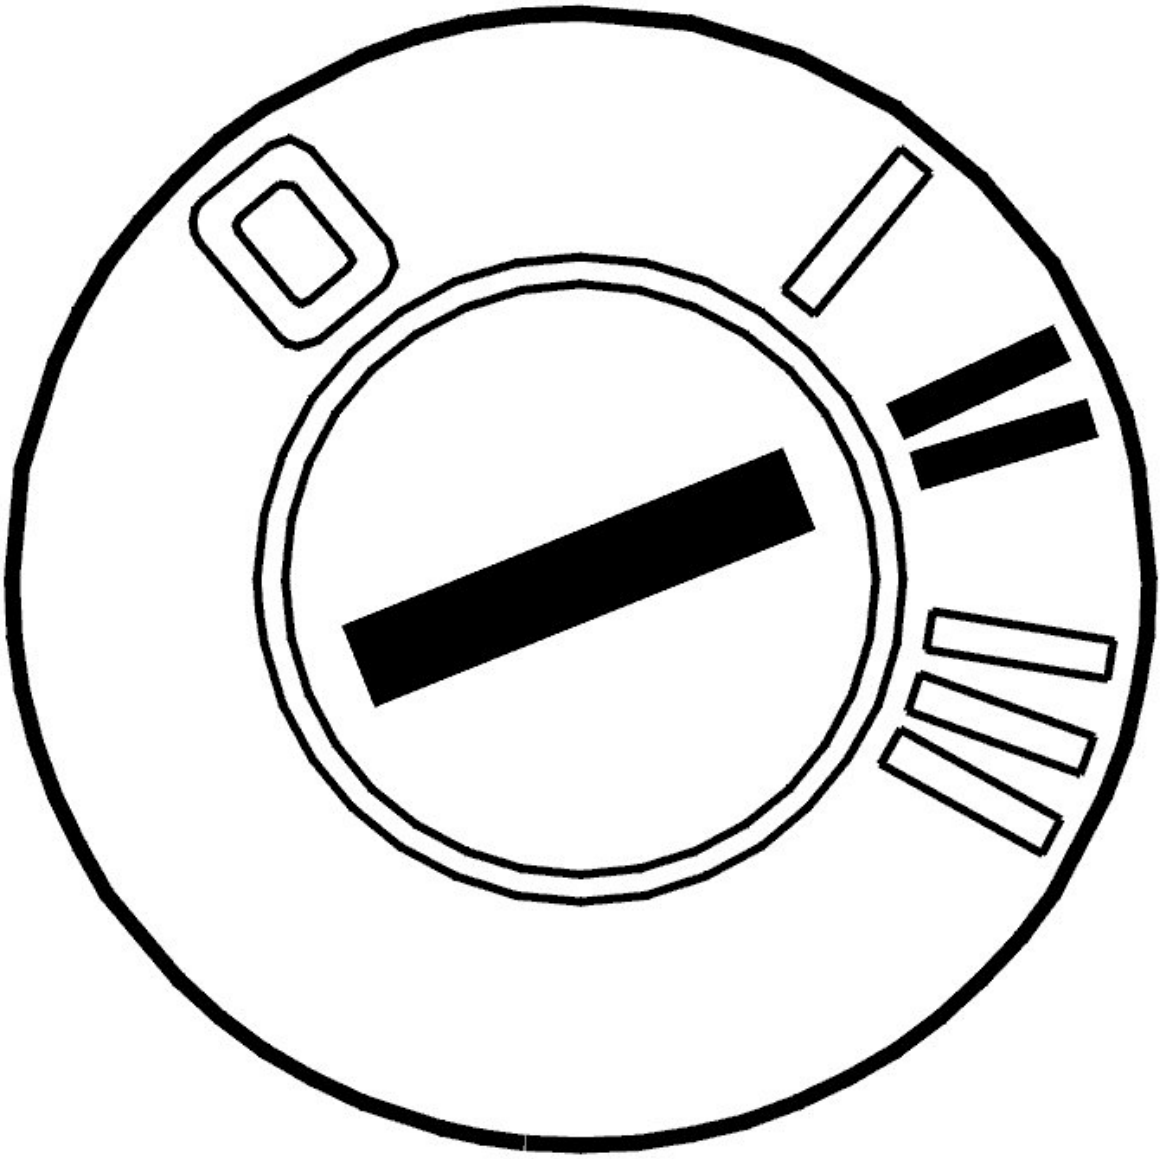
Note! This diagnostic trouble code (DTC) is not due to an internal hardware fault in the Brake control module (BCM) and must not be remedied by replacing the control module.

Fault symptom[s]
- The anti-spin warning lamp is lit (up to and including 2002 model year)
- General yellow warning lamp lit (from model year 2003 inclusive)
- Anti-spin does not function
- The stability control system does not function
- The traction control system does not function.

Signal Missing

Signal missing

Checking for contact resistance and oxidation



- Ignition off
- Check the connectors for the brake control module (BCM) and the active yaw control sensor. Check for contact resistance and oxidation
- Ignition on
- Test drive. See Test Drive Form (DSTC (dynamic stability and traction control) /brake control module), description See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Testing and Inspection/Initial Inspection and Diagnostic Overview/Test Drive Form (DSTC (Dynamic Stability And Traction Control) /Brake Control Module), Description
- Read off diagnostic trouble codes (DTCs).

If the status of the diagnostic trouble code (DTC) is intermittent, the cause of the fault was probably contact resistance or oxidation in the connectors for the control module or the active yaw control sensor.

Other information

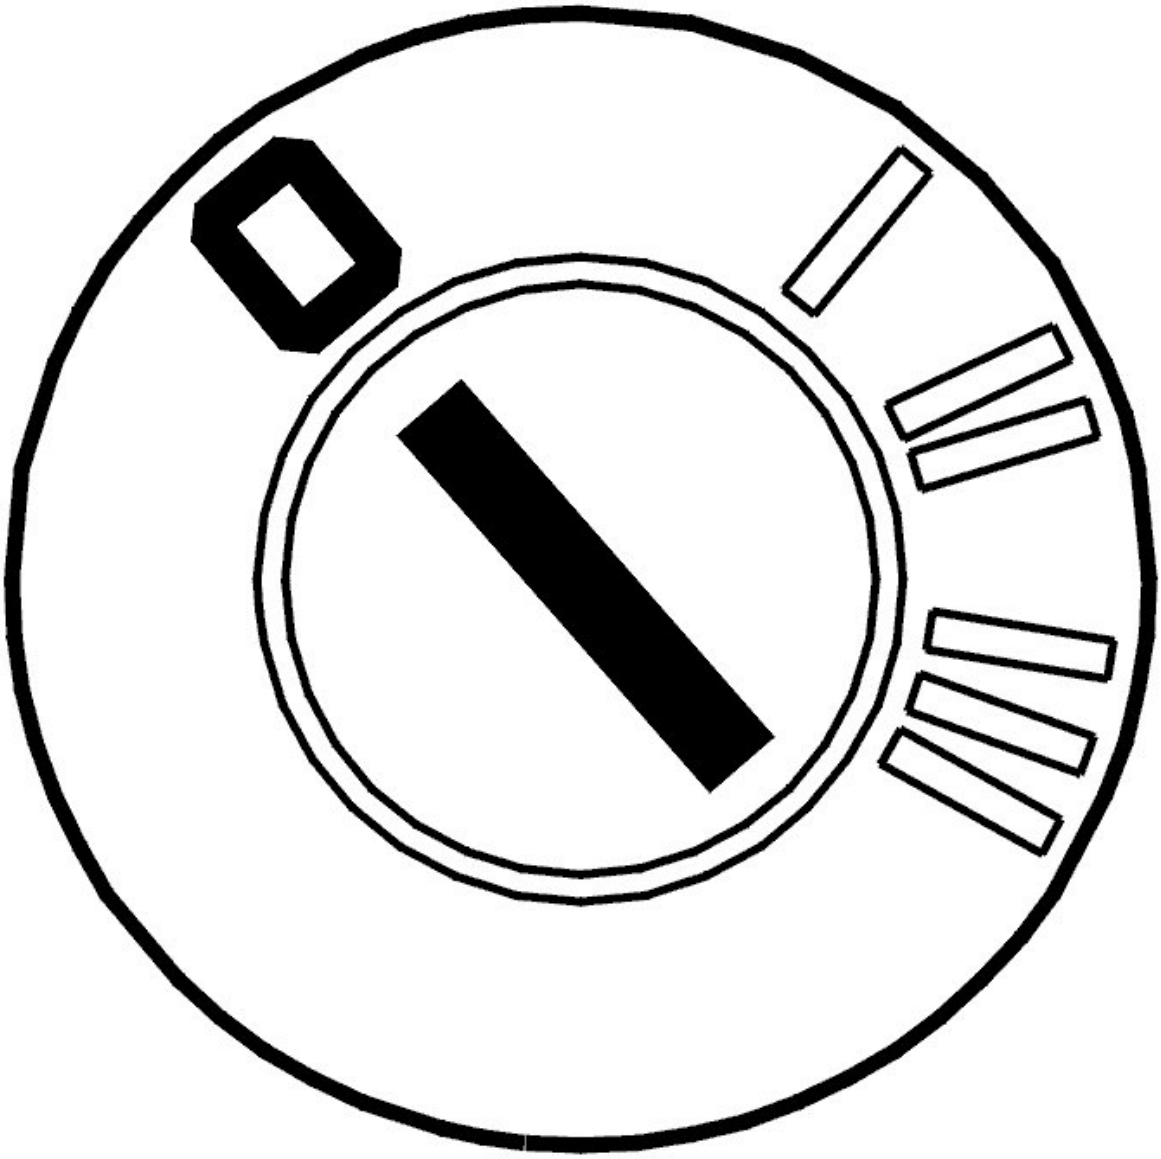
- To access the control module connector, see Connecting the breakout box, brake control module (BCM) See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box/Connecting the Breakout Box, Brake Control Module (BCM)
- To access the active yaw control sensor, see Active yaw control sensor, replacing See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Yaw Rate Sensor/Service and Repair/Active Yaw Control Sensor, Replacing
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals.

Is the status of the diagnostic trouble code (DTC) intermittent?

Yes - Fault Found

No - Checking the wiring

Checking the wiring



- Ignition off.

Check the wiring between the active yaw control sensor:

- terminal #1 and control module terminal #25 (terminal #A25)
- terminal #2 and control module terminal #29 (terminal #A29)
- terminal #3 and control module terminal #6 (#A6)
- terminal #5 and control module terminal #39 (terminal #A39).

check for an open-circuit.
Also check that the active yaw control sensor is correctly installed and that the bracket is secured.
Replace the active yaw control sensor if the wiring is OK and the sensor is correctly installed.

Other information

- To connect the breakout box, see Connecting the breakout box, brake control module (BCM) See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box/Connecting the Breakout Box, Brake Control Module (BCM)

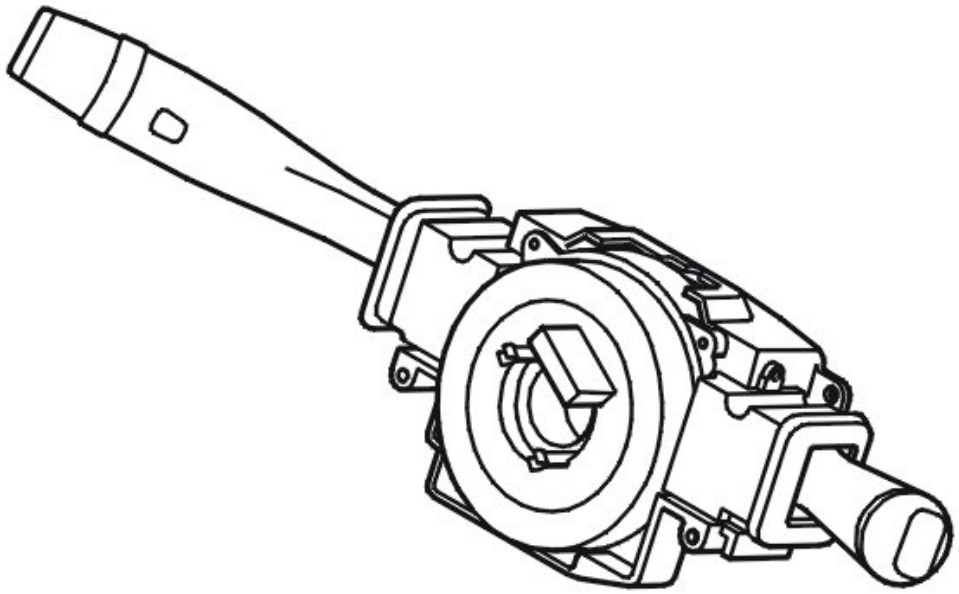
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition



Note! The diagnostic trouble code (DTC) applies only to cars with dynamic stability and traction control (DSTC).

The control module for the steering angle sensor transmits a signal via the Control area network (CAN) which indicates to the brake control module (BCM) whether the function of the steering wheel angle sensor is correct or not.
Diagnostic trouble code (DTC) BCM-0115 is stored if the brake control module (BCM) registers that the signal from the steering angle sensor is missing.
The diagnostic trouble code (DTC) can be diagnosed when the ignition is switched on.

Substitute value
- Traction control is blocked
- Stability control is blocked

- Active yaw control is blocked.

Hint: For information about abbreviations, see Brake system, abbreviations See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Description and Operation/Brake System, Abbreviations.

Possible source
- Disruption or open-circuit on the Control area network (CAN)
- The steering angle sensor is not connected on the Control area network (CAN)
- Internal fault in the steering angle sensor.

Fault symptom[s]
- The anti-spin warning lamp is lit (up to and including 2002 model year)
- General yellow warning lamp lit (from model year 2003 inclusive)
- Anti-spin does not function
- The stability control system does not function
- The traction control system does not function.

Communication With the Steering Angle Sensor. Signal Missing

Communication with the steering angle sensor. Signal missing

Checking diagnostic trouble codes (DTCs) in the central electronic module

Checking diagnostic trouble codes (DTCs) in the central electronic module

Checking other diagnostic trouble codes (DTCs)

In the event of communication problems, the fault may exist in other parts of the communications network.
The role of the central electronic module is to generally control the communications network and to store diagnostic trouble codes (DTCs) in the event of communication problems between control modules.
If there are diagnostic trouble codes (DTCs) stored for communication problems in the central electronic module, stop the fault tracing and fault trace the central electronic module.

Were diagnostic trouble codes (DTCs) for communication problems stored in the central electronic module?

Yes - DONE

No - No Fault Found

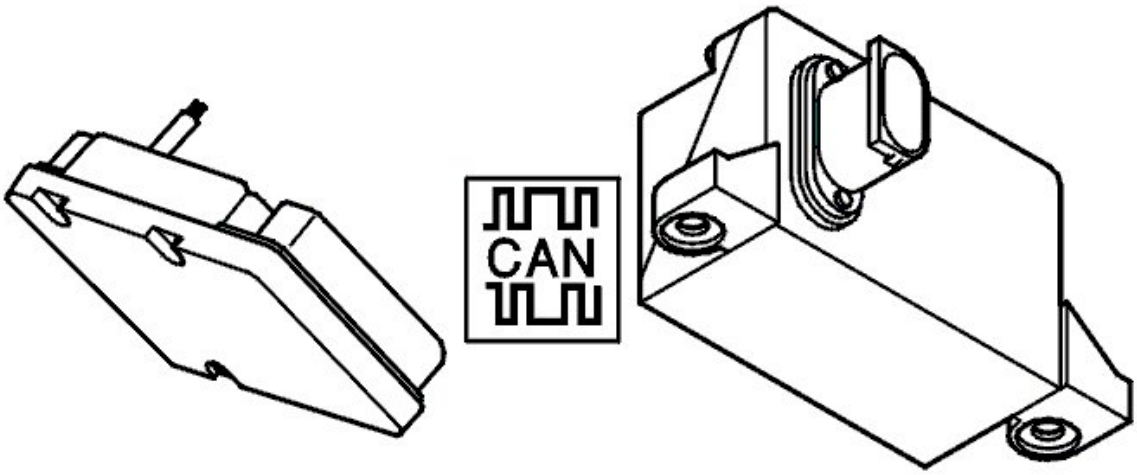
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition



Diagnostic trouble code (DTC) BCM-0116 is stored if the brake control module (BCM) registers that the communication with the active yaw control sensor is not functioning.

Substitute value
- Traction control is blocked
- Stability control is blocked
- Active yaw control is blocked.

Hint: For information about abbreviations, see Brake system, abbreviations See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Description and Operation/Brake System, Abbreviations.

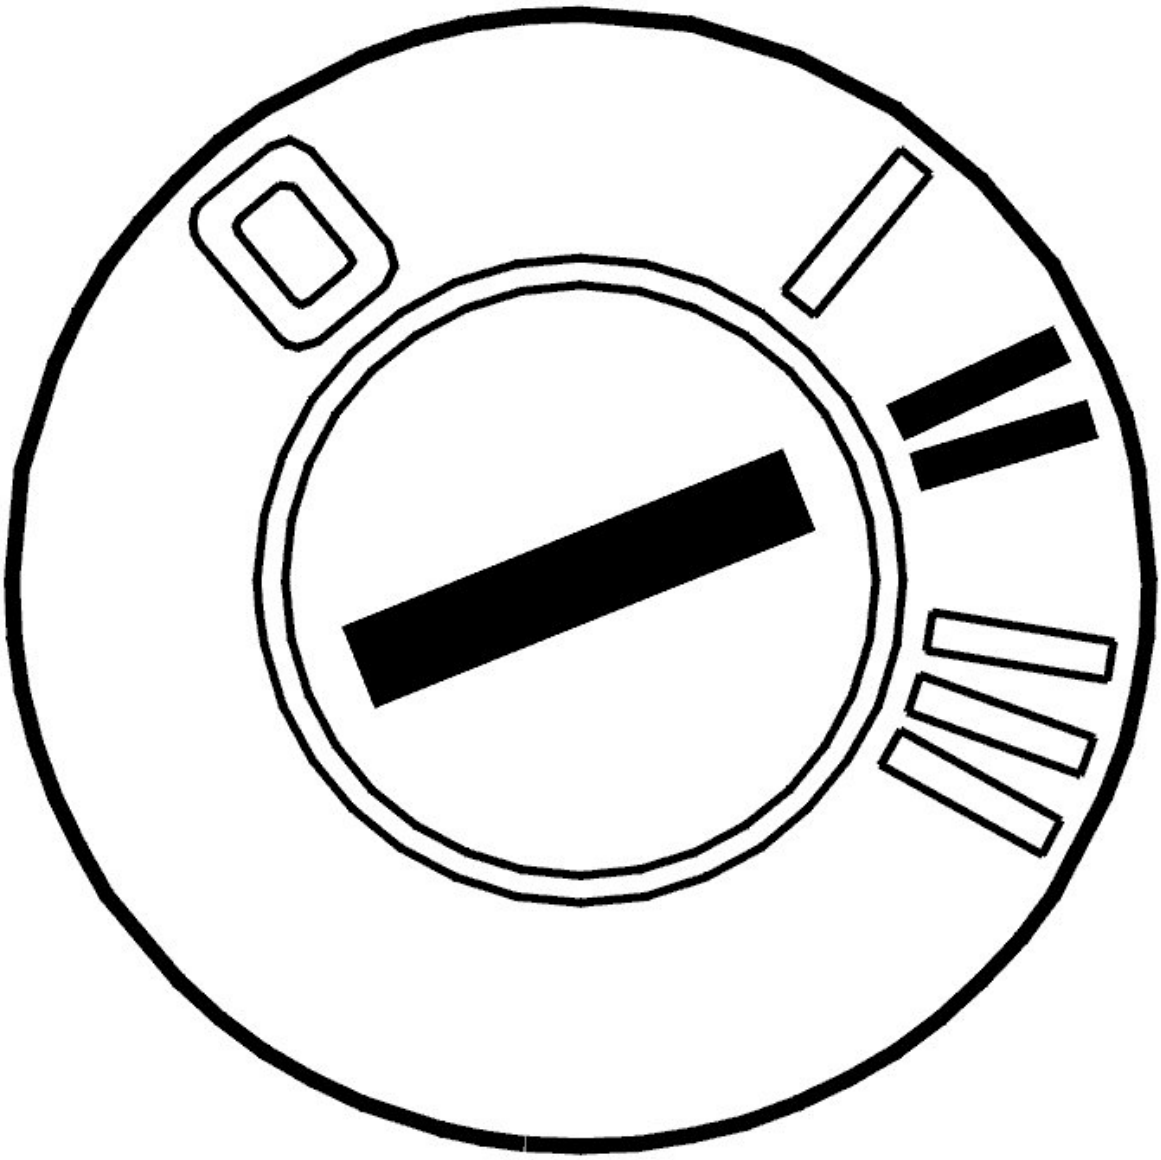
Possible source
- The cables for Control area network (CAN) communication are short-circuited to each other
- Short-circuit to ground or supply voltage in the cables for Control area network (CAN) communication
- Internal fault in the active yaw control sensor
- Internal fault in the brake control module (BCM).

Fault symptom[s]
- The anti-spin warning lamp is lit (up to and including 2002 model year)
- General yellow warning lamp lit (from model year 2003 inclusive)
- Anti-spin does not function
- The stability control system does not function
- The traction control system does not function.

Communication Problems

Communication problems

Checking diagnostic trouble codes (DTCs)



- Ignition off
- Check the connectors for the brake control module (BCM) and the active yaw control sensor. Check for contact resistance and oxidation
- Ignition on
- Wait approximately 60 seconds
- Read off the status of the diagnostic trouble code (DTC).

If the status of the diagnostic trouble code (DTC) is intermittent, the cause of the fault was probably contact resistance or oxidation in the connectors for the control module or the active yaw control sensor.

Other information

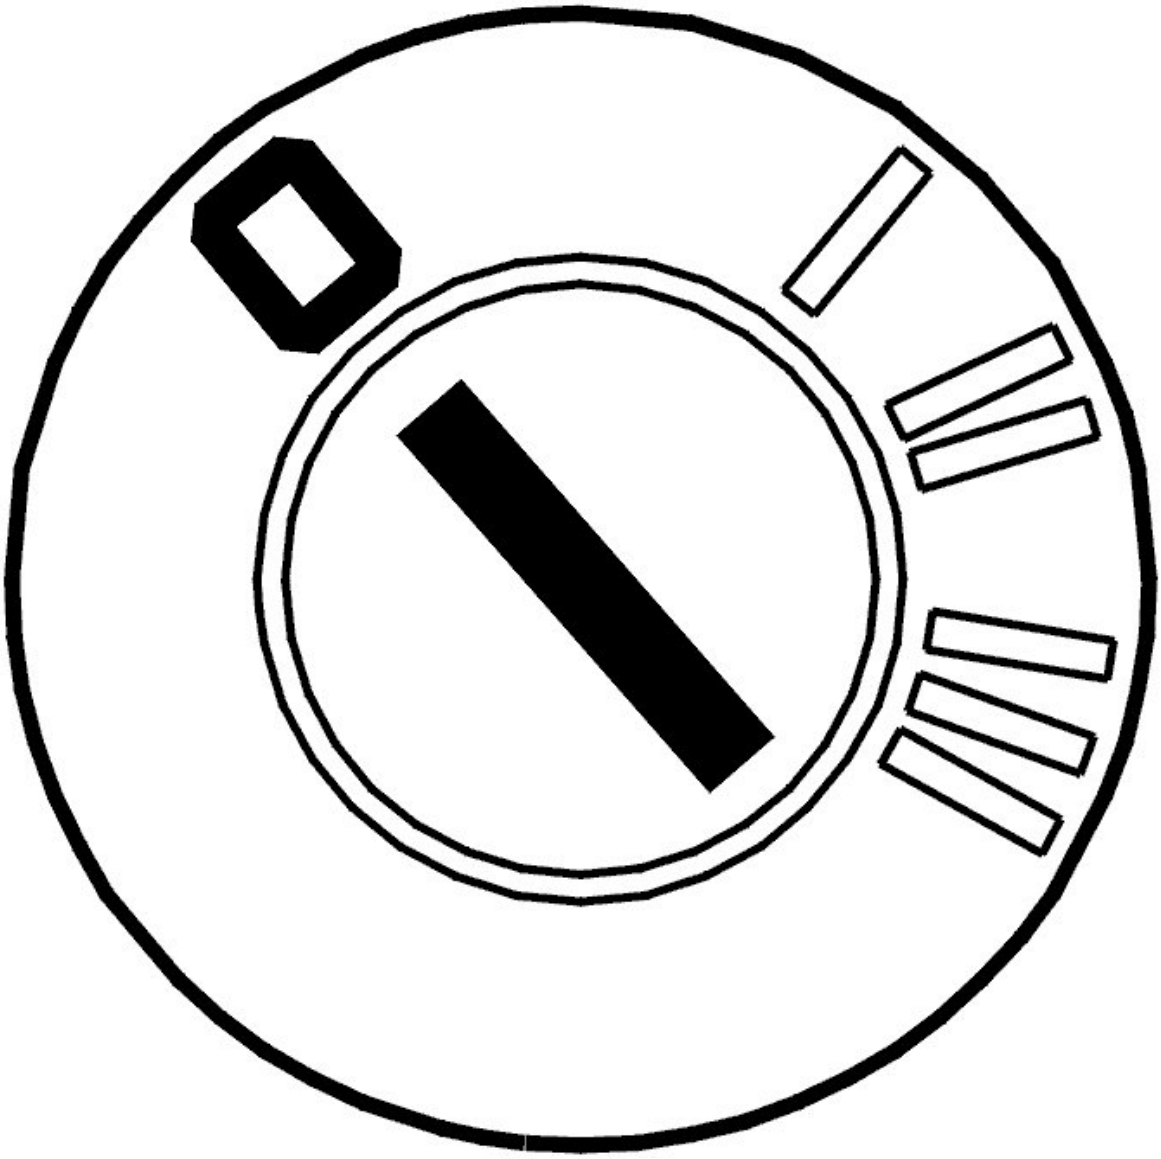
- To disconnect the connector for the active yaw control sensor, see Active yaw control sensor, replacing See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Yaw Rate Sensor/Service and Repair/Active Yaw Control Sensor, Replacing
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals.

Is the status of the diagnostic trouble code (DTC) permanent?

Yes - Checking the wiring

No - Fault Found

Checking the wiring



- Ignition off
- Connect the breakout box.

Check the wiring between the connector for the active yaw control sensor

- terminal #1 and control module terminal #25 (terminal #A25)
- terminal #2 and control module terminal #29 (terminal #A29)
- terminal #3 and control module terminal #6 (#A6)
- terminal #5 and control module terminal #39 (terminal #A39).

check for an open-circuit or short-circuit to ground and for a short-circuit to each other.
Also check that the active yaw control sensor is correctly installed and that the bracket is secured.
If the cables are OK, try a new active yaw control sensor.

Other information

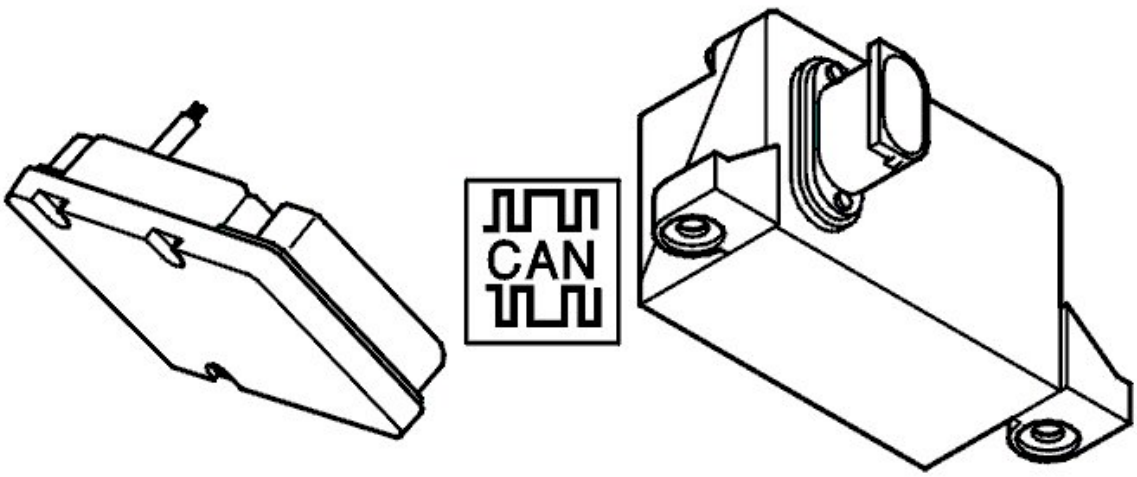
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition



There are two different active yaw control sensors. One is for two wheel drive cars, the other is for four wheel drive cars. Diagnostic trouble code (DTC) BCM-0117 is stored if the brake control module (BCM) registers that the installed active yaw control sensor is not correct for this car.

Substitute value
- Traction control is blocked
- Stability control is blocked
- Active yaw control is blocked.

Hint: For information about abbreviations, see Brake system, abbreviations See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Description and Operation/Brake System, Abbreviations.

Possible source
- An incorrect active yaw control sensor had been installed.

Note! This diagnostic trouble code (DTC) is not due to an internal hardware fault in the Brake control module (BCM) and must not be remedied by replacing the control module.

Fault symptom[s]
- The anti-spin warning lamp is lit (up to and including 2002 model year)
- General yellow warning lamp lit (from model year 2003 inclusive)
- Anti-spin does not function
- The stability control system does not function
- The traction control system does not function.

An Incorrect Active Yaw Control Sensor Had Been Installed

An incorrect active yaw control sensor had been installed

checking the active yaw control sensor

The diagnostic trouble code (DTC) indicates that an active yaw control sensor for a four wheel drive car has been installed in a two wheel drive car or vice-versa.
Replace with the correct sensor. See Active yaw control sensor, replacing See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Yaw Rate Sensor/Service and Repair/Active Yaw Control Sensor, Replacing.

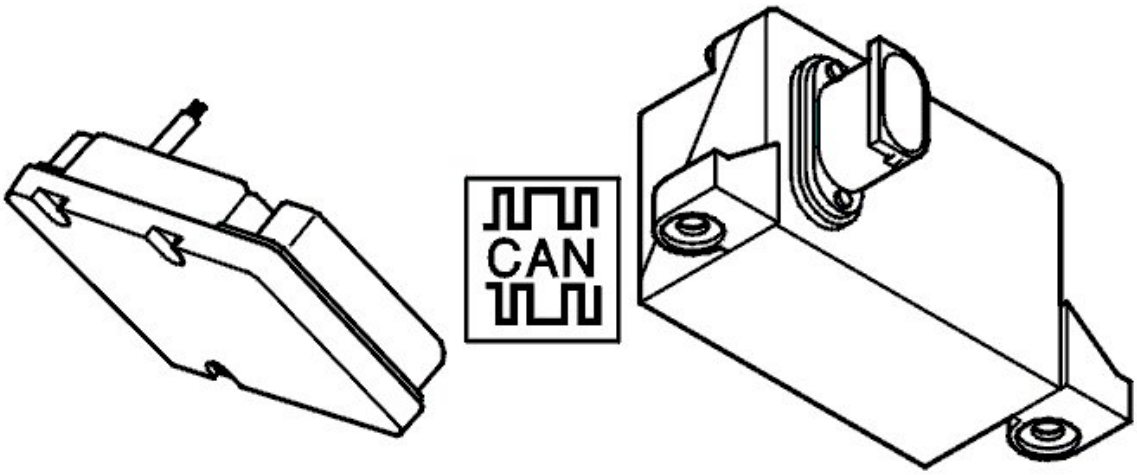
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition



Note! The diagnostic trouble code (DTC) applies only to cars with dynamic stability and traction control (DSTC).

Diagnostic trouble code (DTC) BCM-0118 is stored if the brake control module (BCM) registers that the power supply from the active yaw control sensor exceeds 17 V.

Substitute value
- Traction control is blocked
- Stability control is blocked
- Active yaw control is blocked.

Hint: For information about abbreviations, see Brake system, abbreviations See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Description and Operation/Brake System, Abbreviations.

Possible source
- Short-circuit to supply voltage in the power supply cable
- Internal fault in the active yaw control sensor.

Note! This diagnostic trouble code (DTC) is not due to an internal hardware fault in the Brake control module (BCM) and must not be remedied by replacing the control module.

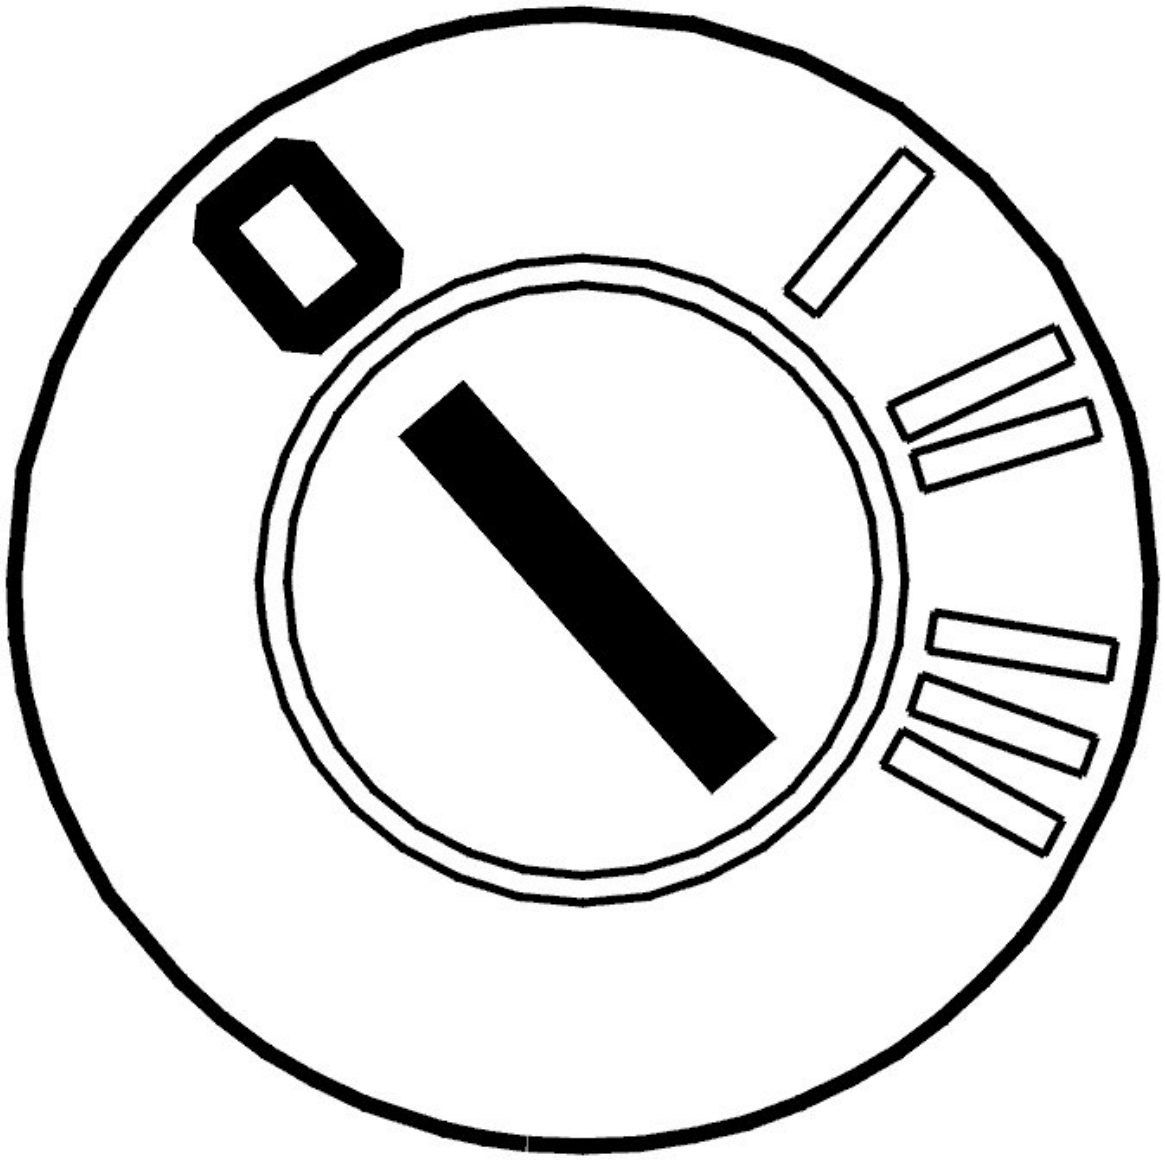
Fault symptom[s]

- The anti-spin warning lamp is lit (up to and including 2002 model year)
- General yellow warning lamp lit (from model year 2003 inclusive)
- Anti-spin does not function
- The stability control system does not function
- The traction control system does not function.

Voltage Too High

Voltage too high

Checking the wiring



- Ignition off
- Connect the breakout box.

Check the wiring between the connector for the active yaw control sensor

- terminal #3 and control module terminal #6 (#A6)
- terminal #5 and control module terminal #39 (terminal #A39).

check for a short-circuit to supply voltage.

Other information

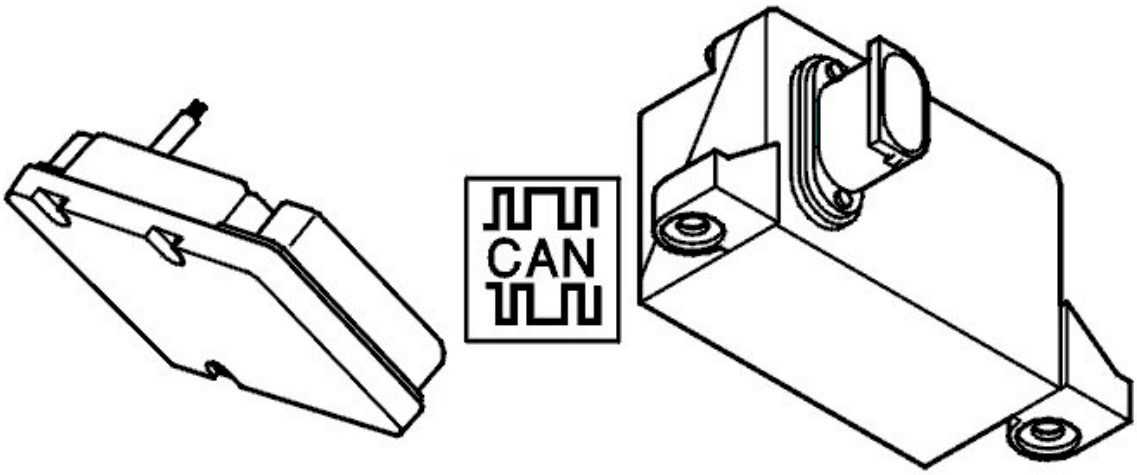
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition



Note! The diagnostic trouble code (DTC) applies only to cars with dynamic stability and traction control (DSTC).

Diagnostic trouble code (DTC) BCM-0119 is stored if the brake control module (BCM) registers that the power supply to the active yaw control sensor is below 6 V ±0.5 V.

Substitute value
- Traction control is blocked
- Stability control is blocked
- Active yaw control is blocked.

Hint: For information about abbreviations, see Brake system, abbreviations See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Description and Operation/Brake System, Abbreviations.

Possible source
- Contact resistance in the terminals on the active yaw control sensor
- Short-circuit to ground in the wiring
- Open-circuit in the wiring
- Internal fault in the active yaw control sensor

Note! This diagnostic trouble code (DTC) is not due to an internal hardware fault in the Brake control module (BCM) and must not be remedied by replacing the control module.

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

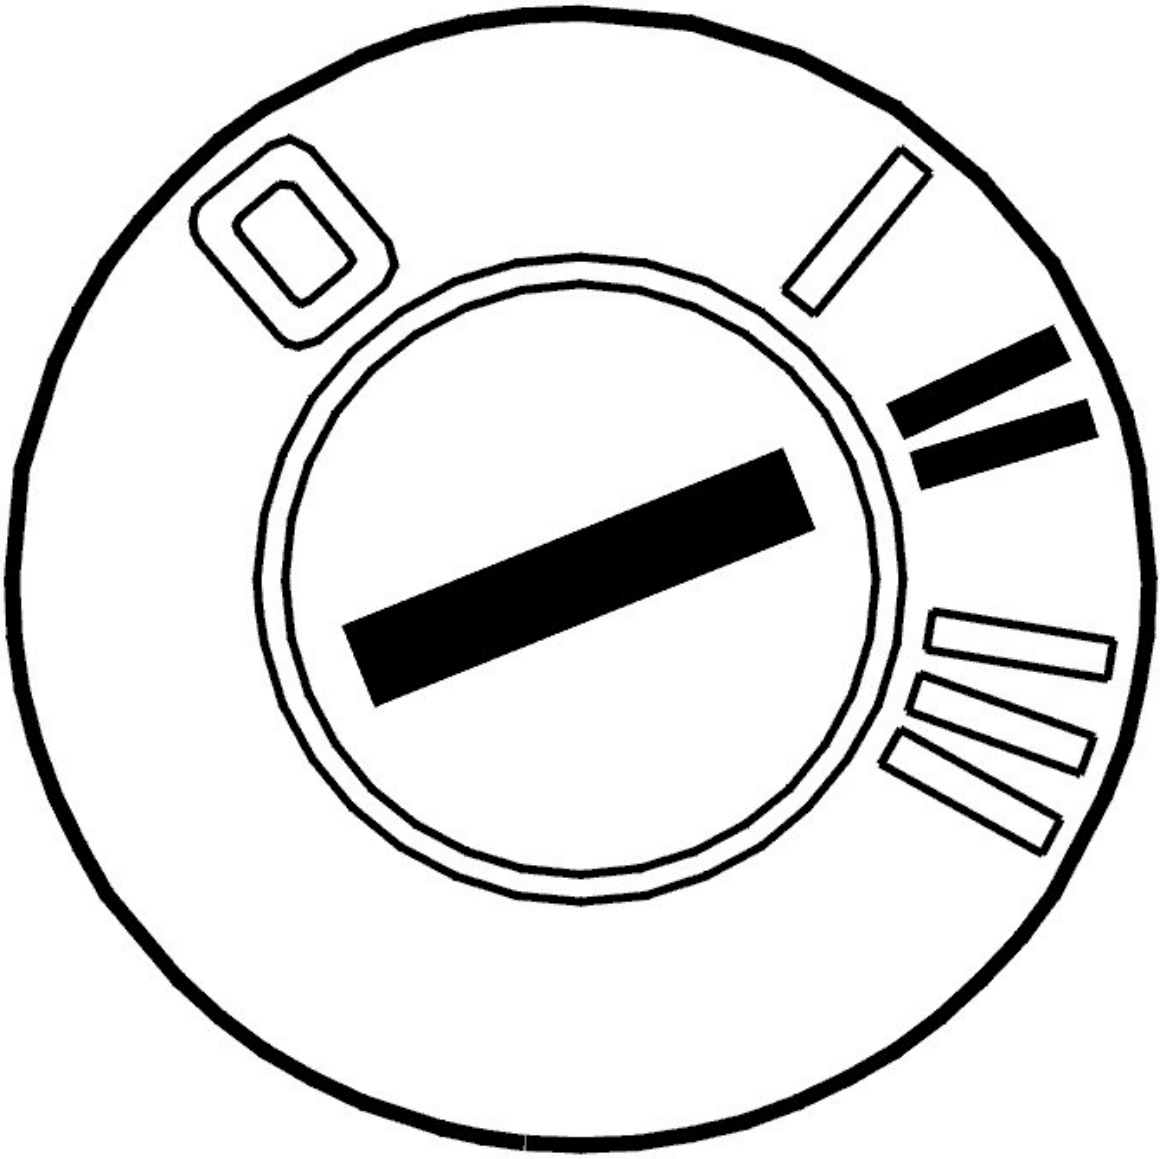
Fault symptom[s]

- The anti-spin warning lamp is lit (up to and including 2002 model year)
- General yellow warning lamp lit (from 2003)
- Anti-spin does not function
- The stability control system does not function
- The traction control system does not function.

Voltage Too Low

Voltage too low

Checking the status of the diagnostic trouble code (DTC)



- Ignition off
- Check the connectors for the brake control module (BCM) and the active yaw control sensor. Check for contact resistance and oxidation
- Test drive the car. See Test Drive Form (DSTC (dynamic stability and traction control) /brake control module), description See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Testing and Inspection/Initial Inspection and Diagnostic Overview/Test Drive Form (DSTC (Dynamic Stability And Traction Control) /Brake Control Module), Description
- Ignition on
- Wait approximately 60 seconds
- Read off diagnostic trouble codes (DTCs).

If the status of the diagnostic trouble code (DTC) intermittent, the cause of the fault was probably contact resistance or oxidation in the connectors for the control module or the active yaw control sensor.

Other information

- To remove the control module connector, see Connecting the breakout box, brake control module (BCM) See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box/Connecting the Breakout Box, Brake Control Module (BCM)
- To access the active yaw control sensor, see Active yaw control sensor, replacing See: Brakes and Traction Control/Antilock Brakes /

Traction Control Systems/Yaw Rate Sensor/Service and Repair/Active Yaw Control Sensor, Replacing

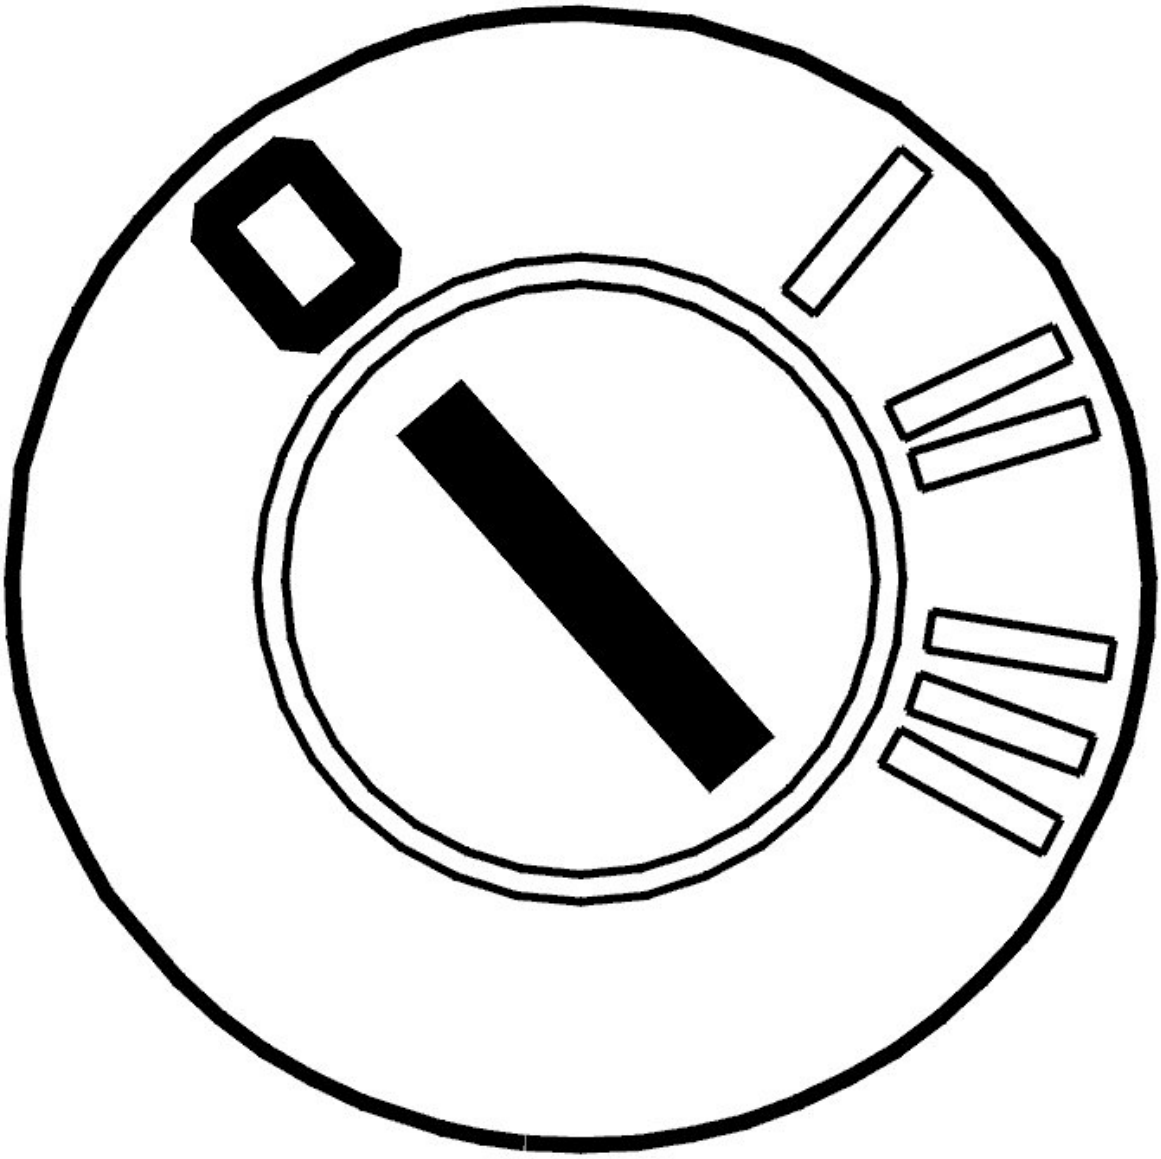
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

Is the status of the diagnostic trouble code (DTC) intermittent?

Yes - Fault Found

No - Checking the wiring

Checking the wiring



- Ignition off
- Connect the breakout box.

Check the wiring between the connector for the active yaw control sensor:

- terminal #3 and control module terminal #6 (#A6)
- terminal #5 and control module terminal #39 (terminal #A39).

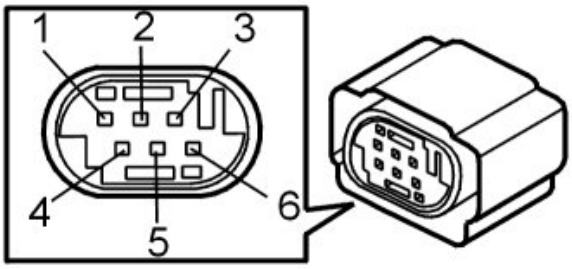
check for an open-circuit or short-circuit to ground.

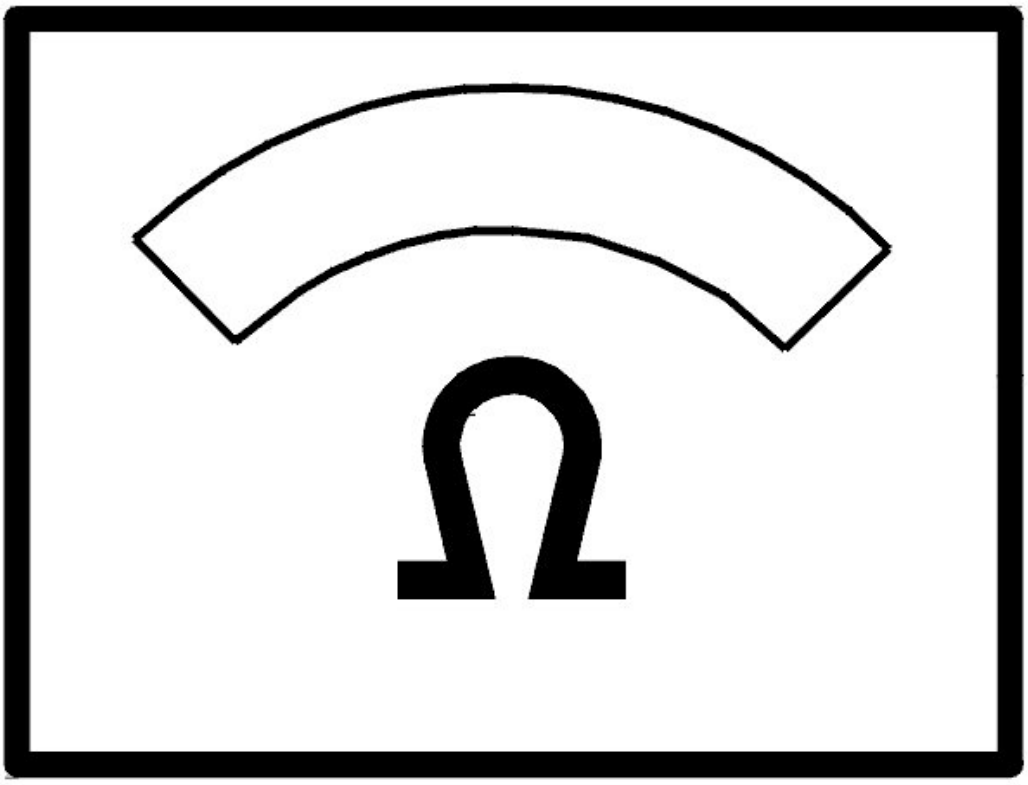
Other information

- To connect the breakout box, see Connecting the breakout box, brake control module (BCM) See: Brakes and Traction Control/Antilock

Brakes / Traction Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box/Connecting the Breakout Box, Brake Control Module (BCM)

- To access and replace the active yaw control sensor, see Active yaw control sensor, replacing See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Yaw Rate Sensor/Service and Repair/Active Yaw Control Sensor, Replacing
- For information about signals, see Signal specification, brake control module (BCM) with DSTC (dynamic stability and traction control) See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Specification
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals.





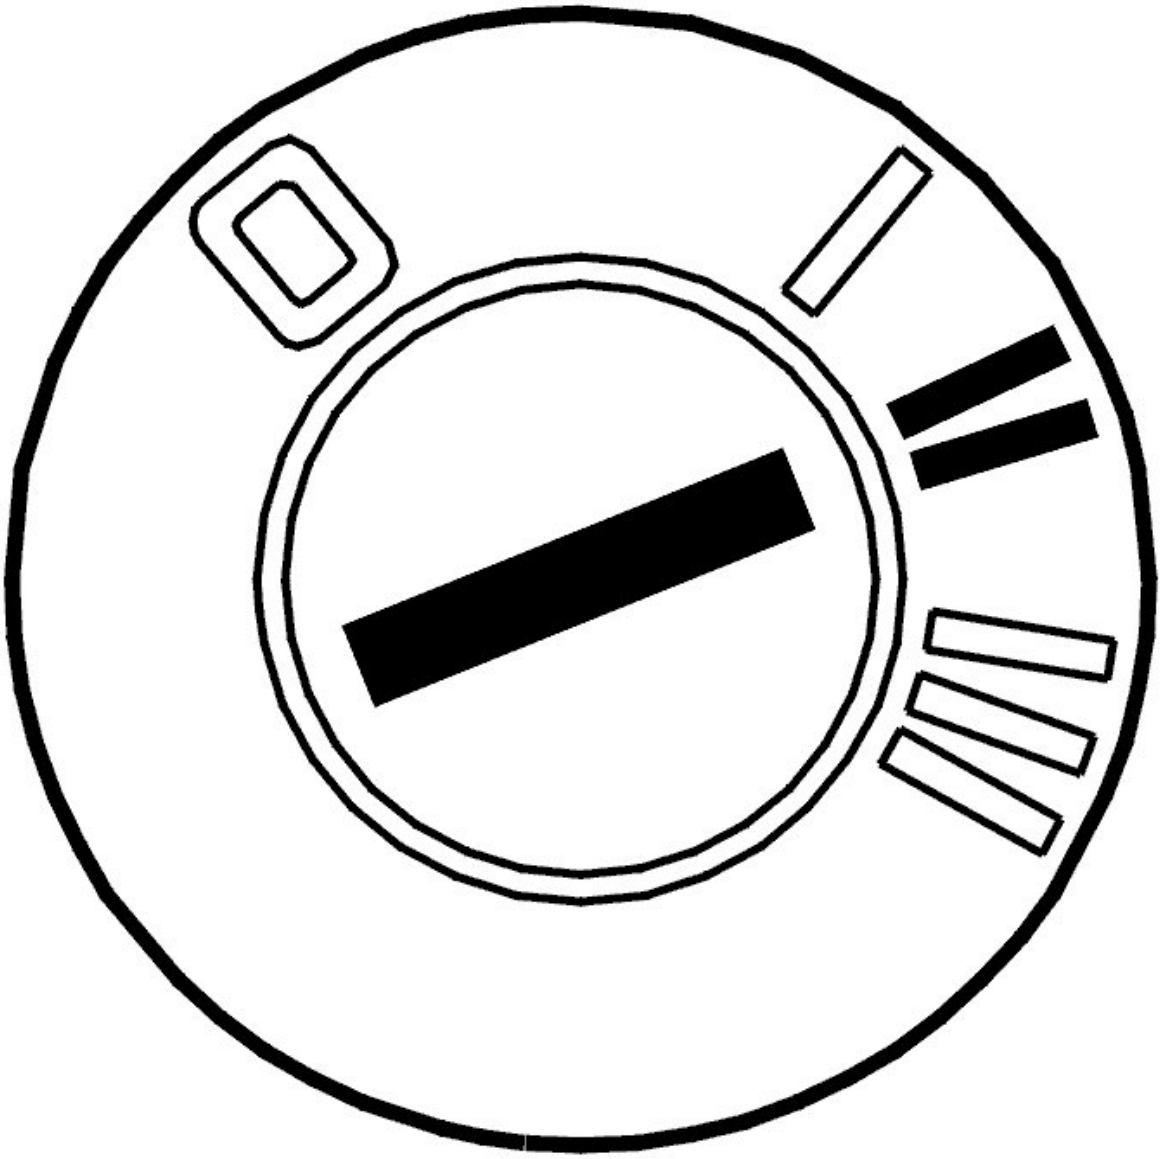
Was a fault detected?

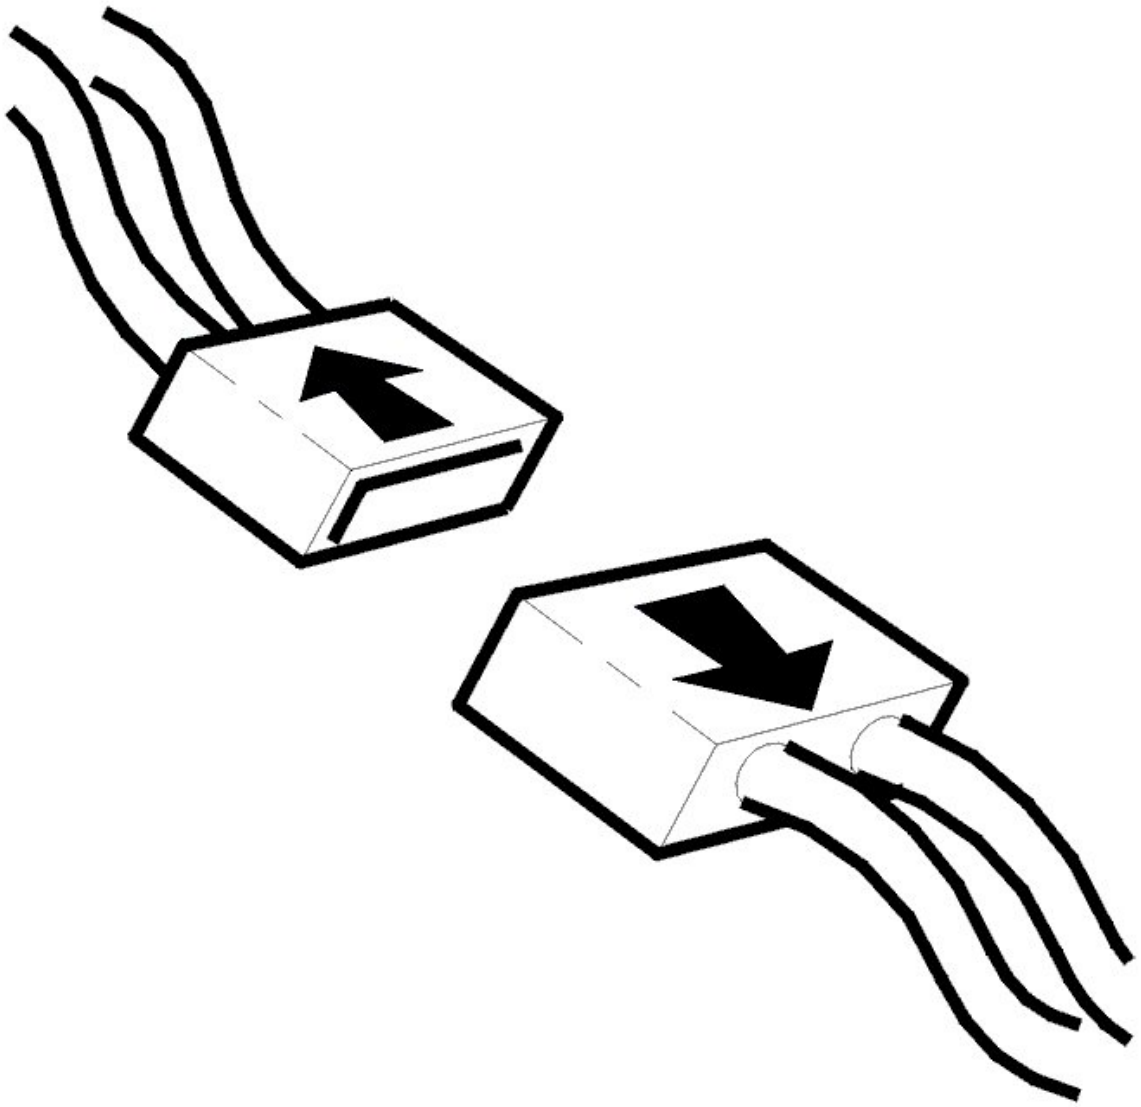
Yes - Verification

No - Checking the power supply

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

Checking the power supply



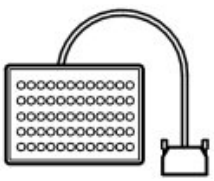


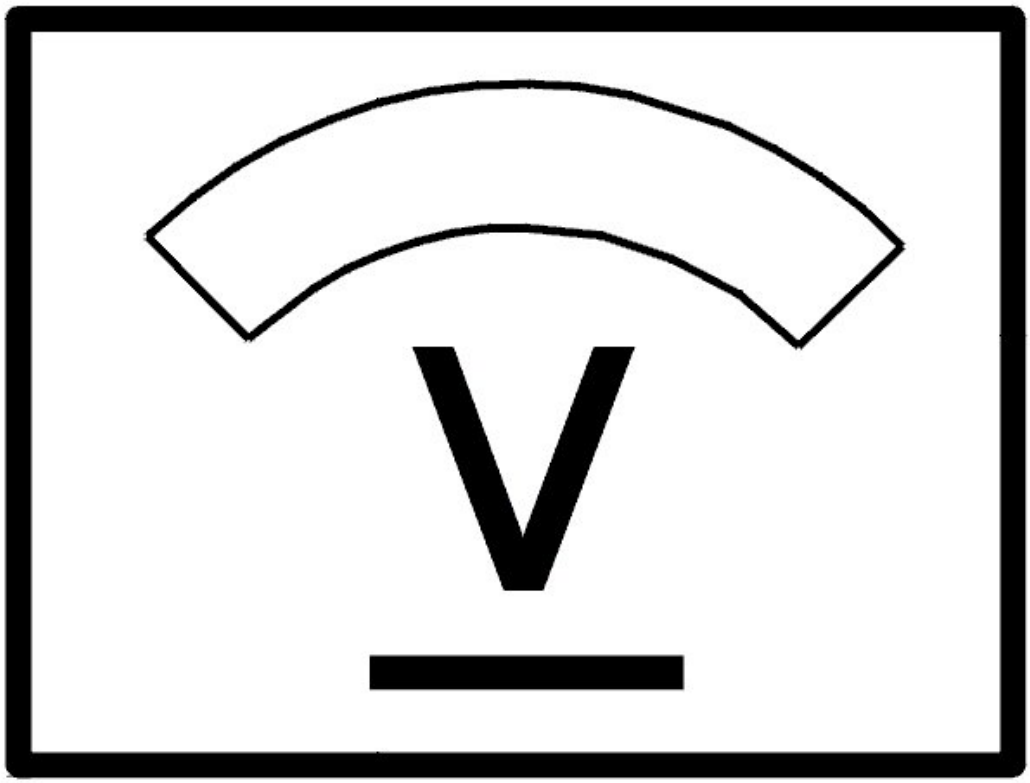
- Ignition off
- The breakout box connected
- Disconnect the connector for the active yaw control sensor
- Ignition on.

Connect a voltmeter to terminals #6 (#A6) and #39 (#A39) on the breakout box.
The voltage must be normal system voltage.
Replace the active yaw control sensor if the voltage is OK.
Replace the control module if the voltage is incorrect.

Other information

- To access and replace the active yaw control sensor, see Active yaw control sensor, replacing See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Yaw Rate Sensor/Service and Repair/Active Yaw Control Sensor, Replacing
- To access or replace the brake control module (BCM), see Brake Control Module (BCM), replacing See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Electronic Brake Control Module/Service and Repair/Brake Control Module (BCM), Replacing
- For information about signals, see Signal specification, brake control module (BCM) with DSTC (dynamic stability and traction control) See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Specification.





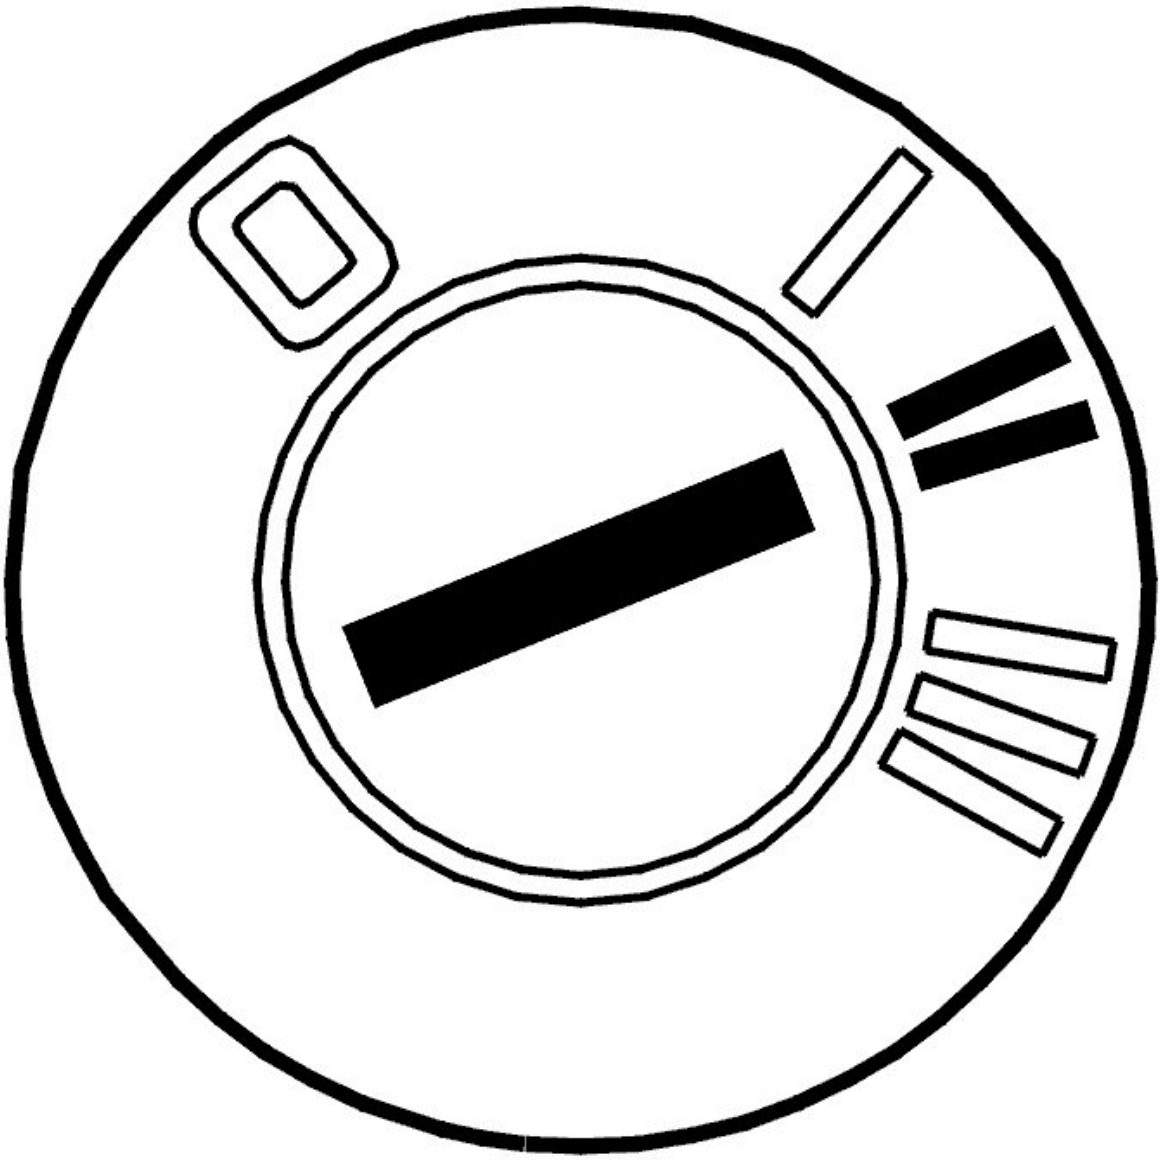
Continue - Verification

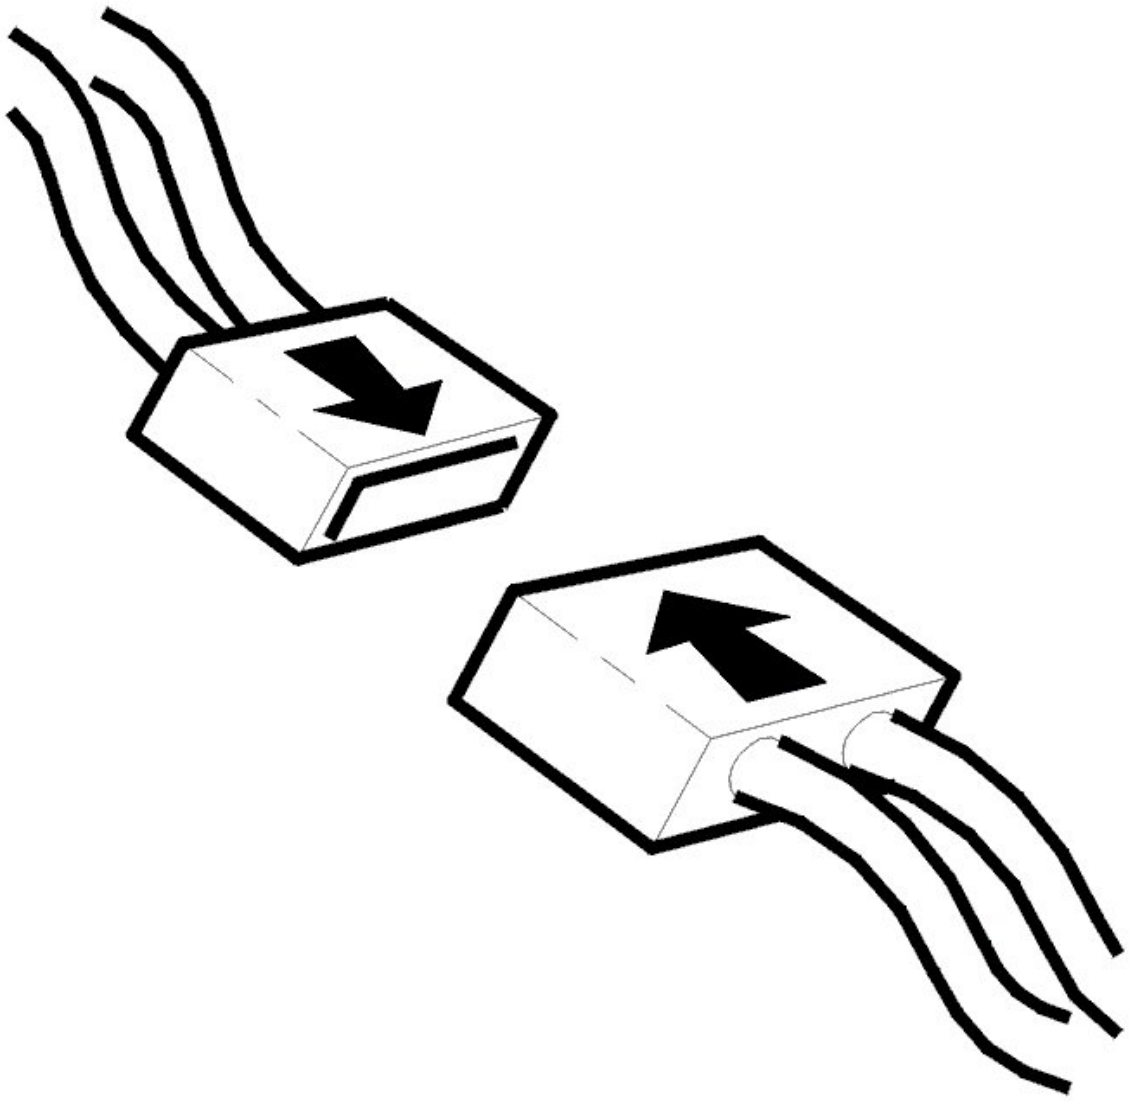
Verification

Verification

Verification

Hint: After carrying out the repair, check that the fault has been remedied.





- Ignition off
- Reconnect the connectors, reinstall components etc.
- Test drive the car. See Test Drive Form (DSTC (dynamic stability and traction control) /brake control module), description See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Testing and Inspection/Initial Inspection and Diagnostic Overview/Test Drive Form (DSTC (Dynamic Stability And Traction Control) /Brake Control Module), Description
- Ignition on.

Read off the status of the diagnostic trouble code (DTC).

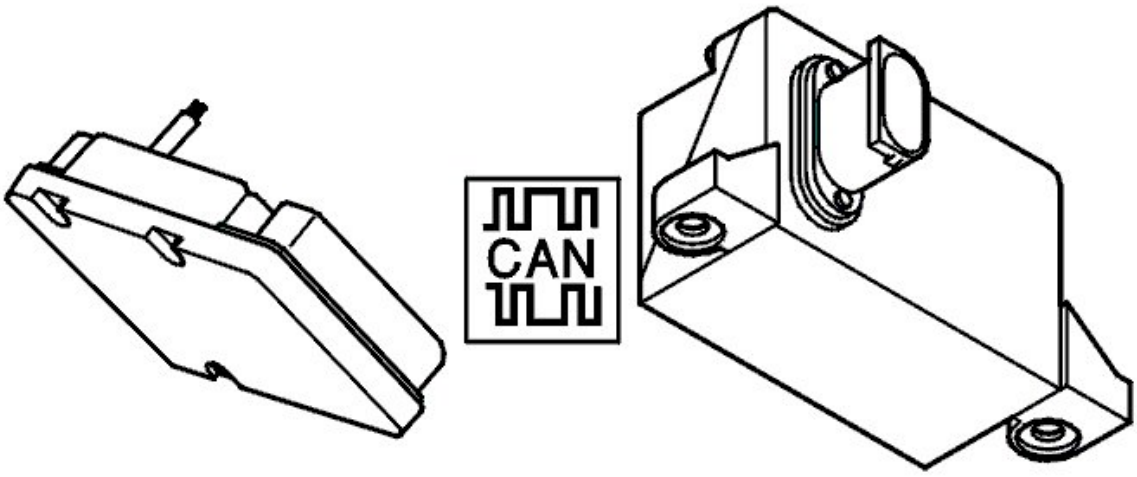
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

Condition



Note! The diagnostic trouble code (DTC) applies only to cars with dynamic stability and traction control (DSTC).

The yaw rate sensor, lateral accelerometer, accelerometer (only AWD) and angle of lean sensor (only RSC) are integrated in the active yaw control sensor. This in turn is connected to the brake control module (BCM) via its own Control area network (CAN) cable. The sensors transmit information to the brake control module (BCM) indicating the size of the yaw angle, the lateral acceleration of the car, the forward acceleration and the car's lateral angle of lean.
Diagnostic trouble code (DTC) BCM-0121, BCM-0125, BCM-0127 or BCM-0129 is stored, depending on the sensor, if the control module registers that the signal from any of the sensors is outside its permitted range.

- BCM-0121: Yaw rate sensor
- BCM-0125: Lateral acceleration sensor
- BCM-0127: Tilt angle sensor
- BCM-0129: Accelerometer.

Substitute value

- Traction control is blocked
- Stability control is blocked
- Active yaw control is blocked
- RSC is blocked (cars equipped with RSC only).

Hint: For information about abbreviations, see Brake system, abbreviations See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Description and Operation/Brake System, Abbreviations.

Possible source

- Interference or noise on the wiring has disrupted the active yaw control sensor calculations
- The power supply to the active yaw control sensor is too low
- Incorrect wheel alignment
- Internal fault in the active yaw control sensor.

Note! This diagnostic trouble code (DTC) is not due to an internal hardware fault in the Brake control module (BCM) and must not be remedied by replacing the control module.

Fault symptom[s]

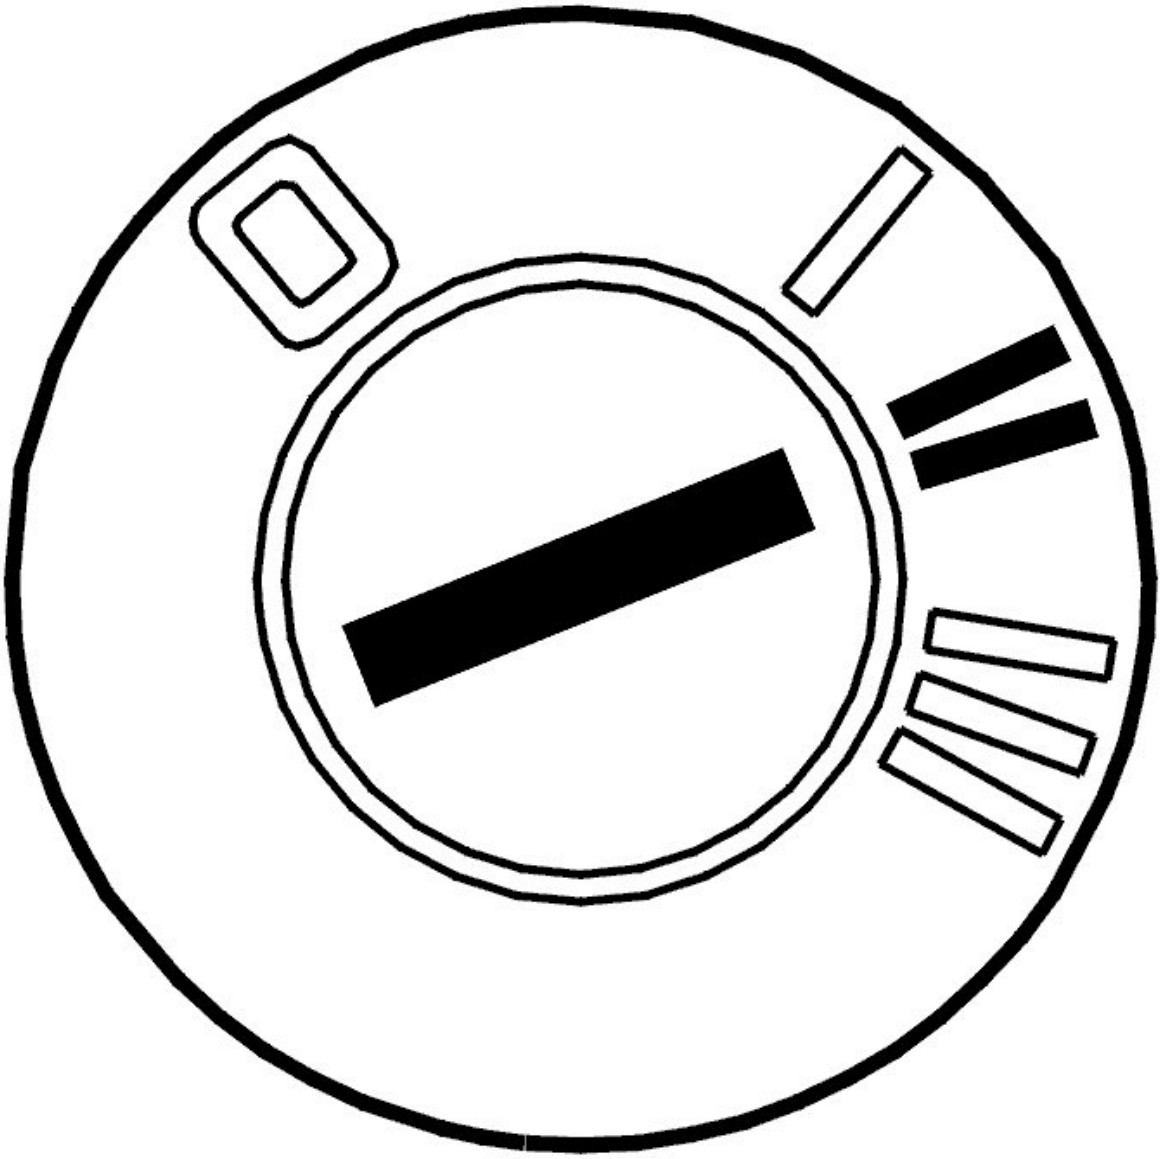
- The anti-spin warning lamp is lit (up to and including 2002 model year)
- General yellow warning lamp lit (from model year 2003)
- Anti-spin does not function
- The stability control system does not function
- The traction control system does not function.

Signal Outside Its Permitted Range

Signal outside its permitted range

Checking the connectors

Note! If diagnostic trouble codes (DTCs) other than BCM-0121, BCM-0125, BCM-0127 or BCM-0129 are stored in the brake control module (BCM), select cancel and fault trace these diagnostic trouble codes (DTCs) first.

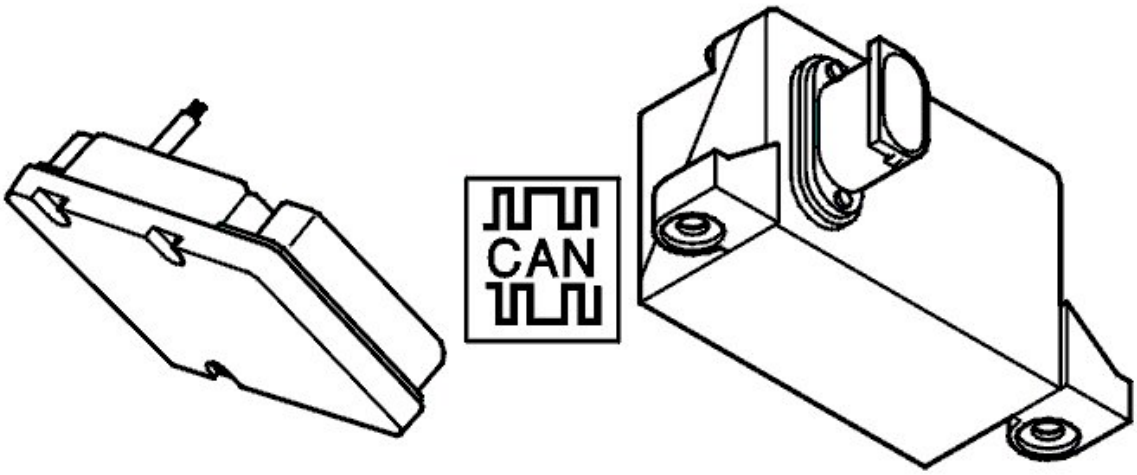


- Ignition off
- Check the brake control module (BCM) and the active yaw control sensor connectors. Check for contact resistance and oxidation
- Ensure that no sources of interference, such as a mobile telephone or radio receiver, are in the vicinity of the active yaw control sensor
- Test drive the car. See the test drive schedule. See Test Drive Form (DSTC (dynamic stability and traction control) /brake control module), description See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Testing and Inspection/Initial Inspection and Diagnostic Overview/Test Drive Form (DSTC (Dynamic Stability And Traction Control) /Brake Control Module), Description
- Ignition on
- Read off diagnostic trouble codes (DTCs).

If the diagnostic trouble code (DTC) status is intermittent the cause of the fault was probably either contact resistance in the control module or active yaw control sensor connectors, or a source of interference too close to the sensor.

Other information

- To remove the connector for the active yaw control sensor, see Active yaw control sensor, replacing See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Yaw Rate Sensor/Service and Repair/Active Yaw Control Sensor, Replacing
- To remove the brake control module (BCM) connector, see Connecting the breakout box, brake control module (BCM) See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box/Connecting the Breakout Box, Brake Control Module (BCM).

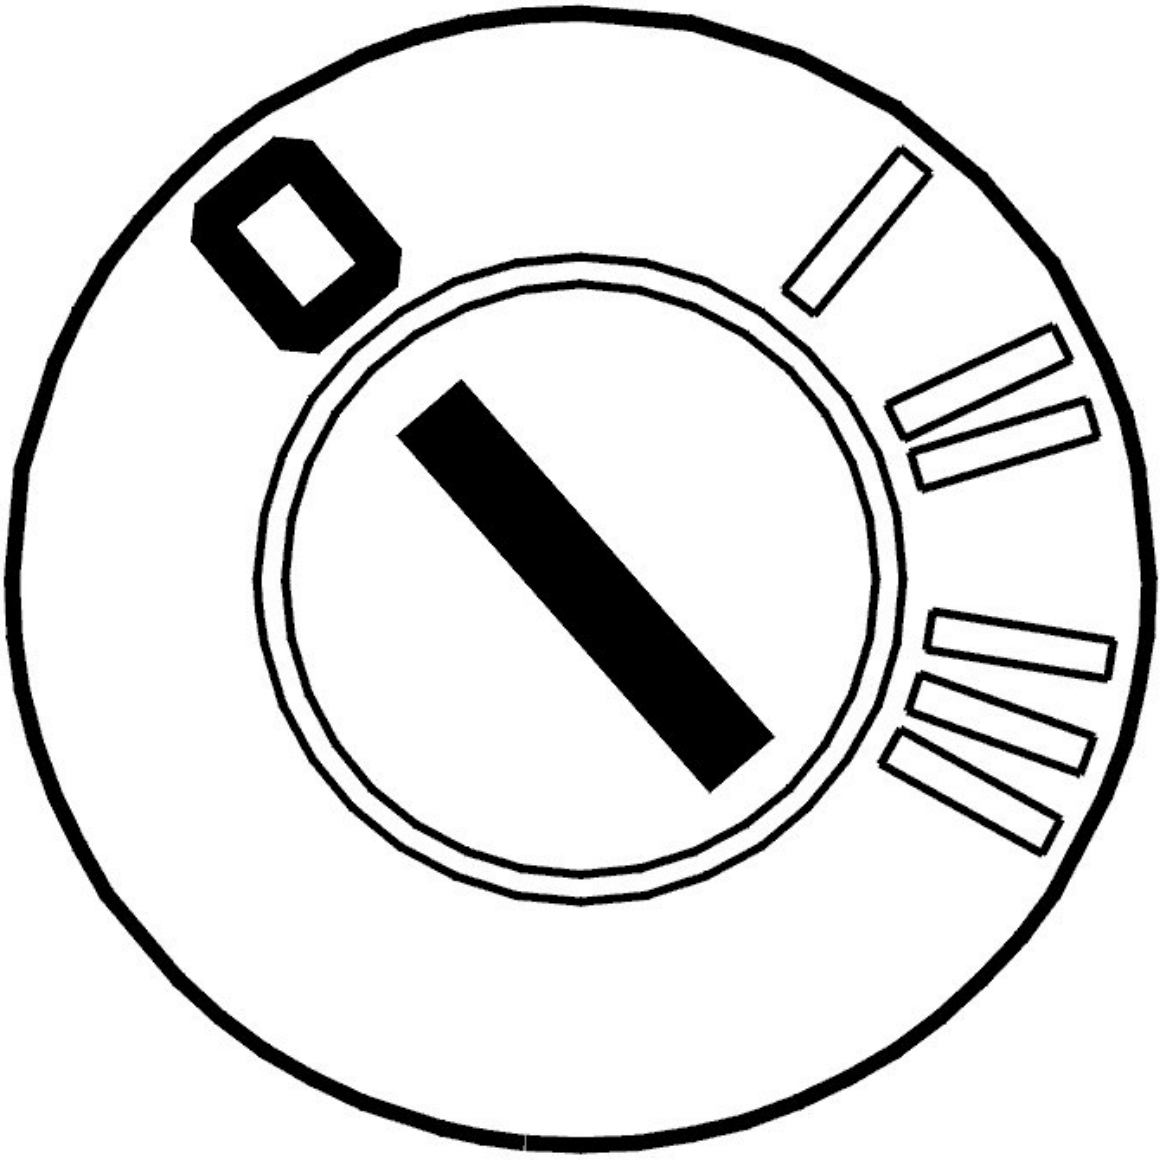


Was the status of the diagnostic trouble code (DTC) permanent?

Yes - Checking the wiring

No - Fault Found

Checking the wiring



- Ignition off.

Check the brake control module (BCM) and the active yaw control sensor connectors. Check for contact resistance and oxidation.
Check the wiring between the connector for the active yaw control sensor:

- terminal #1 and control module terminal #A25 (#A25)
- terminal #2 and control module terminal #A29 (#A29)
- terminal #3 and control module terminal #A6 (#A6)
- terminal #5 and control module terminal #A39 (#A39).

Check for an open-circuit.
Check the wheel alignment.
Remedy as necessary.

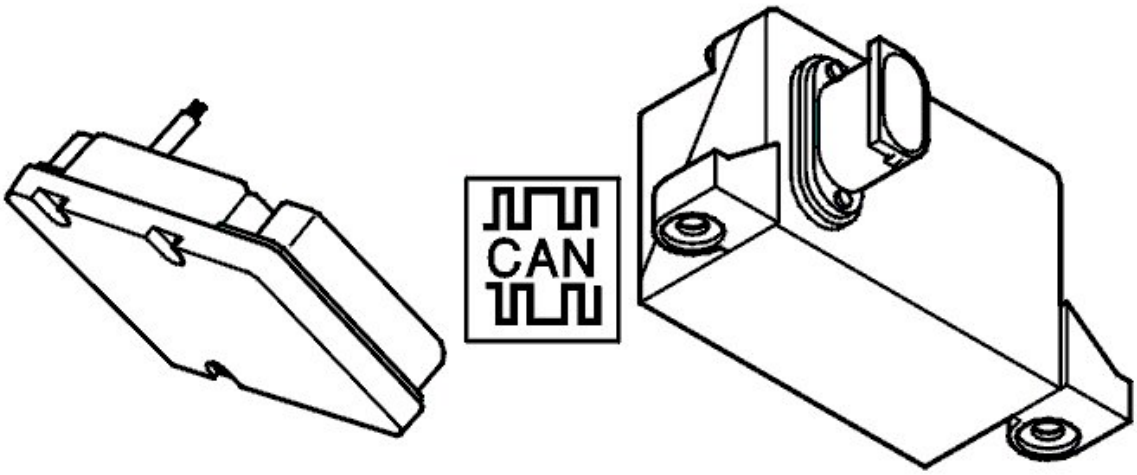
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition



Note! The diagnostic trouble code (DTC) applies only to cars with dynamic stability and traction control (DSTC).

The active yaw control sensor is supplied with 12 V. The signal voltage of the sensors to the brake control module (BCM) is approximately 2.5 V for a stationary car. The control module compares the voltage with a reference value.
Diagnostic trouble code (DTC) BCM-0123 is stored if the voltage is outside the reference value or if an internal fault in the active yaw control sensor is registered.

Substitute value
- Traction control is blocked
- Stability control is blocked
- Active yaw control is blocked.

Hint: For information about abbreviations, see Brake system, abbreviations See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Description and Operation/Brake System, Abbreviations.

Possible source
- Signals which disrupt the active yaw control sensor
- Voltage to the active yaw control sensor is too low
- Internal fault in the active yaw control sensor.

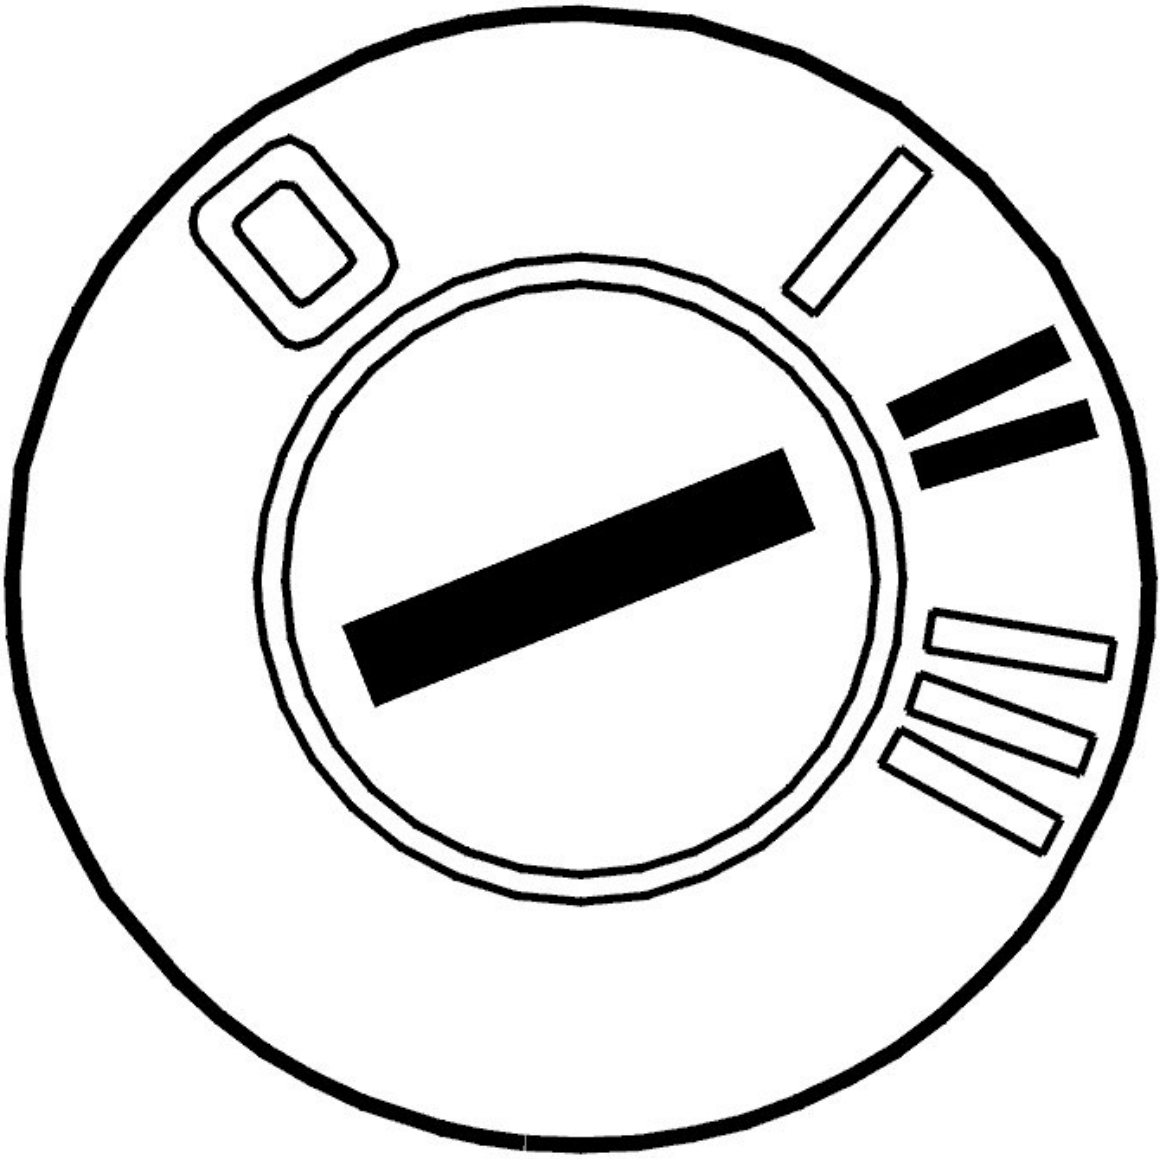
Fault symptom[s]

- The anti-spin warning lamp is lit (up to and including 2002 model year)
- General yellow warning lamp lit (from model year 2003 inclusive)
- Anti-spin does not function
- The stability control system does not function
- The traction control system does not function.

Internal Fault

Internal fault

Checking the present value of the sensors

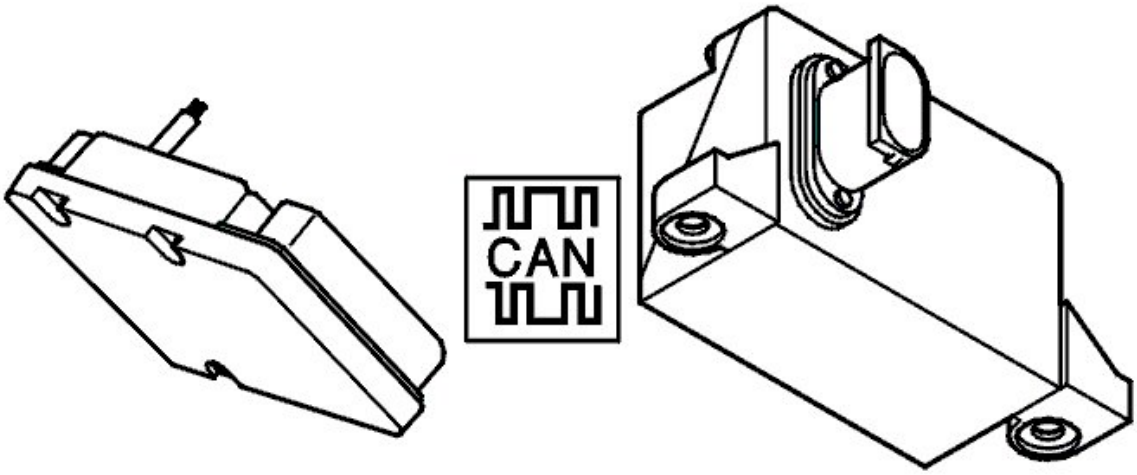


- Ignition off
- Check the connectors for the brake control module (BCM) and the active yaw control (AYC) sensor. Check for contact resistance. Check for oxidation
- Ignition on
- Read off the present value.

Check the read off value for the relevant component against the value in the table.

Component	Value
Yaw rate sensor	-6°/s - +6°/s
Lateral accelerometer	-1.7 m/s^2 - +1.7 m/s^2
Accelerometer	-1.7 m/s^2 - +1.7 m/s^2

Note! The accelerometer can only be read off if the car is four wheel drive.

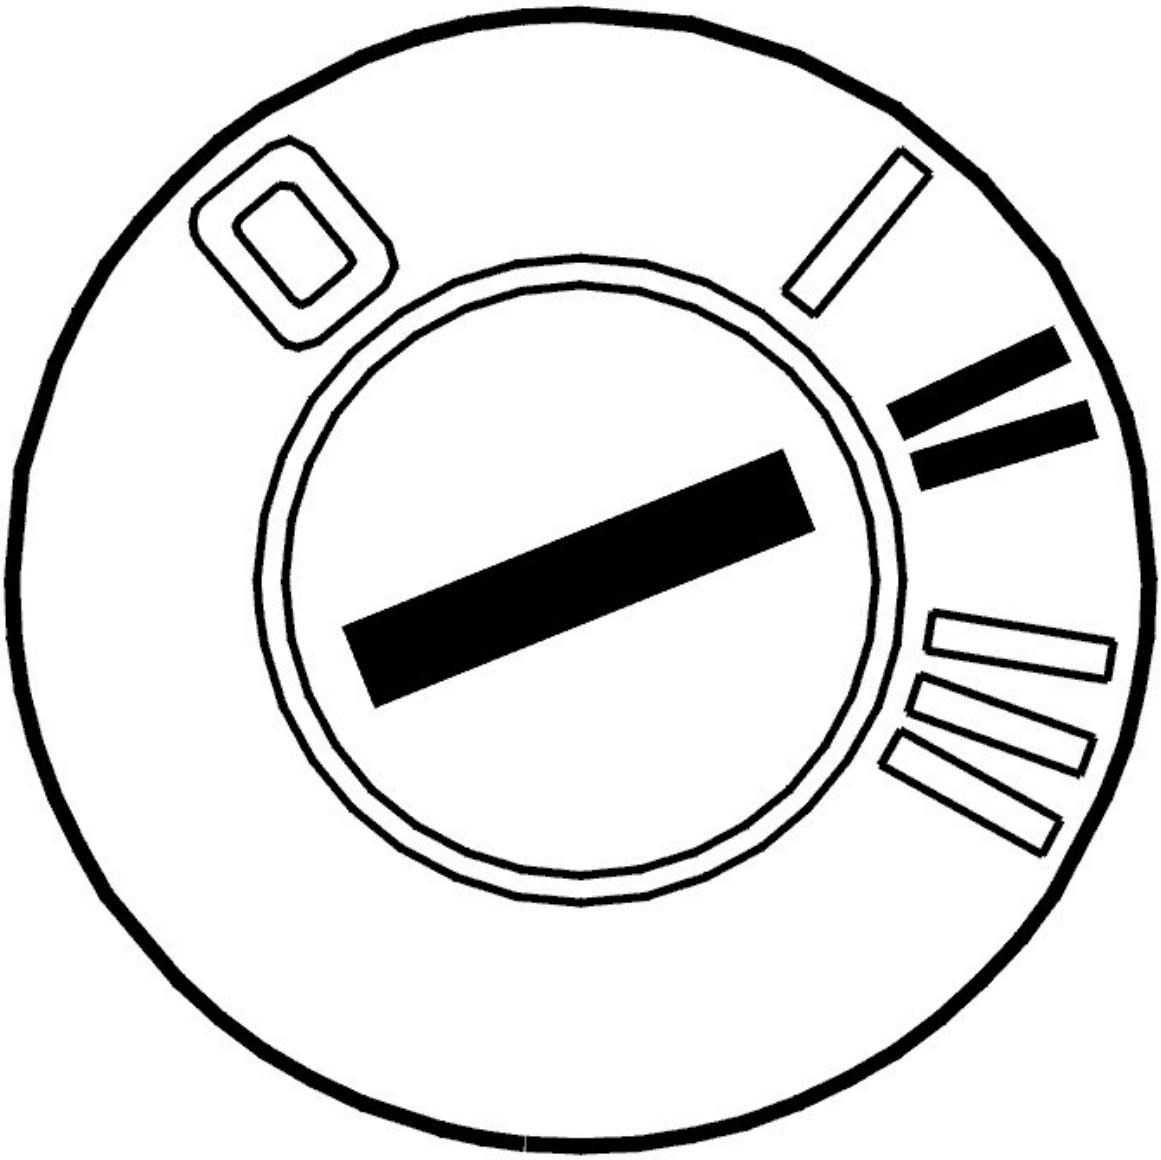


Are the present values OK?

Yes - Fault Found

No - Checking the power supply

Checking the power supply



- Ignition off
- Connect the breakout box to the brake control module (BCM)
- Ignition on.

Check the power supply to the active yaw control sensor by connecting a voltmeter between terminals #6 (#A6) and #39 (#A39) on the breakout box. The voltage must be normal system voltage.
Replace the control module if the voltage is incorrect.
If the voltage is OK, check the power supply cables between the active yaw control sensor (AYC):

- terminal #3 and control module terminal #6 (#A6)
- terminal #5 and control module terminal #39 (terminal #A39).

check for an open-circuit.
Replace the active yaw control sensor if the wiring is OK.

Other information

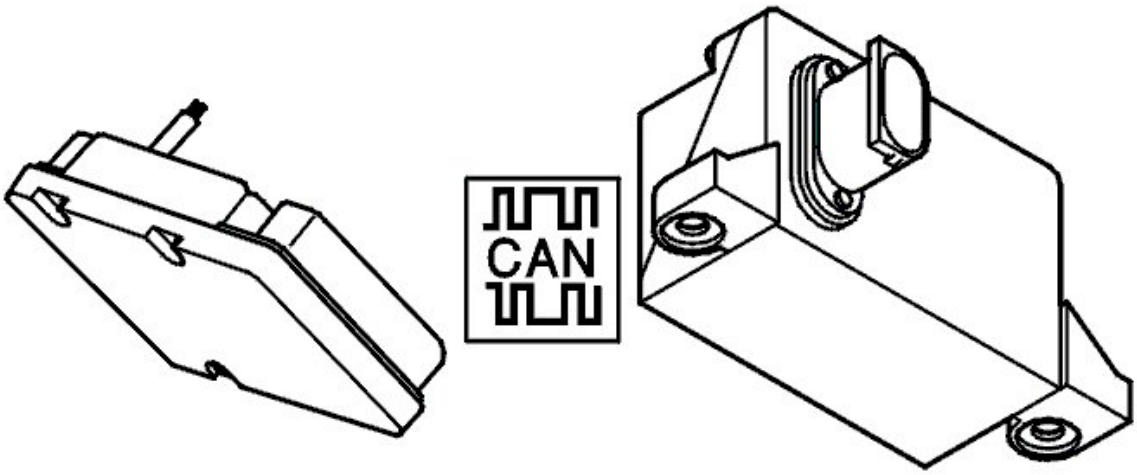
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition



Note! The diagnostic trouble code (DTC) applies only to cars with dynamic stability and traction control (DSTC).

The yaw rate sensor, lateral accelerometer, accelerometer (only AWD) and angle of lean sensor (only RSC) are integrated in the active yaw control sensor. This in turn is connected to the brake control module (BCM) via its own Control area network (CAN) cable. The sensors transmit information to the brake control module (BCM) indicating the size of the yaw angle, the lateral acceleration of the car, the forward acceleration and the car's lateral angle of lean.
Diagnostic trouble code (DTC) BCM-0121, BCM-0125, BCM-0127 or BCM-0129 is stored, depending on the sensor, if the control module registers that the signal from any of the sensors is outside its permitted range.

- BCM-0121: Yaw rate sensor
- BCM-0125: Lateral acceleration sensor
- BCM-0127: Tilt angle sensor
- BCM-0129: Accelerometer.

Substitute value

- Traction control is blocked
- Stability control is blocked
- Active yaw control is blocked
- RSC is blocked (cars equipped with RSC only).

Hint: For information about abbreviations, see Brake system, abbreviations See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Description and Operation/Brake System, Abbreviations.

Possible source

- Interference or noise on the wiring has disrupted the active yaw control sensor calculations
- The power supply to the active yaw control sensor is too low
- Incorrect wheel alignment
- Internal fault in the active yaw control sensor.

Note! This diagnostic trouble code (DTC) is not due to an internal hardware fault in the Brake control module (BCM) and must not be remedied by replacing the control module.

Fault symptom[s]

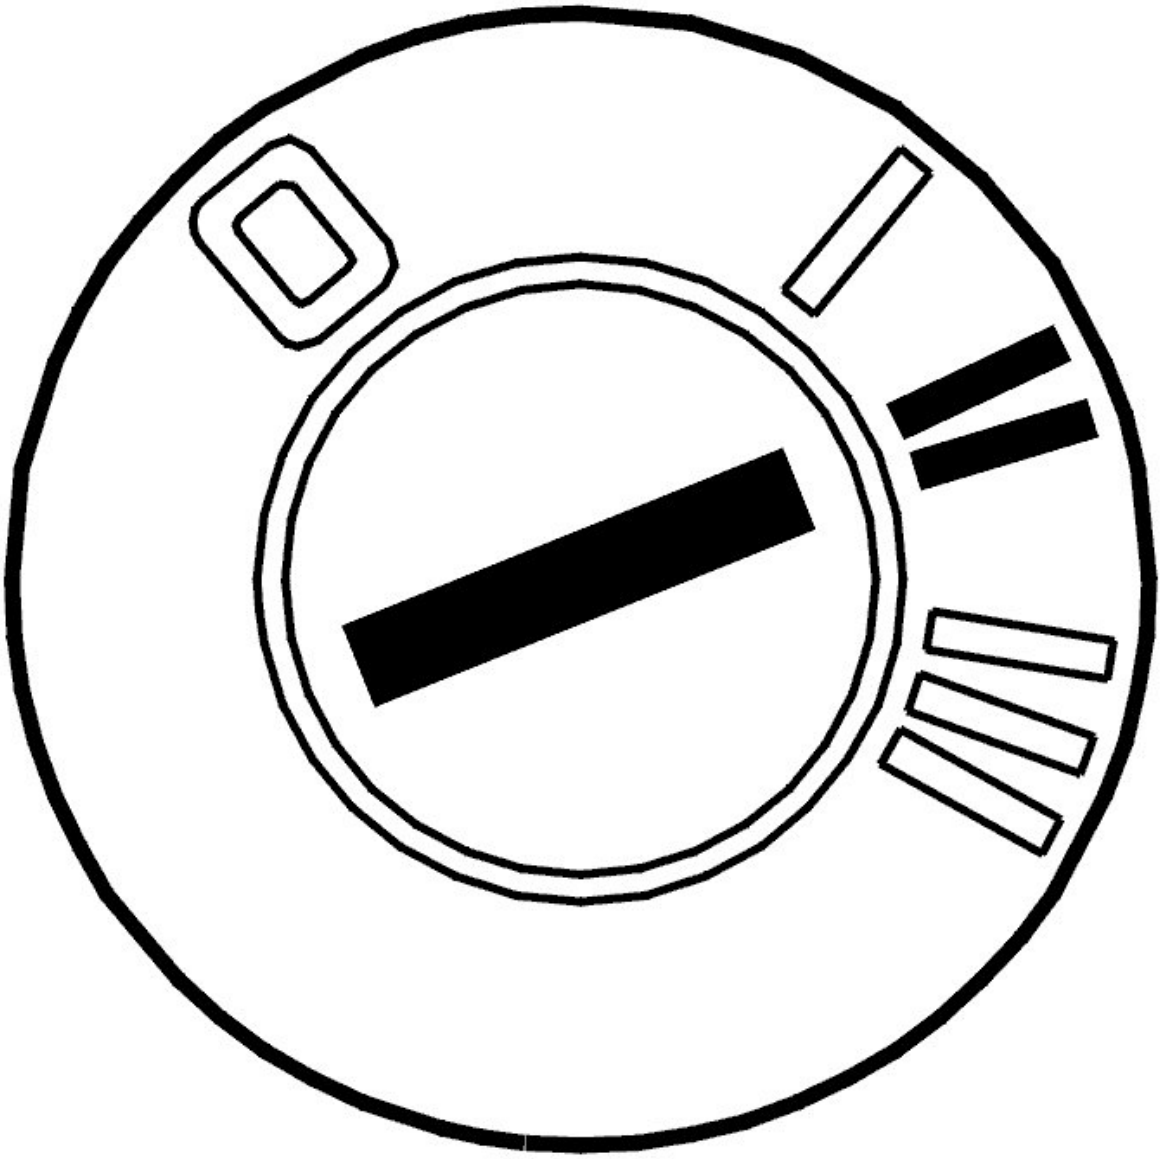
- The anti-spin warning lamp is lit (up to and including 2002 model year)
- General yellow warning lamp lit (from model year 2003)
- Anti-spin does not function
- The stability control system does not function
- The traction control system does not function.

Signal Outside Its Permitted Range

Signal outside its permitted range

Checking the connectors

Note! If diagnostic trouble codes (DTCs) other than BCM-0121, BCM-0125, BCM-0127 or BCM-0129 are stored in the brake control module (BCM), select cancel and fault trace these diagnostic trouble codes (DTCs) first.

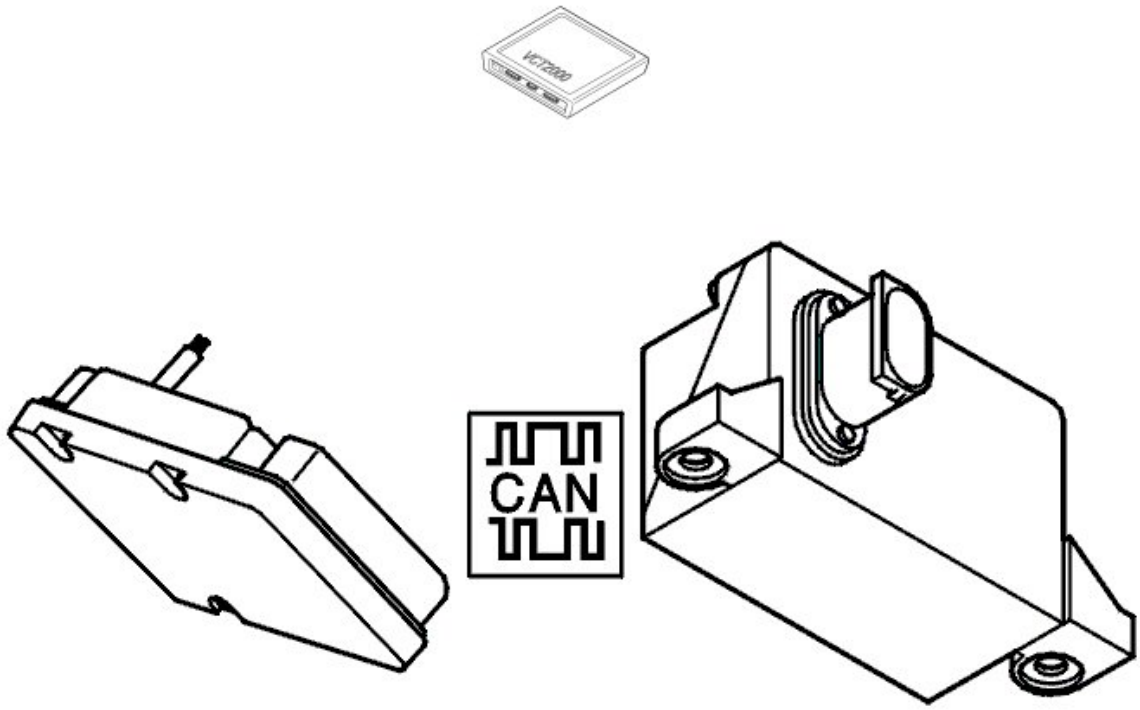


- Ignition off
- Check the brake control module (BCM) and the active yaw control sensor connectors. Check for contact resistance and oxidation
- Ensure that no sources of interference, such as a mobile telephone or radio receiver, are in the vicinity of the active yaw control sensor
- Test drive the car. See the test drive schedule. See Test Drive Form (DSTC (dynamic stability and traction control) /brake control module),

description See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Testing and Inspection/Initial Inspection and Diagnostic Overview/Test Drive Form (DSTC (Dynamic Stability And Traction Control) /Brake Control Module), Description
- Ignition on
- Read off diagnostic trouble codes (DTCs).

If the diagnostic trouble code (DTC) status is intermittent the cause of the fault was probably either contact resistance in the control module or active yaw control sensor connectors, or a source of interference too close to the sensor.

Other information
- To remove the connector for the active yaw control sensor, see Active yaw control sensor, replacing See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Yaw Rate Sensor/Service and Repair/Active Yaw Control Sensor, Replacing
- To remove the brake control module (BCM) connector, see Connecting the breakout box, brake control module (BCM) See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box/Connecting the Breakout Box, Brake Control Module (BCM).

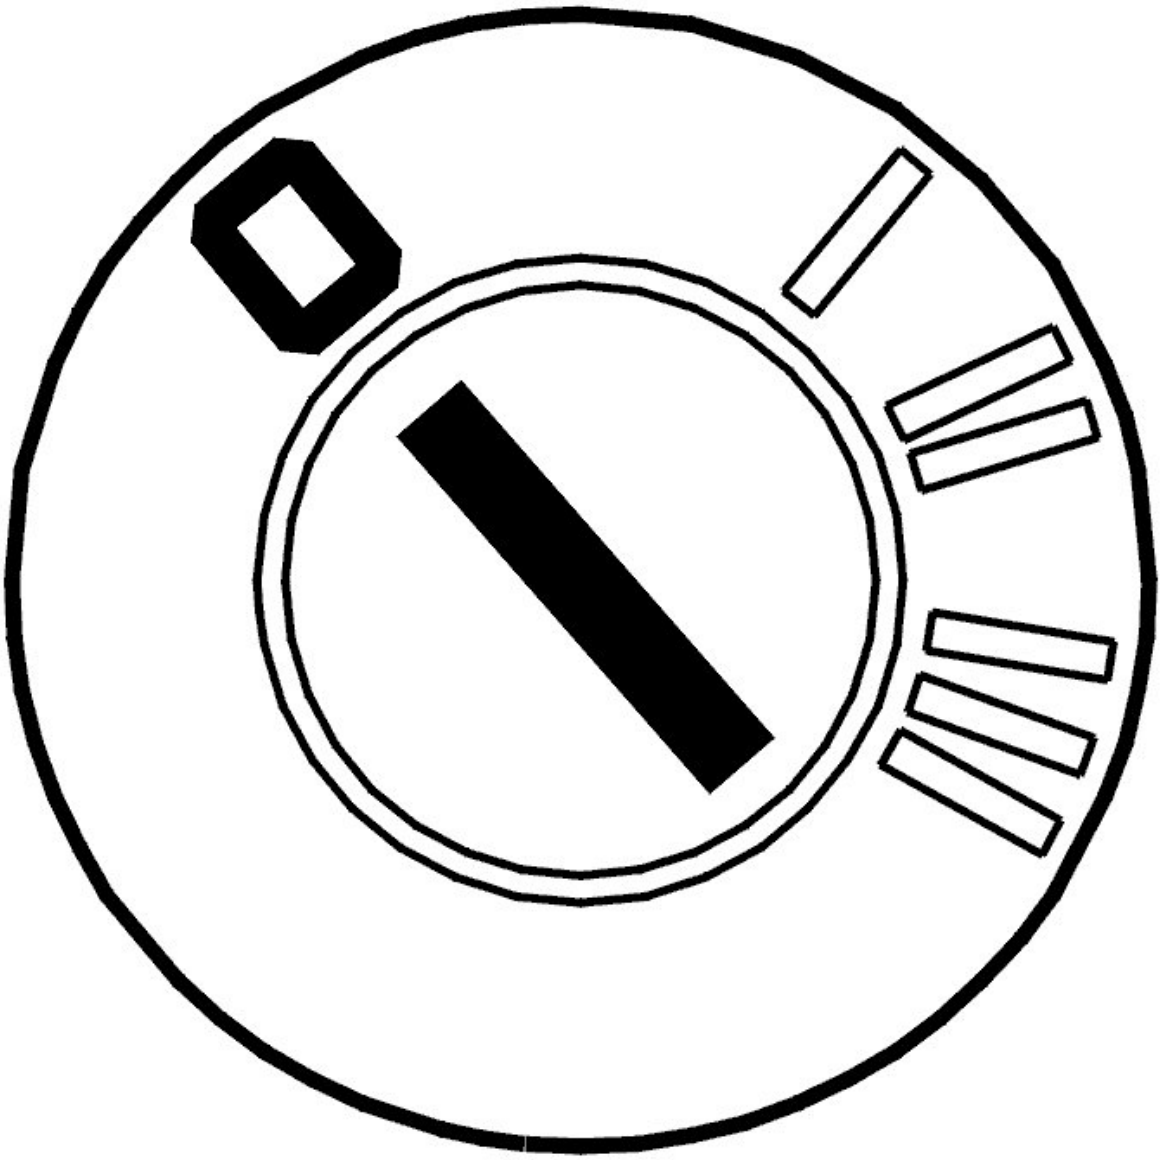


Was the status of the diagnostic trouble code (DTC) permanent?

Yes - Checking the wiring

No - **Fault Found**

Checking the wiring



- Ignition off.

Check the brake control module (BCM) and the active yaw control sensor connectors. Check for contact resistance and oxidation.
Check the wiring between the connector for the active yaw control sensor:

- terminal #1 and control module terminal #A25 (#A25)
- terminal #2 and control module terminal #A29 (#A29)
- terminal #3 and control module terminal #A6 (#A6)
- terminal #5 and control module terminal #A39 (#A39).

Check for an open-circuit.
Check the wheel alignment.
Remedy as necessary.

Other information

- To connect the breakout box, see Connecting the breakout box, brake control module (BCM) See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box/Connecting the Breakout Box, Brake Control Module (BCM)
- For information about signals, see Signal specification, brake control module (BCM) with DSTC (dynamic stability and traction control) See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Specification
- To check the wheel alignment, see Wheel alignment, checking / adjusting See: Maintenance/Alignment/Service and Repair
- To replace the active yaw control sensor, see Active yaw control sensor, replacing See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Yaw Rate Sensor/Service and Repair/Active Yaw Control Sensor, Replacing

FAULT-TRACING FAILED - FAULT-TRACING FAILED

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition

Note! This diagnostic trouble code (DTC) applies only to vehicles with dynamic stability and traction control (DSTC).

The brake pressure sensors transmit signals to the brake control module (BCM) indicating the pressure in the brake system. If the control module registers an incorrect signal from any brake pressure sensor, then trouble code BCM-0130 or BCM-0133 is generated depending on sensor.

Note! When cables to the brake pressure sensors are physically interchanged when installing, troubleshoot both sensors when trouble code BCM-0130 or BCM-0133 is detected.

Substitute value
- Traction control is blocked.
- SC is blocked.

- Active yaw control is blocked.

Hint: For more information about abbreviations, see: Brake system, abbreviations See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Description and Operation/Brake System, Abbreviations

Possible source
- Open-circuit in the wiring.
- Wiring is short-circuited to ground or supply voltage.
- Damaged pressure sensor.
- Internal fault in the control module.

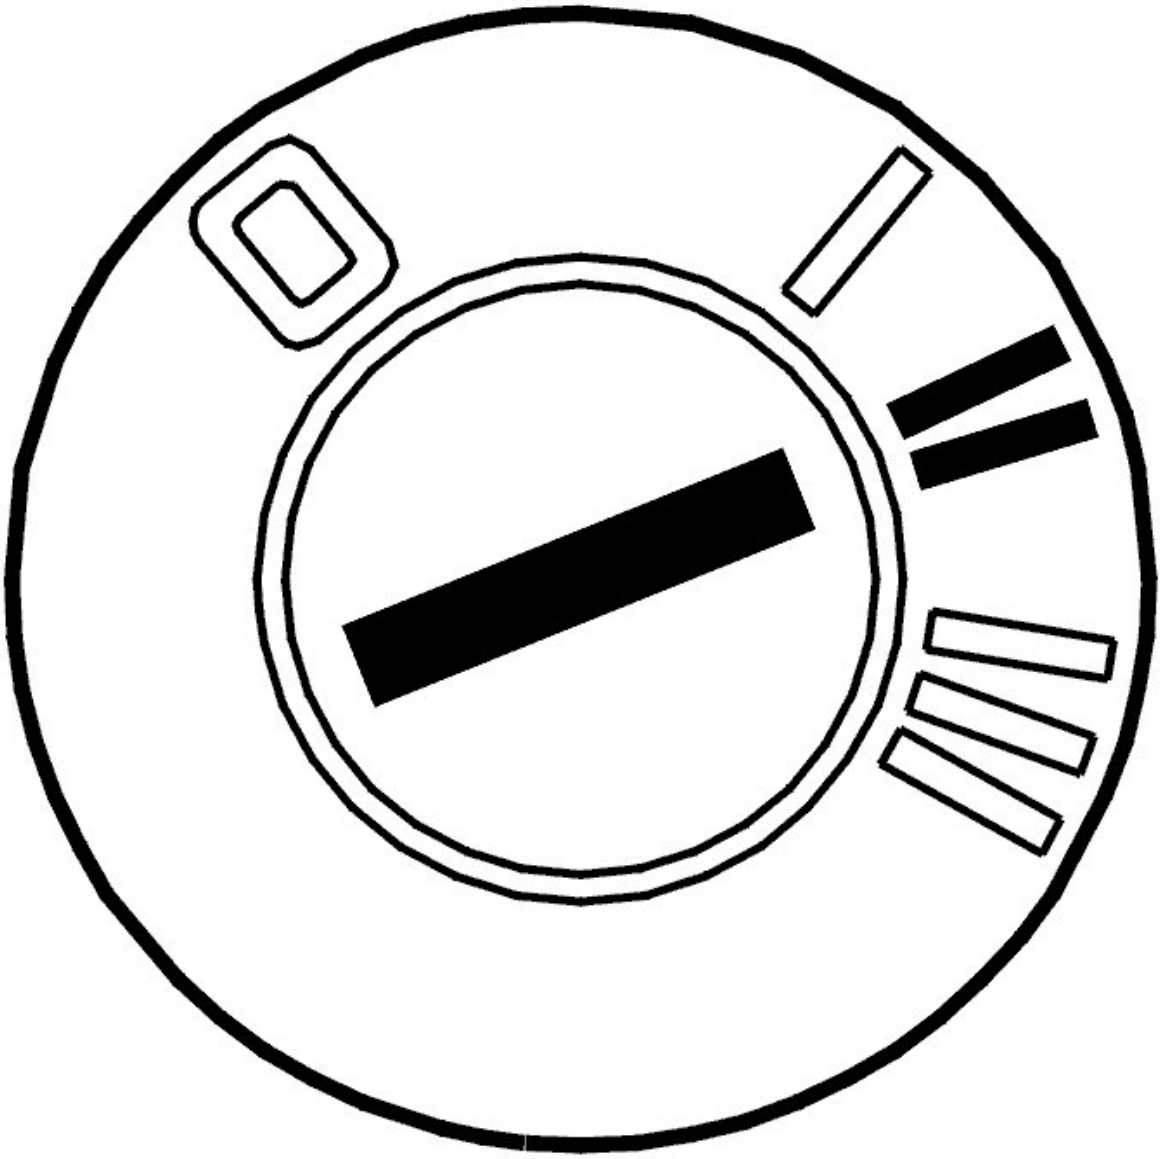
Fault symptom[s]
- Warning light anti-spin on (applies to model year -2002)
- General yellow warning light on (applies to model year 2003-)
- Anti-spin not working
- Stability function is not working
- Anti skid function is not working

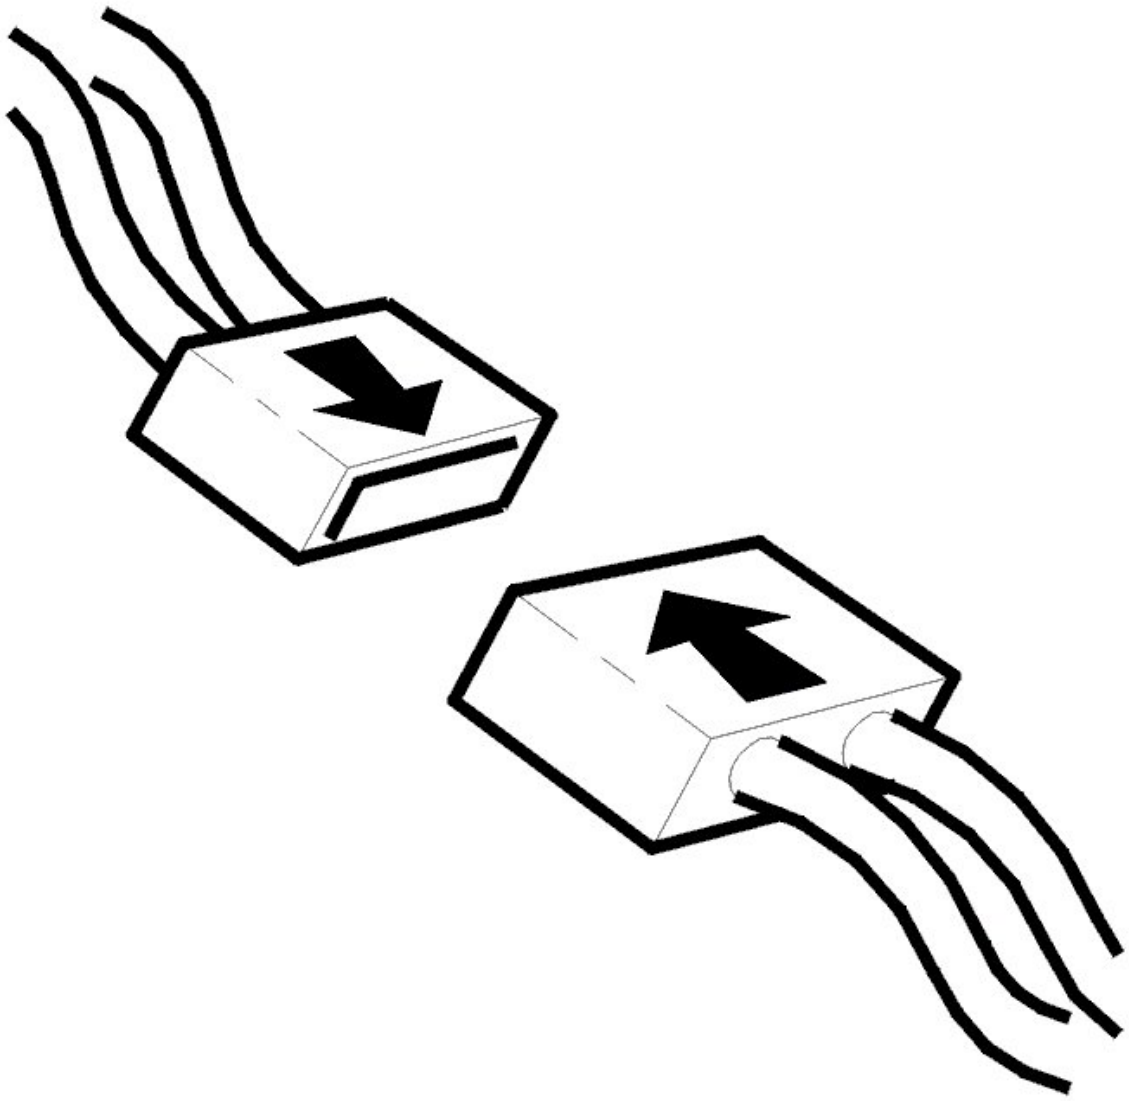
Signal Too Low

Signal too low

Checking the connectors

Note! When cables to the brake pressure sensors are physically interchanged when installing, troubleshoot both sensors when trouble code BCM-0130 or BCM-0133 is detected.



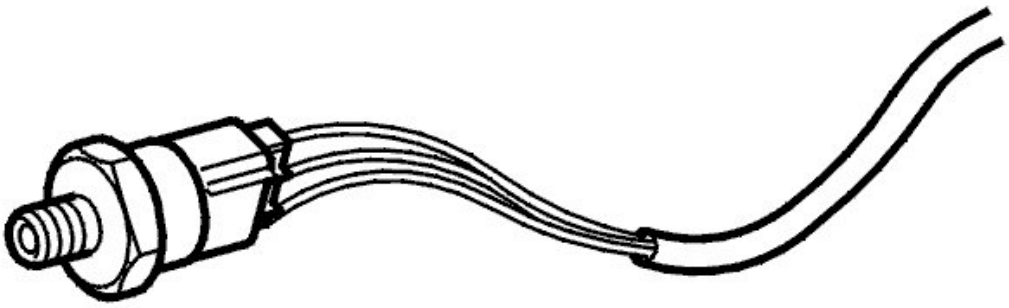


- Ignition off
- Check the brake control module (BCM) and the brake pressure sensor connectors. Check for contact resistance and oxidation
- Reinstall the components, reconnect the connectors etc.
- Ignition on
- Read off the pressure in the brake system from the relevant pressure sensor
- Depress the brake pedal.

The brake pressure must increase with increased pedal pressure. If the brake pressure increases the cause of the fault was probably contact resistance or oxidation in the control module or pressure sensor connectors.

Other information

- To remove the control module connector, see Connecting the breakout box, brake control module (BCM) See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box/Connecting the Breakout Box, Brake Control Module (BCM)
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

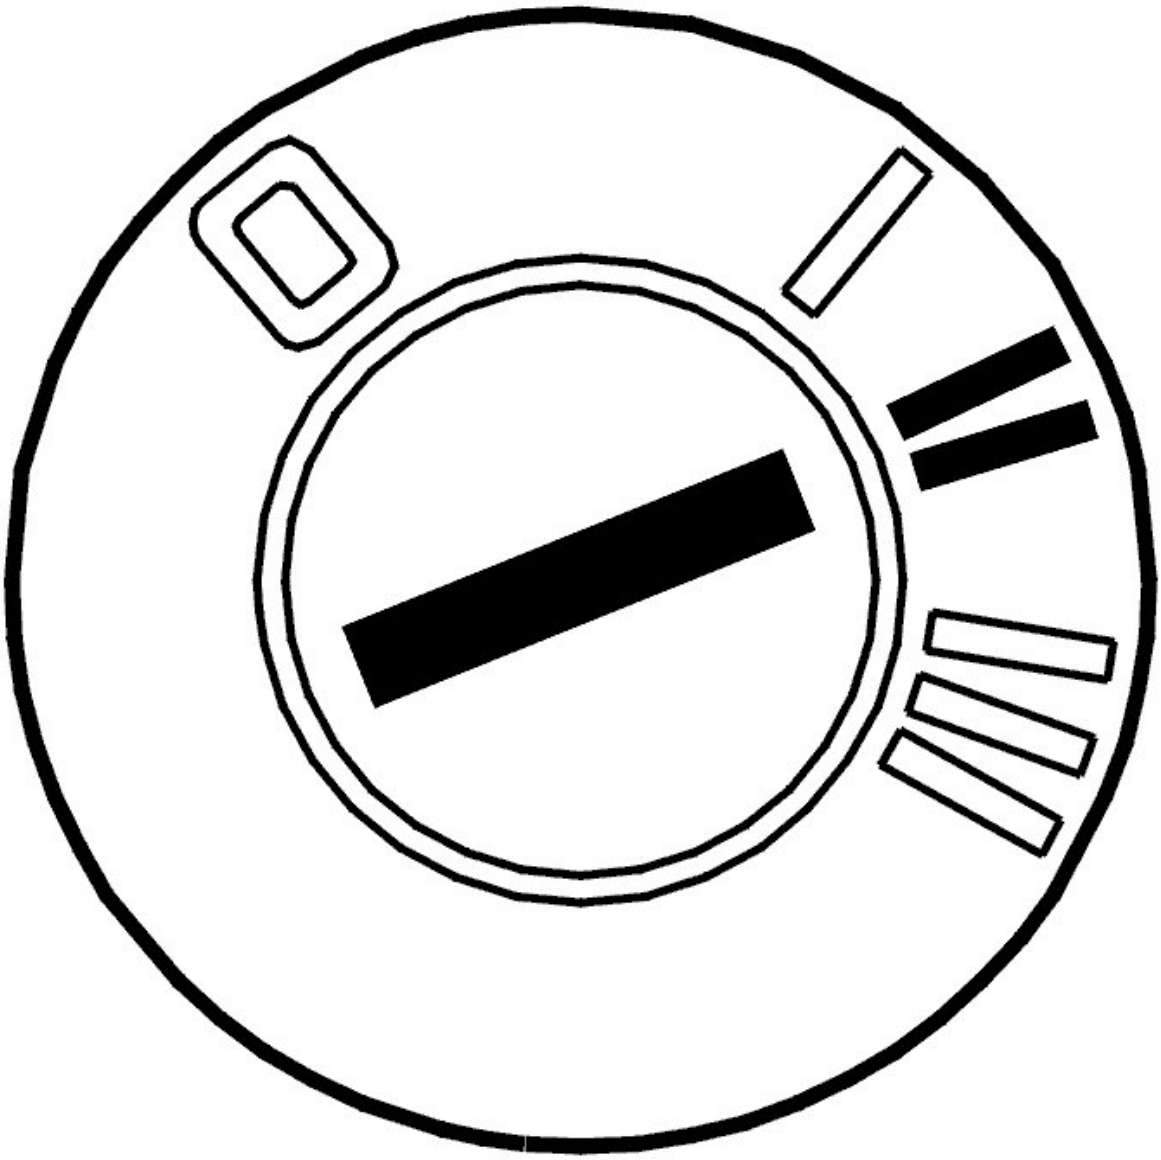


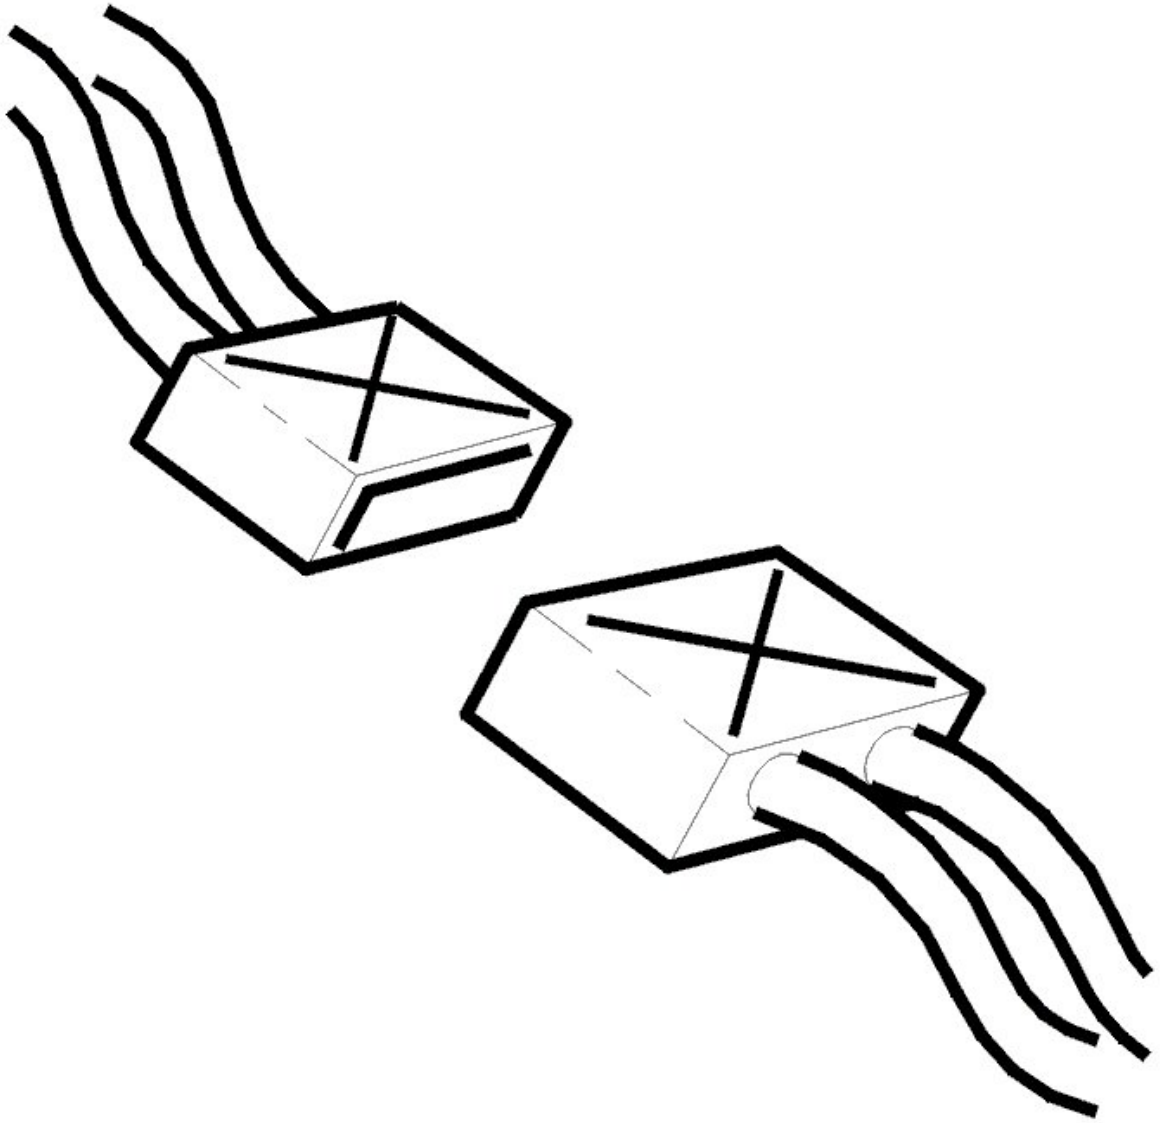
Does the brake pressure increase?

Yes - Fault Found

No - Checking the control module

Checking the control module





- Ignition on
- Pressure sensor connector disconnected
- The breakout box connected.

Check the voltage supply using a voltmeter:

Pressure sensor 1

- between terminal #A21 and terminal #A22 on the breakout box.

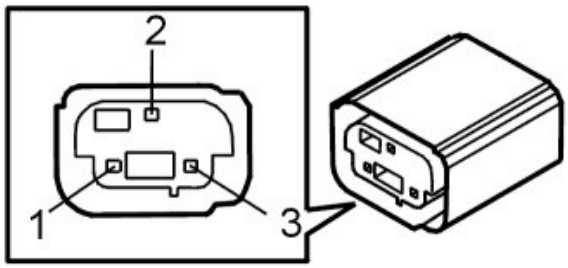
Pressure sensor 2

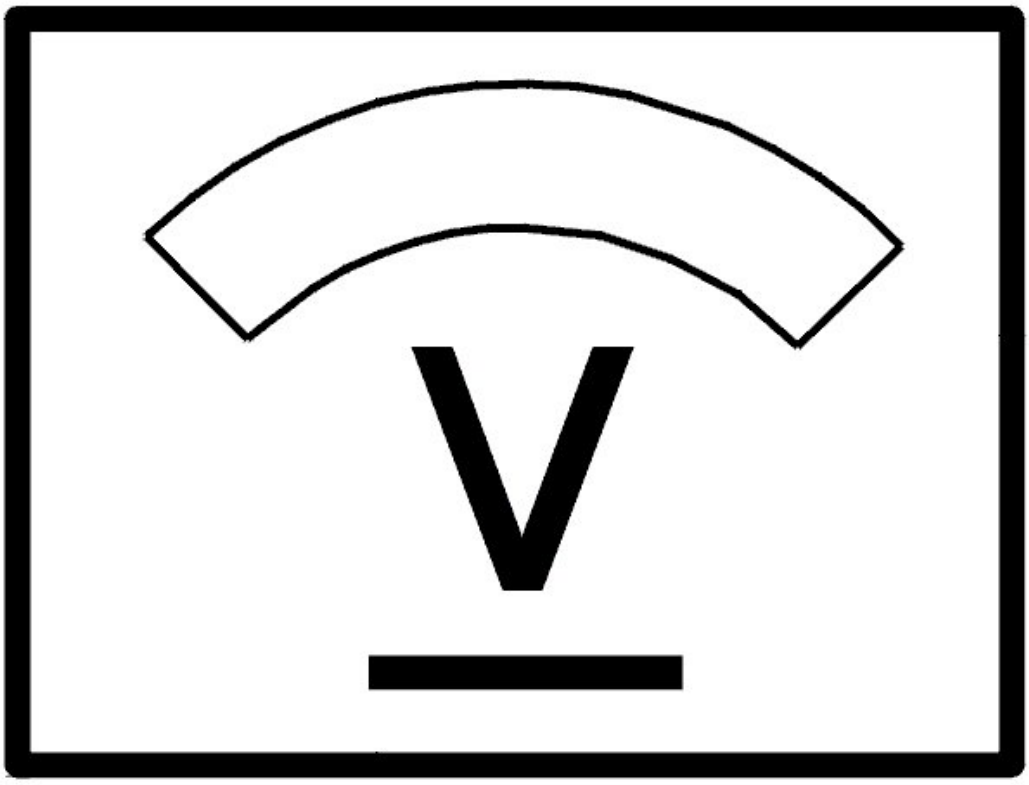
- between terminal #A18 and terminal #A19 on the breakout box.

The voltage must be approximately 5 V. Replace the brake control module (BCM) if the voltage is incorrect.

Other information

- To connect the breakout box, see Connecting the breakout box, brake control module (BCM) See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box/Connecting the Breakout Box, Brake Control Module (BCM)
- To replace the control module, see Brake Control Module (BCM), replacing See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Electronic Brake Control Module/Service and Repair/Brake Control Module (BCM), Replacing
- For information about signals, see Signal specification, brake control module (BCM) with DSTC (dynamic stability and traction control) See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Specification.



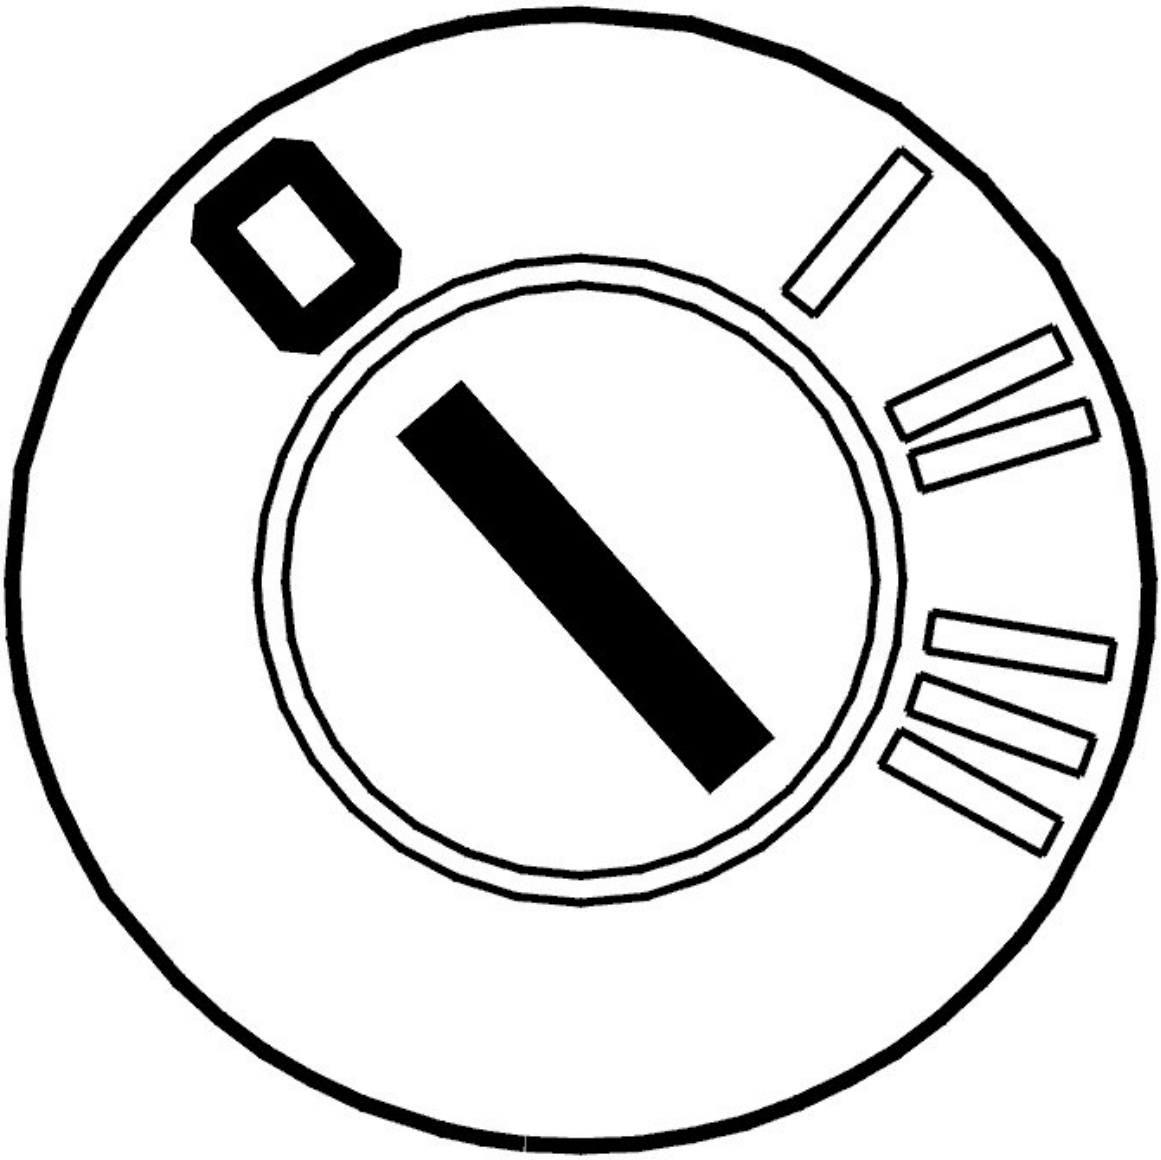


Was the voltage OK?

Yes - Checking wiring and sensors

No - Verification

Checking wiring and sensors



- Ignition off
- Connect the breakout box.

Check the wiring between the pressure sensor and the control module. Check for an open-circuit. Check for a short-circuit to ground.

For pressure sensor 1, check the wiring

- between pressure sensor terminal #1 and control module terminal #21 (#A21)
- between pressure sensor terminal #2 and control module terminal #23 (#A23)
- between pressure sensor terminal #3 and control module terminal #22 (#A22).

For pressure sensor 2, check the wiring

- between pressure sensor terminal #1 and control module terminal #19 (#A19)
- between pressure sensor terminal #2 and control module terminal #20 (#A20)
- between pressure sensor terminal #3 and control module terminal #18 (#A18).

Hint: Check the relevant brake pressure sensor by measuring the signal from the sensor, with the ignition switched on and the breakout box connected:

Pressure sensor 1

- between terminal #A21 and terminal #A22 on the breakout box. The voltage must be approximately 5 V
- between terminal #A21 and terminal #A23 on the breakout box. Voltage must be between 0.25- 4.75 V, depending on brake pressure.

Pressure sensor 2

- between terminal #A18 and terminal #A19 on the breakout box. The voltage must be approximately 5 V
- between terminal #A19 and terminal #A20 on the breakout box. Voltage must be between 0.25- 4.75 V, depending on brake pressure.

Replace the pressure sensor if the voltage does not change when the brake pedal is depressed.

Other information

- To connect the breakout box, see Connecting the breakout box, brake control module (BCM) See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout

Box/Connecting the Breakout Box, Brake Control Module (BCM)

- To replace the pressure sensor, see Pressure sensor, master cylinder, replacing See: Brakes and Traction Control/Hydraulic System/Brake Fluid Pressure Sensor/Switch/Service and Repair
- For information about signals, see Signal specification, brake control module (BCM) with DSTC (dynamic stability and traction control) See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Specification.

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition

Note! The diagnostic trouble code (DTC) applies only to ABS systems equipped with dynamic stability and traction control (DSTC).

Brake pressure sensors 1 and 2 provide a signal with the brake system pressure to the brake control module (BCM). Diagnostic trouble code (DTC) BCM-0136 is stored if the control module registers that the signal from any of the pressure sensors is outside its permitted range.

Substitute value
- Traction control is blocked
- Stability control is blocked
- Active yaw control is blocked.

Hint: For information about abbreviations, see Brake system, abbreviations See: Brakes and Traction Control/Antilock Brakes / Traction Control

Systems/Description and Operation/Brake System, Abbreviations.

Possible source
- Open-circuit in the ground lead
- Fault in the brake circuit
- Defective pressure sensor.

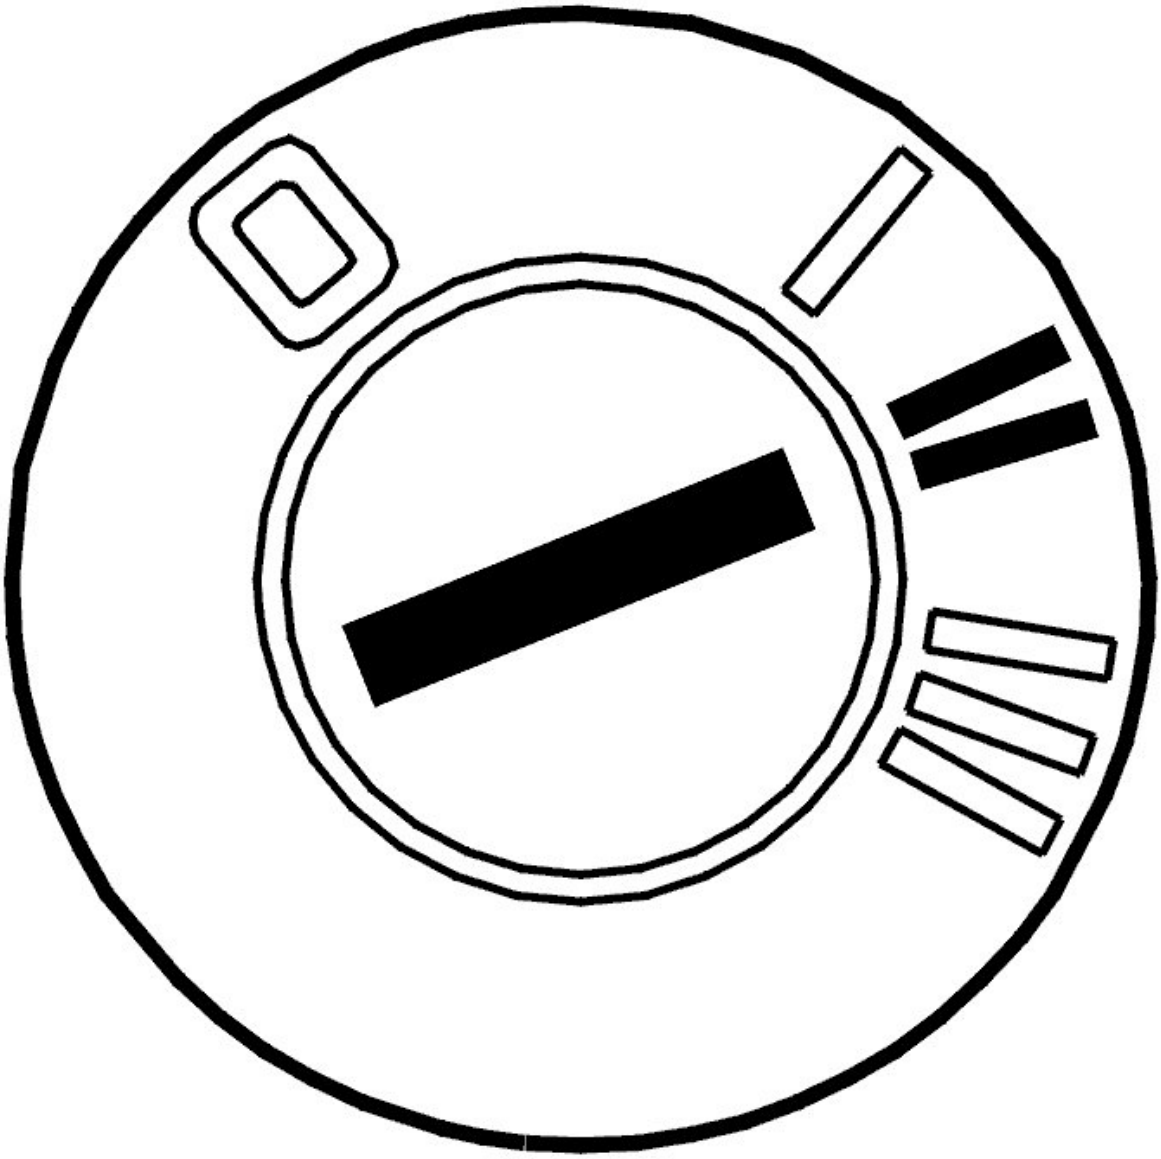
Fault symptom[s]
- The anti-spin warning lamp is lit (up to and including 2002 model year)
- General yellow warning lamp lit (from model year 2003 inclusive)
- Anti-spin does not function
- The stability control system does not function
- The traction control system does not function.

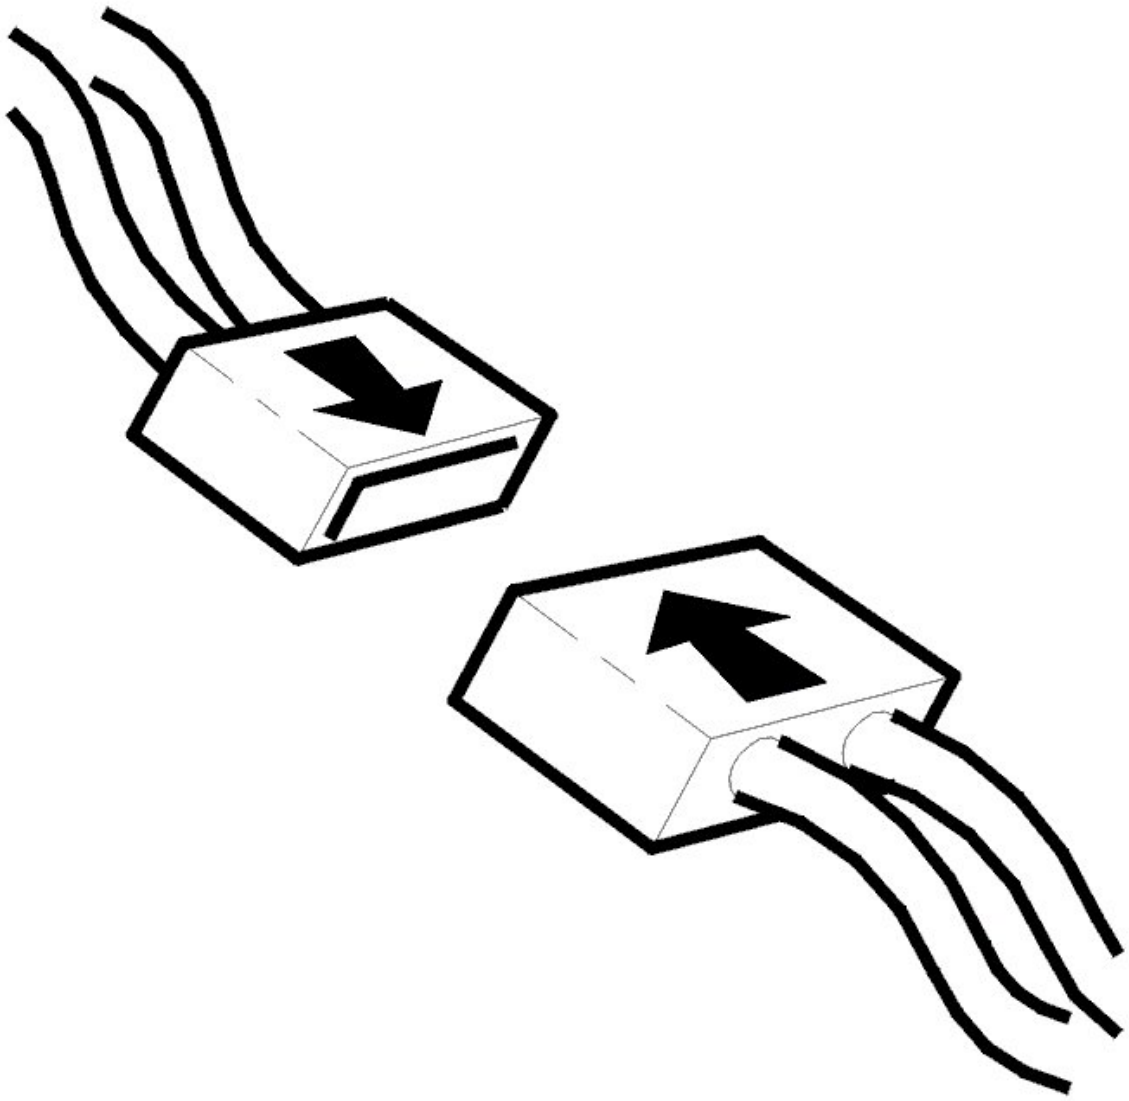
Signal Outside Its Permitted Range

Signal outside its permitted range

Checking the connectors

Note! When cables to the brake pressure sensors are physically interchanged when installing, troubleshoot both sensors when trouble code BCM-0136.





- Ignition off
- Check the brake control module (BCM) and the brake pressure sensor connectors. Check for contact resistance and oxidation
- Reinstall the components, reconnect the connectors etc.
- Ignition on
- Read off the pressure from the brake system
- Depress the brake pedal.

The brake pressure must increase in both pressure sensors with increased pedal pressure. If the brake pressure increases for both pressure sensors, the cause of the fault was probably contact resistance or oxidation in the control module or pressure sensor connectors.

Other information

- To access the control module connector, see Connecting the breakout box, brake control module (BCM) See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box/Connecting the Breakout Box, Brake Control Module (BCM)

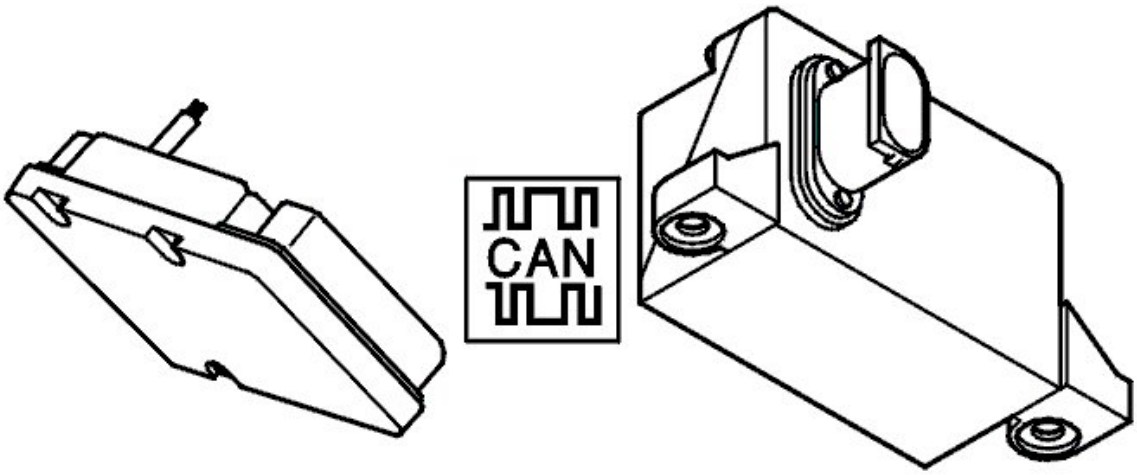
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition



Note! This diagnostic trouble code (DTC) applies only to brake systems with dynamic stability and traction control (DSTC).

The active yaw control sensor is supplied with 12 V.
Diagnostic trouble code (DTC) BCM-0138 is stored if the brake control module (BCM) registers that the supply voltage to the active yaw control sensor is too high or too low.

Substitute value
- Traction control is blocked
- Stability control is blocked
- Active yaw control is blocked.

Hint: For information about abbreviations, see Brake system, abbreviations See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Description and Operation/Brake System, Abbreviations.

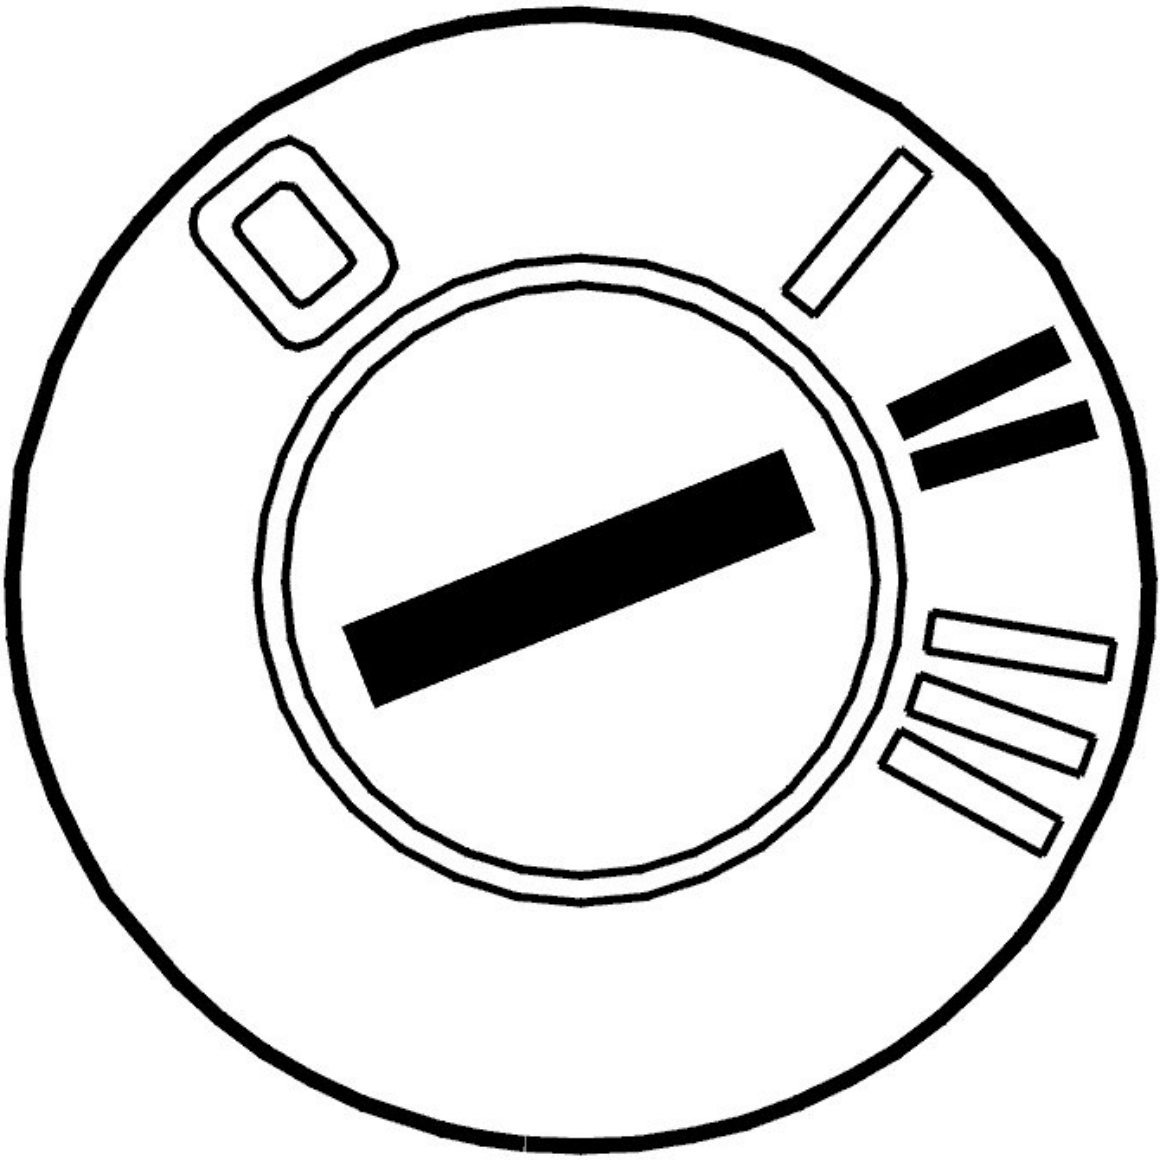
Possible source
- Contact resistance or oxidation in the terminals or connections
- Short-circuit to ground or to supply voltage in the power supply wiring for the active yaw control sensor
- Open-circuit in the power supply cable for the active yaw control sensor
- Internal fault in the active yaw control sensor
- Internal fault in the control module.

Fault symptom[s]
- The anti-spin warning lamp is lit (up to and including 2002 model year)
- General yellow warning lamp lit (from model year 2003 inclusive)
- Anti-spin does not function
- The stability control system does not function
- The traction control system does not function.

Faulty Voltage

Faulty voltage

Checking the connectors



- Ignition off
- Check the connectors for the brake control module (BCM) and the active yaw control sensor. Check for contact resistance and oxidation
- Ignition on
- Wait approximately 60 seconds
- Read off diagnostic trouble codes (DTCs).

If the status of the diagnostic trouble code (DTC) is intermittent, the cause of the fault was probably contact resistance or oxidation in the connectors for the control module or the active yaw control sensor.

Other information

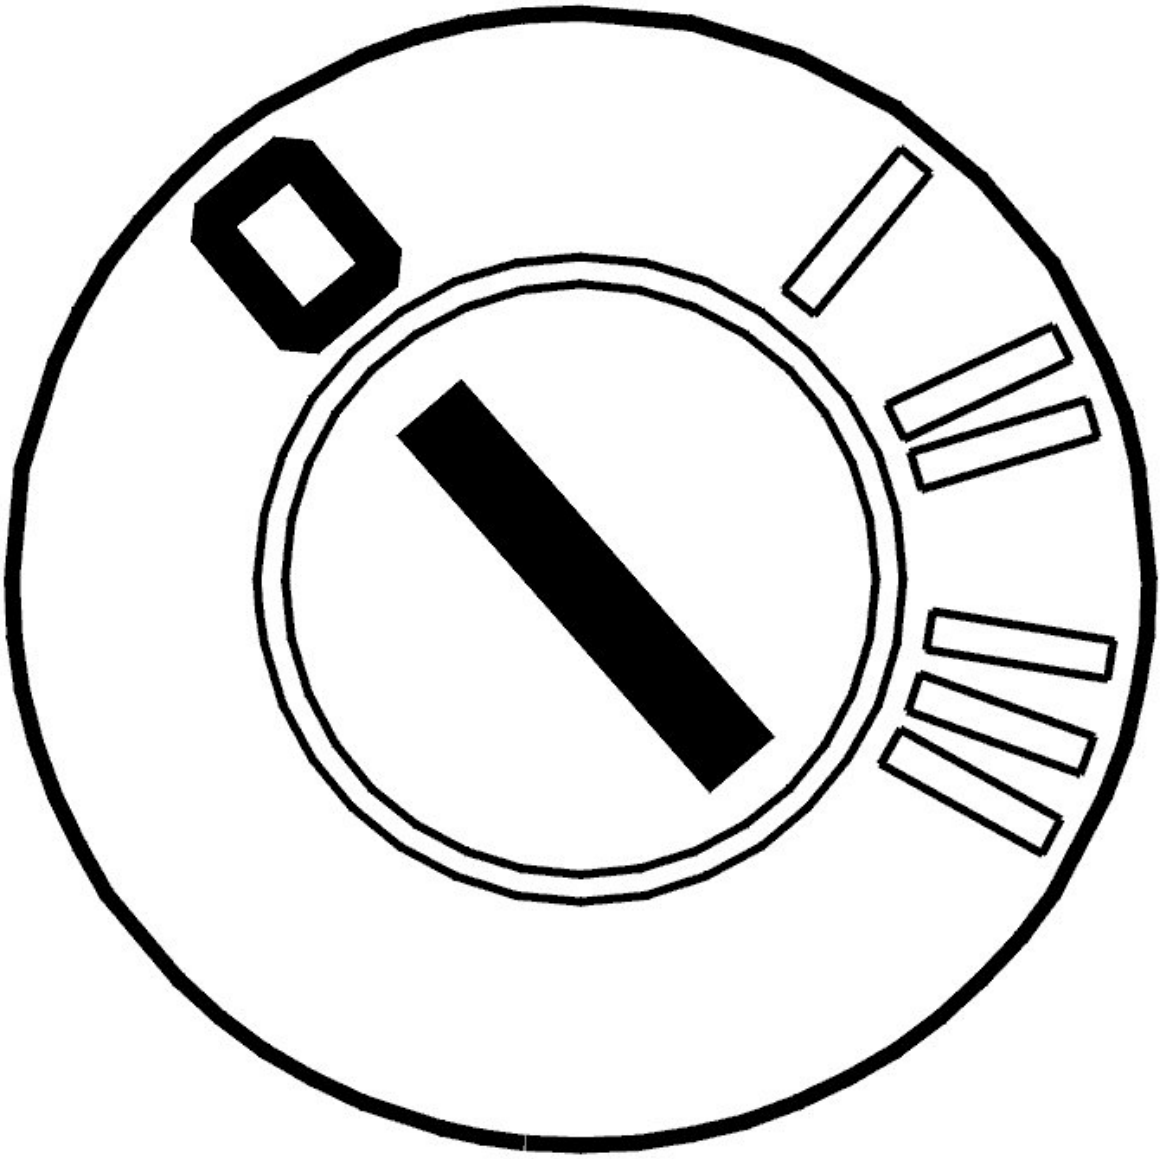
- To access the control module connector, see Connecting the breakout box, brake control module (BCM) See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box/Connecting the Breakout Box, Brake Control Module (BCM)
- To access the active yaw control sensor, see Active yaw control sensor, replacing See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Yaw Rate Sensor/Service and Repair/Active Yaw Control Sensor, Replacing
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

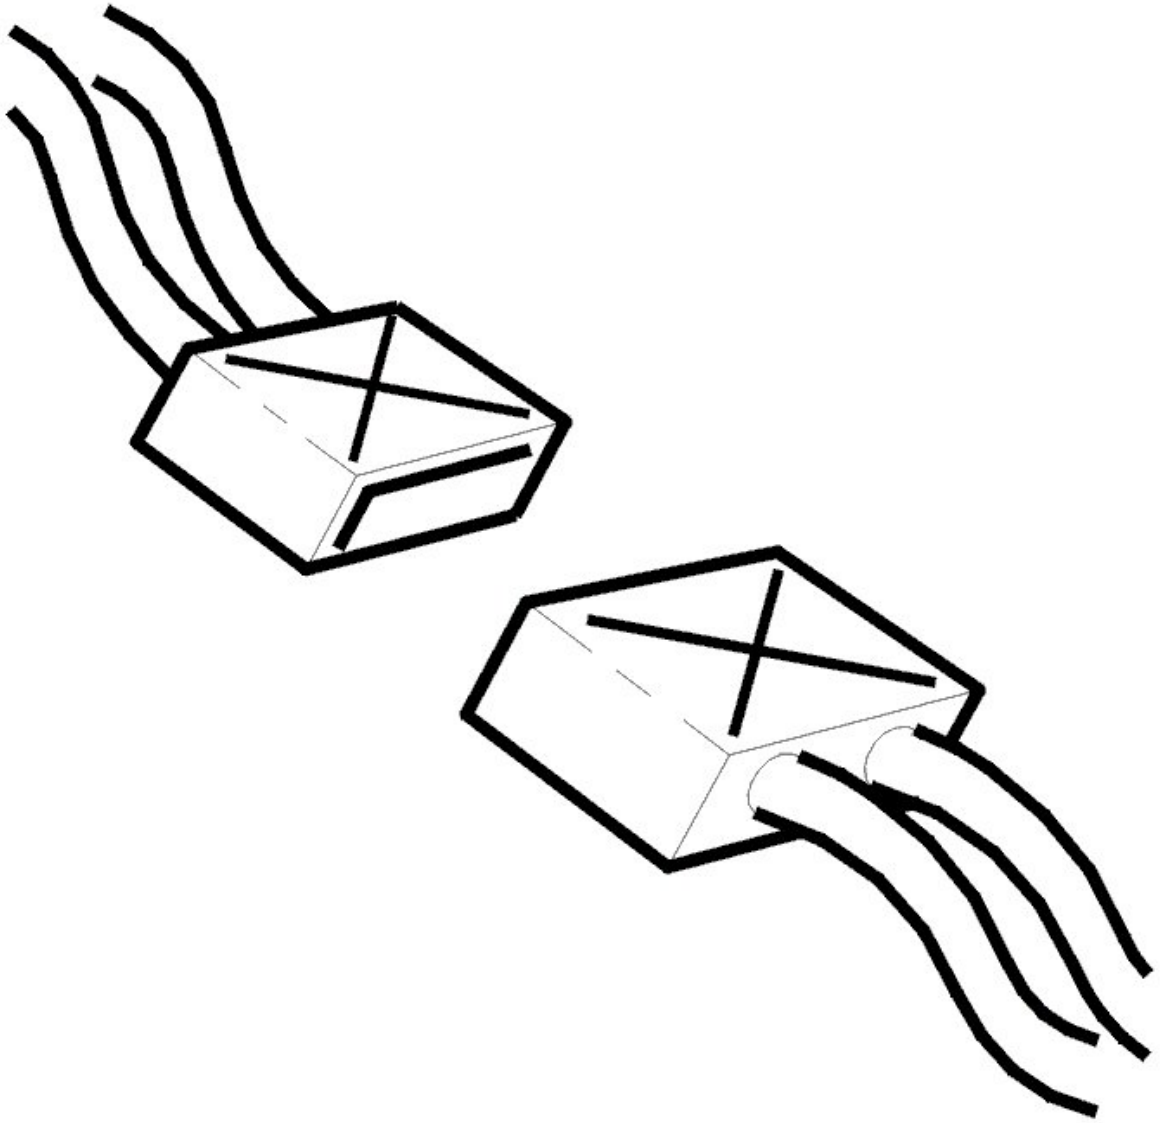
Is the status of the diagnostic trouble code (DTC) intermittent?

Yes - Fault Found

No - Checking the active yaw control sensor

Checking the active yaw control sensor



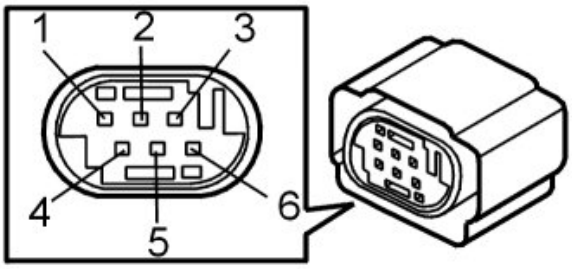


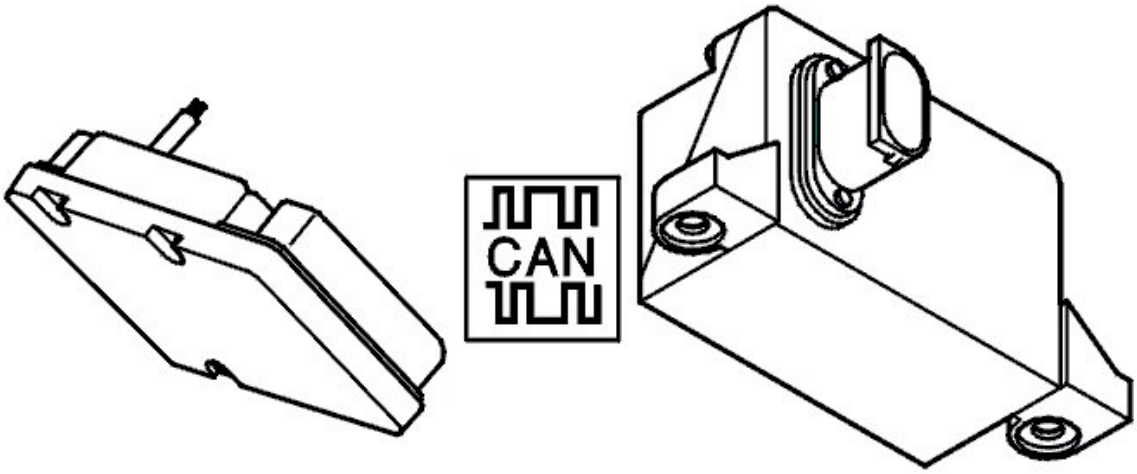
- Ignition off
- Breakout box connected to the brake control module (BCM)
- Ignition on
- Read off the power supply to the brake control module (BCM).

Check the power supply to the active yaw control sensor by connecting a voltmeter between control module terminals #6 (#A6) and #39 (#A39).
The voltage must be approximately the same as the read off value for the brake control module (BCM).
Replace the active yaw control sensor if the power supply to the sensor is OK.
Remedy as necessary.

Other information

- To connect the breakout box, see Connecting the breakout box, brake control module (BCM) See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box/Connecting the Breakout Box, Brake Control Module (BCM)
- To replace the active yaw control sensor, see Active yaw control sensor, replacing See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Yaw Rate Sensor/Service and Repair/Active Yaw Control Sensor, Replacing
- For information about signals, see Signal specification, brake control module (BCM) with DSTC (dynamic stability and traction control) See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Specification.



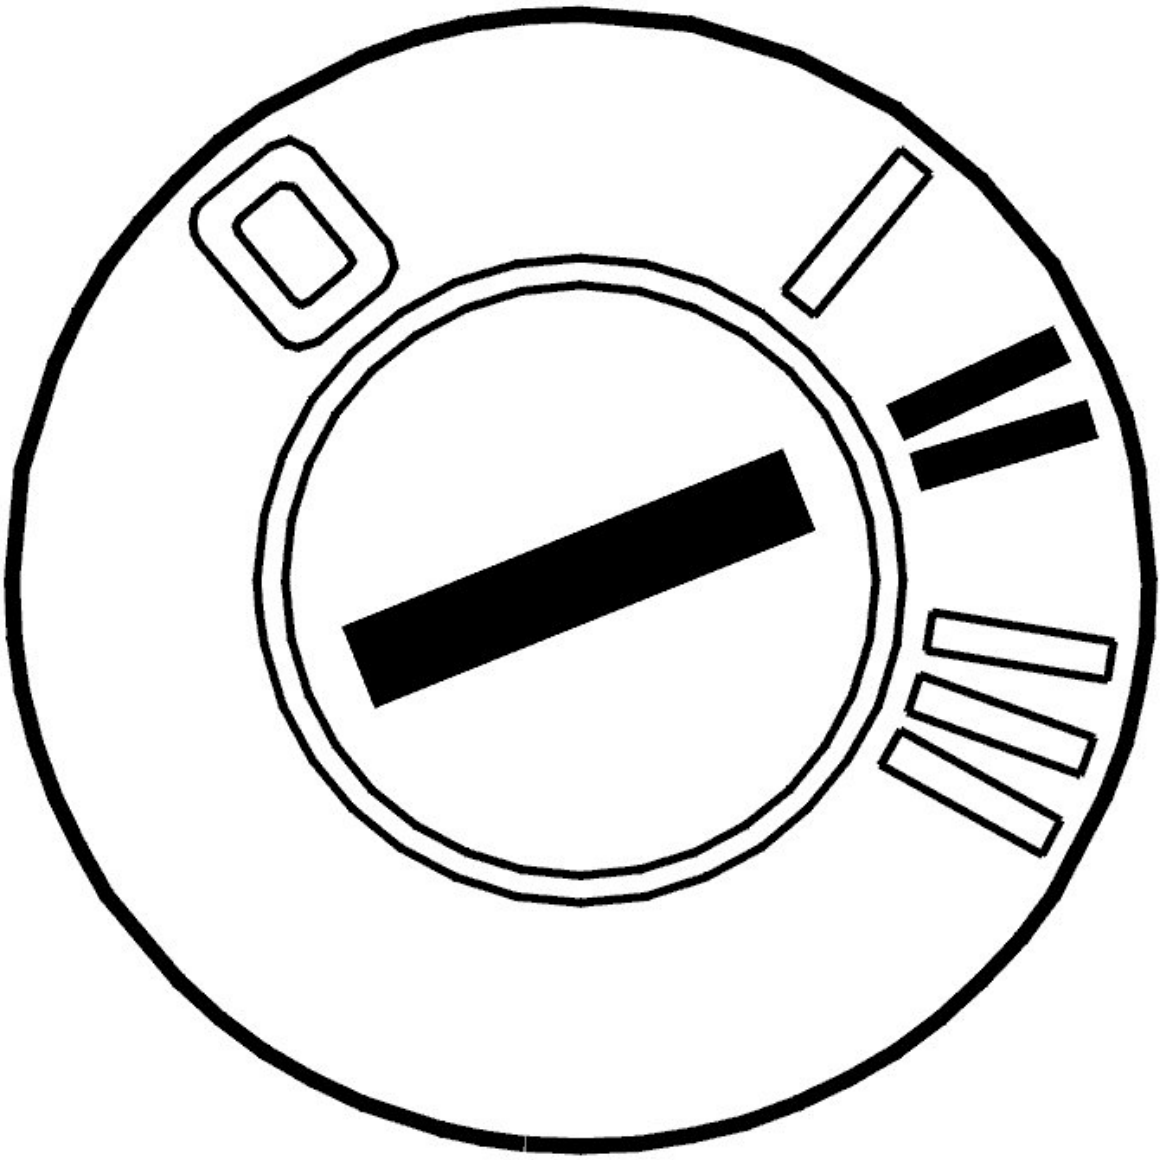


Was the voltage OK?

Yes - Checking the wiring

No - Verification

Checking the wiring



- Ignition off.

Check the power supply wiring between the active yaw control sensor:

- terminal #3 and brake control module (BCM) terminal #6 (#A6)
- terminal #5 and brake control module (BCM) terminal #39 (#A39).

check for a short-circuit to ground. Check for a short-circuit to supply voltage.
Replace the control module if the wiring is OK.

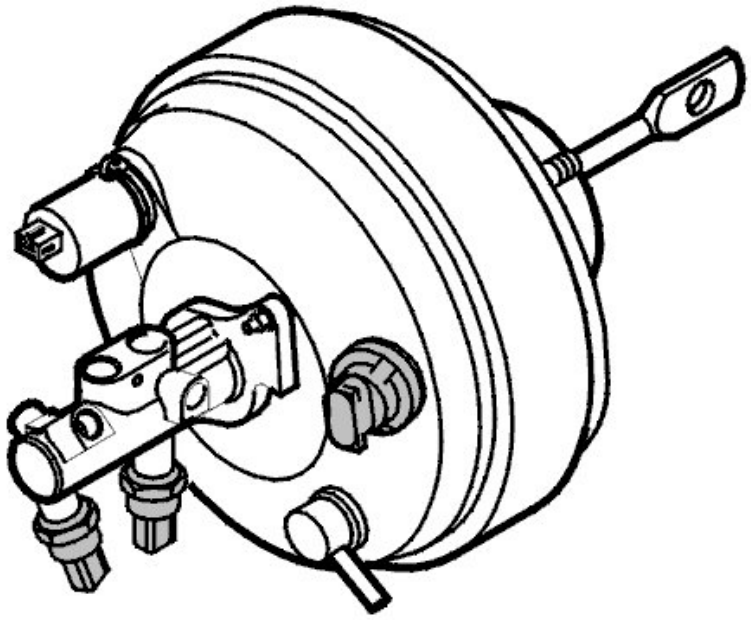
Diagnostic trouble code (DTC) information

Condition



Note! This diagnostic trouble code (DTC) applies only to brake systems with dynamic stability and traction control (DSTC).

During stability control the brake control module (BCM) transmits a signal to the pressure build-up valve. The valve opens and releases atmospheric pressure into the brake power booster. This increases the brake pressure in the brake system automatically. The function is used for traction control and in active brake assistance.
Diagnostic trouble code (DTC) BCM-0139 is stored if the control module registers an implausible signal from the pressure build-up valve.

Substitute value
- Traction control is blocked
- Stability control is blocked
- Active yaw control is blocked

- Brake assistance is blocked.

Hint: For information about abbreviations, see Brake system, abbreviations See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Description and Operation/Brake System, Abbreviations.

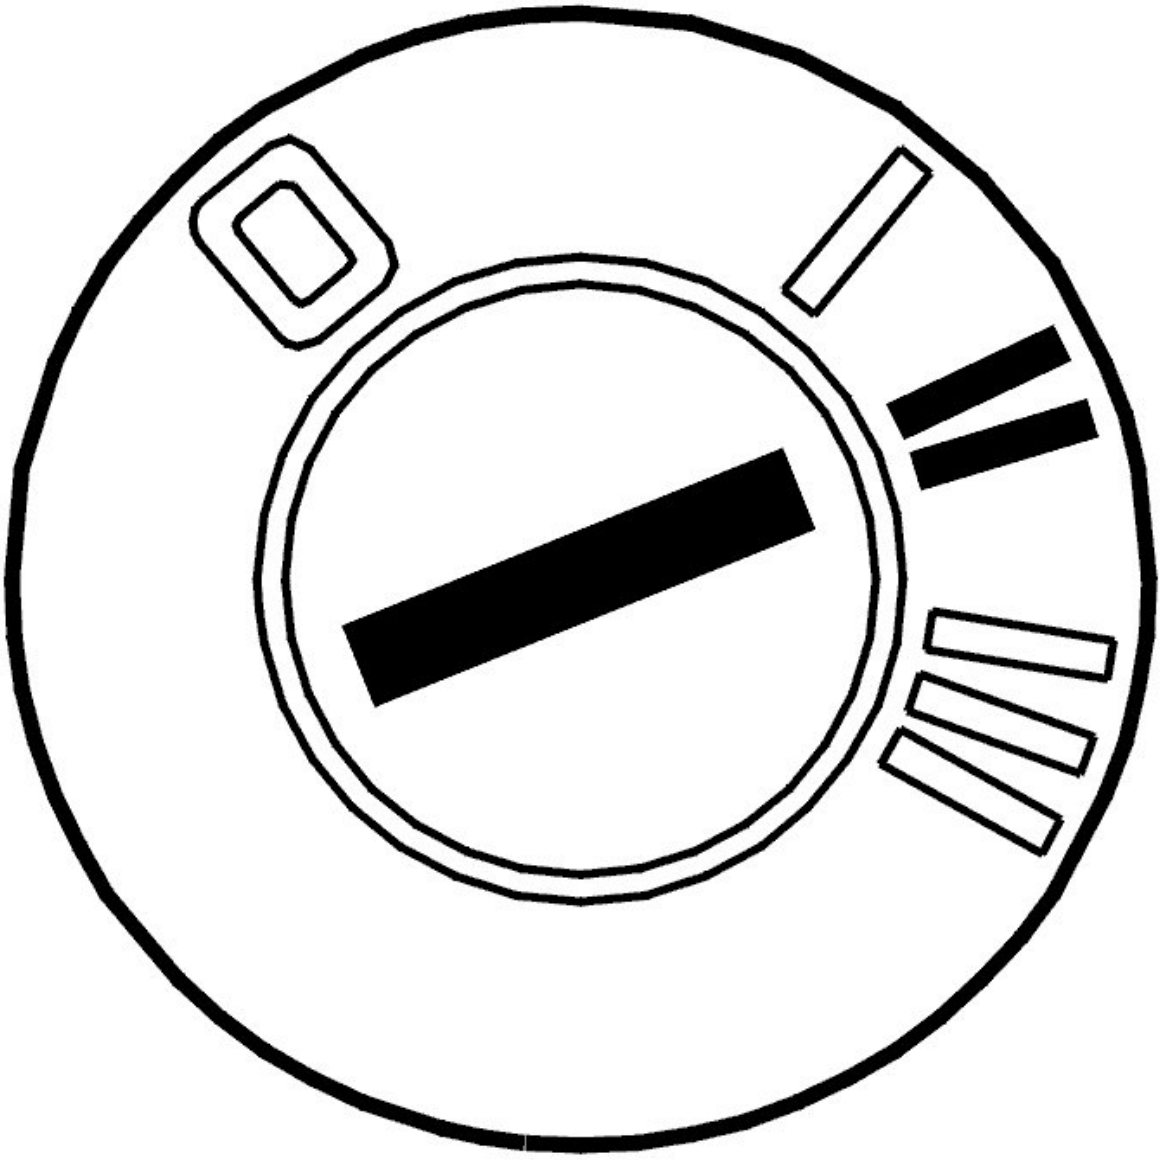
Possible source
- Contact resistance or oxidation in the terminals or connections
- Short-circuit to ground or supply voltage in the wiring
- Incorrectly installed sensor
- Defective pressure build-up valve
- Internal fault in the control module.

Fault symptom[s]
- General warning lamp lit
- The anti-spin warning lamp is lit (up to and including 2002 model year)
- Anti-spin does not function
- The stability control system does not function
- The traction control system does not function.

Signal Outside Its Permitted Range

Signal outside its permitted range

Checking the connectors



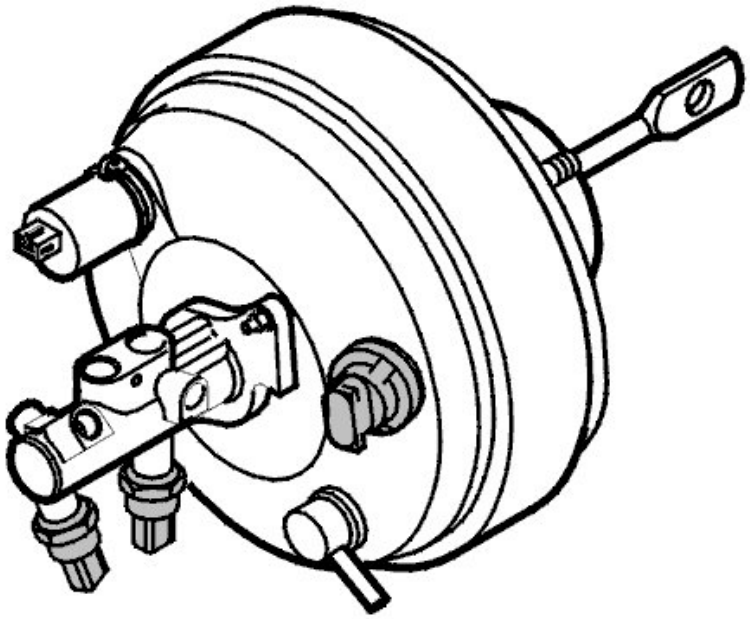
- Ignition off
- Check the connectors of the brake control module (BCM) and the pressure build-up valve/pedal pressure sensor for contact resistance and oxidation.
- Reinstall the components, reconnect the connectors etc.
- Ignition on

- Use the Activation function to activate the pressure build-up valve.

A mechanical pumping sound should be audible from the engine compartment and the pedal should move slightly.

Other information

- For removal of the control module connectors: Connecting the breakout box, brake control module (BCM) See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box/Connecting the Breakout Box, Brake Control Module (BCM)
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals



Was the function OK?

Yes - Fault Found

No - Checking wiring and sensors

Checking wiring and sensors

Check the cables between the pressure build-up valve:

- #3 and brake control module (BCM) #31 (#A31)
- #4 and brake control module (BCM) #17 (#A17)

check for an open-circuit, a short-circuit to ground and a short-circuit to supply voltage.

Hint: Check the pressure build-up valve by, with the ignition off and the breakout box connected, reading the resistance between terminals #17 and #31 on the breakout box. Resistance must be approximately 3ohms.

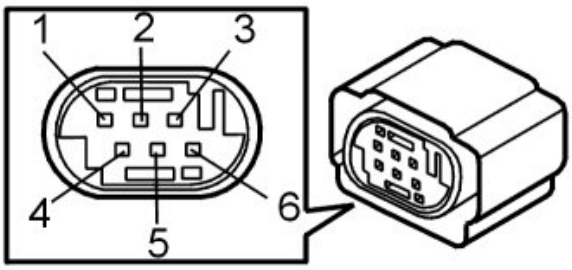
Remedy as necessary.

Other information

- Connecting the breakout box, brake control module (BCM) See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box/Connecting the Breakout Box,

Brake Control Module (BCM)

- For replacing the pressure build-up valve (brake booster): Power brake booster, replacing See: Brakes and Traction Control/Power Brake Assist/Vacuum Brake Booster/Service and Repair/Power Brake Booster, Replacing



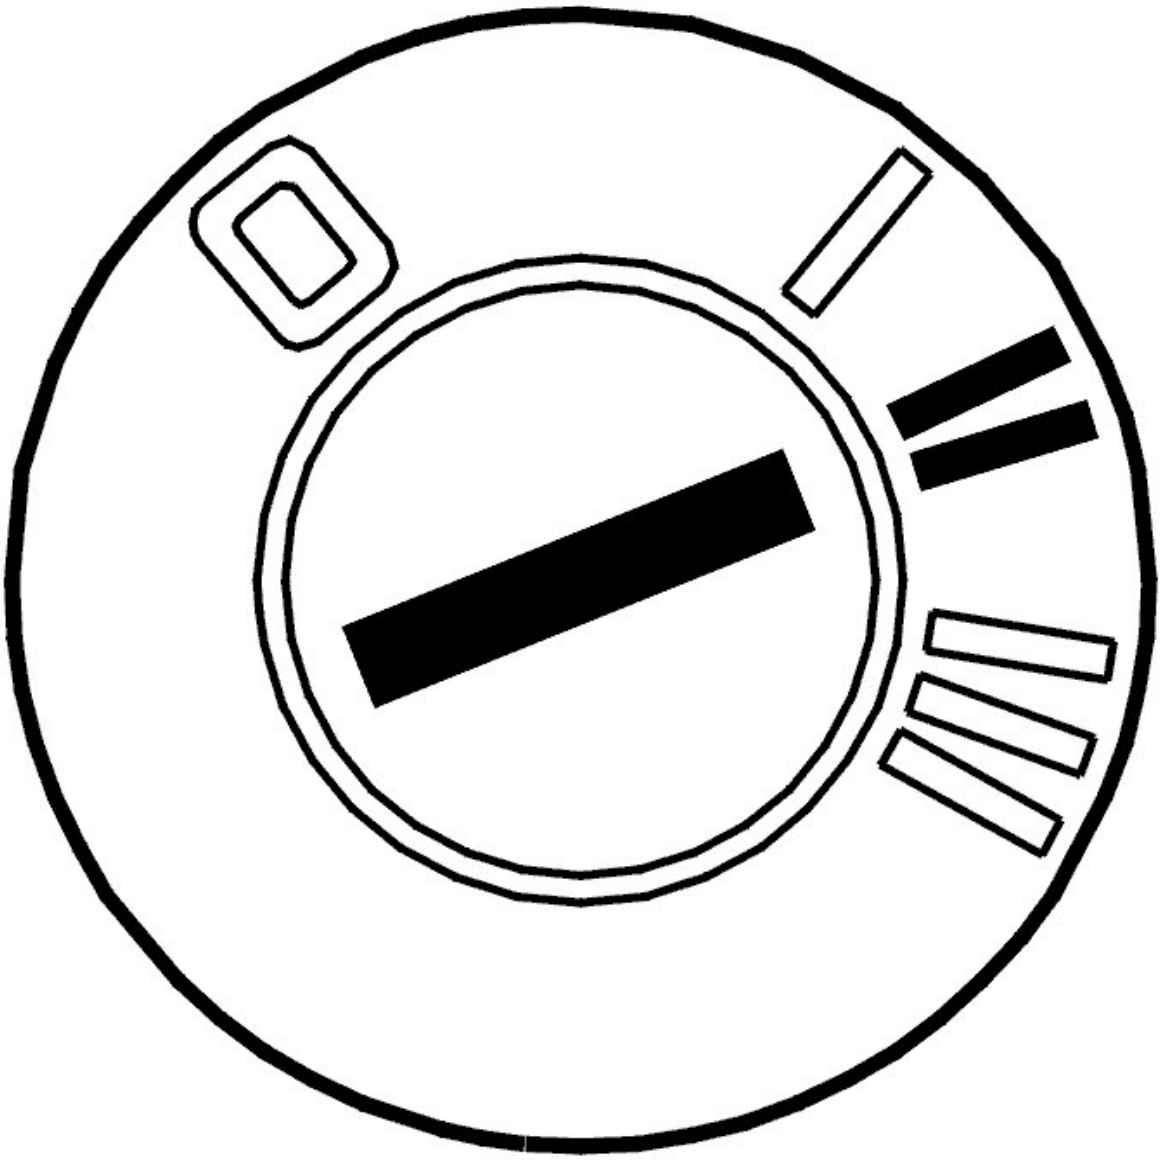
Was a fault detected?

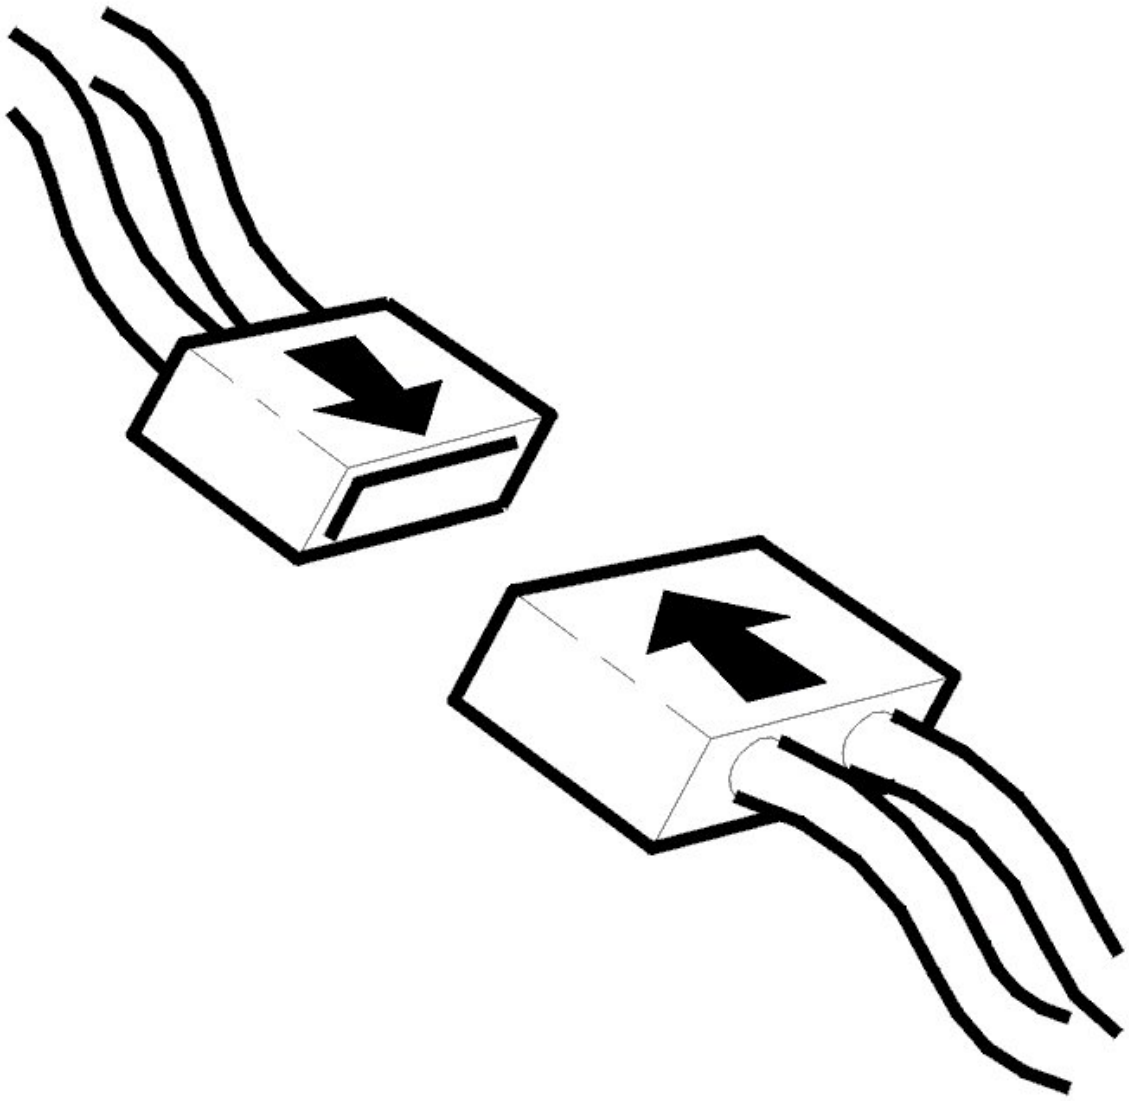
Yes - Verification

No - No Fault Found

Verification

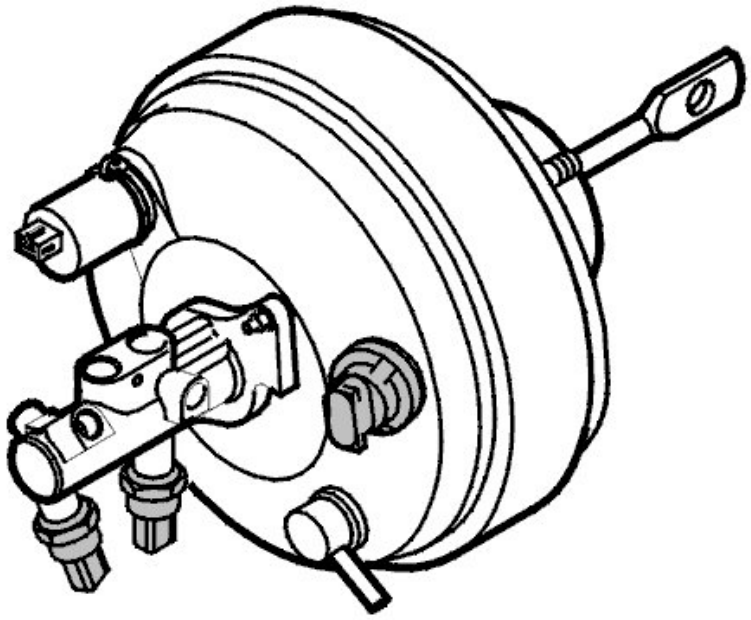
Hint: After carrying out the repair, check that the fault has been remedied.





- Ignition off
- Reinstall the components, reconnect the connectors etc.
- Ignition on
- Use the Activation function to activate the pressure build-up valve.

A mechanical pumping sound should be audible from the engine compartment and the pedal should move slightly.



Was the function OK?

Yes - Fault Found

No - Fault-tracing information

Fault-tracing information

Information

Fault-tracing information

The fault should have been detected and remedied. As this is not the case fault-tracing has failed.
Exit fault-tracing for this diagnostic trouble code (DTC) or make another attempt.

Do you want to exit fault-tracing?

Yes - FAULT-TRACING FAILED

No - Attempt New Test

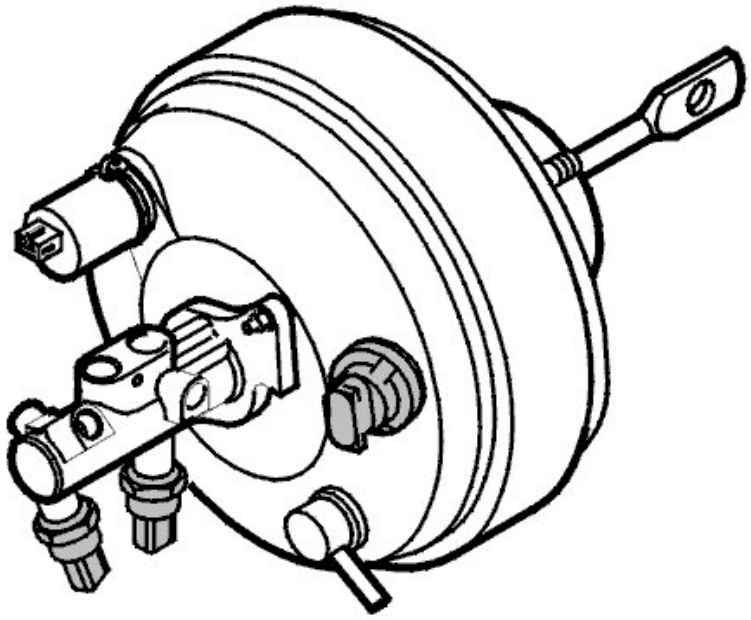
FAULT-TRACING FAILED - FAULT-TRACING FAILED

Attempt New Test - Checking the connectors

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition



Note! This diagnostic trouble code (DTC) applies only to brake systems with dynamic stability and traction control (DSTC).

The pedal pressure sensor is located in the power brake booster and informs the brake control module (BCM) when the brake pedal is pressed. The control module uses the information to disengage active yaw control and active brake assistance if the functions are activated and the driver presses the brake pedal.
Diagnostic trouble code (DTC) BCM-0140 is stored if the control module registers an implausible signal from the pedal pressure sensor.

Substitute value
- Traction control is blocked
- Stability control is blocked
- Active yaw control is blocked
- Brake assistance is blocked.

Hint: For information about abbreviations, see Brake system, abbreviations See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Description and Operation/Brake System, Abbreviations.

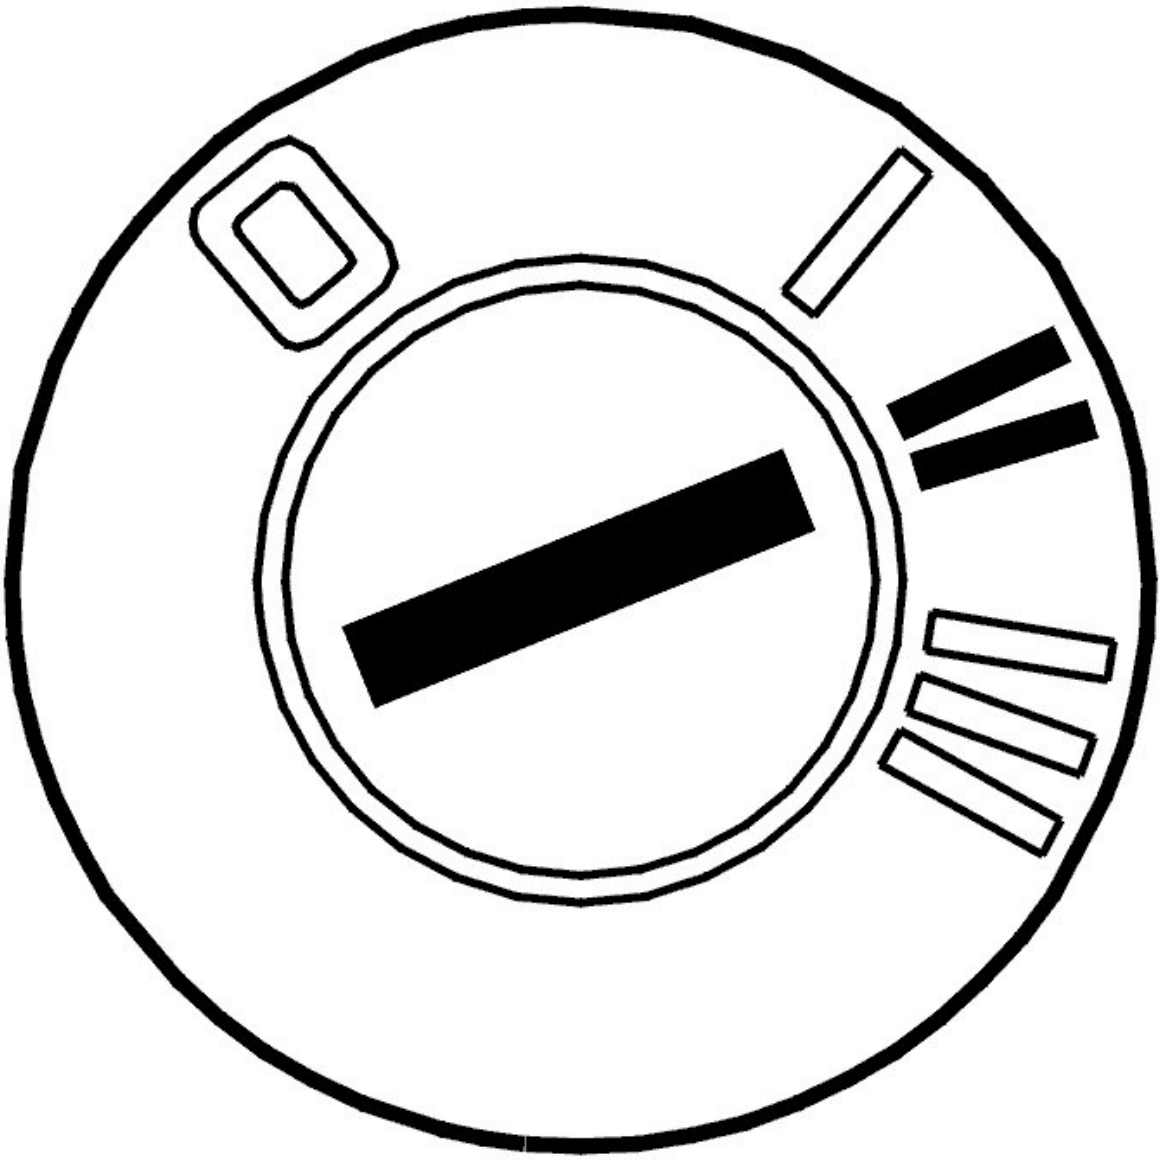
Possible source
- Contact resistance or oxidation in the terminals or connections
- Open-circuit in the wiring
- Short-circuit to ground or supply voltage in the wiring
- Defective pedal pressure sensor
- Defective brake control module (BCM).

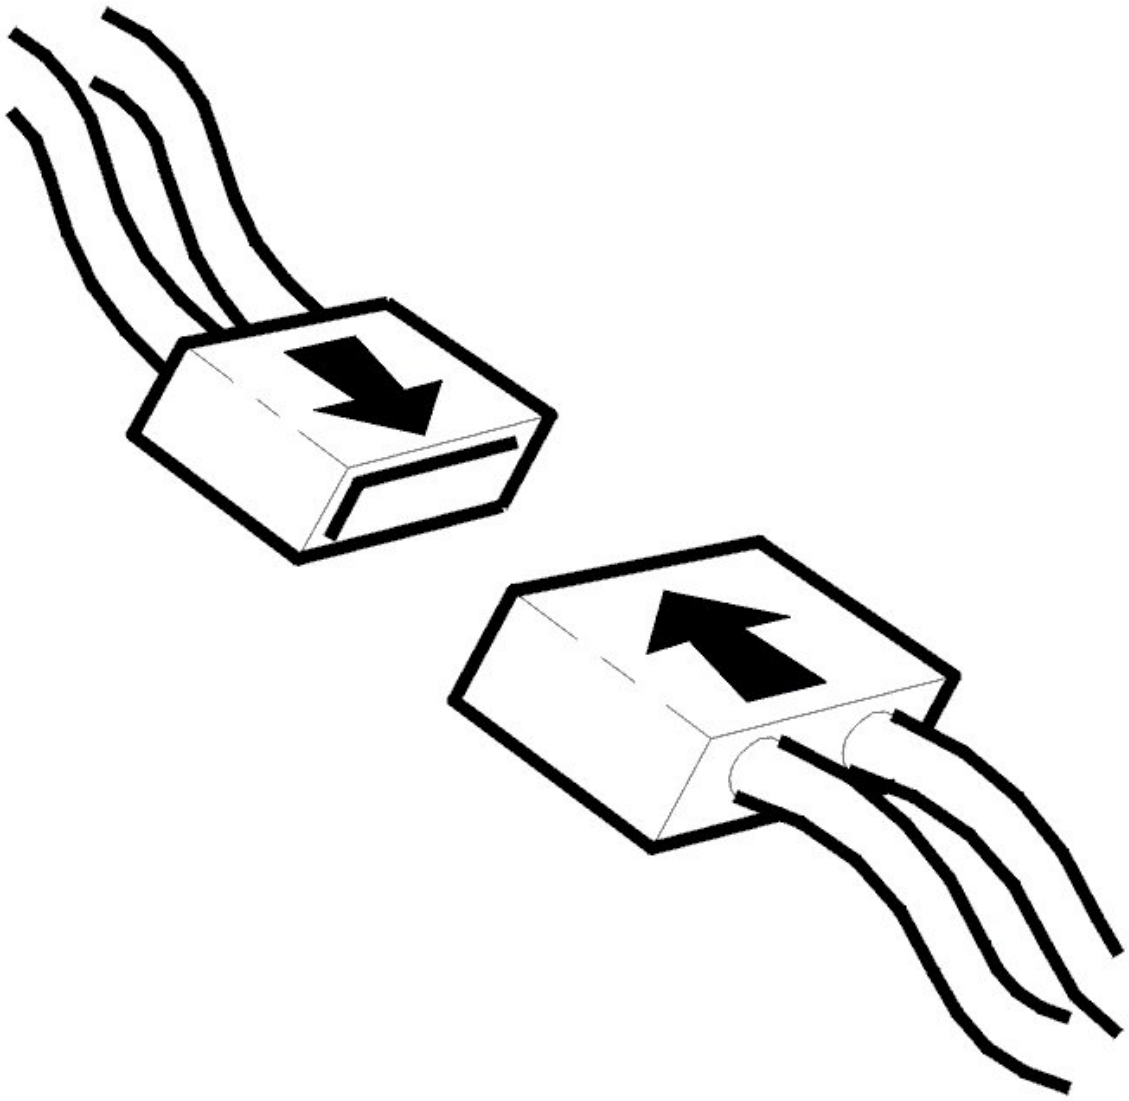
Fault symptom[s]
- The anti-spin warning lamp is lit (up to and including 2002 model year)
- General warning lamp lit
- Anti-spin does not function
- The stability control system does not function
- The traction control system does not function.

Signal Outside Its Permitted Range

Signal outside its permitted range

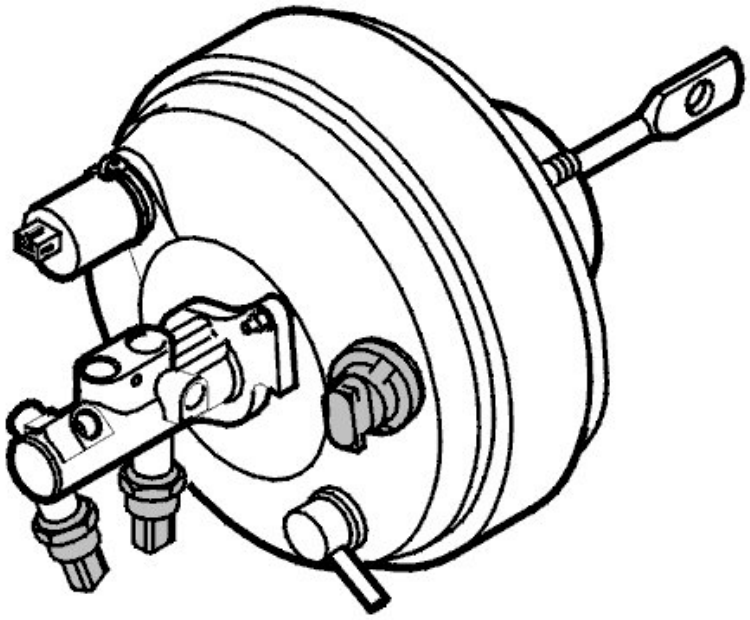
Checking the connectors





- Ignition off
- Check the brake control module (BCM) and pedal pressure sensor connectors. Check for contact resistance and oxidation
- Reinstall the components, reconnect the connectors etc.
- Ignition on
- Read off the status of the pedal pressure sensor.

The status must be OFF with the brake pedal unaffected and change to ON when the brake pedal is pressed. If the status changes, the cause of the fault was probably contact resistance or oxidation in the control module or in the pedal pressure sensor connectors.



Does the status change?

Yes - Fault Found

No - Checking the wiring

Checking the wiring

Check the wiring between the pedal pressure sensor:
- terminal #1 and control module terminal #27 (#A27)
- terminal #2 and control module terminal #30 (#A30)
- terminal #5 and control module terminal #28 (#A28).

check for an open-circuit, a short-circuit to ground and a short-circuit to supply voltage.
Remedy as necessary.

Other information
- To connect the breakout box, see Connecting the breakout box, brake control module (BCM) See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box/Connecting the Breakout Box, Brake Control Module (BCM)
- To fault-trace the wiring and connections, see Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals
- To replace the pedal pressure sensor (power brake booster), see Power brake booster, replacing See: Brakes and Traction Control/Power Brake Assist/Vacuum Brake Booster/Service and Repair/Power Brake Booster, Replacing
- For information about signals, see Signal specification, brake control module (BCM) with DSTC (dynamic stability and traction control) See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Specification.

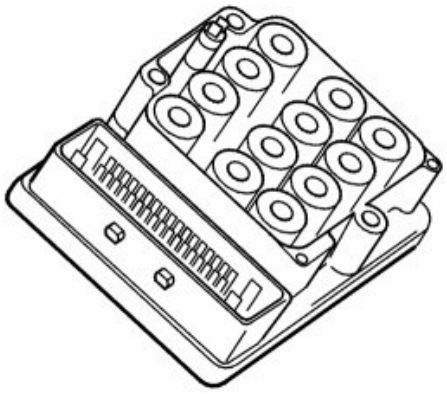
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition



Note! The diagnostic trouble code (DTC) applies only to cars with dynamic stability and traction control (DSTC).

Diagnostic trouble code (DTC) BCM-0145 is stored If the brake control module (BCM) registers that the stability function operates for more than 15 seconds non-stop.

Substitute value
- Traction control is blocked
- Stability control is blocked
- Active yaw control is blocked.

Hint: For information about abbreviations, see Brake system, abbreviations See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Description and Operation/Brake System, Abbreviations.

Possible source
- Incorrectly installed steering wheel
- Incorrect wheel alignment
- Loose or incorrectly installed active yaw control sensor
- Defective active yaw control sensor.

Note! This diagnostic trouble code (DTC) is not due to an internal hardware fault in the Brake control module (BCM) and must not be remedied by replacing the control module.

Fault symptom[s]
- The anti-spin warning lamp is lit (up to and including 2002 model year)

- General yellow warning lamp lit (from model year 2003 inclusive)
- Anti-spin does not function
- The stability control system does not function
- The traction control system does not function.

Too Long Stability Control

Too long stability control

Visually checking the brakes

Hint: The diagnostic trouble code (DTC) indicates that the stability function has been active for too long.

Check the front and rear brakes. Check there is no overheating damage to brake caliper, brake pads or brake disc. Replace damaged components. Tell the customer why the anti-spin function was temporarily blocked and why the ABS warning lamp was lit.

Other information

- To remove or replace brake calipers, see Brake calipers front, replacing See: Brakes and Traction Control/Disc Brake System/Brake Caliper/Service and Repair/Removal and Replacement and Brake calipers rear, replacing See: Brakes and Traction Control/Disc Brake System/Brake Caliper/Service and Repair/Removal and Replacement
- To remove or replace brake pad, see Brake pads front, replacing See: Brakes and Traction Control/Disc Brake System/Brake Pad/Service and Repair and Brake pads rear, replacing See: Brakes and Traction Control/Disc Brake System/Brake Pad/Service and Repair
- To remove or replace brake disc, see Brake disc front, replacing See: Brakes and Traction Control/Disc Brake System/Brake Rotor/Disc/Service and Repair and Brake discs rear, replacing See: Brakes and Traction Control/Disc Brake System/Brake Rotor/Disc/Service and Repair.

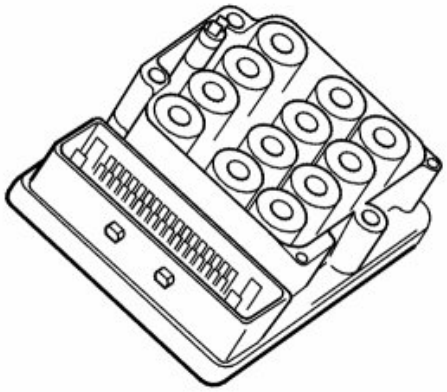
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition



Note! The diagnostic trouble code (DTC) applies only to cars with dynamic stability and traction control (DSTC).

Diagnostic trouble code (DTC) BCM-0146 is stored if the brake control module (BCM) registers that the factory test was not completed.

Substitute value

- Traction control is blocked
- Stability control is blocked
- Active yaw control is blocked.

Hint: For information about abbreviations, see Brake system, abbreviations See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Description and Operation/Brake System, Abbreviations.

Possible source

- Active yaw control operation during the factory test
- Factory test not completed satisfactorily.

Note! This diagnostic trouble code (DTC) is not due to an internal hardware fault in the Brake control module (BCM) and must not be remedied by replacing the control module.

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

Fault symptom[s]
- The anti-spin warning lamp is lit (up to and including 2002 model year)
- General yellow warning lamp lit (from model year 2003 inclusive)
- Anti-spin does not function
- The stability control system does not function
- The traction control system does not function.

Test Cycle Not Approved

Test cycle not approved

Fault-tracing information

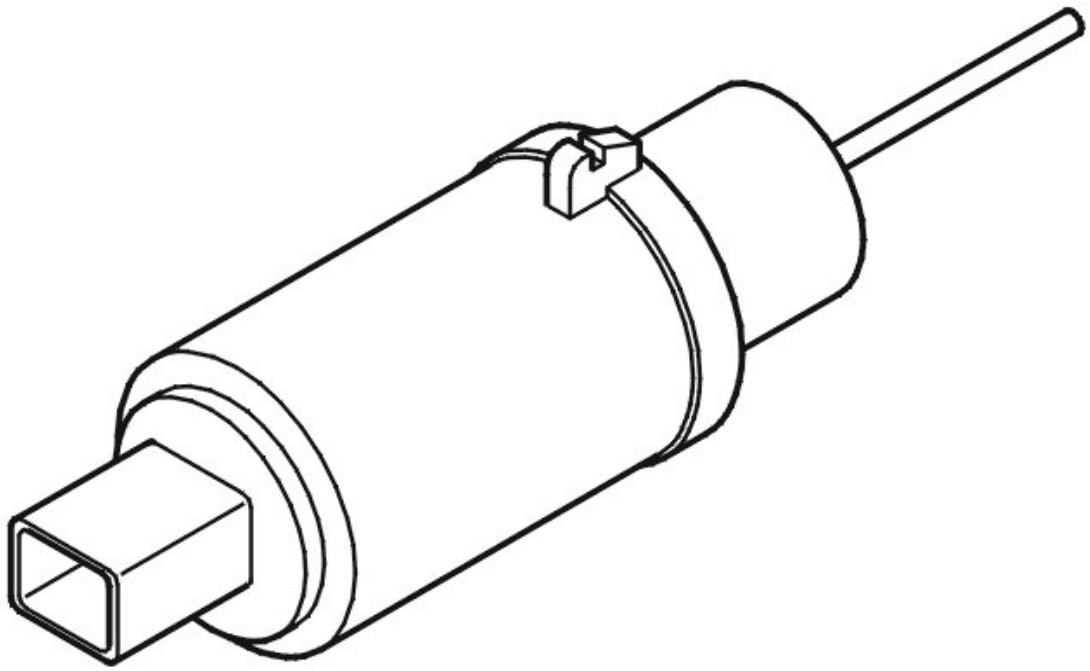
The diagnostic trouble code (DTC) indicates that active yaw control has been active. This means that the test cycle was not completed correctly and must be repeated.

Continue - DONE

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition



The brake pedal position sensor is part of "Active brake assistance". The sensor transmits a signal to the brake control module about the position of the brake pedal and the speed at which it is pressed. These signals are required to determine how much brake power is required in each brake situation.
The pedal position sensor is included on cars without brake assistance and is then used by the control module to check the operation of the stop lamp switch.
Diagnostic trouble code (DTC) BCM-0147 is stored if the control module registers a faulty signal from the pedal position sensor.
The diagnostic trouble code (DTC) can be diagnosed after the brake pedal has been depressed to the maximum, the engine has been started, and the brake pedal released. After having been stationary for approximately 10 seconds and then driven faster than 10 km/h for at least 10 seconds. Then stopped the car by braking.

Substitute value
- Brake assistance is blocked.

Hint: For information about abbreviations, see Brake system, abbreviations See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Description and Operation/Brake System, Abbreviations.

Possible source

- Open-circuit in the wiring
- Short-circuit to ground or supply voltage in the wiring
- Incorrectly installed pedal position sensor
- Defective pedal position sensor
- Defective brake control module.

Fault symptom[s]

- General yellow warning lamp lit.

Faulty Signal

Faulty signal

Checking diagnostic trouble codes in the central electronic module (CEM) and the engine control module (ECM)

If there are diagnostic trouble codes (DTCs) for the brake pedal position sensor or stop lamp switch stored in the engine control module (ECM) or central electronic module (CEM), these must be fault traced first.

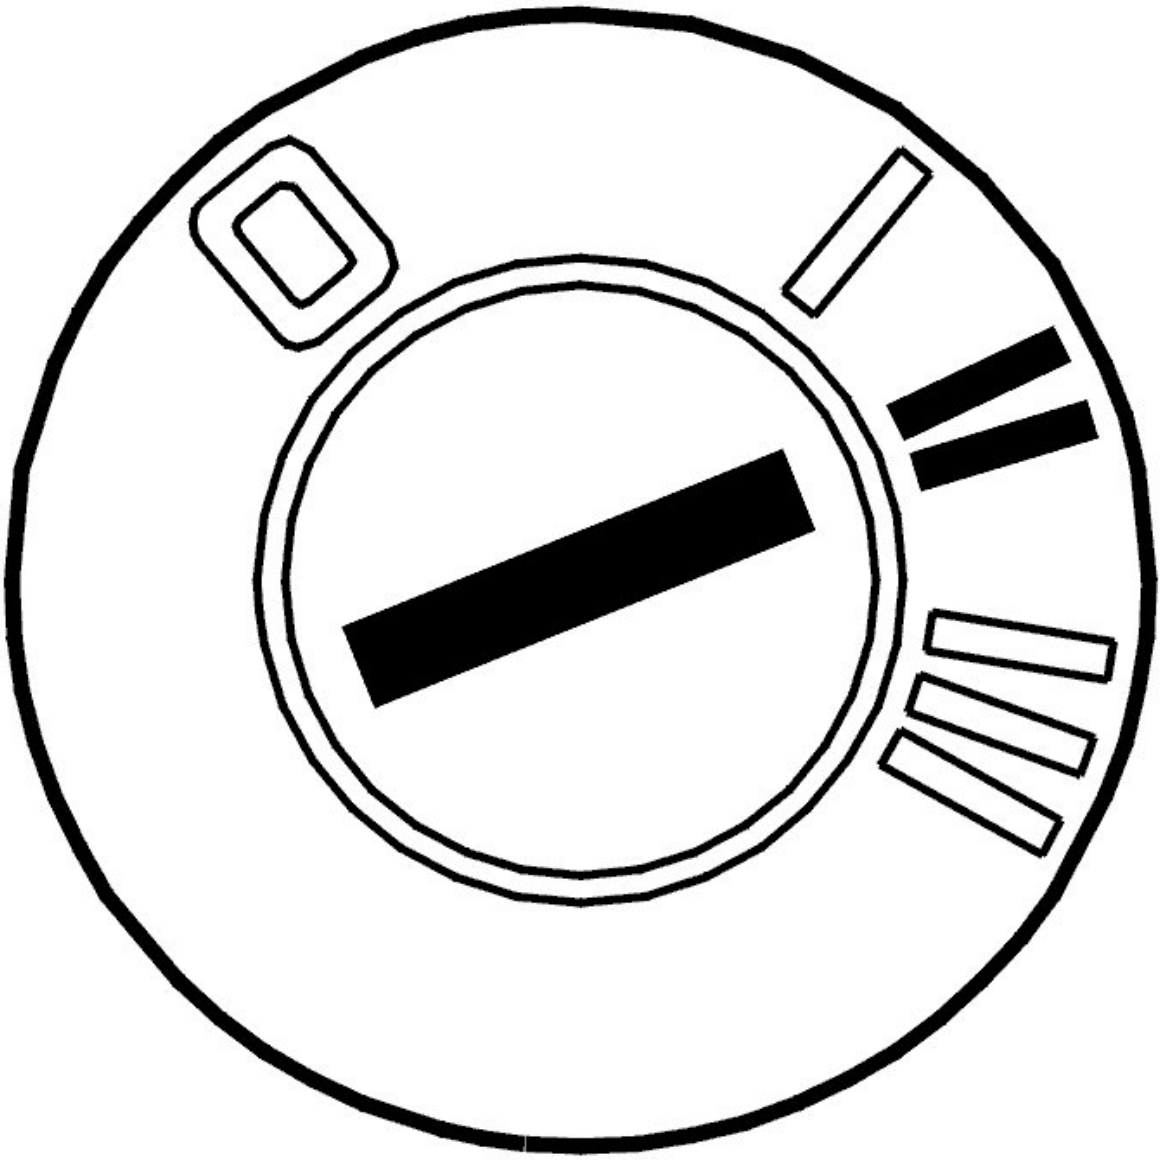
Were diagnostic trouble codes (DTCs) stored for the pedal position sensor or the stop lamp switch?

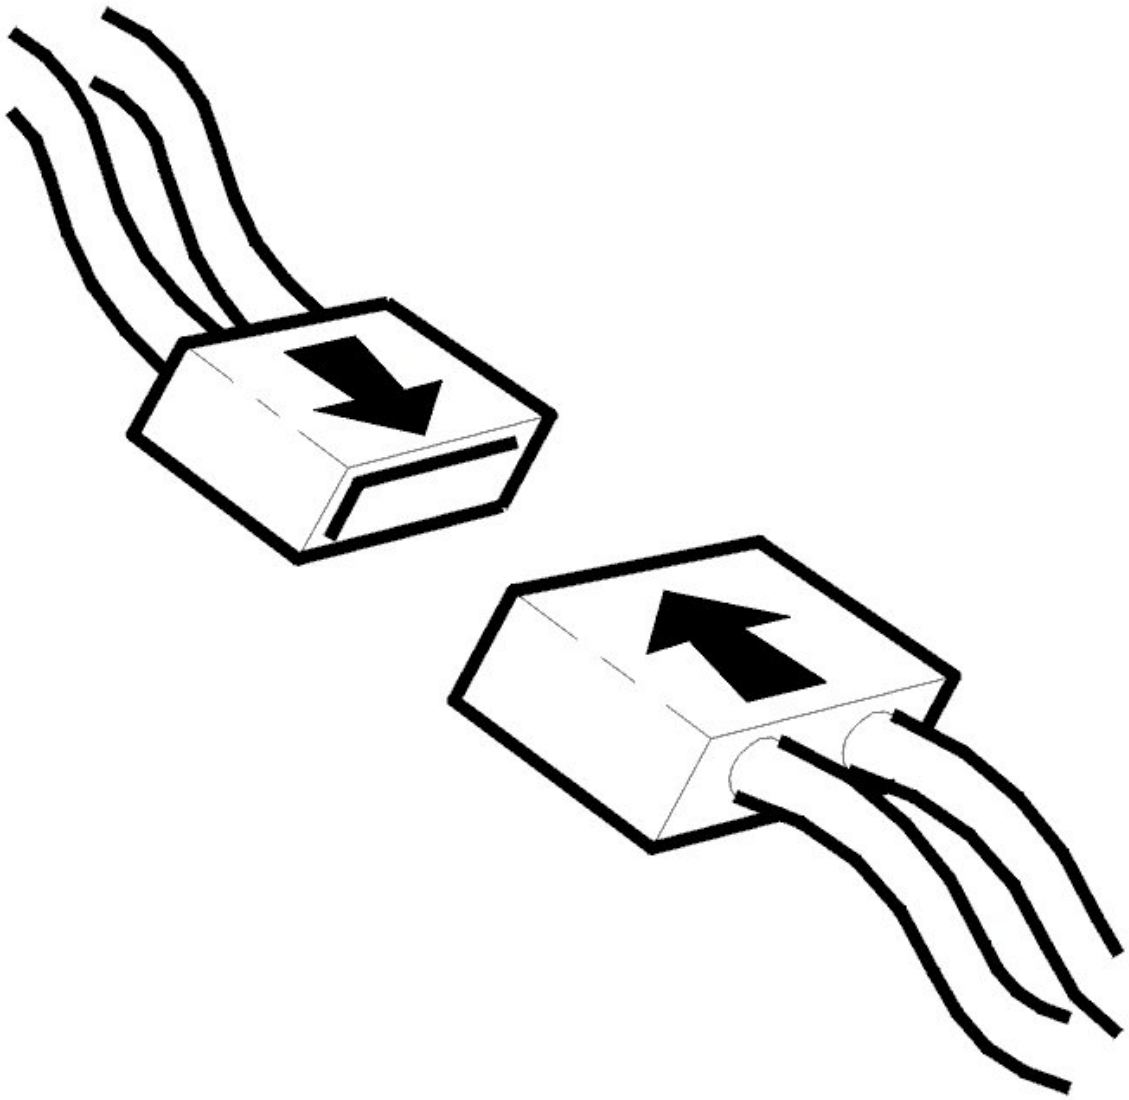
Yes - DONE

No - Checking the control module and sensor connectors

Checking the control module and sensor connectors

Hint: The cause of the diagnostic trouble code (DTC) may be in the circuit for the stop lamp switch or for the pedal position sensor.





- Ignition off
- Check the connectors for the brake control module (BCM), the stop lamp switch and the pedal position sensor. Check for contact resistance and oxidation
- Reinstall the components, reconnect the connectors etc.
- Ignition on
- Read off the status of the stop lamp switch and the position of the pedal position sensor.

Depress and release the brake pedal. The value must change between OFF and ON and the position of the pedal position sensor must be updated.

Other information

- To disconnect the connector for the brake control module (BCM), see Connecting the breakout box, brake control module (BCM) See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box/Connecting the Breakout Box, Brake Control Module (BCM)
- To access the stop lamp switch, see Stop lamp switch, replacing See: Lighting and Horns/Brake Light Switch/Service and Repair
- To access the pedal position sensor, see Pedal sensor power brake booster, replacing See: Brakes and Traction Control/Power Brake Assist/Brake Booster Vacuum Sensor/Service and Repair
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

Select an option:

1. The value for the stop lamp switch does not change
2. The value for the pedal position sensor is not updated
3. These values are OK.

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

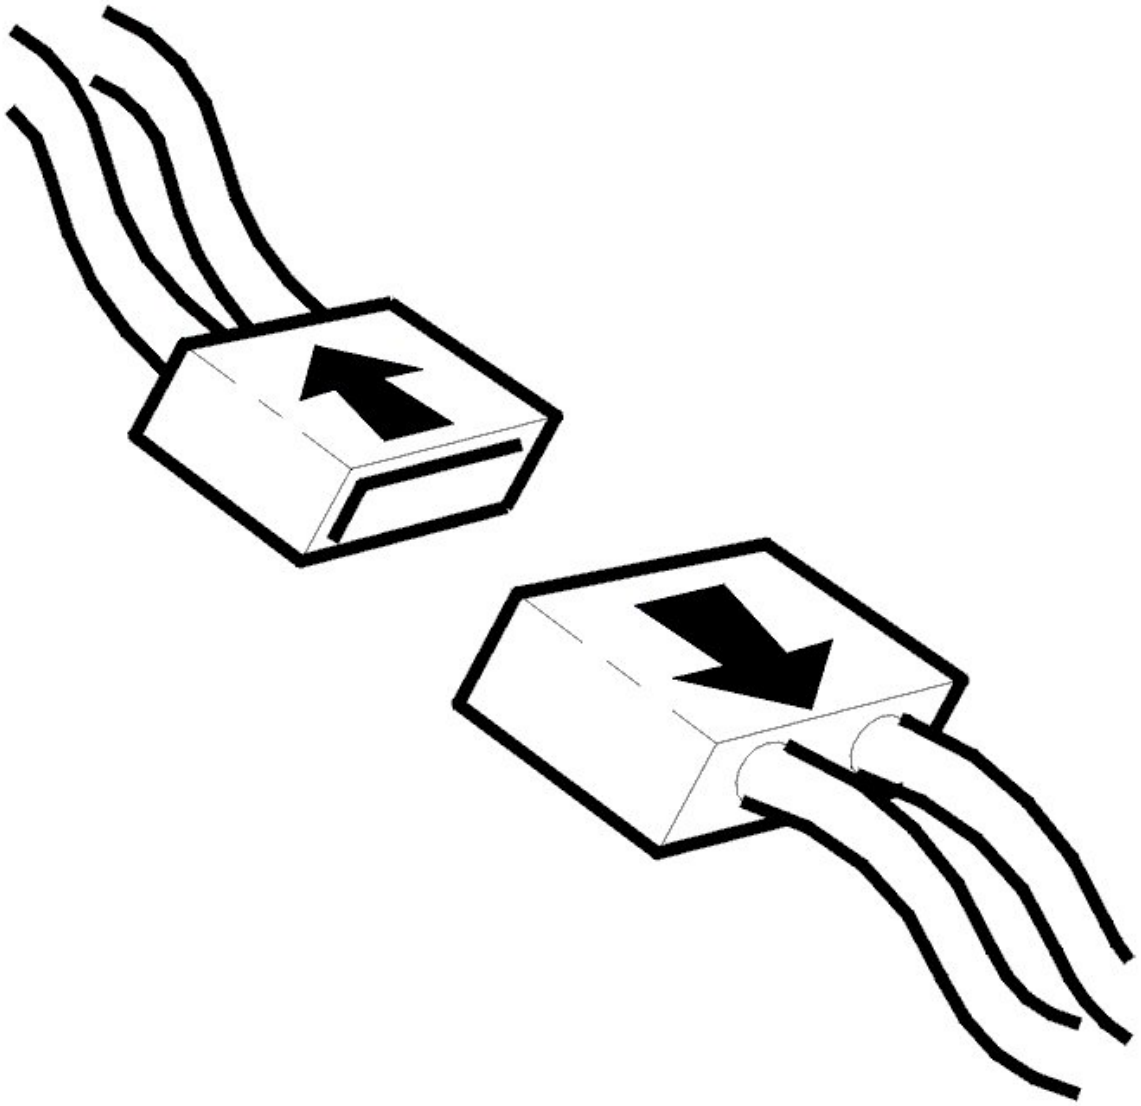
Does the value change?

1 - Checking the fuse, wiring and sensors

2 - Signal outside its permitted range

3 - **No Fault Found**

Checking the fuse, wiring and sensors



Check that the fuse for the stop lamp circuit is intact. If the fuse is blown, first check the circuit for the stop lamp switch before replacing the fuse. Check for a short-circuit to supply.
If the fuse is intact, check the circuit for the stop lamp switch. Check for an open-circuit and a short-circuit to ground.
Remedy as necessary.

Other information

- To connect the breakout box to the brake control module (BCM), see Connecting the breakout box, brake control module (BCM) See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box/Connecting the Breakout Box, Brake Control Module (BCM)
- To connect the breakout box to the Engine control module (ECM), see: Connecting the breakout box, B5244T5, B5254T2 See: Pinout Values and Diagnostic Parameters/Connecting the Breakout Box

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition

Diagnostic trouble code (DTC) BCM-0150 is stored if the brake control module (BCM) registers that the stop (brake) lamp switch is not activated when the brake pedal is depressed.
There are diagnostics for this diagnostic trouble code (DTC) when the ignition is on and in the following cases:

- Braking from a speed in excess of 40 km/h to standstill 3 times in succession within the same ignition cycle without control
- The brake pedal is kept pressed down and the stop lamp switch is activated for longer than 6 minutes.

Substitute value

- None.

Possible source

- Mechanical fault in the stop lamp switch.

Note! This diagnostic trouble code (DTC) is not due to an internal hardware fault in the Brake control module (BCM) and must not be remedied by replacing the control module.

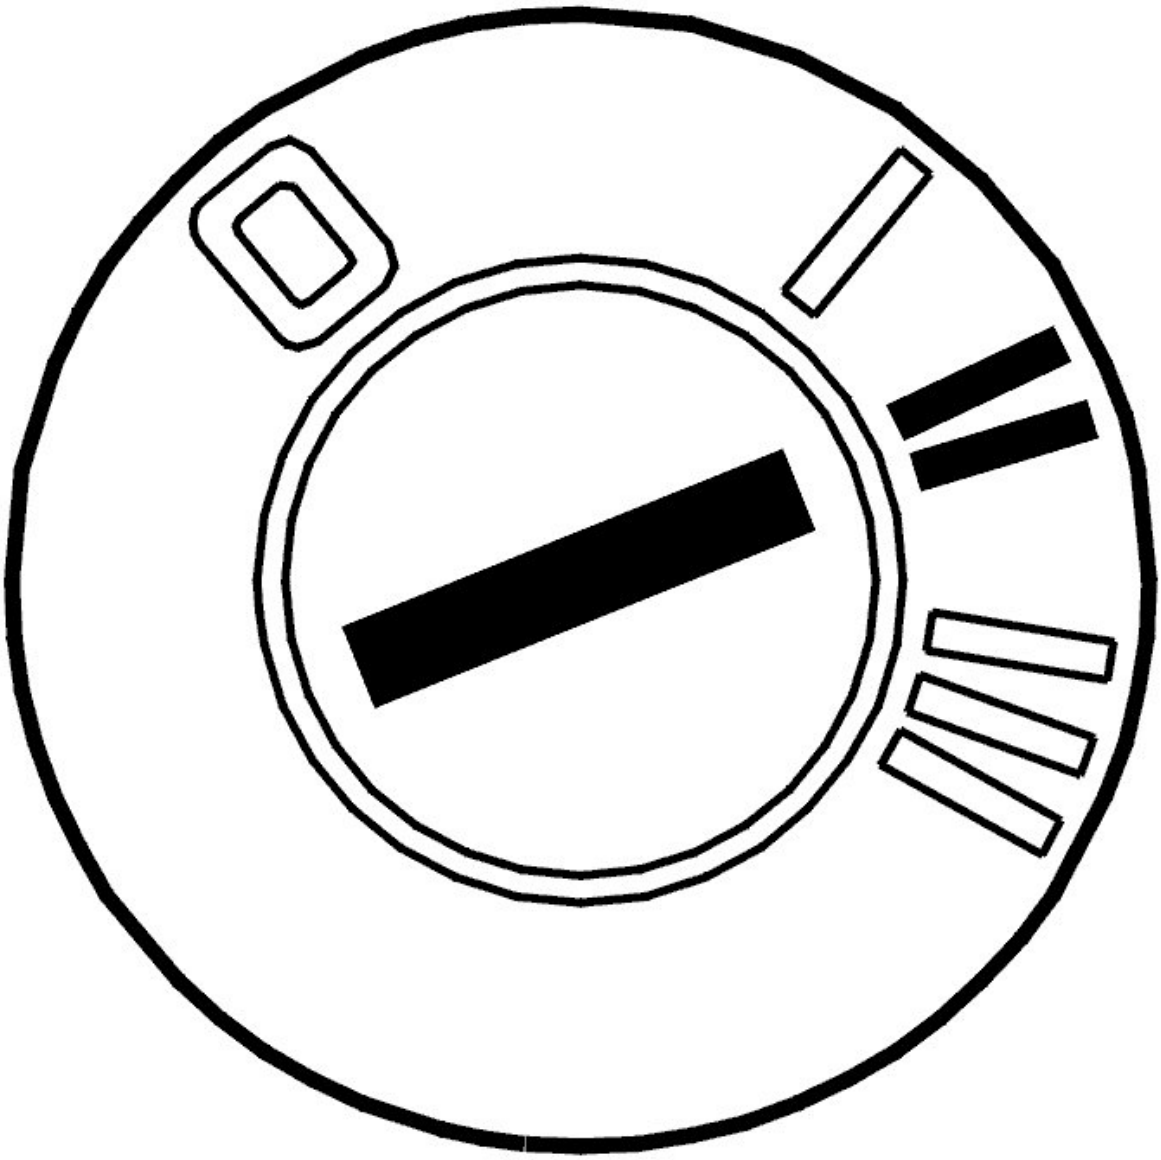
Fault symptom[s]

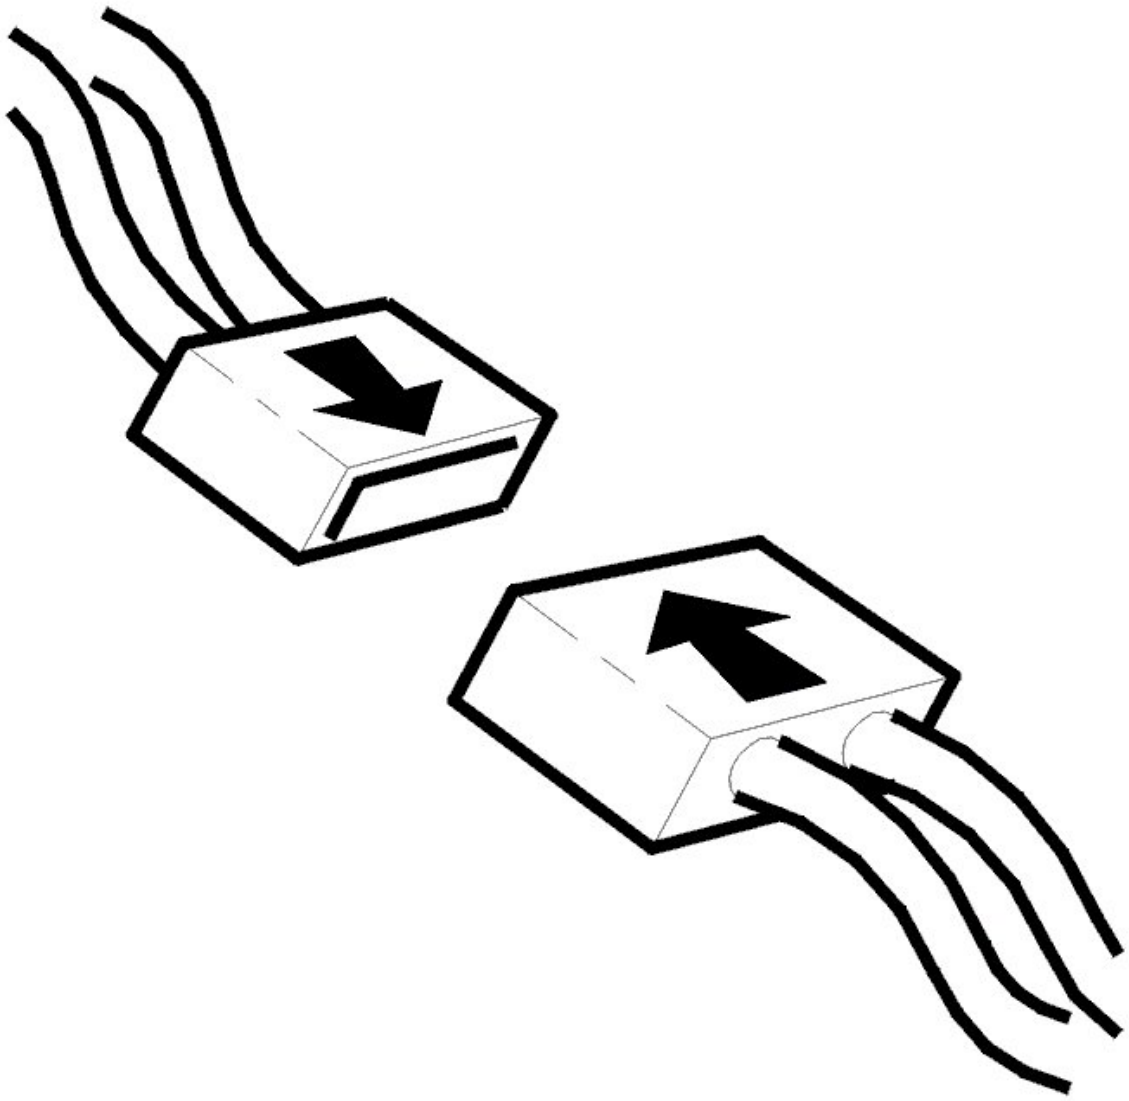
- None.

Signal Outside Its Permitted Range

Signal outside its permitted range

Checking the control module and wheel sensor connectors





- Ignition off
- Check the brake control module (BCM) and stop (brake) lamp switch connectors. Check for contact resistance and oxidation
- Reinstall the components, reconnect the connectors etc.
- Ignition on
- Read off the status of the stop lamp switch.

Depress and release the brake pedal. The value must change between OFF and ON.
If the value changes, the cause of the fault was loose connections in the control module or wheel sensor connectors.

Other information

- For information about removing the brake control module (BCM) connector, see Connecting the breakout box, brake control module (BCM) See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box/Connecting the Breakout Box, Brake Control Module (BCM)
- To fault-trace the wiring and connections, see Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals.

Does the value change?

Yes - Fault Found

No - wiring and sensors

Checking the fuse, wiring and sensors

Check that the fuse for the stop (brake) lamp switch in the integrated relay / fusebox in the engine compartment is intact.
Check the cable between stop lamp switch terminal #1 and the fuse in the integrated relay / fusebox in the engine compartment and between stop lamp switch terminal #5 and the splice. Check for an open-circuit. Check for a short-circuit to ground. Check for a short-circuit to supply voltage.
Check the cable between the splice and central electronic module (CEM) terminal #B4 and between the splice and engine control module (ECM) terminal #B26. Check for an open-circuit. Check for a short-circuit to ground. Check for a short-circuit to supply voltage.

Hint: Check the stop lamp switch by measuring the resistance between terminals #1 and #5 on the stop lamp switch. When the brake pedal is depressed the resistance should be infinite. When the brake pedal is not depressed the resistance should be 0 ohms.

Remedy as necessary.

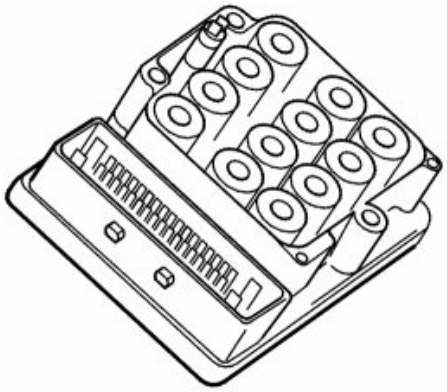
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition



The control modules in the car continually transmit and receive information over the data network (Controller Area Network). When the brake control module (BCM) is supplied with voltage the CAN controller which handles Controller Area Network communication is initialized. Diagnostic trouble code (DTC) BCM-0151 is stored if initialization of the CAN controller fails.
The diagnostic trouble code (DTC) can be diagnosed while the ignition is switched on.

Substitute value
- Traction control is blocked
- Stability control is blocked
- Active yaw control is blocked
- All communication to and from the brake control module (BCM) is shut off.

Hint: For information about abbreviations, see Brake system, abbreviations See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Description and Operation/Brake System, Abbreviations.

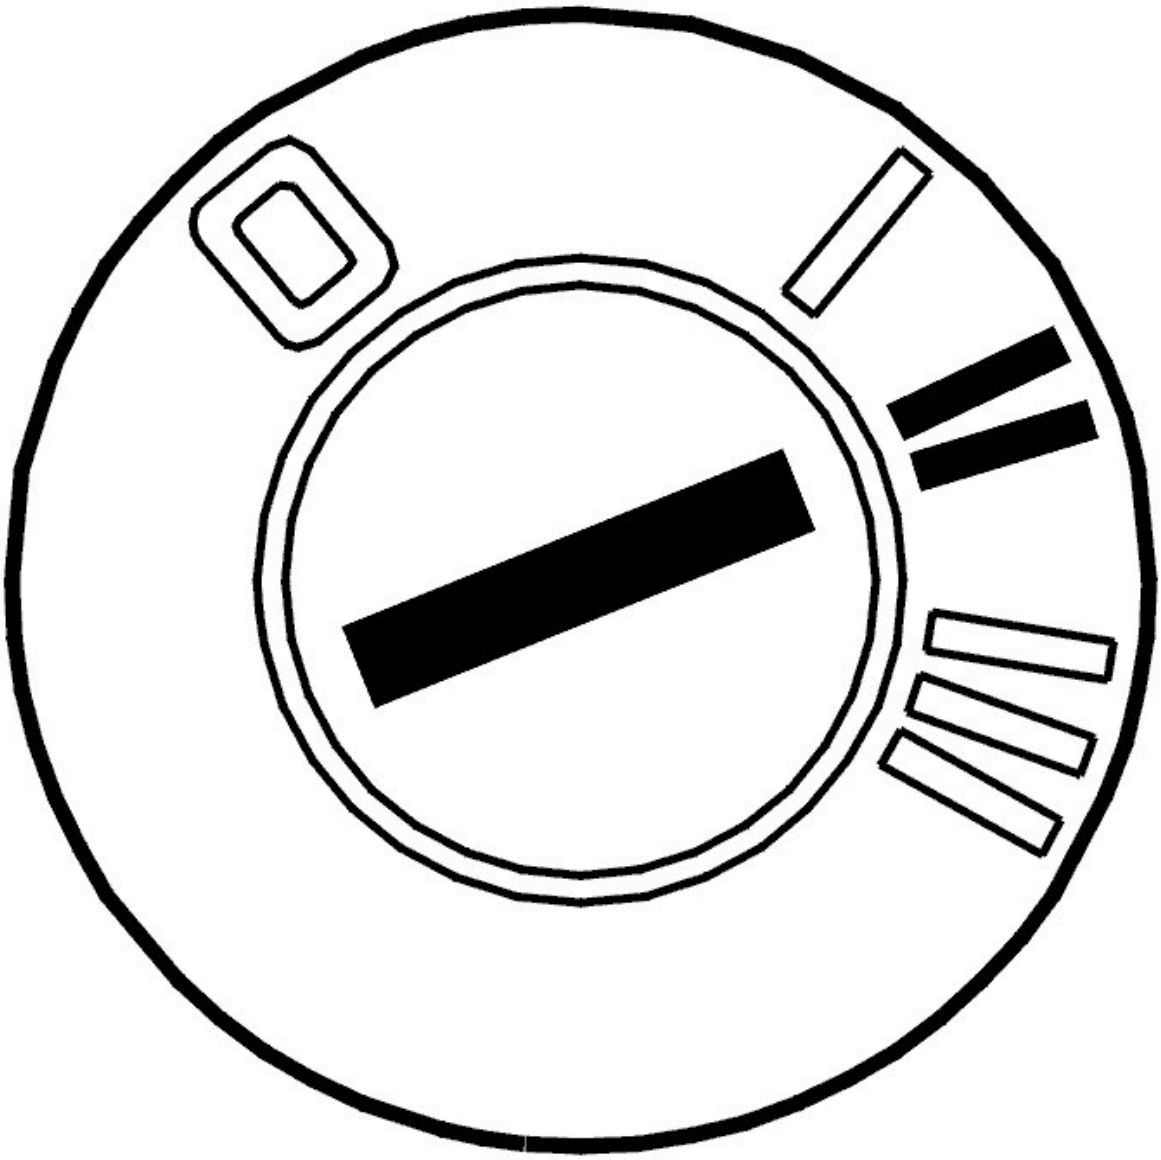
Possible source
- Internal fault in the brake control module (BCM).

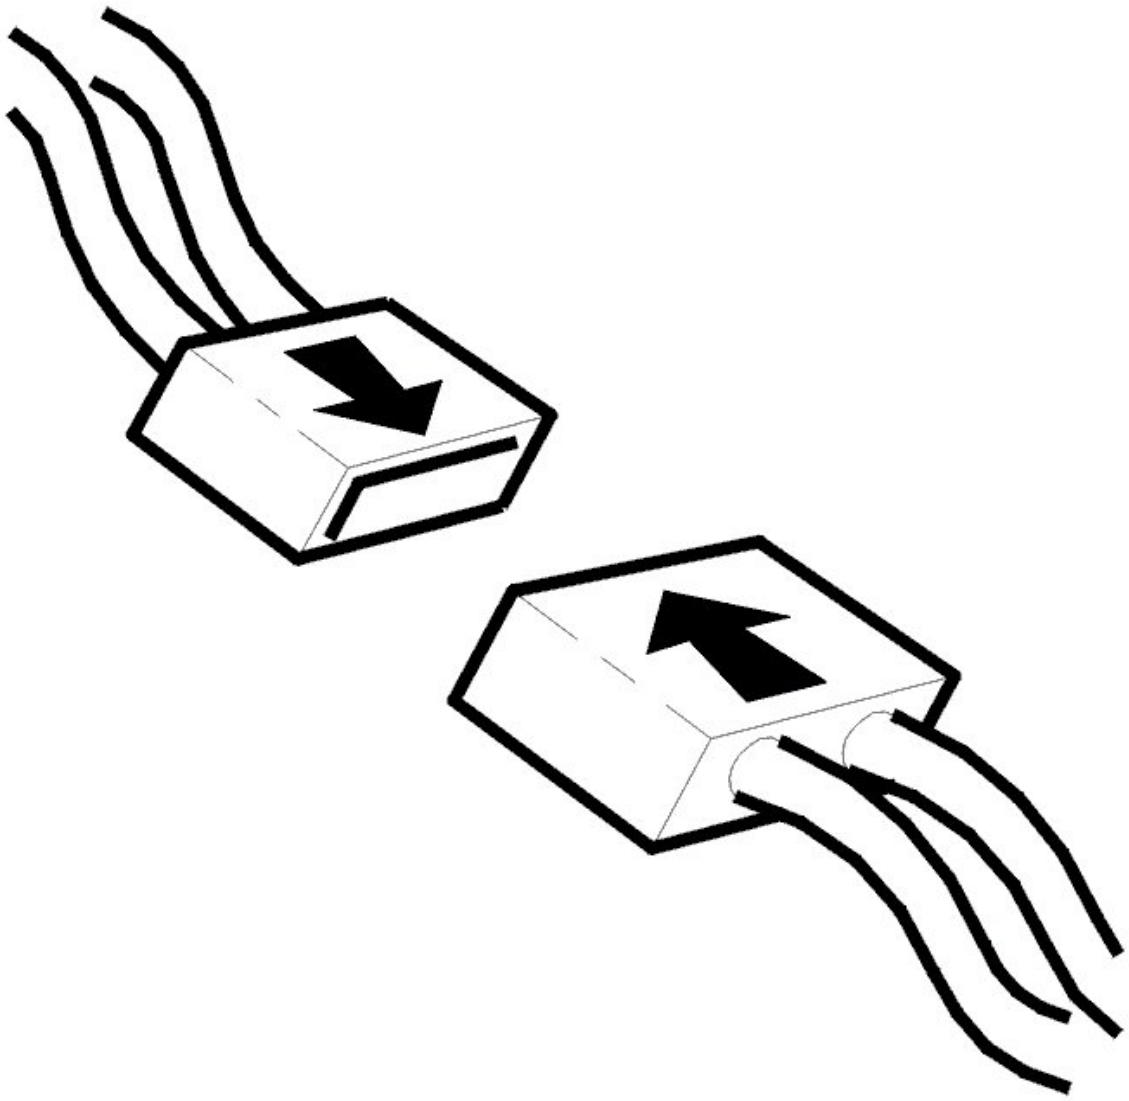
Fault symptom[s]
- The anti-spin warning lamp is lit (up to and including 2002 model year)
- General yellow warning lamp lit (from model year 2003 inclusive)
- The stability control system does not function
- The traction control system does not function.

Internal Memory Fault

Internal memory fault

Checking diagnostic trouble codes (DTCs)





- Ignition off
- Check the brake control module (BCM) connector. Check for contact resistance and oxidation
- Reinstall the components, reconnect the connectors etc.
- Ignition on
- Wait approximately 60 seconds
- Read off the status of the diagnostic trouble code (DTC).

Replace the brake control module (BCM) if the status of the fault is permanent.

Other information

- To access the control module connector, see Connecting the breakout box, brake control module (BCM) See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box/Connecting the Breakout Box, Brake Control Module (BCM)
- To replace the brake control module (BCM), see Brake Control Module (BCM), replacing See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Electronic Brake Control Module/Service and Repair/Brake Control Module (BCM), Replacing
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

Was the status of the diagnostic trouble code (DTC) permanent?

Yes - Fault Found

No - Fault-tracing information

Fault-tracing information

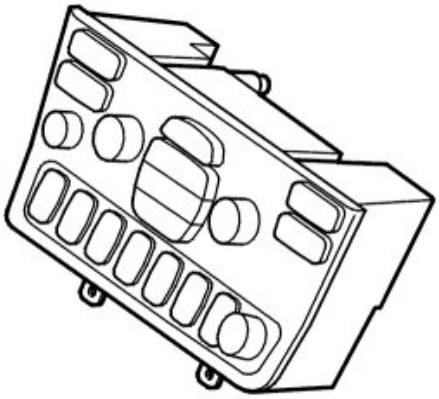
Make a note of the code. Report the code to VIDA customer support.

Continue - DONE

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CCM-DD00

Condition



The diagnostic trouble code (DTC) is stored if the climate control module (CCM) detects that data that is sent on LIN bus 1 is incorrect.
The following components communicate with the climate control module (CCM) via LIN bus 1:

- damper motor module (DMM) air distribution
- damper motor module (DMM) temperature left
- damper motor module (DMM) recirculation (only on right-hand drive cars)
- air quality sensor (AQS) (only on right-hand drive cars)
- seat heating module (SHM) left.

The diagnostic trouble code (DTC) can be diagnosed in ignition positions I and II.

Substitute value

- None.

Possible source

- Incorrect data during communication on LIN bus 1.

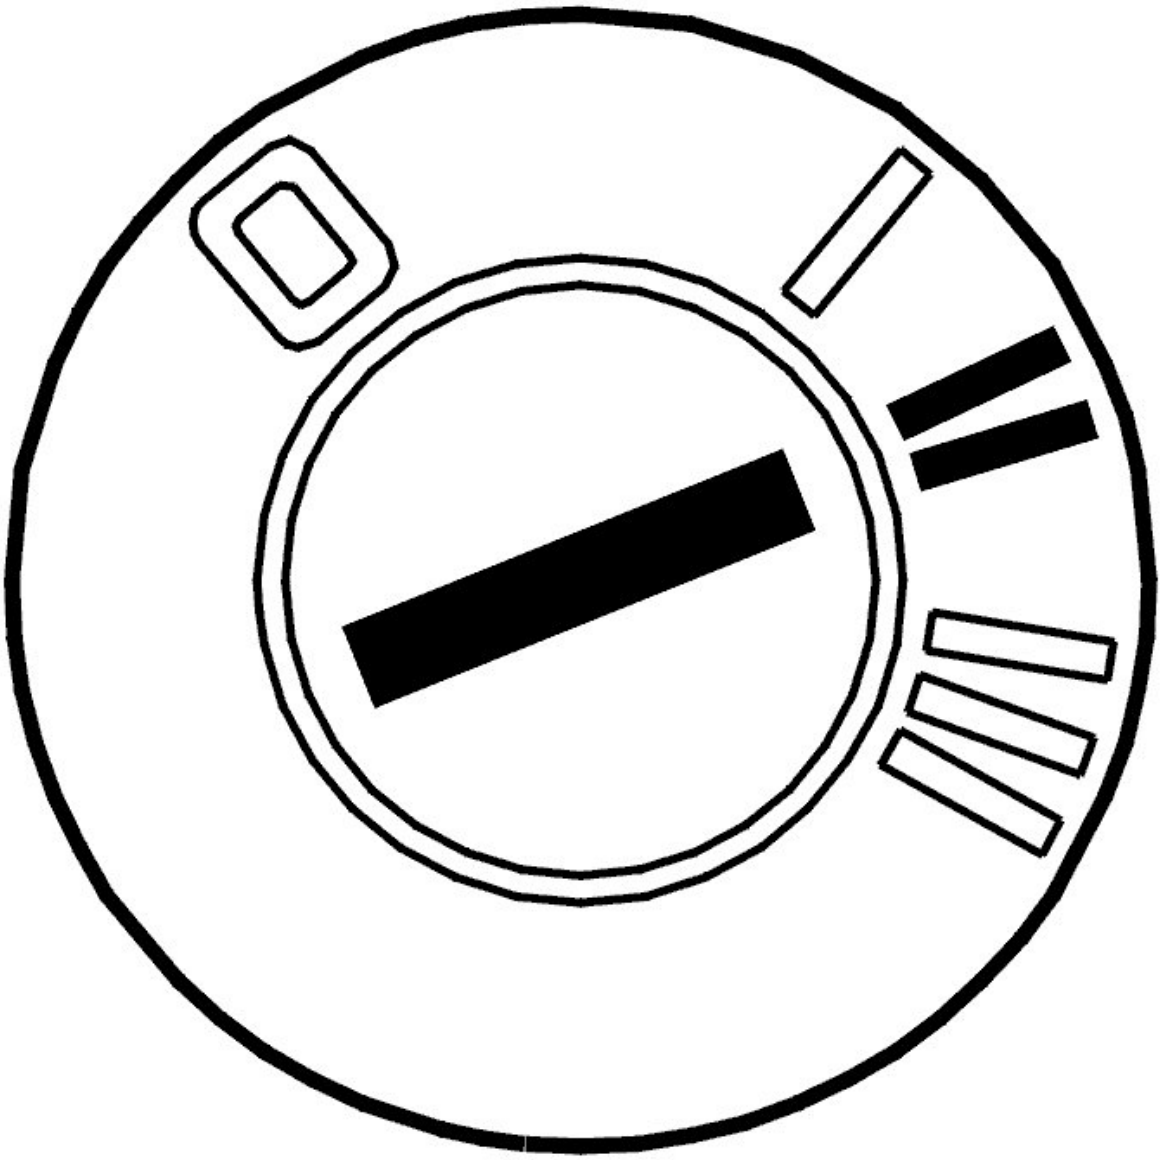
Fault symptom[s]

- Misting on the windows and/or door mirrors.
- Air flow problem.
- Poor heating in the passenger compartment.
- The front seat heating does not function.
- Poor air quality in the passenger compartment.

Incorrect Data

Incorrect data

Checking components



- Ignition off
- Disconnect connector A for the seat heating module (SHM) left
- Ignition on.

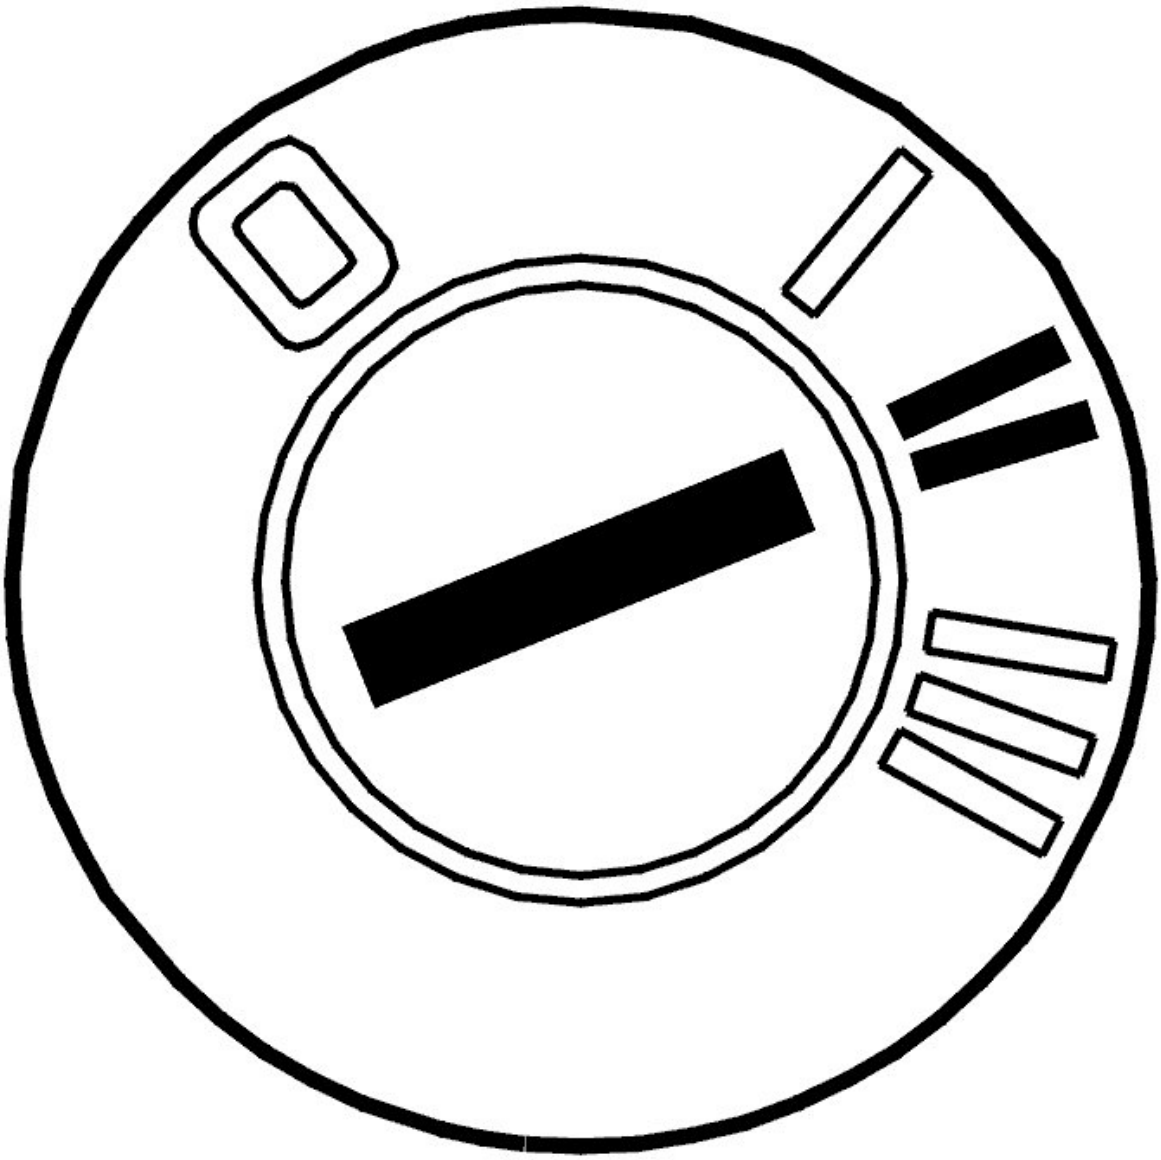
The climate control module (CCM) has detected that a component on LIN bus 1 is transmitting incorrect data and disrupting communication on the LIN bus.
Check the communication by disconnecting the seat heating module (SHM) left.
If other control modules on LIN bus 1 now function, replace the seat heating module (SHM) left.

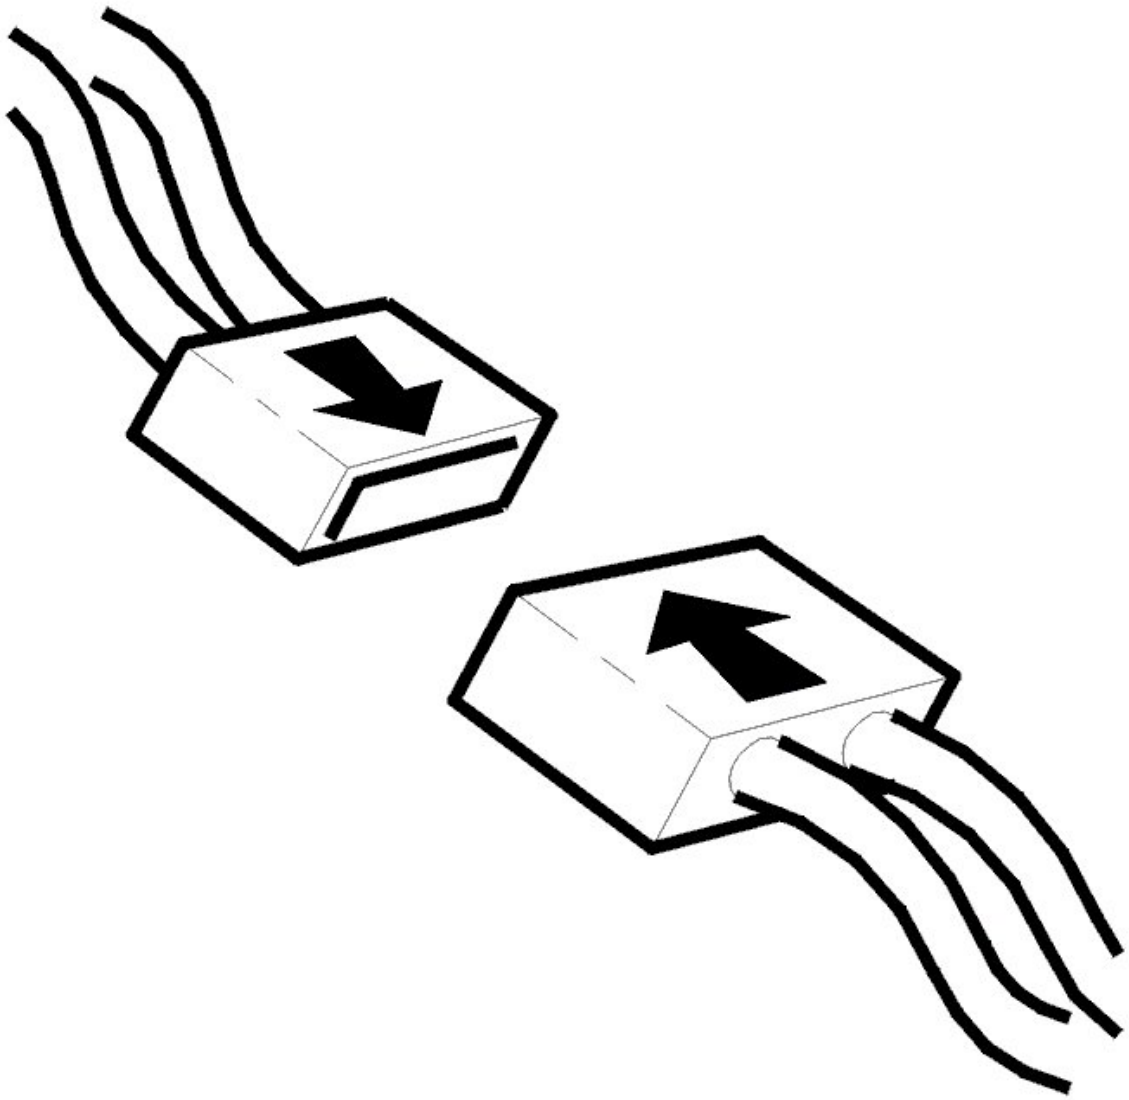
Was a fault detected?

Yes - Verification

No - Checking components

Checking components





- Ignition off
- Reconnect connector A for the seat heating module (SHM)
- Ignition on.

Check the components on the climate control unit as follows:

- Disconnect the connectors for the components one at a time
- Check whether the other components regain functionality, for example by activating seat heating
- If the functionality for the other components returns, the fault is probably in the disconnected components.

Remedy as necessary.

Other information:

- For further information about the connectors, fuses and relays, see the relevant section in the Wiring Diagram
- Connecting the breakout box See: Heating and Air Conditioning/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box, Climate Control Module (CCM)

Continue - Identifying the Damper Motor Module (DMM)

Identifying the Damper Motor Module (DMM)

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

Information

- The control module must be identified after replacing the Damper Motor Module (DMM).

Note! Identification must only be carried out when replacing the Damper Motor Module (DMM).

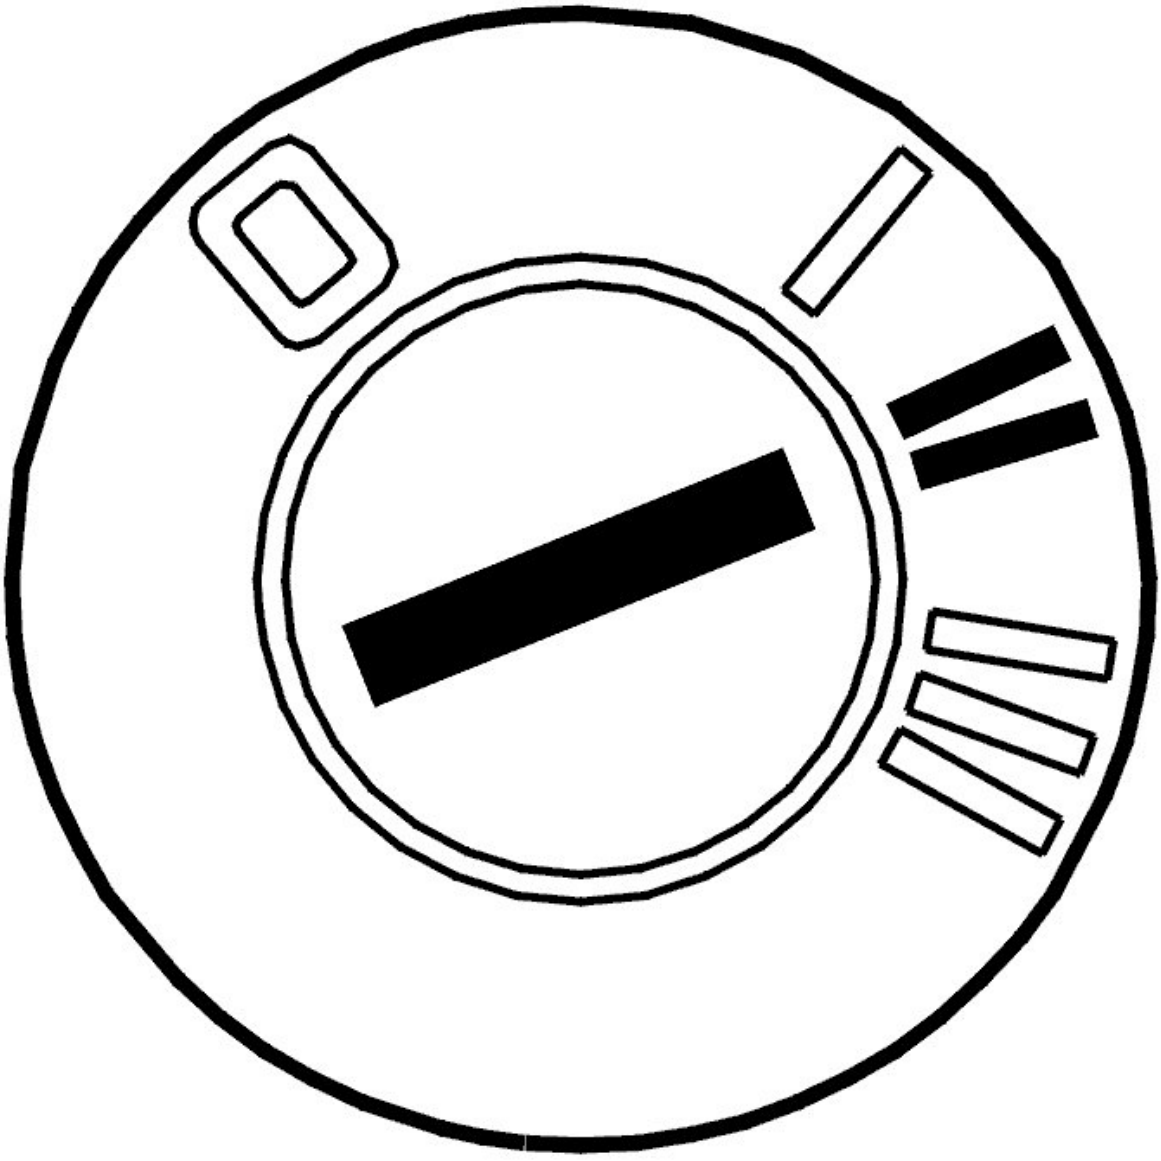
Have any damper motors been replaced?

Yes - Identifying the Damper Motor Module (DMM)

No - DONE

Identifying the Damper Motor Module (DMM)

Hint: When identifying damper motors, each damper motor must be run to its limit position. These operations can take up to 30 seconds. When identifying the damper motors it is important that a battery charger is connected.



- Ignition off
- Reinstall the connectors, components etc.

Note! Climate Control Module (CCM) and damper motors can be affected by the temperature. The vehicle should have normal room temperature when performing this service.

Carry out identification as follows:

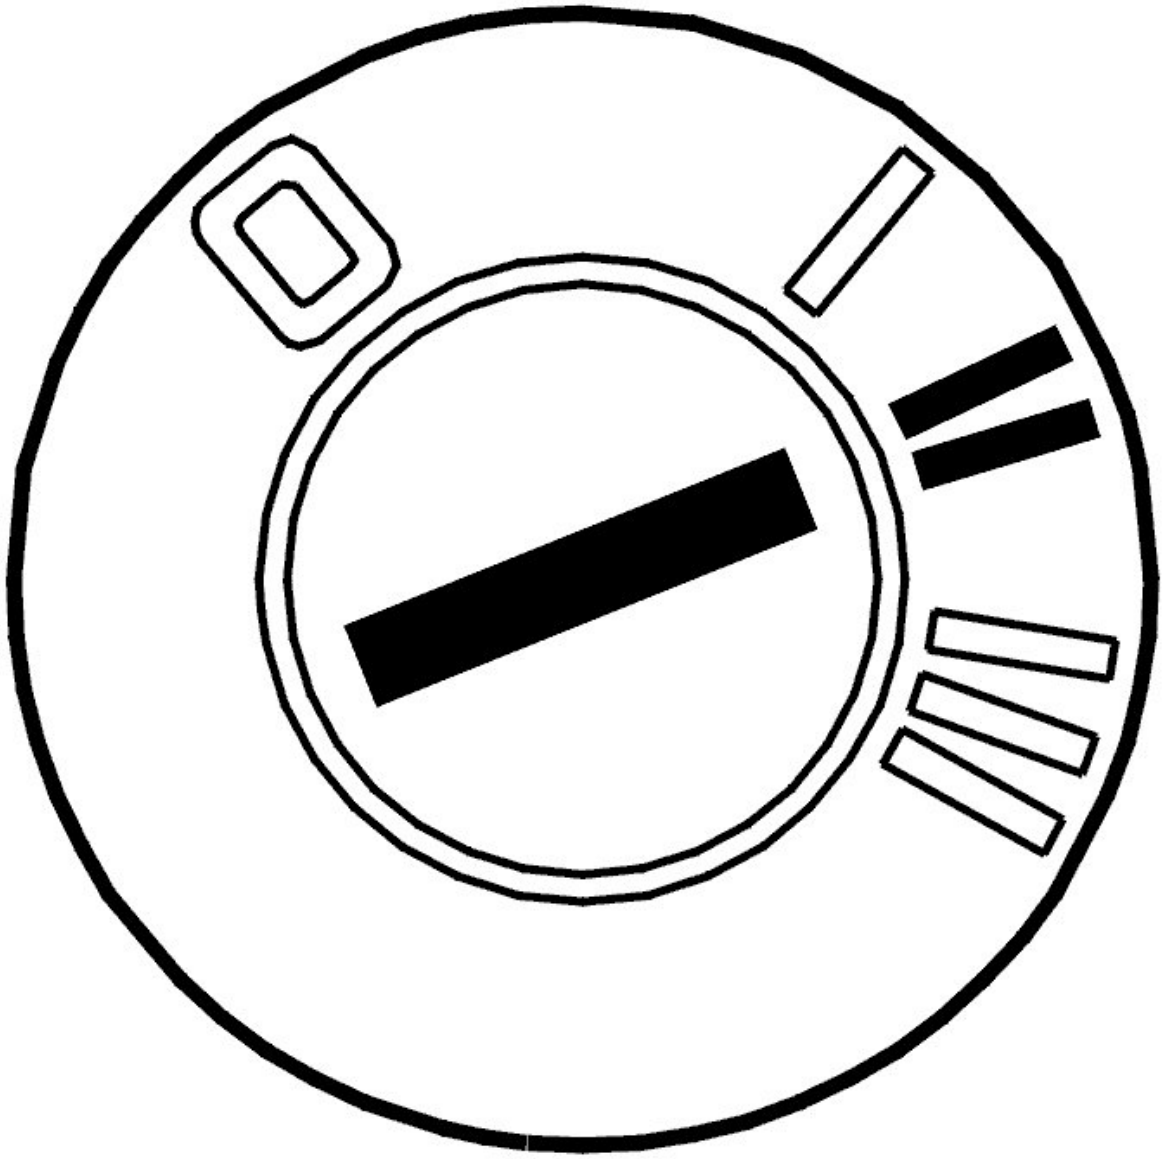
- Ignition on.
- Click on the VCT2000 symbol. Wait until identification has been carried out.
- Ignition off.

Continue - Calibrating the Climate Control Module (CCM)

Calibrating the Climate Control Module (CCM)

Caution! When activating this function, calibration of the Climate Control Module (CCM) starts. After carrying out calibration read off of the diagnostic trouble codes (DTCs) starts. To ensure that diagnostics for the Climate Control Module (CCM) have been carried out, delay for 30 seconds before reading out diagnostic trouble codes (DTCs) after calibration.

Note! Climate Control Module (CCM) and damper motors can be affected by the temperature. The vehicle should have normal room temperature when performing this service.



Carry out calibration as follows:

- Ignition on.
- Click on the VCT2000 symbol. Wait until calibration has been carried out and diagnostic trouble codes (DTCs) read out.
- Ignition off.

This function controls the components that communicate with the Climate Control Module (CCM) via LIN bus 1 and LIN bus 2. In the event of a fault in any of the LIN buses, diagnostic trouble codes (DTCs) CCM-0070 to CCM-0071 will be stored depending on the fault. These diagnostic trouble codes (DTCs) can only be stored in conjunction with this diagnostic function.
If any of these diagnostic trouble codes (DTCs) recur, recalibrate to check if the problem was overcome. If the diagnostic trouble code (DTC) recurs, fault-trace the relevant diagnostic trouble code (DTC).

Continue - DONE

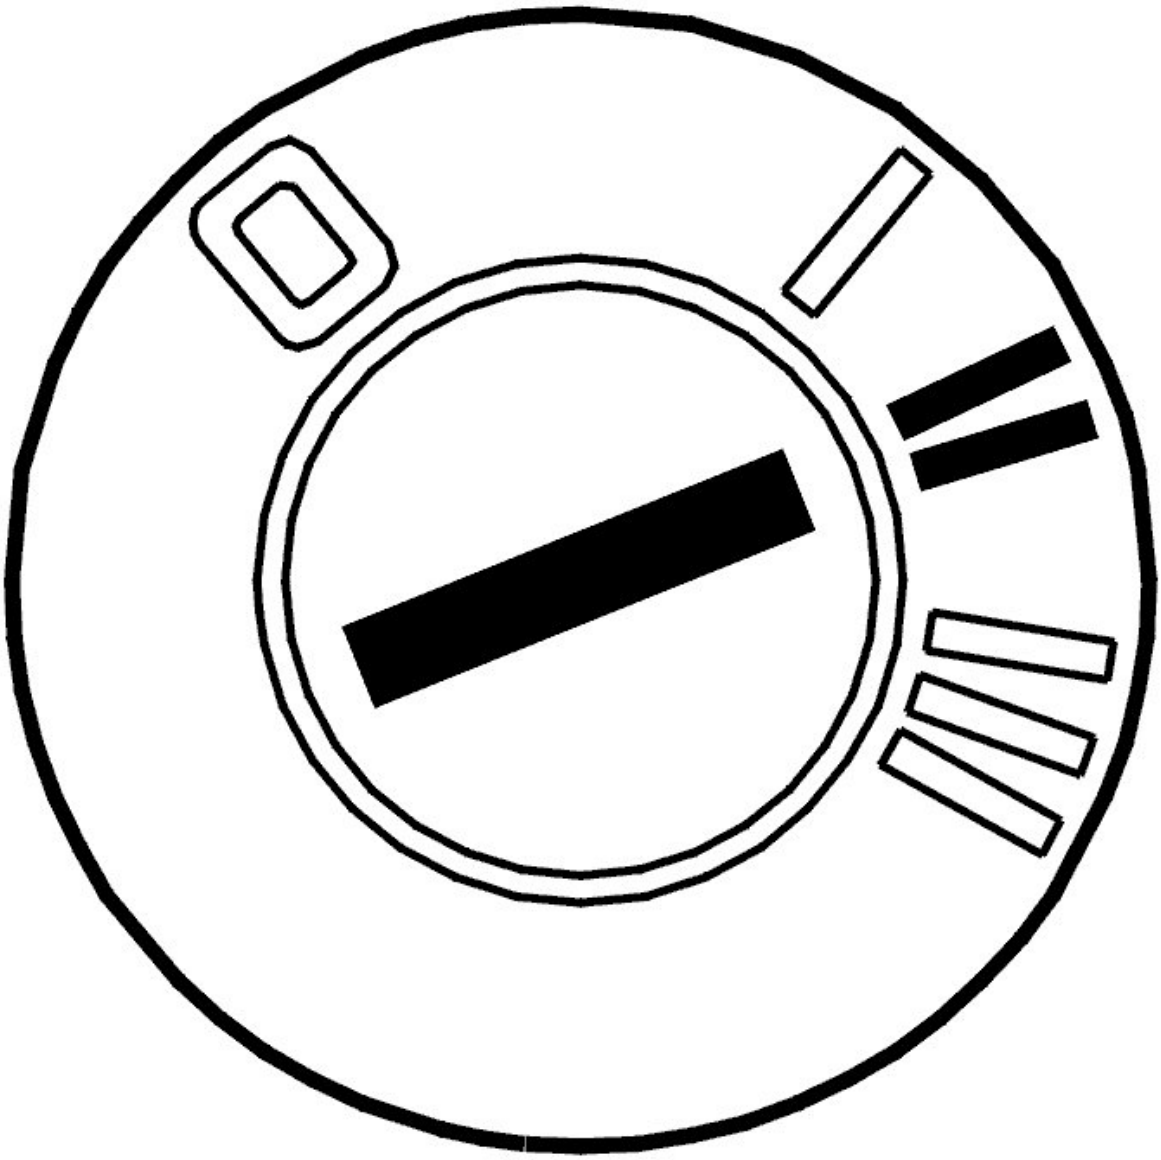
DONE - Verification

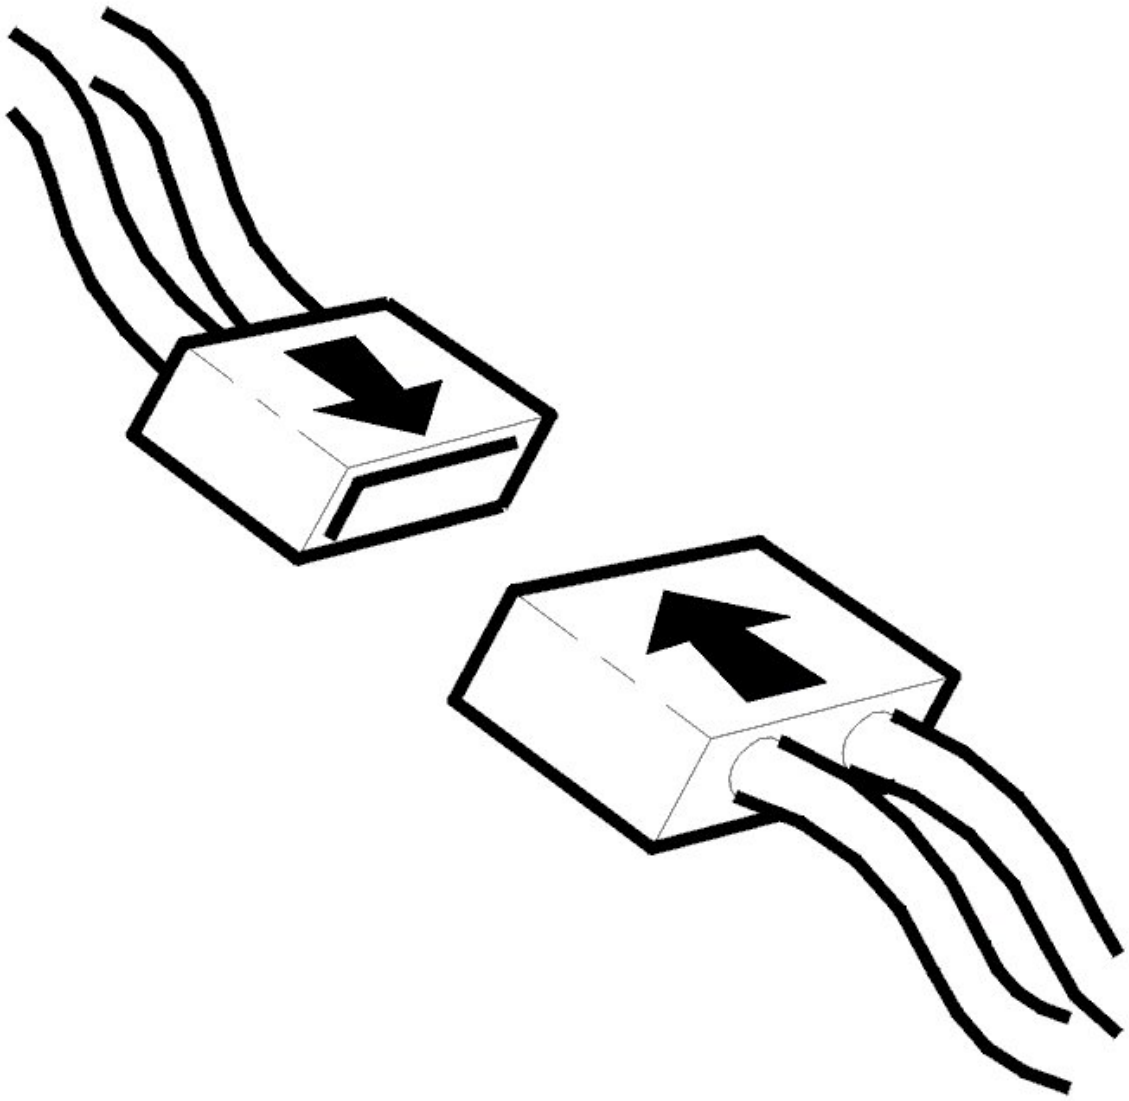
Verification

Verification

Verification

Hint: After carrying out the repair, check that the fault has been remedied.





- Ignition off
- Reinstall the connectors, components etc.
- Ignition on.

Check that the relevant diagnostic trouble code (DTC) has switched status from permanent to intermittent fault.
Check also that diagnostic trouble code (DTC) CCM-0070, CCM-0071 CCM-0072 or CCM-0073 has not been stored during identification of the damper motors.
These diagnostic trouble codes (DTCs) can only be stored when identifying damper motors. They mean that the identification has failed for some reason.
Remedy by correctly identifying the damper motor. Fault-trace according to the relevant information.

Has the status of the diagnostic trouble code (DTC) changed?

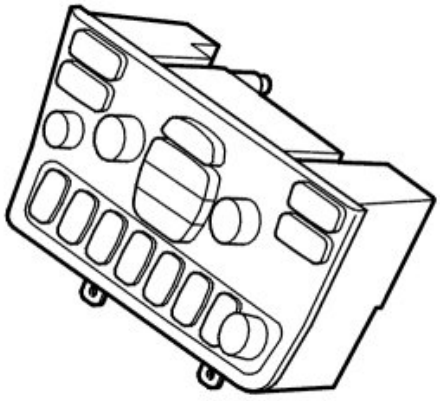
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CCM-DD01

Condition



The diagnostic trouble code (DTC) is stored if the climate control module (CCM) detects a short-circuit to supply voltage or ground in LIN bus 1.
A short-circuit to supply voltage or ground in the LIN bus will affect communications and the function of all the components.
The climate control module (CCM) communicates with damper motors, air quality sensors and seat heating via two LIN buses.

The number of components in LIN bus 1 can vary depending on the vehicle equipment (ECC/MCC and options) and if the vehicle has right-hand drive or left-hand drive.
The following components communicate on LIN bus 1:

- damper motor air distribution
- damper motor, temperature left
- damper motor recirculation (only on right-hand drive cars)
- air quality sensor (AQS) (only on right-hand drive cars)
- left seat heater.

The diagnostic trouble code (DTC) can be diagnosed in ignition positions I and II.

Substitute value

- None.

Possible source

- Short-circuit to supply voltage in LIN bus 1
- Short-circuit to ground in LIN bus 1.

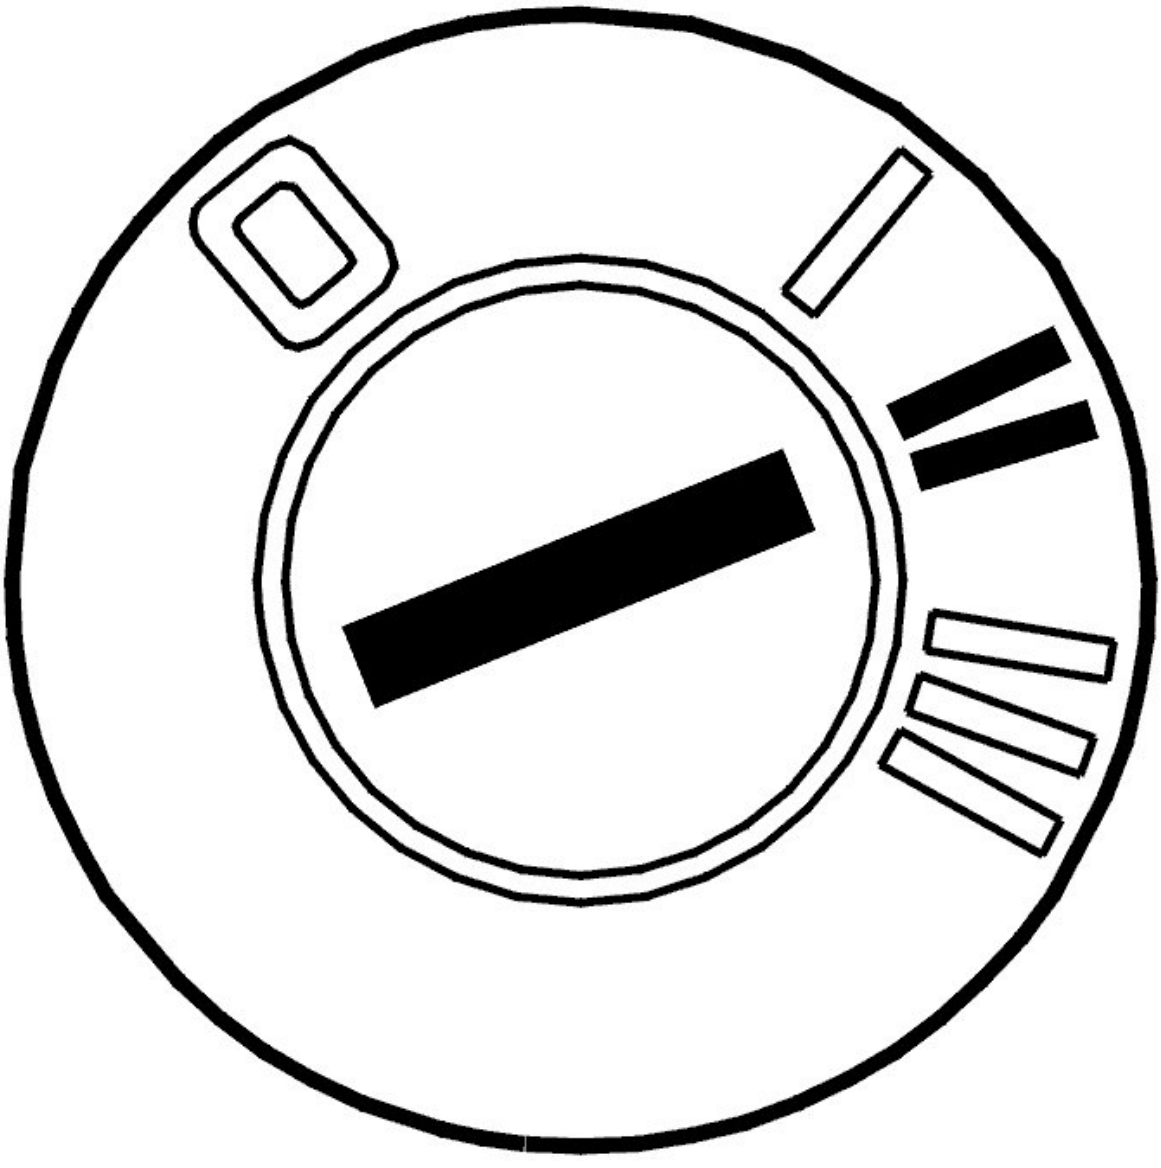
Fault symptom[s]

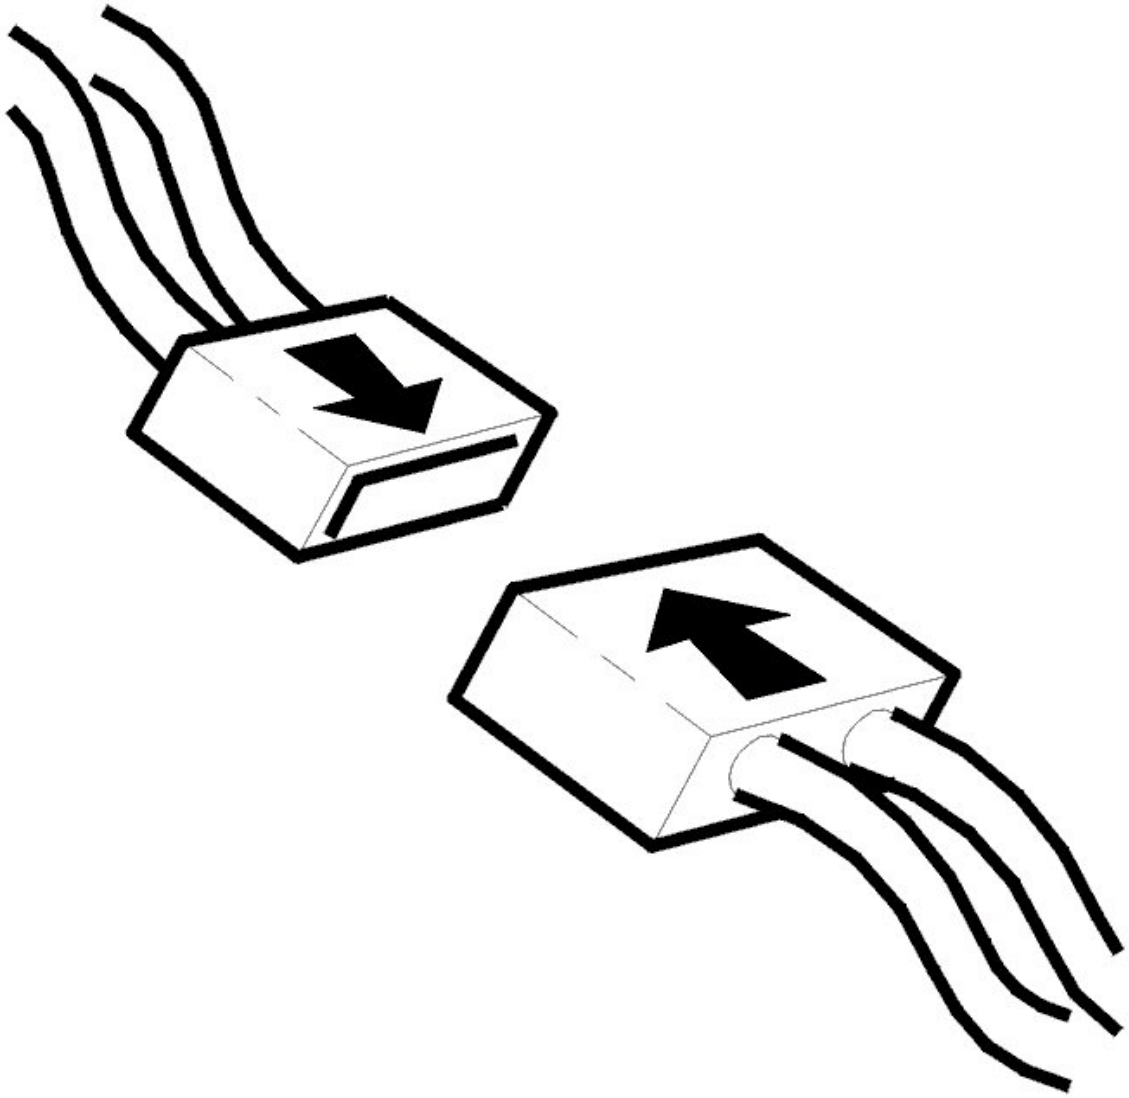
- Misting on the windows and/or door mirrors.
- Air flow problem.
- Poor heating in the passenger compartment.
- The front seat heating does not function.
- Poor air quality in the passenger compartment.

Signal Too High / Signal Too Low

Signal too high / Signal too low

Checking the cable





- Ignition off
- Disconnect the connector for the climate control module (CCM)
- Ignition on.

Check LIN bus 1. Check for a short-circuit to supply voltage.
Take a reading on the connector for the climate control module (CCM) between terminals #12 (#36) and #1 (#25).
If there is a short-circuit to supply voltage in LIN bus 1, continue fault-tracing by locating where the short-circuit has occurred as follows:

- Disconnect the connector on the climate control unit that connects LIN bus 1 from the climate control module (CCM) to other components on the climate control unit
- Check the section of LIN bus 1 that connects the climate control module (CCM) to the left-hand seat heating module (SHM) and the connector on the climate control unit. Take a reading on the connector for the climate control module (CCM) between terminals #12 (#36) and #1 (#25).

If the fault persists, fault-trace LIN bus 1 between the climate control module (CCM), the left-hand seat heating module (SHM) and the connector for the climate control unit. Check for a short-circuit to supply voltage.
If the fault is no longer present, fault-trace LIN bus 1 between the connector and the components of the climate control unit. Check for a short-circuit to supply voltage.
Remedy as necessary.

Other information:

- For further information about the connectors, fuses and relays, see the relevant section in the Wiring Diagram

Possible source

- Incorrect data during communication on LIN bus 1.

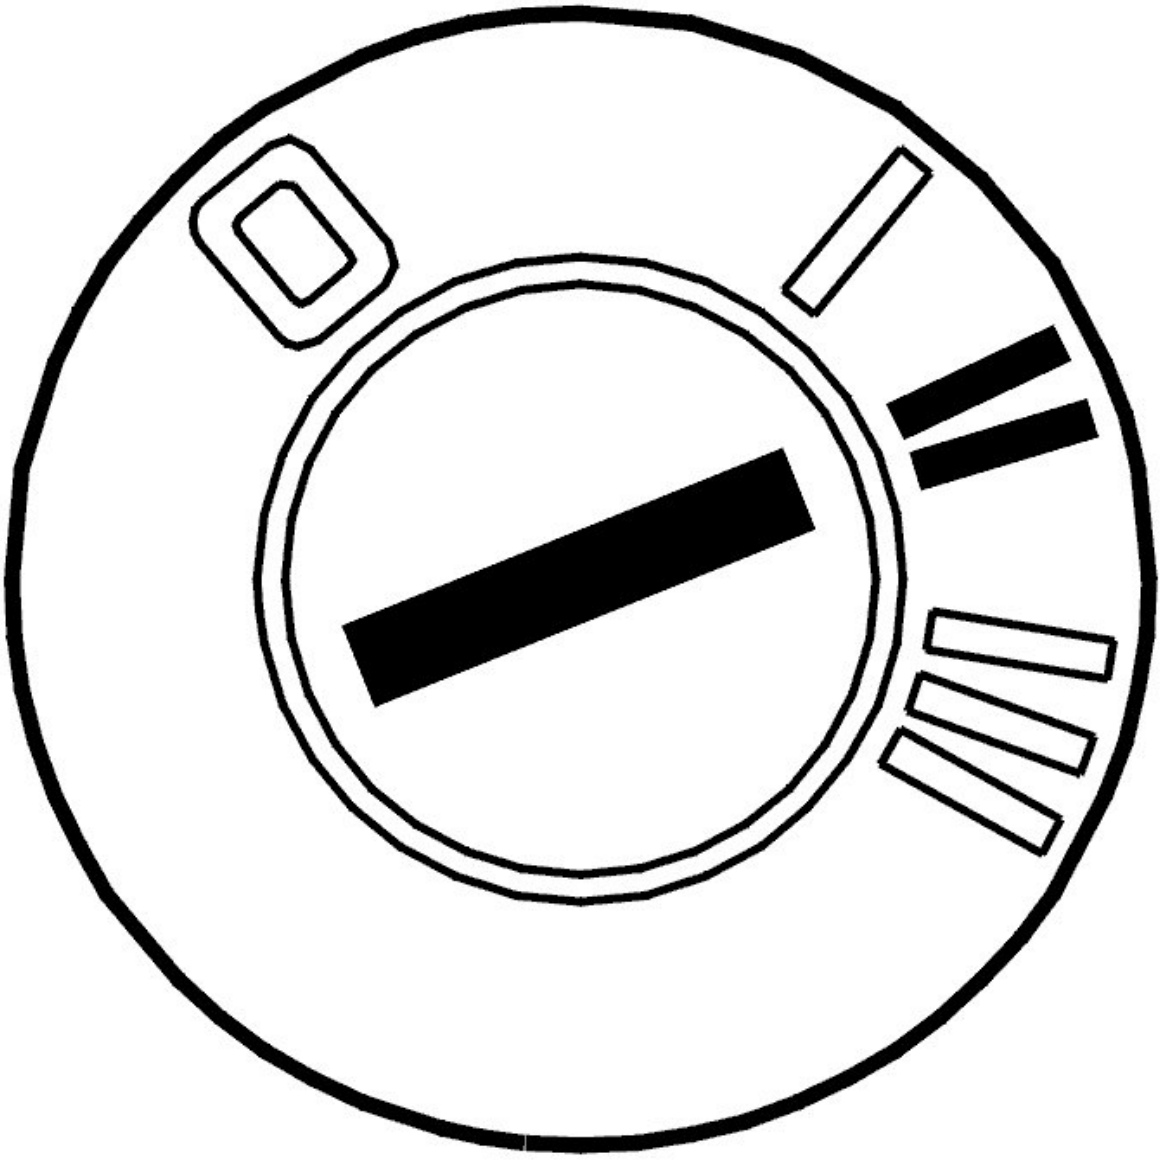
Fault symptom[s]

- Misting on the windows and/or door mirrors.
- Air flow problem.
- Poor heating in the passenger compartment.
- The front seat heating does not function.
- Poor air quality in the passenger compartment.

Faulty Check Sum

Faulty check sum

Checking components



- Ignition on.

The climate control module (CCM) has diagnosed that two or more damper motor modules (DMM) have the same identity on LIN bus 1.
This may be because one damper motor module (DMM) has been installed incorrectly.
After replacing a damper motor module (DMM), it must be allocated a correct identity by the climate control module (CCM). This is performed during identification of the damper motors on the LIN bus.

If a damper motor module (DMM) is installed that already has an identity allocated to it, this can lead to a conflict on the LIN bus. Remedy by correctly identifying the damper motor.

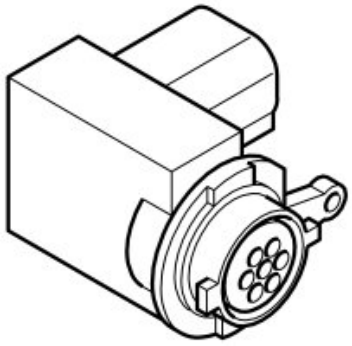
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CCM-DD10

Condition



The diagnostic trouble code (DTC) is stored if the climate control module (CCM) detects an open-circuit in the communication between the air quality sensor (AQS) and the climate control module (CCM) on LIN bus 1.
The diagnostic trouble code (DTC) can occur together with diagnostic trouble codes (DTCs) for other components on LIN bus 1 (CCM-DD10 -

CCM-DD16) depending on where the open-circuit has occurred.
The diagnostic trouble code (DTC) can be diagnosed at ignition switch position II.
The diagnostic trouble code (DTC) can only be diagnosed for the electronic climate control module (CCM) (ECC).

Substitute value
- None.

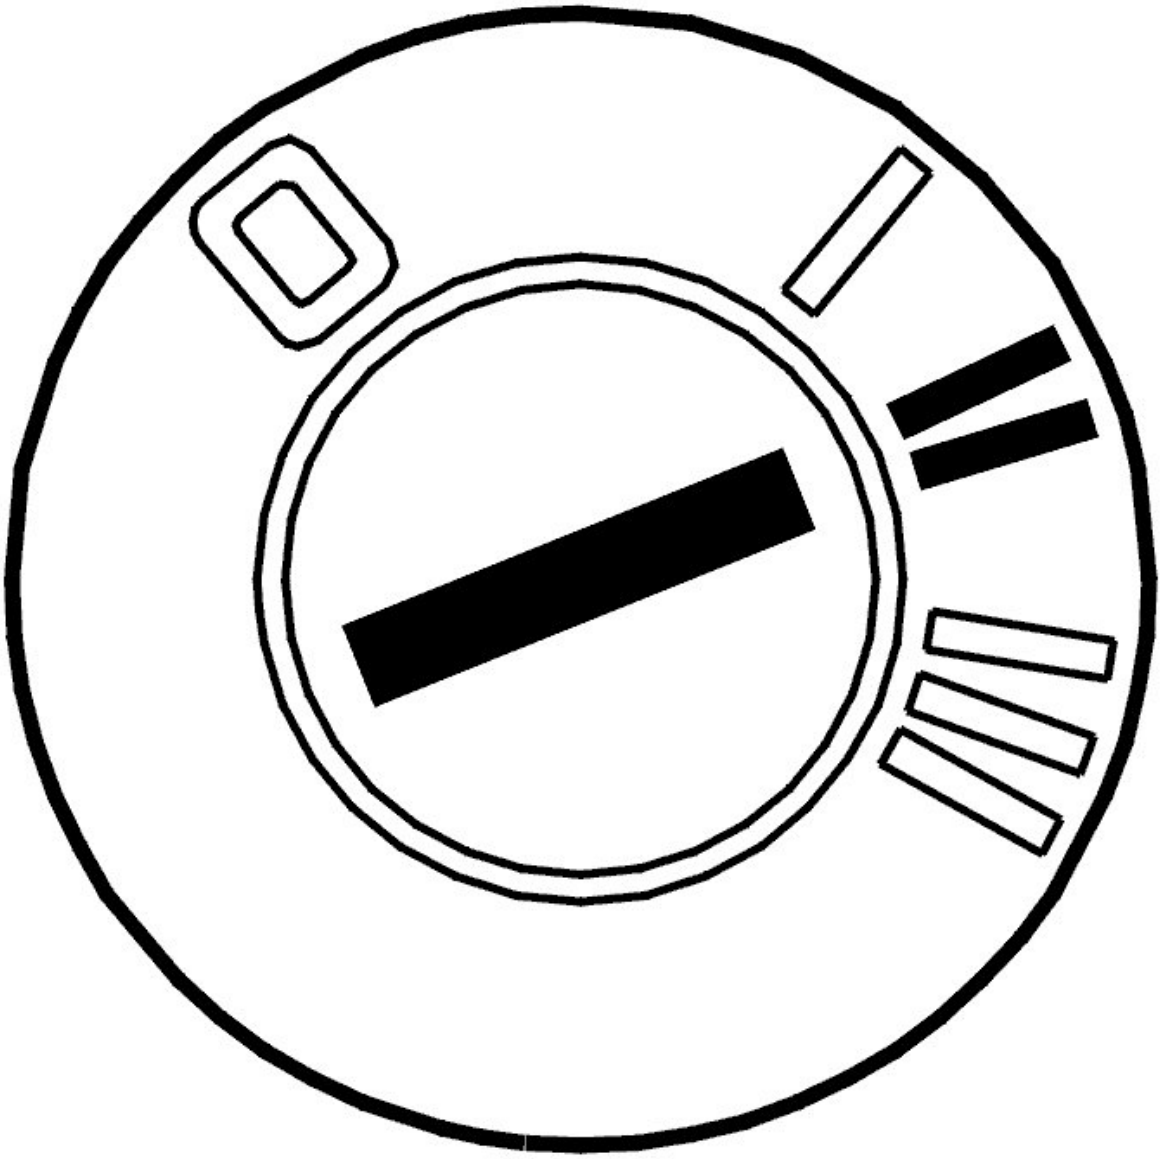
Possible source
- Open-circuit on LIN bus 1 between the climate control module (CCM) and the air quality sensor (AQS)
- Contact resistance, oxidation or loose connections in the connectors.

Fault symptom[s]
- Poor air quality in the passenger compartment.

No Communication

No communication

Checking the diagnostic trouble codes (DTCs)



- Ignition on.

The diagnostic trouble code (DTC) may occur together with diagnostic trouble codes (DTCs) for other components that communicate with the climate control module (CCM) via LIN bus 1 and LIN bus 2.
Check whether the diagnostic trouble code (DTC) has been stored together with other diagnostic trouble codes (DTCs) for other components on the climate control unit.
Select one of the following options:

1. The diagnostic trouble code (DTC) is stored together with diagnostic trouble codes (DTCs) for components in both LIN bus 1 and LIN bus 2 (CCM-DD10 - CCM-DD16, CCM-DD30 - CCM-DD34)
2. The diagnostic trouble code (DTC) is stored together with diagnostic trouble codes (DTCs) for components only on LIN bus 1 (CCM-DD10 - CCM-DD16)

3. The diagnostic trouble code (DTC) is not together with diagnostic trouble codes (DTCs) for other components on LIN bus 1 and LIN bus 2.

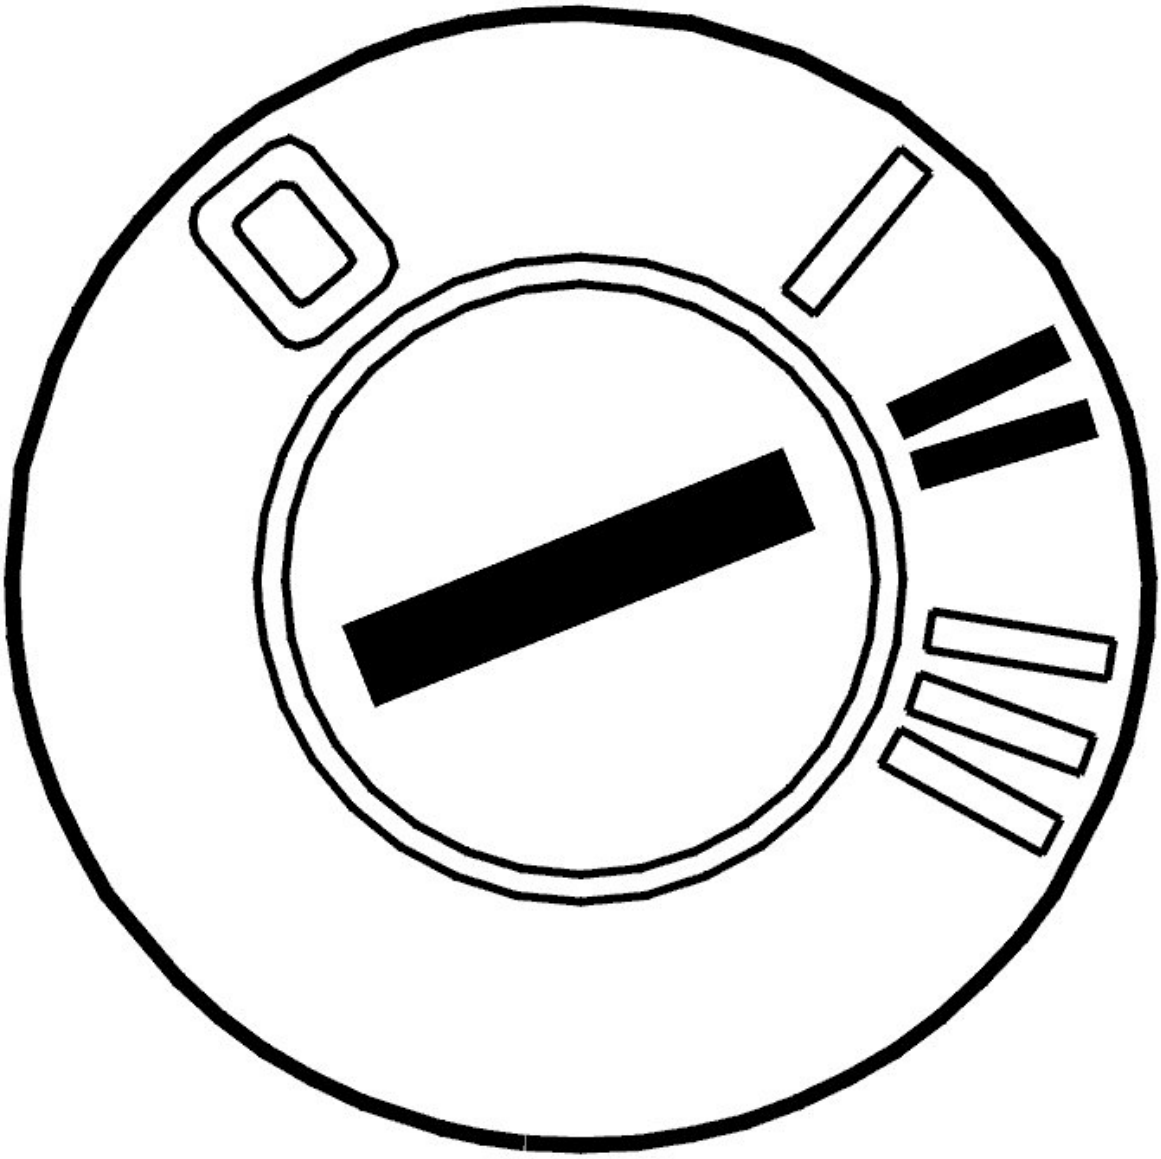
Select an alternative.

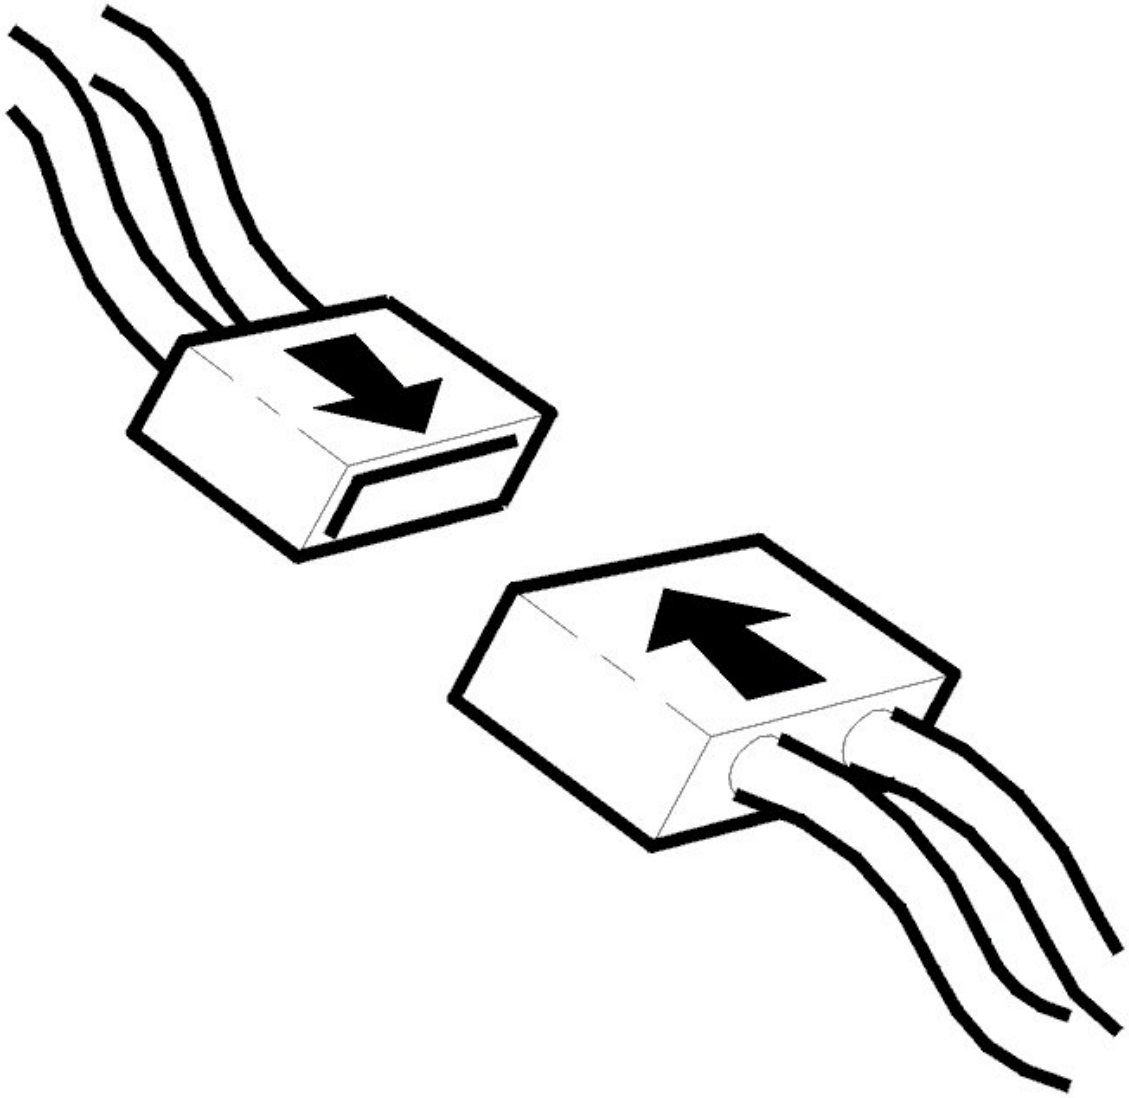
1 - Checking the connectors and wiring

2 - Checking LIN bus 1 and connector

3 - Checking the wiring and component

Checking the connectors and wiring





- Ignition off
- Disconnect the connector for the climate control module (CCM)
- Disconnect the connector for the central electronic module (CEM)
- Ignition on.

Checking the power supply and ground terminals

The following applies to components on the climate control unit that communicate with the climate control module (CCM) via LIN bus 1 and LIN bus 2:

- All components are jointly powered via a fuse from the central electronic module (CEM)
- All components are grounded via a common ground terminal.

Check the power supply to the components on the climate control unit by taking a reading on connector A for the central electronic module (CEM) between terminal #A44 (C44) and chassis ground.
Also check the fuse on the central electronic module (CEM).
Check the power supply cable between the central electronic module (CEM) and the connector for the climate control unit. Check for an open-circuit. Measure between terminal #1 on the connector for the climate control unit and chassis ground.
Check the ground terminal for the components on the climate control unit. Measure between the connector for climate control unit terminal #6 and chassis ground.
Check the connector for the climate control unit and connector A for the central electronic module (CEM). Check for contact resistance. Check for oxidation. Check for loose connections.

Checking LIN bus

Check both LIN bus 1 and LIN bus 2. Check for an open-circuit.
Take readings between:

- The connector for climate control module (CCM) terminal #12 (#36) and the connector for climate control unit terminal #2
- The connector for climate control module (CCM) terminal #7 (#31) and the connector for climate control unit terminal #5.

Check the wiring between the connector and the components on the climate control unit. Check for an open-circuit.
Remedy as necessary.

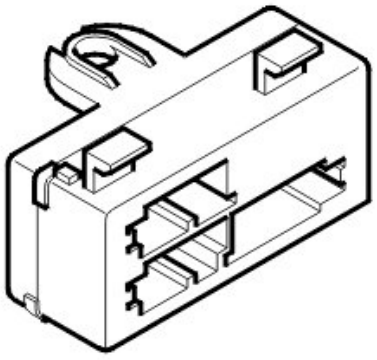
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CCM-DD12

Condition



The diagnostic trouble code (DTC) is stored if the climate control module (CCM) detects an open-circuit in the communication between the left seat heater and the climate control module (CCM) on LIN bus 1.
The diagnostic trouble code (DTC) can occur together with diagnostic trouble codes (DTCs) for other components on LIN bus 1 (CCM-DD10 -

CCM-DD16) depending on where the open-circuit has occurred.
The diagnostic trouble code (DTC) can be diagnosed at ignition switch position II.
The diagnostic trouble code (DTC) can only be diagnosed for the climate control module (CCM) when seat heating is installed in the car.

Substitute value
- None.

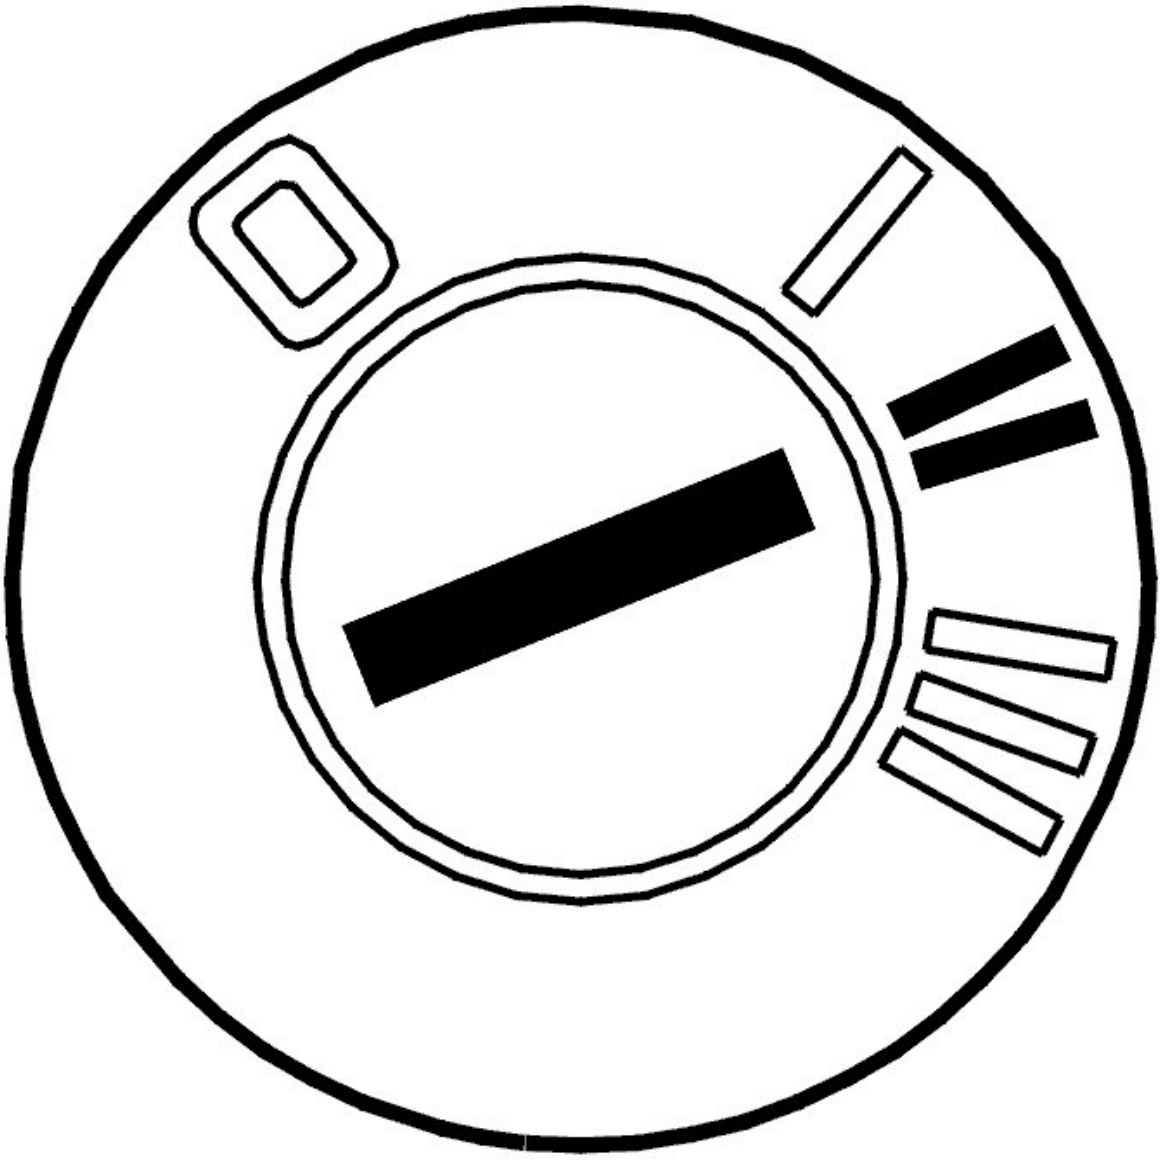
Possible source
- Open-circuit on LIN bus 1 between the climate control module (CCM) and the left seat heater
- Contact resistance, oxidation or loose connections in the connectors.

Fault symptom[s]
- The front seat heating does not function.

No Communication

No communication

Checking the diagnostic trouble codes (DTCs)



- Ignition on.

Check that the fuse for the Seat heating module (SHM) is intact.
The diagnostic trouble code (DTC) may occur together with diagnostic trouble codes (DTCs) for other components that communicate with the climate control module (CCM) via LIN bus 1.
Check whether the diagnostic trouble code (DTC) has been stored together with other diagnostic trouble codes (DTCs) for other components on the climate control unit.
Select one of the following options:
1. The diagnostic trouble code (DTC) is stored together with diagnostic trouble codes (DTCs) for components on LIN bus 1 (CCM-DD10 - CCM-DD16)
2. The diagnostic trouble code (DTC) is not stored together with diagnostic trouble codes (DTCs) for other components on LIN bus 1.

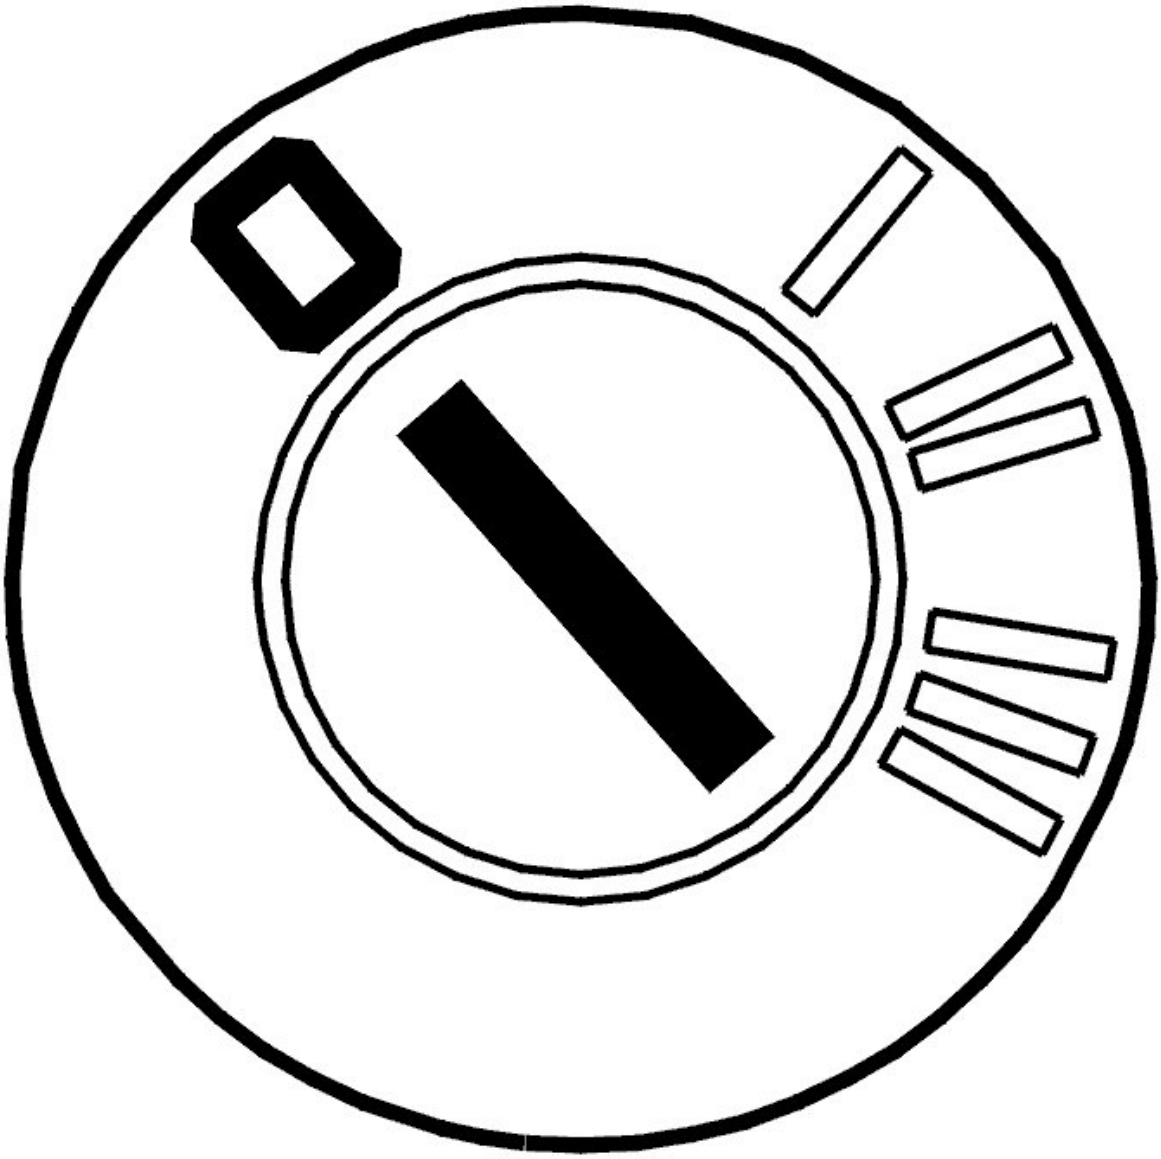
Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

Select an alternative.

1 - Checking LIN bus 1 and connector

2 - Checking the wiring and component

Checking LIN bus 1 and connector



- Ignition off
- Disconnect the connector for the climate control module (CCM).

Check the climate control module (CCM) connector. Check for contact resistance. Check for oxidation. Check for loose connections.
Check LIN bus 1 between the climate control module (CCM), the connector for the climate control unit and the left-hand seat heating module (SHM). Check for an open-circuit.
Take readings between:

- The connector for climate control module (CCM) terminal #12 (#36) and the connector for climate control unit terminal #2
- The connector for climate control module (CCM) terminal #12 (#36) and connector A for seat heating module (SHM) left terminal #2.

Check LIN bus 1 between the components (the damper motors and the air quality sensor (AQS)) and the connector for the climate control unit. Check for an open-circuit.
Check the connector for the climate control unit. Check for contact resistance. Check for oxidation. Check for loose connections.
Remedy as necessary.

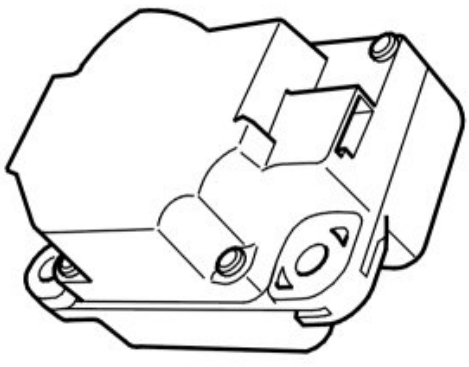
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CCM-DD14

Condition



The diagnostic trouble code (DTC) is stored if the climate control module (CCM) detects an open-circuit in the communication between the damper motor recirculation and the climate control module (CCM) on LIN bus 1.
The diagnostic trouble code (DTC) can occur together with diagnostic trouble codes (DTCs) for other components on LIN bus 1 (CCM-DD10 -

CCM-DD16) depending on where the open-circuit has occurred.
The diagnostic trouble code (DTC) can be diagnosed at ignition switch position II.

Substitute value
- None.

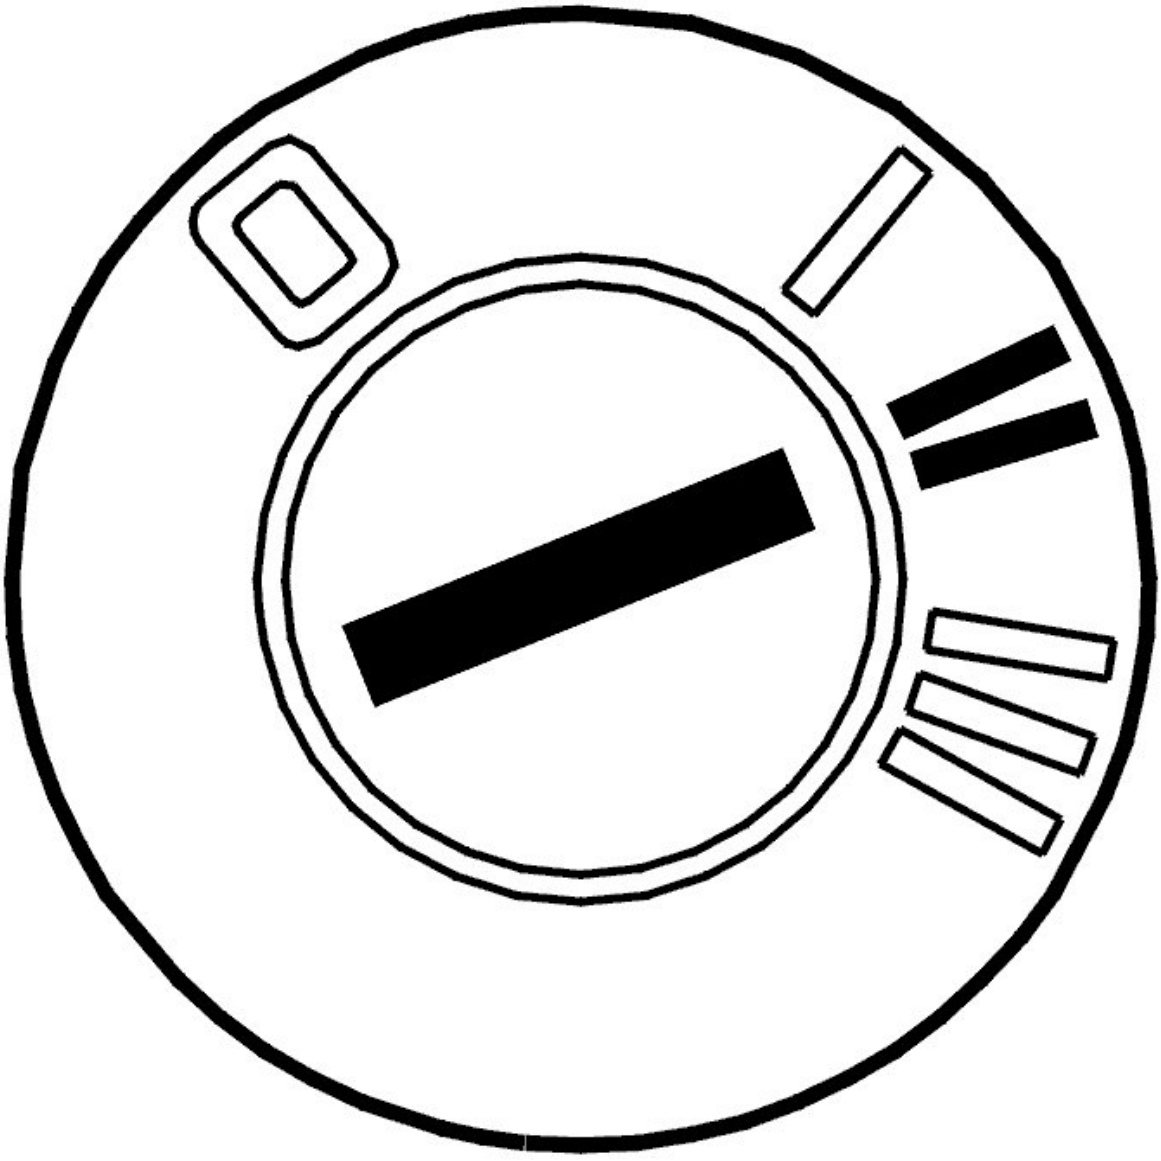
Possible source
- Open-circuit on LIN bus 1 between the climate control module (CCM) and the damper motor module (DMM) recirculation
- Contact resistance, oxidation or loose connections in the connectors.

Fault symptom[s]
- No recirculation.

No Communication

No communication

Checking the diagnostic trouble codes (DTCs)



- Ignition on.

The diagnostic trouble code (DTC) may occur together with diagnostic trouble codes (DTCs) for other components that communicate with the climate control module (CCM) via LIN bus 1 and LIN bus 2.
Check whether the diagnostic trouble code (DTC) has been stored together with other diagnostic trouble codes (DTCs) for other components on the climate control unit.
Select one of the following options:

1. The diagnostic trouble code (DTC) is stored together with diagnostic trouble codes (DTCs) for components in both LIN bus 1 and LIN bus 2 (CCM-DD10 - CCM-DD16, CCM-DD30 - CCM-DD34)
2. The diagnostic trouble code (DTC) is stored together with diagnostic trouble codes (DTCs) for components only on LIN bus 1 (CCM-DD10 - CCM-DD16)
3. The diagnostic trouble code (DTC) is not together with diagnostic trouble codes (DTCs) for other components on LIN bus 1 and LIN bus 2.

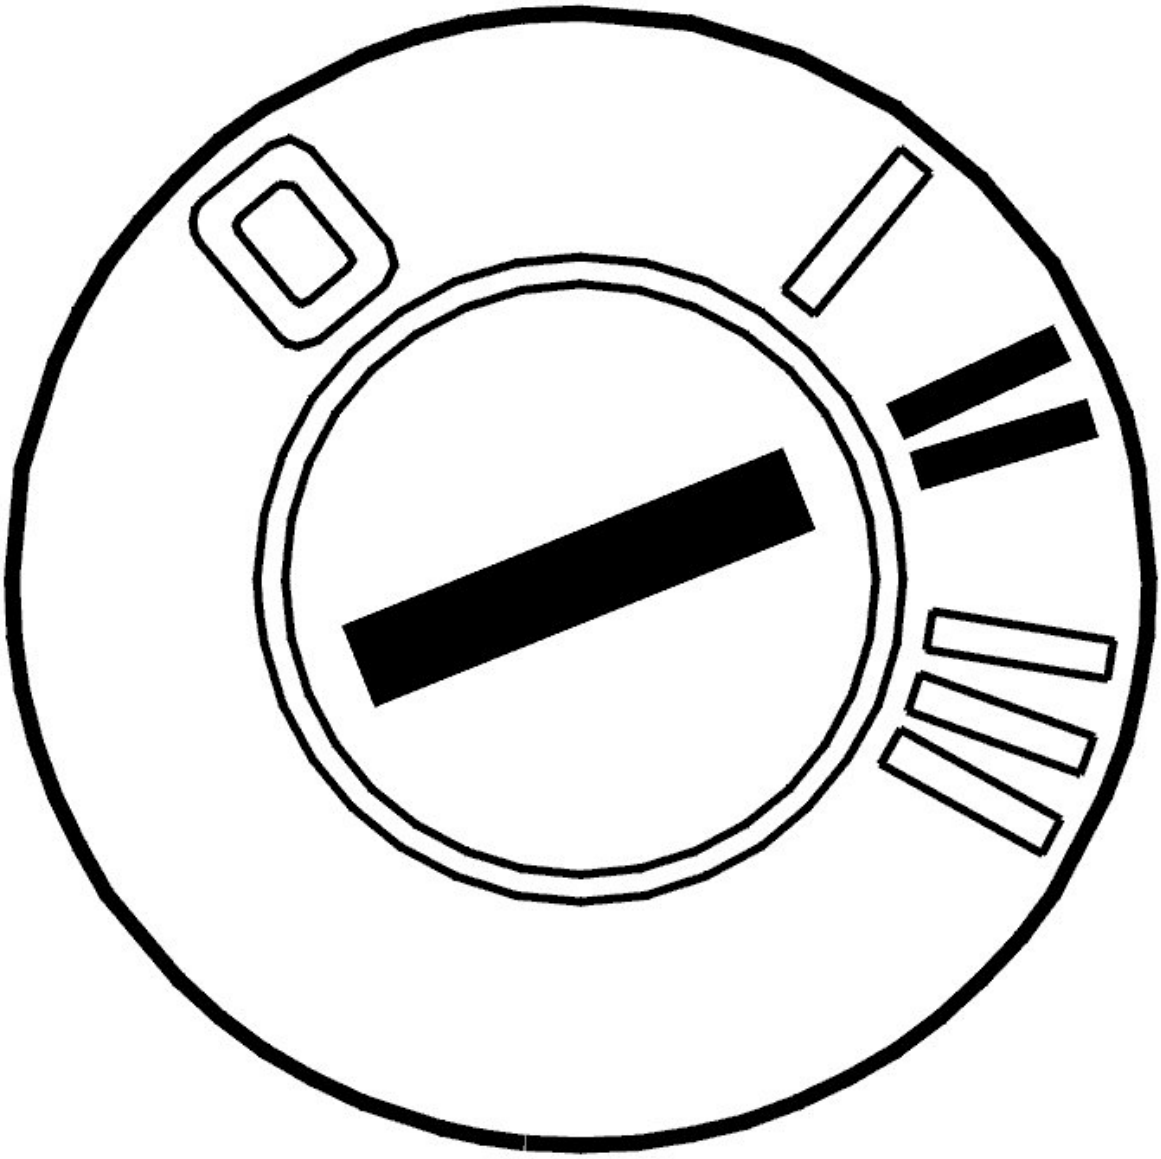
Select an alternative.

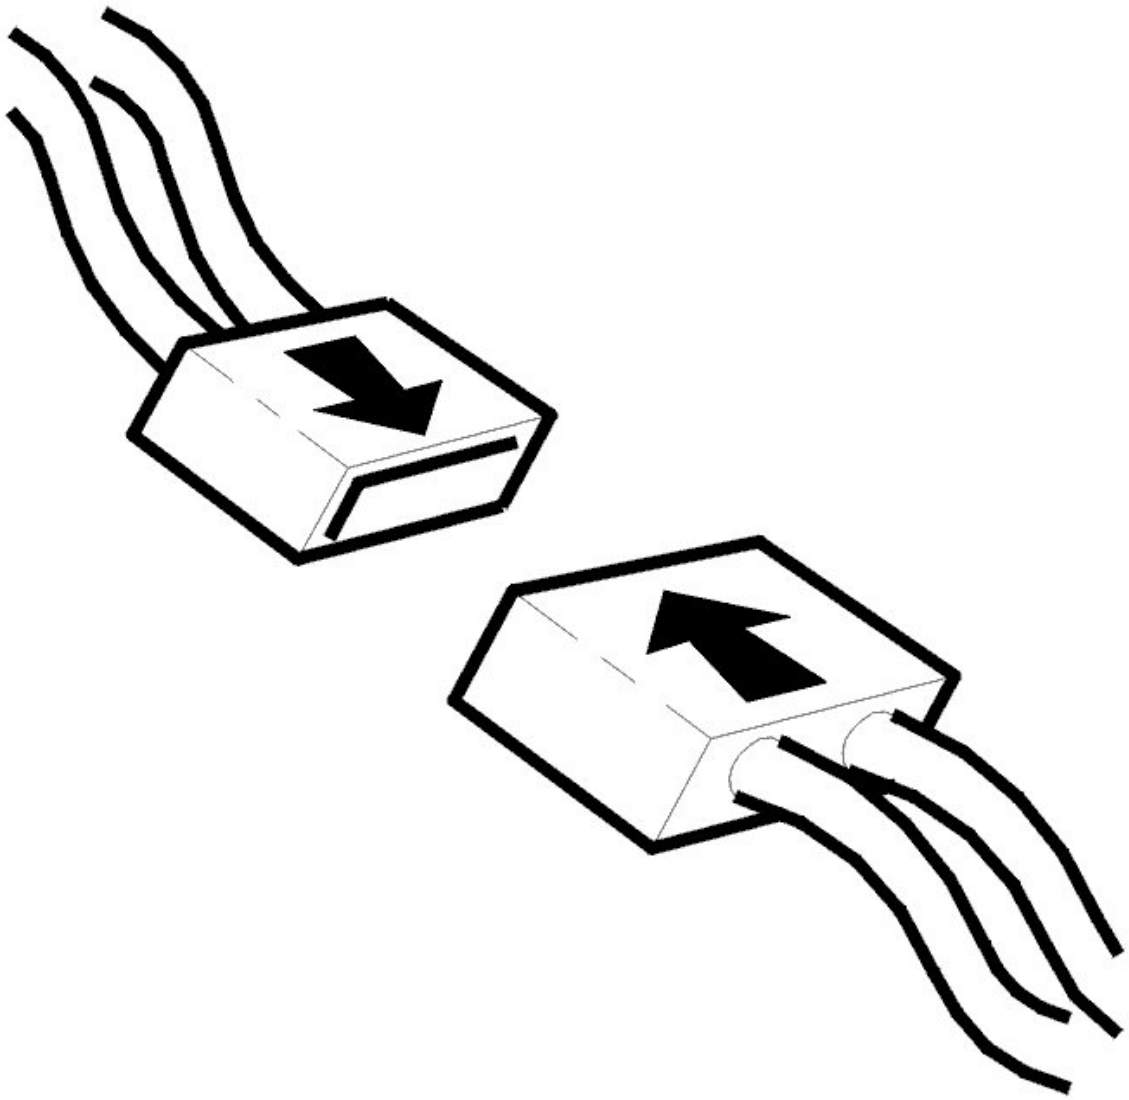
1 - Checking the connectors and wiring

2 - Checking LIN bus 1 and connector

3 - Checking the wiring and component

Checking the connectors and wiring





- Ignition off
- Disconnect the connector for the climate control module (CCM)
- Disconnect the connector for the central electronic module (CEM)
- Ignition on.

Checking the power supply and ground terminals

The following applies to components on the climate control unit that communicate with the climate control module (CCM) via LIN bus 1 and LIN bus 2:

- All components are jointly powered via a fuse from the central electronic module (CEM)
- All components are grounded via a common ground terminal.

Check the power supply to the components on the climate control unit by taking a reading on connector A for the central electronic module (CEM) between terminal #A44 (C44) and chassis ground.
Also check the fuse on the central electronic module (CEM).
Check the power supply cable between the central electronic module (CEM) and the connector for the climate control unit. Check for an open-circuit. Measure between terminal #1 on the connector for the climate control unit and chassis ground.
Check the ground terminal for the components on the climate control unit. Measure between the connector for climate control unit terminal #5 and chassis ground.
Check the connector on the climate control unit and connector A for the central electronic module (CEM). Check for contact resistance. Check for oxidation. Check for loose connections.

Checking LIN bus

Check both LIN bus 1 and LIN bus 2. Check for an open-circuit.
Take readings between:

- The connector for climate control module (CCM) terminal #12 (#36) and the connector for climate control unit terminal #2
- The connector for climate control module (CCM) terminal #7 (#31) and the connector for climate control unit terminal #5.

Check the wiring between the connector and the components on the climate control unit. Check for an open-circuit.
Remedy as necessary.

The diagnostic trouble code (DTC) can occur together with diagnostic trouble codes (DTCs) for other components on LIN bus 1 (CCM-DD10 -

CCM-DD16) depending on where the open-circuit has occurred.
The diagnostic trouble code (DTC) can be diagnosed at ignition switch position II.

Substitute value
- None.

Possible source
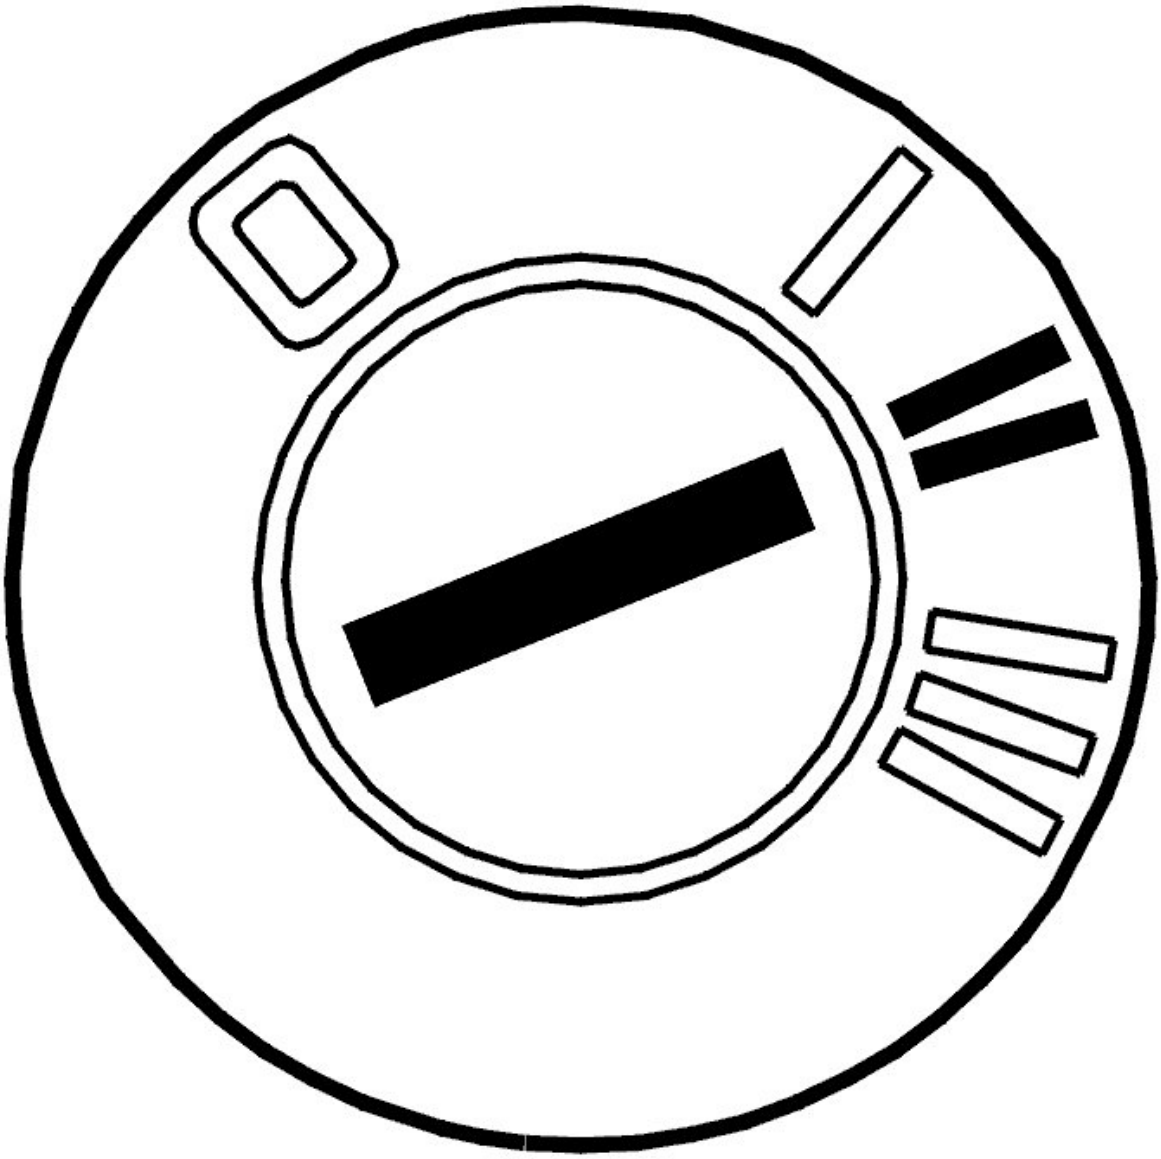
- Open-circuit on LIN bus 1 between the climate control module (CCM) and the damper motor module (DMM) air distribution
- Contact resistance, oxidation or loose connections in the connectors.

Fault symptom[s]
- Misting on the windows and/or door mirrors.
- Air flow problem.

No Communication

No communication

Checking the diagnostic trouble codes (DTCs)



- Ignition on.

The diagnostic trouble code (DTC) may occur together with diagnostic trouble codes (DTCs) for other components that communicate with the climate control module (CCM) via LIN bus 1 and LIN bus 2.
Check whether the diagnostic trouble code (DTC) has been stored together with other diagnostic trouble codes (DTCs) for other components on the climate control unit.
Select one of the following options:

1. The diagnostic trouble code (DTC) is stored together with diagnostic trouble codes (DTCs) for components in both LIN bus 1 and LIN bus 2 (CCM-DD10 - CCM-DD16, CCM-DD30 - CCM-DD34)
2. The diagnostic trouble code (DTC) is stored together with diagnostic trouble codes (DTCs) for components only on LIN bus 1 (CCM-DD10 - CCM-DD16)

3. The diagnostic trouble code (DTC) is not together with diagnostic trouble codes (DTCs) for other components on LIN bus 1 and LIN bus 2.

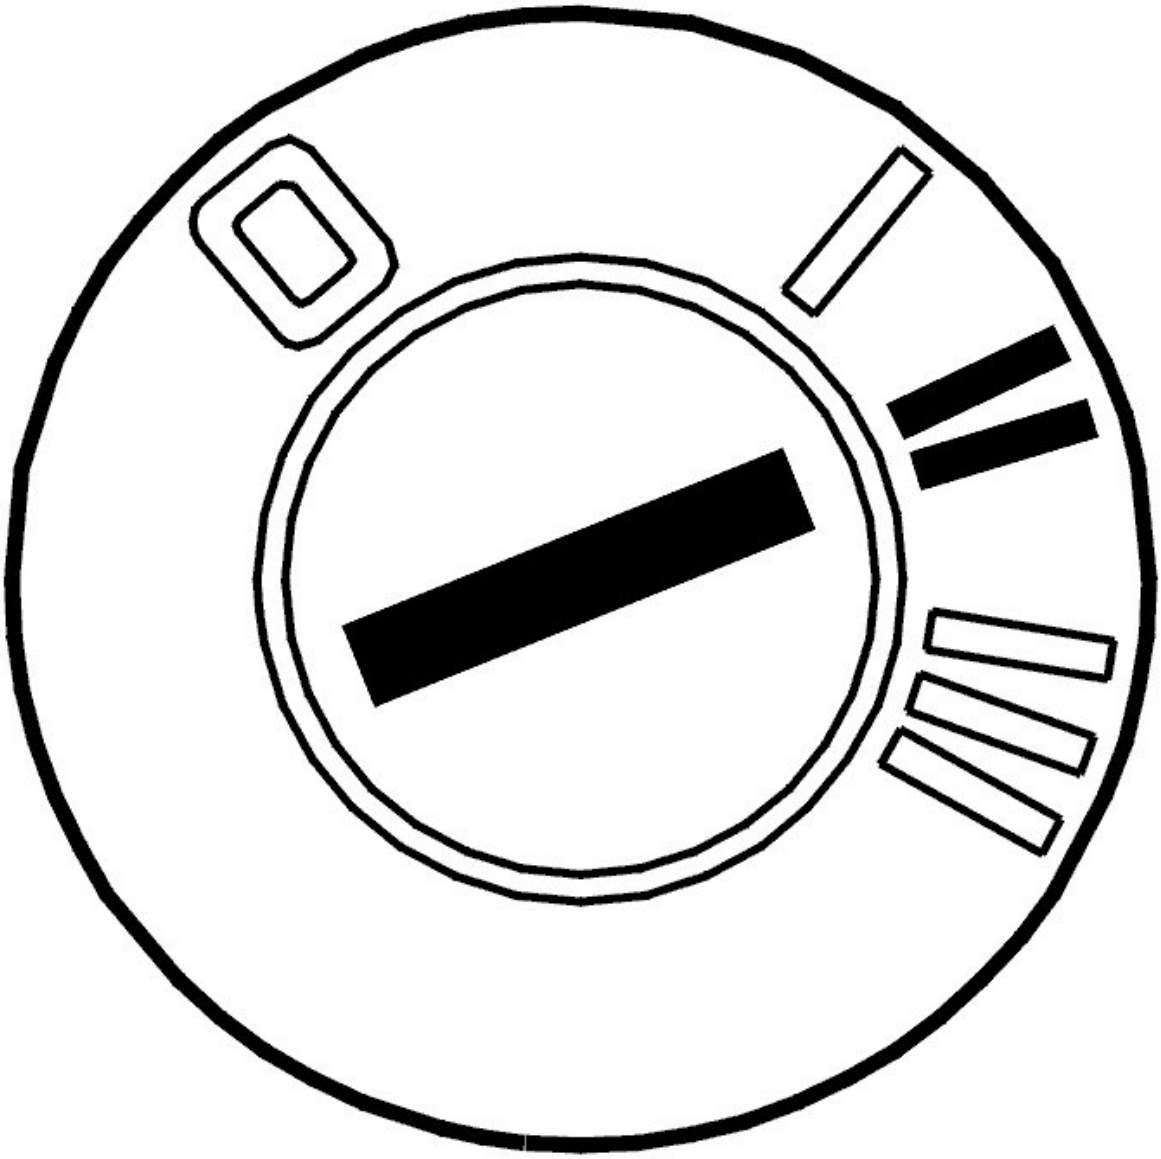
Select an alternative.

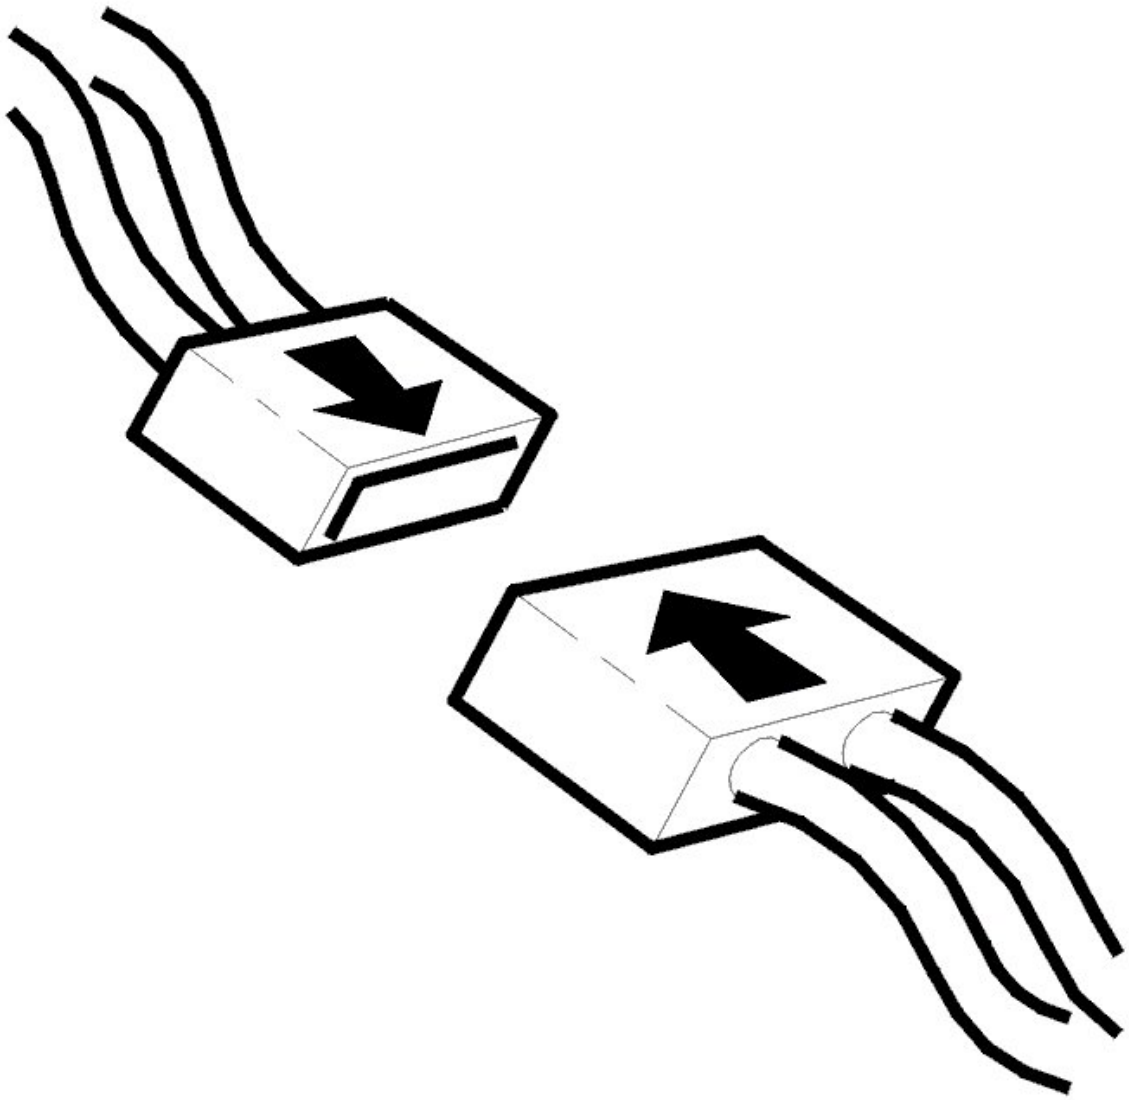
1 - Checking the connectors and wiring

2 - Checking LIN bus 1 and connector

3 - Checking the wiring and component

Checking the connectors and wiring





- Ignition off
- Disconnect the connector for the climate control module (CCM)
- Disconnect the connector for the central electronic module (CEM)
- Ignition on.

Checking the power supply and ground terminals

The following applies to components on the climate control unit that communicate with the climate control module (CCM) via LIN bus 1 and LIN bus 2:

- All components are jointly powered via a fuse from the central electronic module (CEM)
- All components are grounded via a common ground terminal.

Check the power supply to the components on the climate control unit by taking a reading on connector A for the central electronic module (CEM) between terminal #A44 (C44) and chassis ground.
Also check the fuse on the central electronic module (CEM).
Check the power supply cable between the central electronic module (CEM) and the connector for the climate control unit. Check for an open-circuit. Measure between terminal #1 on the connector for the climate control unit and chassis ground.
Check the ground terminal for the components on the climate control unit. Measure between the connector for climate control unit terminal #6 and chassis ground.
Check the connector for the climate control unit and connector A on the central electronic module (CEM). Check for contact resistance. Check for oxidation. Check for loose connections.

Checking LIN bus

Check both LIN bus 1 and LIN bus 2. Check for an open-circuit.
Take readings between:

- The connector for climate control module (CCM) terminal #12 (#36) and the connector for climate control unit terminal #2
- The connector for climate control module (CCM) terminal #7 (#31) and the connector for climate control unit terminal #5.

Check the wiring between the connector and the components on the climate control unit. Check for an open-circuit.
Remedy as necessary.

Other information:

- For further information about the connectors, fuses and relays, see the relevant section in the Wiring Diagram

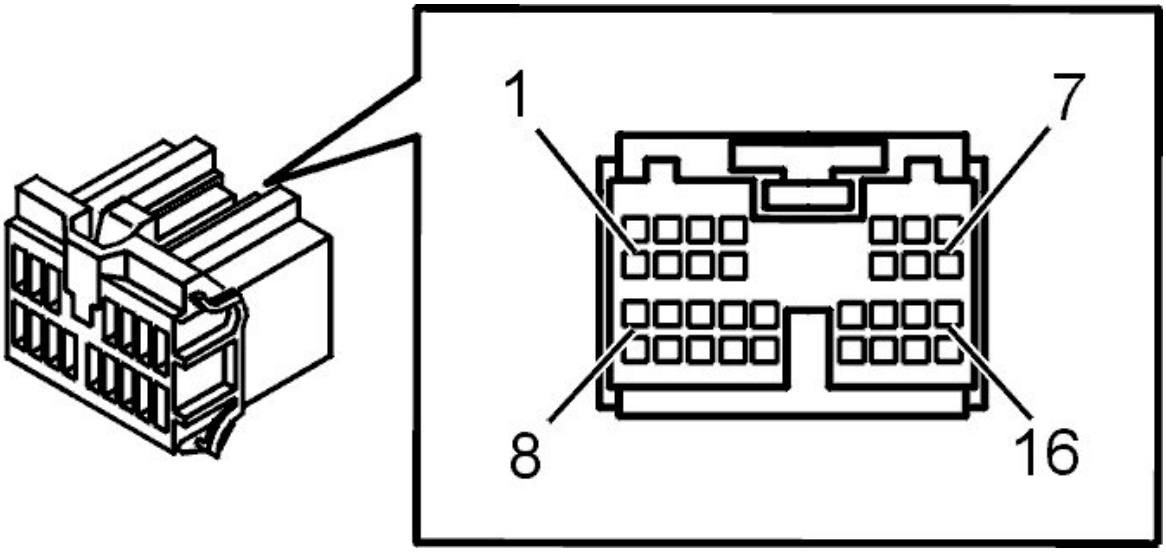
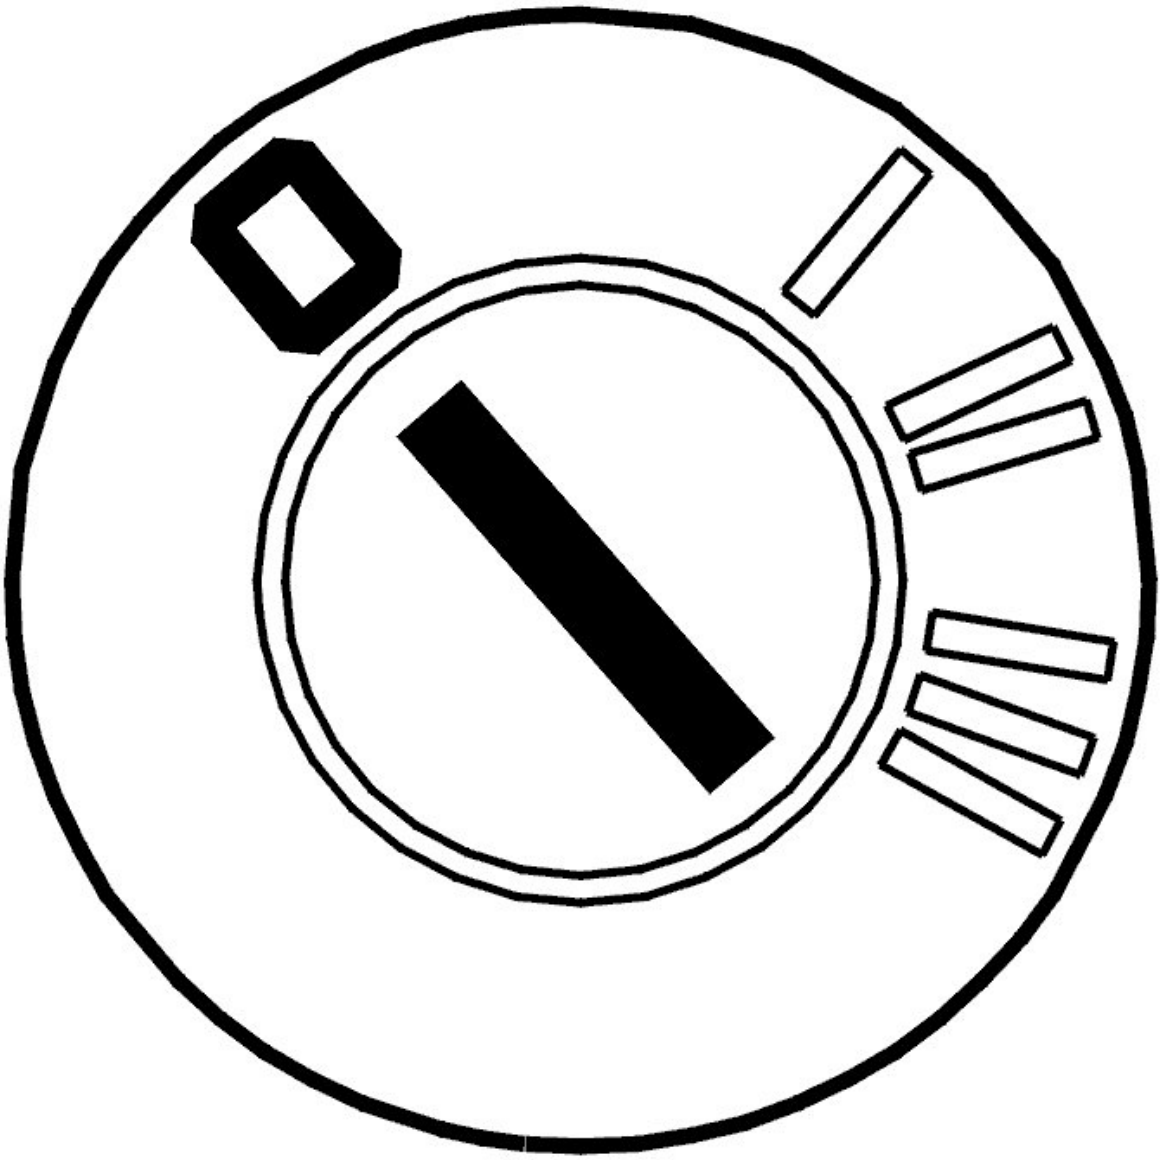
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals



Continue - Verification

Checking LIN bus 1 and connector



- Ignition off
- Disconnect the connector for the climate control module (CCM).

Check the climate control module (CCM) connector. Check for contact resistance. Check for oxidation. Check for loose connections.
Check LIN bus 1 between the climate control module (CCM), the connector for the climate control unit and the seat heating module (SHM) left. Check for an open-circuit.
Take readings between:

- The connector for climate control module (CCM) terminal #12 (#36) and the connector for climate control unit terminal #2
- The connector for climate control module (CCM) terminal #12 (#36) and connector A for seat heating module (SHM) left terminal #2.

Check LIN bus 1 between the components (the damper motors and the air quality sensor (AQS)) and the connector for the climate control unit. Check for an open-circuit.
Check the connector for the climate control unit. Check for contact resistance. Check for oxidation. Check for loose connections. Remedy as necessary.

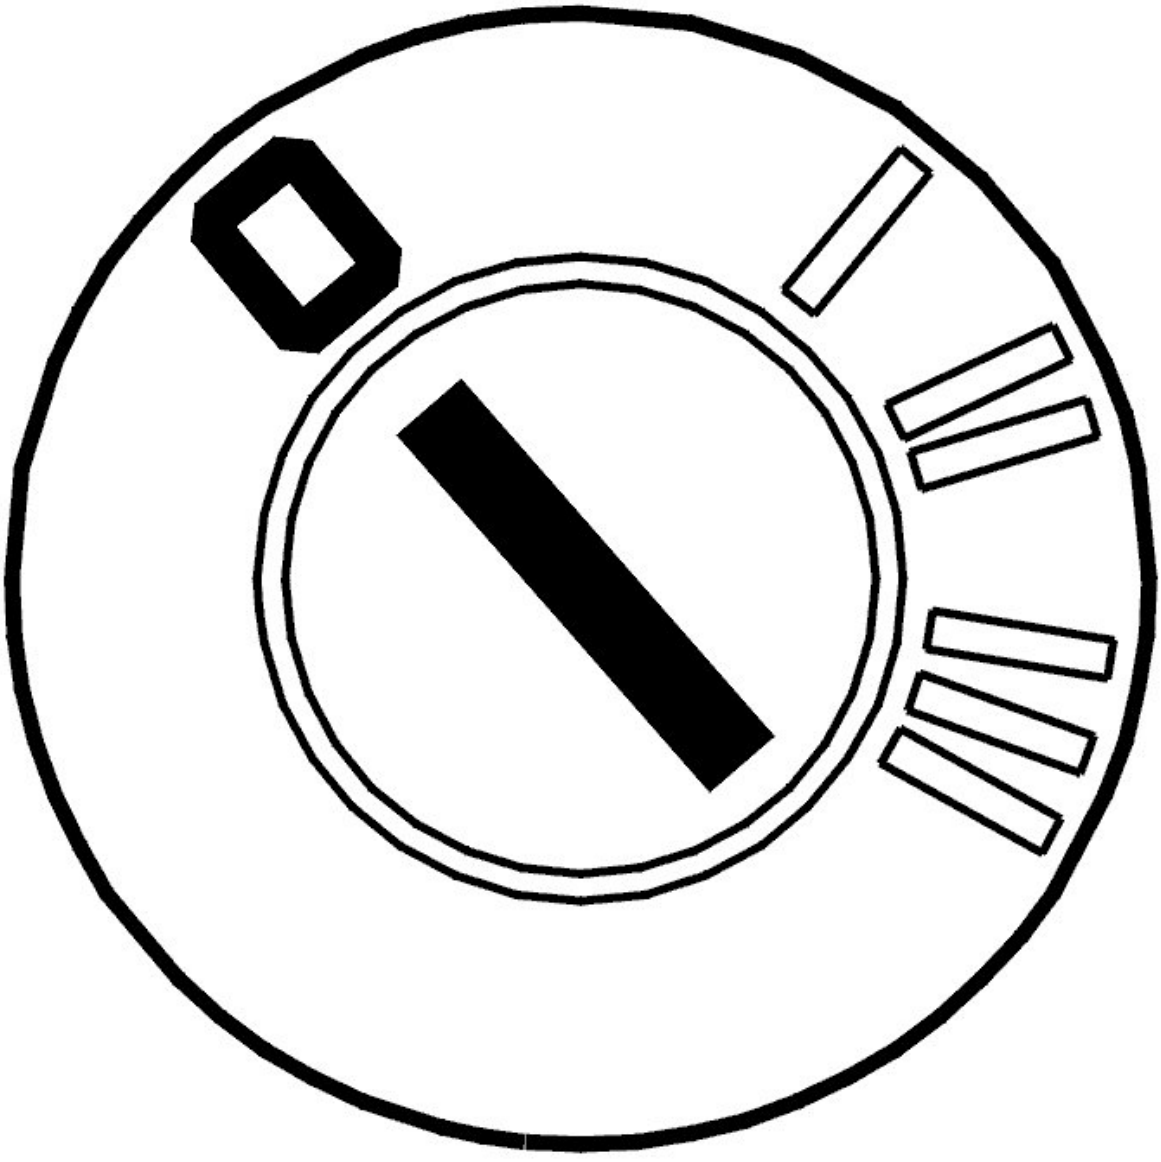
Continue - Verification

Checking the wiring and component



- Ignition off
- Disconnect the connector for the damper motor module (DMM) for air distribution
- Ignition on.

Check the connector. Check for contact resistance. Check for oxidation. Check for loose connections.
Check that the damper motor module (DMM) is connected to power supply and ground.

Measure the voltage on the connector for the damper motor module (DMM) between terminals #1 and #3
Check LIN bus 1 by taking a reading between the damper motor module (DMM) connector terminal #2 and the connector for the climate control unit terminal #2. Check for an open-circuit.
Try replacing the damper motor module (DMM) if no fault is found.
Remedy as necessary.

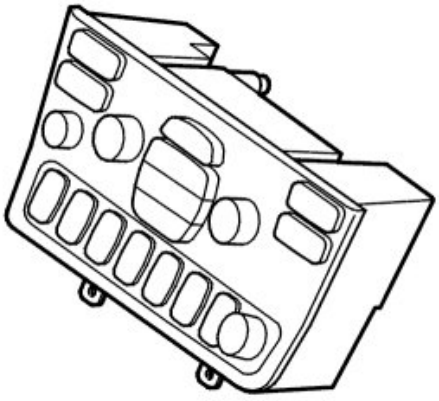
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CCM-DD20

Condition



The diagnostic trouble code (DTC) is stored if the climate control module (CCM) detects that data that is sent on LIN bus 2 is incorrect.
The following components communicate with the climate control module (CCM) via LIN bus 2:

- damper motor module (DMM) defroster

- damper motor module (DMM) temperature right (only ECC)
- damper motor module (DMM) recirculation (only on left-hand drive cars)
- air quality sensor (AQS) (only on left-hand drive cars)
- seat heating module (SHM) right.

The diagnostic trouble code (DTC) can be diagnosed in ignition positions I and II.

Substitute value
- None.

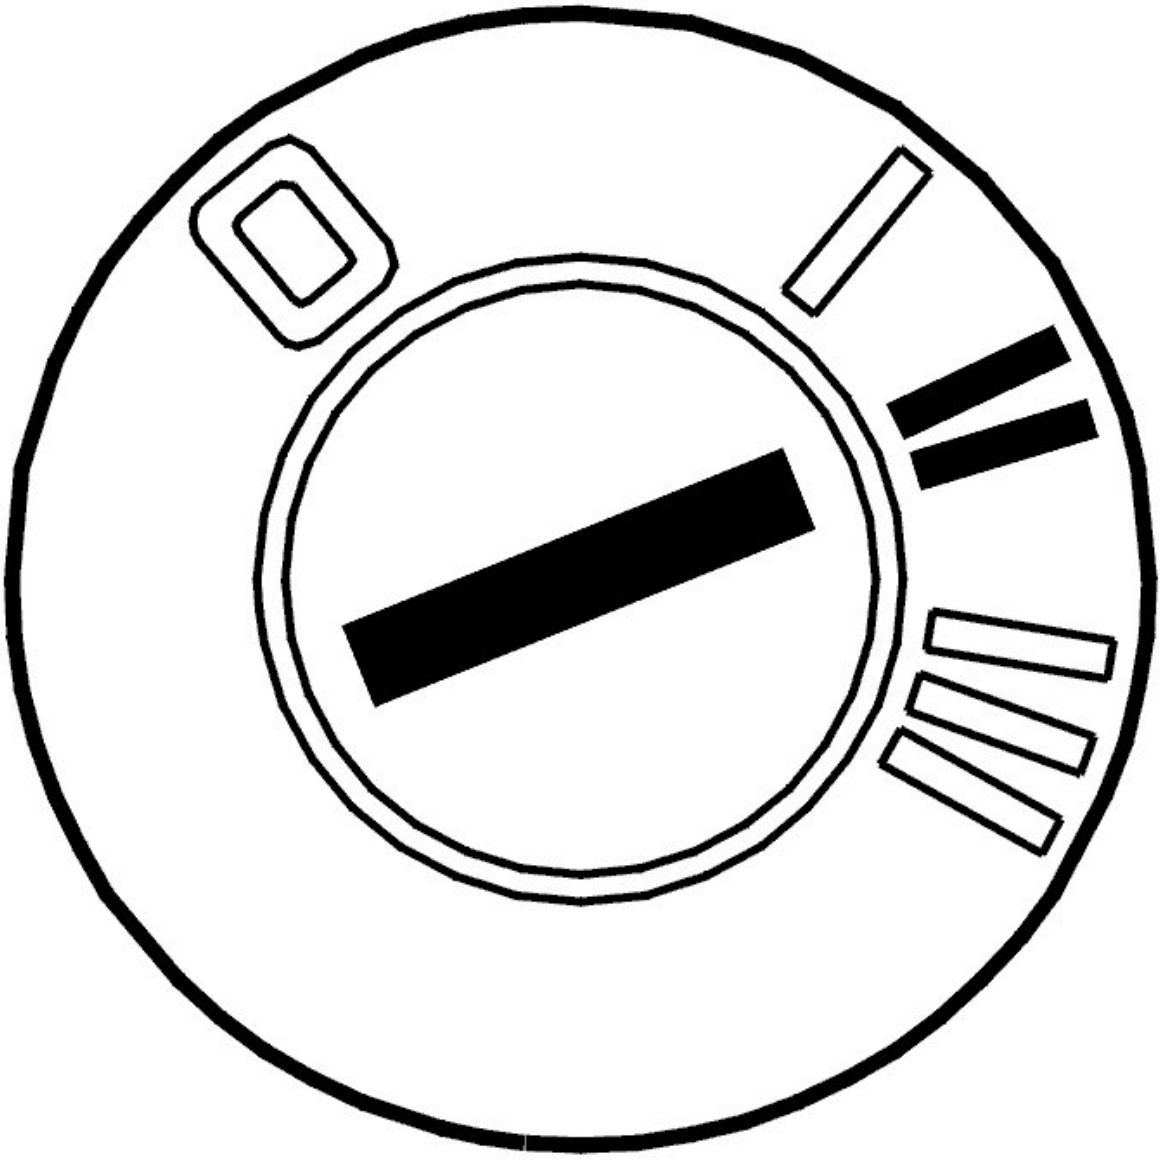
Possible source
- Incorrect data during communication on LIN bus 2.

Fault symptom[s]
- Misting on the windows and/or door mirrors.
- Air flow problem.
- Poor heating in the passenger compartment.
- The front seat heating does not function.
- Poor air quality in the passenger compartment.

Incorrect Data

Incorrect data

Checking components



- Ignition off
- Disconnect connector A for the seat heating module (SHM) right
- Ignition on.

The climate control module (CCM) has detected that a component on LIN bus 2 is transmitting incorrect data and disrupting communication on the LIN bus.

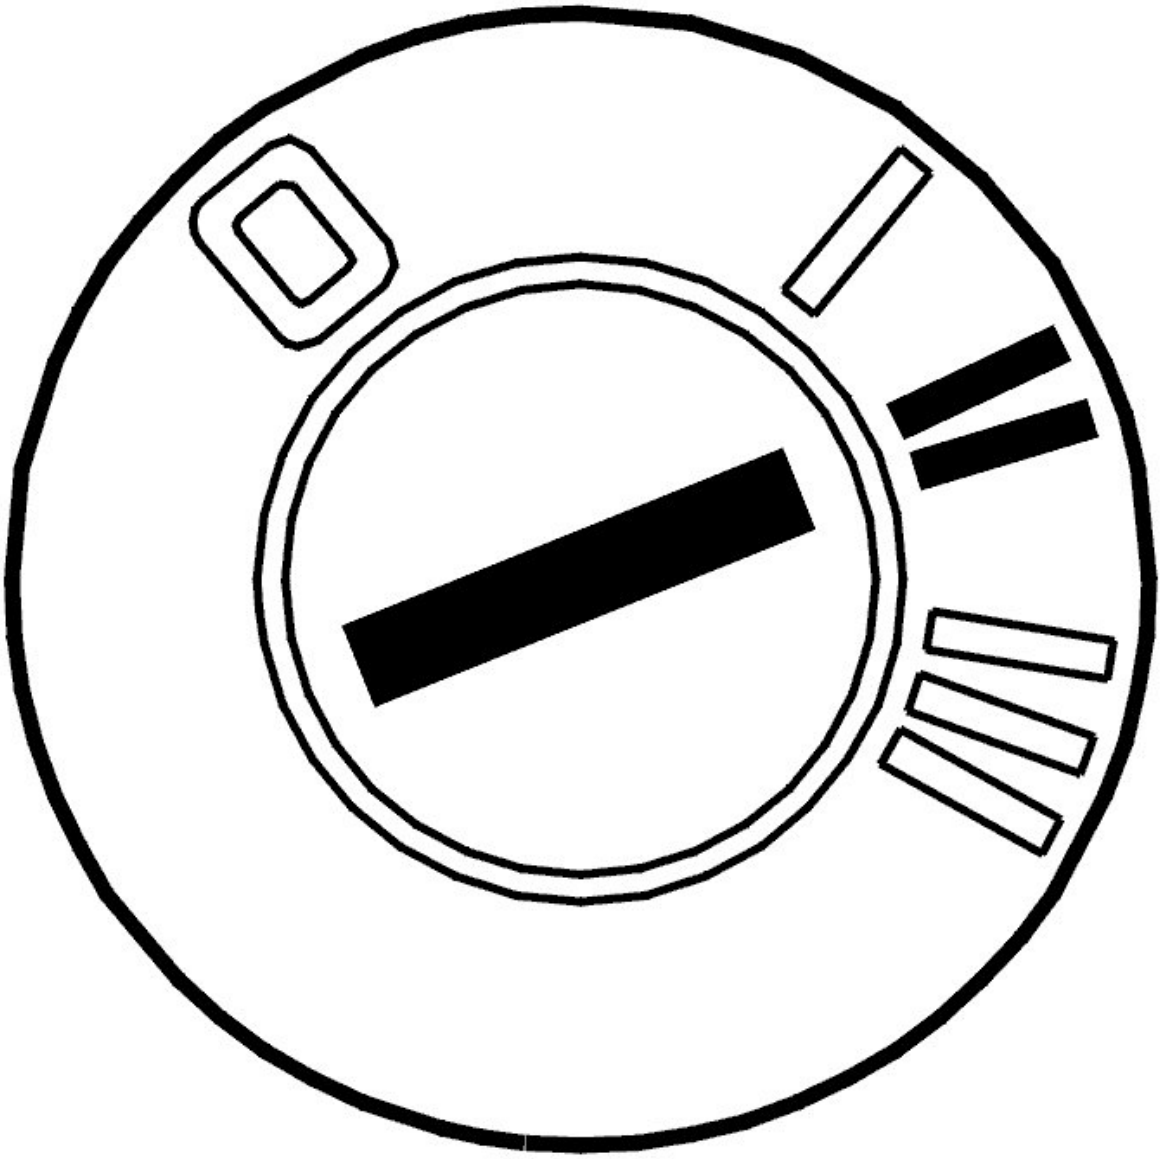
Check the communication by disconnecting the seat heating module (SHM) right.
If other control modules on LIN bus 2 now function, replace the seat heating module (SHM) right.

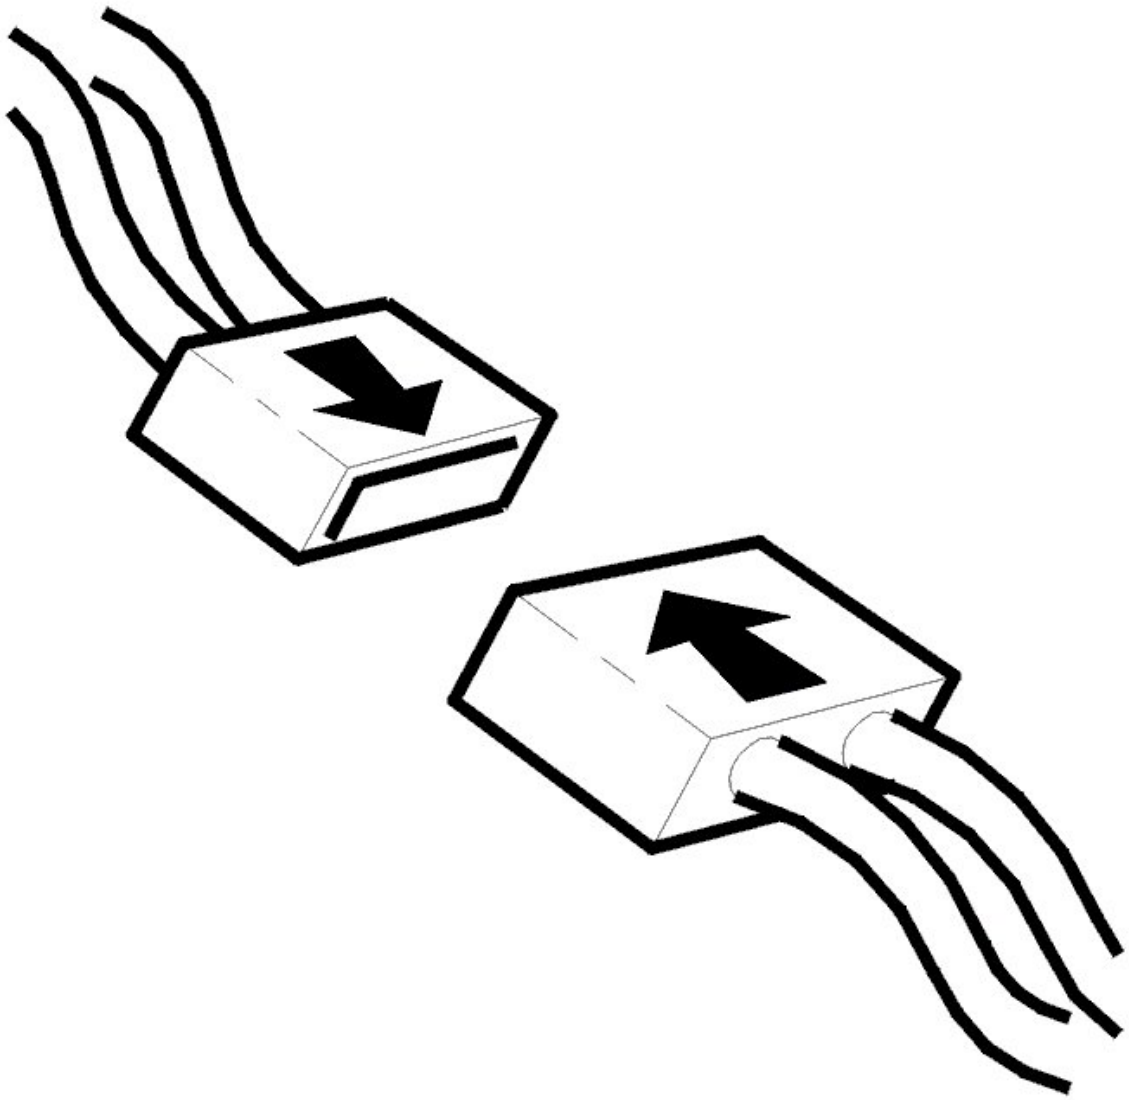
Was a fault detected?

Yes - Verification

No - Checking components

Checking components





- Ignition off
- Reconnect connector A for the seat heating module (SHM)
- Ignition on.

Check the components on the climate control unit as follows:

- Disconnect the connectors for the components one at a time
- Check whether the other components regain functionality, for example by activating seat heating
- If the functionality for the other components returns, the fault is probably in the disconnected components.

Remedy as necessary.

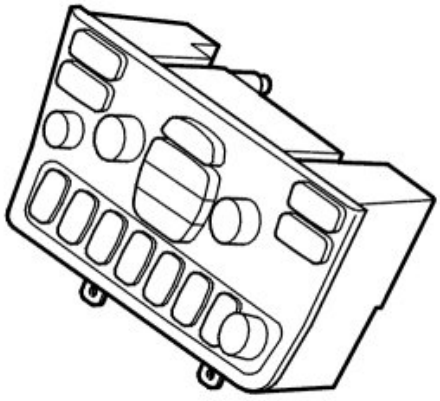
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CCM-DD21

Condition



The diagnostic trouble code (DTC) is stored if the climate control module (CCM) detects a short-circuit to supply voltage or ground in LIN bus 2.
A short-circuit to supply voltage or ground in the LIN bus will affect communications and the function of all the components.
The climate control module (CCM) communicates with the damper motors, air quality sensors and seat heating via two LIN buses.

The number of components in LIN bus 2 can vary depending on the vehicle equipment (ECC/MCC and options) and if the vehicle has right-hand drive or left-hand drive.
The following components communicate on LIN bus 2:

- damper motor module (DMM) defroster
- damper motor module (DMM) temperature right (only ECC)
- damper motor module (DMM) recirculation (only on left-hand drive cars)
- air quality sensor (AQS) (only on left-hand drive cars)
- seat heating module (SHM) right.

The diagnostic trouble code (DTC) can be diagnosed in ignition positions I and II.

Substitute value

- None.

Possible source

- LIN bus 2 short-circuited to supply voltage
- LIN bus 2 short-circuited to ground.

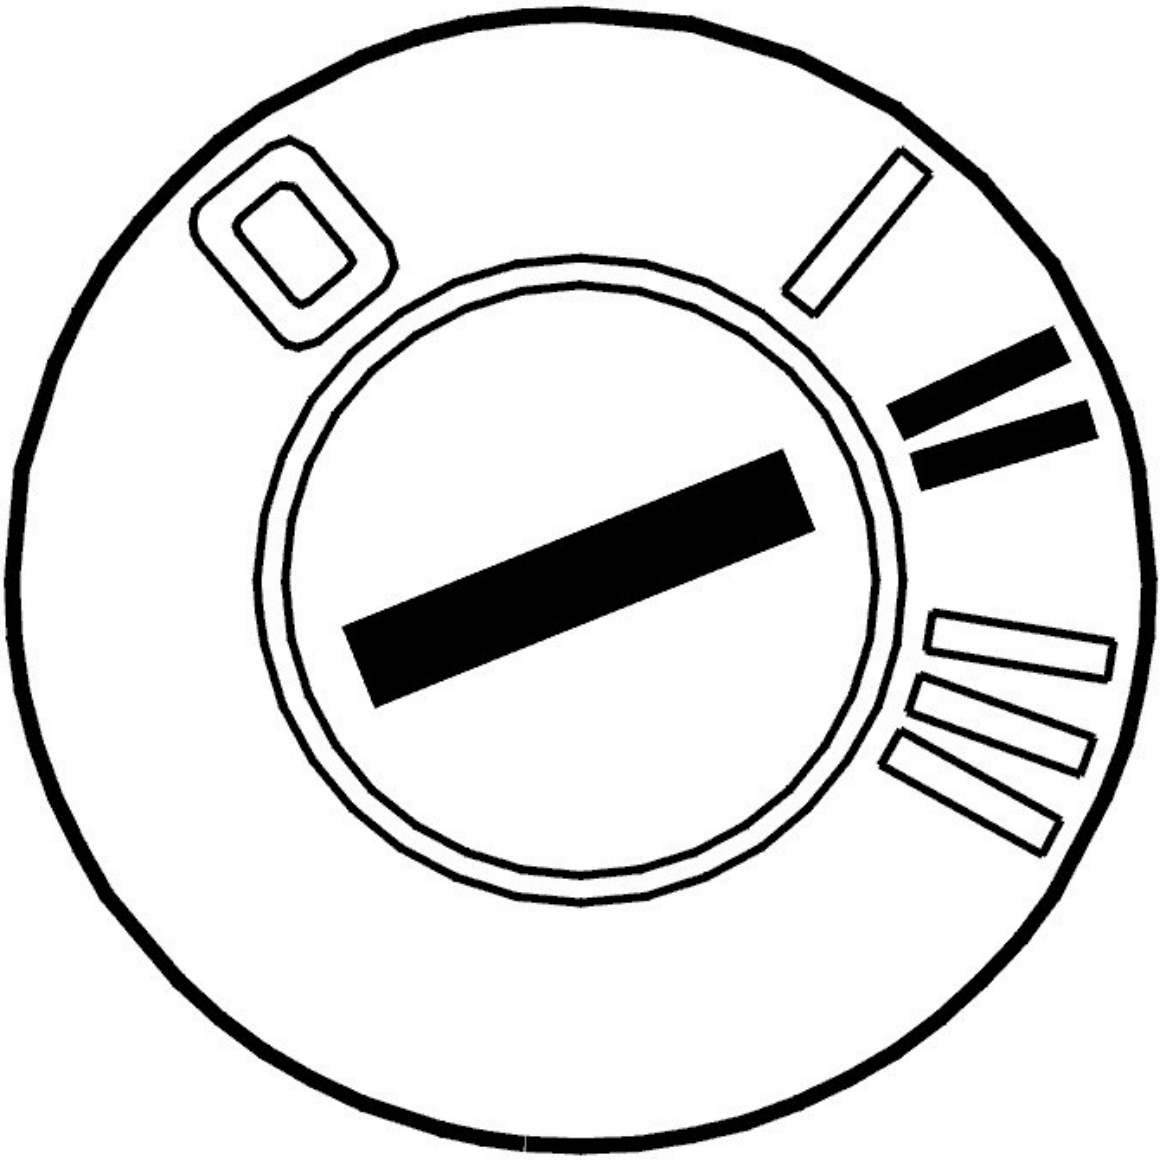
Fault symptom[s]

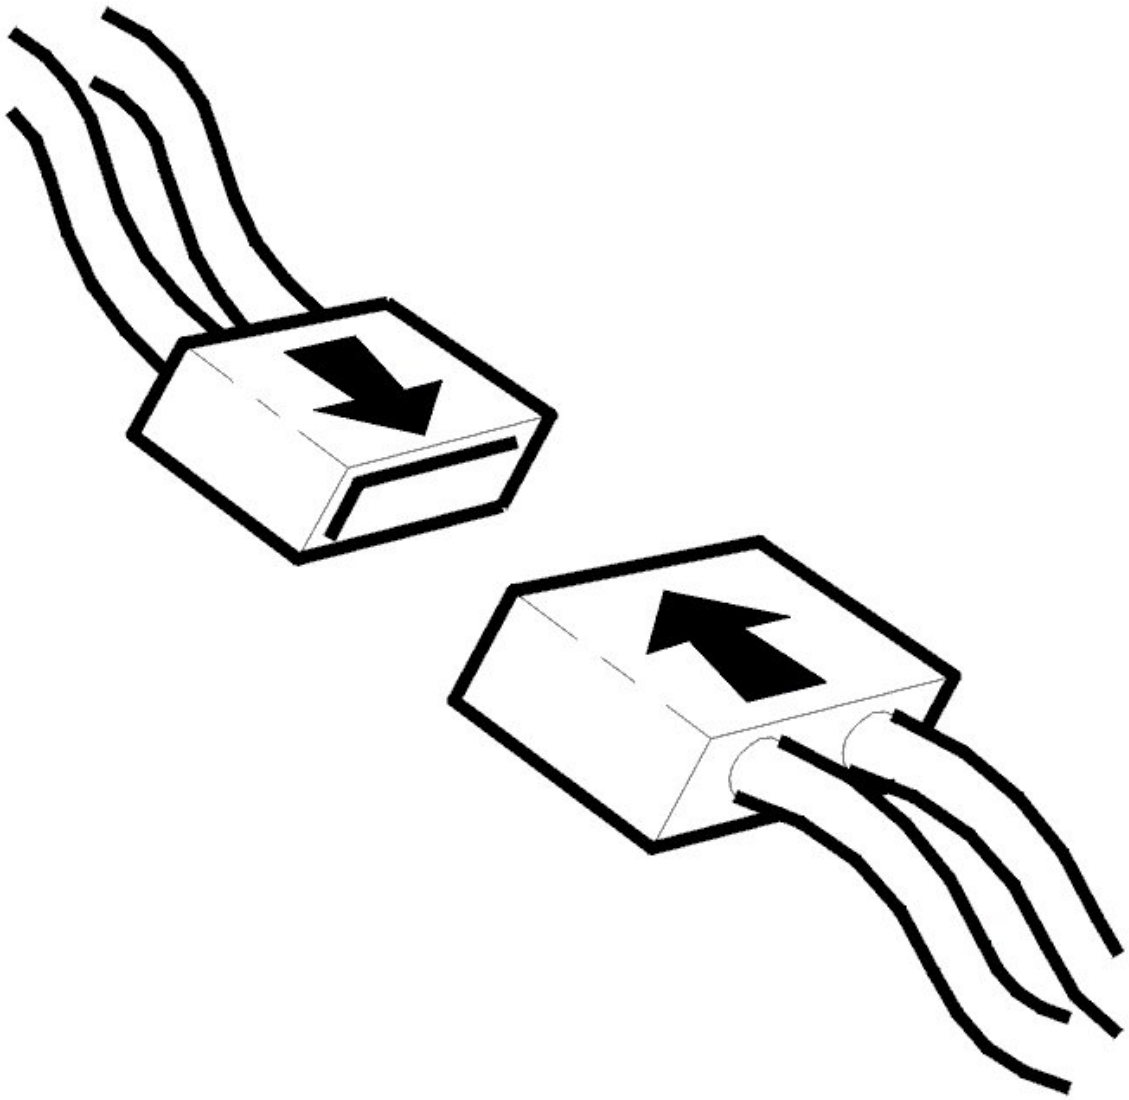
- Misting on the windows and/or door mirrors.
- Poor heating in the passenger compartment.
- The front seat heating does not function.
- Poor air quality in the passenger compartment.

Signal Too High / Signal Too Low

Signal too high / Signal too low

Checking the cable





- Ignition off
- Disconnect the connector for the climate control module (CCM)
- Ignition on.

Check LIN bus 2. Check for a short-circuit to supply voltage.
Take a reading on the connector for the climate control module (CCM) between terminals #7 (#31) and #1 (#25).
If there is a short-circuit to supply voltage in LIN bus 2, continue fault-tracing by locating where the short-circuit has occurred as follows:

- Disconnect the connector on the climate control unit that connects LIN bus 2 from the climate control module (CCM) to other components on the climate control unit
- Check the section of LIN bus 2 that connects the climate control module (CCM) to the right-hand seat heating module (SHM) and the connector on the climate control unit. Take a reading on the connector for the climate control module (CCM) between terminals #7 (#31) and #1 (#25).

If the fault persists, fault-trace LIN bus 2 between the climate control module (CCM), the right-hand seat heating module (SHM) and the connector on the climate control unit. Check for a short-circuit to supply voltage.
If the fault is no longer present, fault-trace LIN bus 2 between the connector and the components on the climate control unit. Check for a short-circuit to supply voltage.
Remedy as necessary.

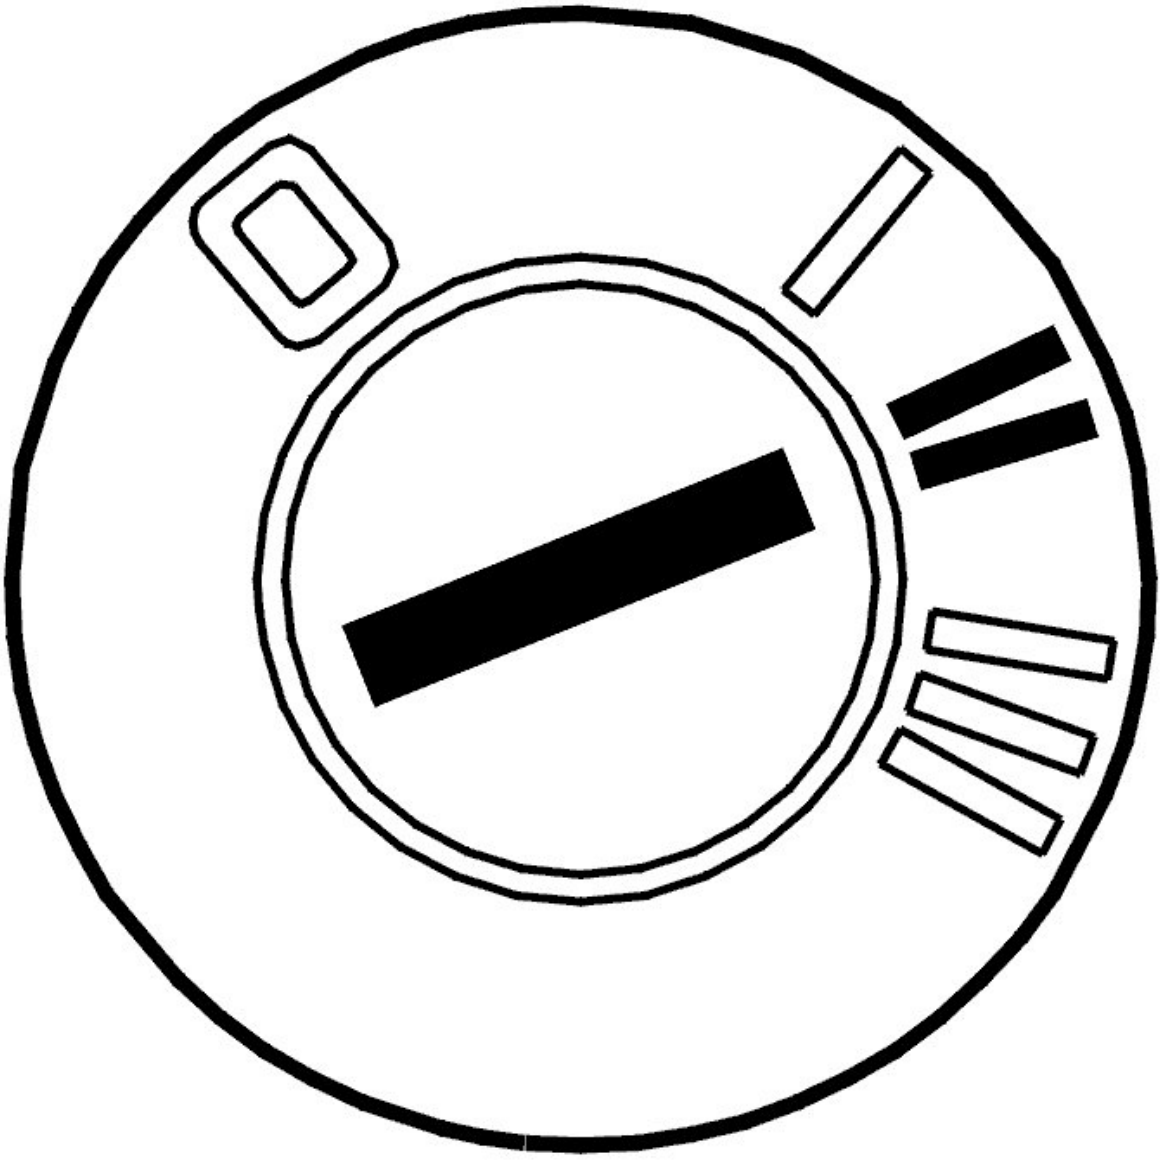
- The front seat heating does not function.
- Poor air quality in the passenger compartment.

Faulty Check Sum

Faulty check sum

Checking components



- Ignition on.

The climate control module (CCM) has diagnosed that two or more damper motor modules (DMM) have the same identity on LIN bus 2.
This may be because one damper motor module (DMM) has been installed incorrectly.
After replacing a damper motor module (DMM), it must be allocated a correct identity by the climate control module (CCM). This is performed during identification of the damper motors on the LIN bus.

If a damper motor module (DMM) is installed that already has an identity allocated to it, this can lead to a conflict on the LIN bus. Remedy by correctly identifying the damper motor.

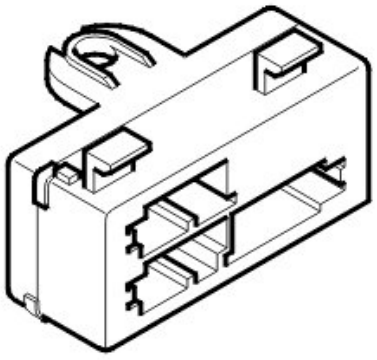
Condition



The diagnostic trouble code (DTC) is stored if the climate control module (CCM) detects an open-circuit in the communication between the right-hand seat heater and the climate control module (CCM) on LIN bus 2.
The diagnostic trouble code (DTC) may occur together with diagnostic trouble codes (DTCs) for other components on LIN bus 2 (CCM-DD30 -

CCM-DD34) depending on where the open-circuit has occurred.
The diagnostic trouble code (DTC) can be diagnosed at ignition switch position II.
The diagnostic trouble code (DTC) can only be diagnosed for the climate control module (CCM) when seat heating is installed in the car.

Substitute value
- None.

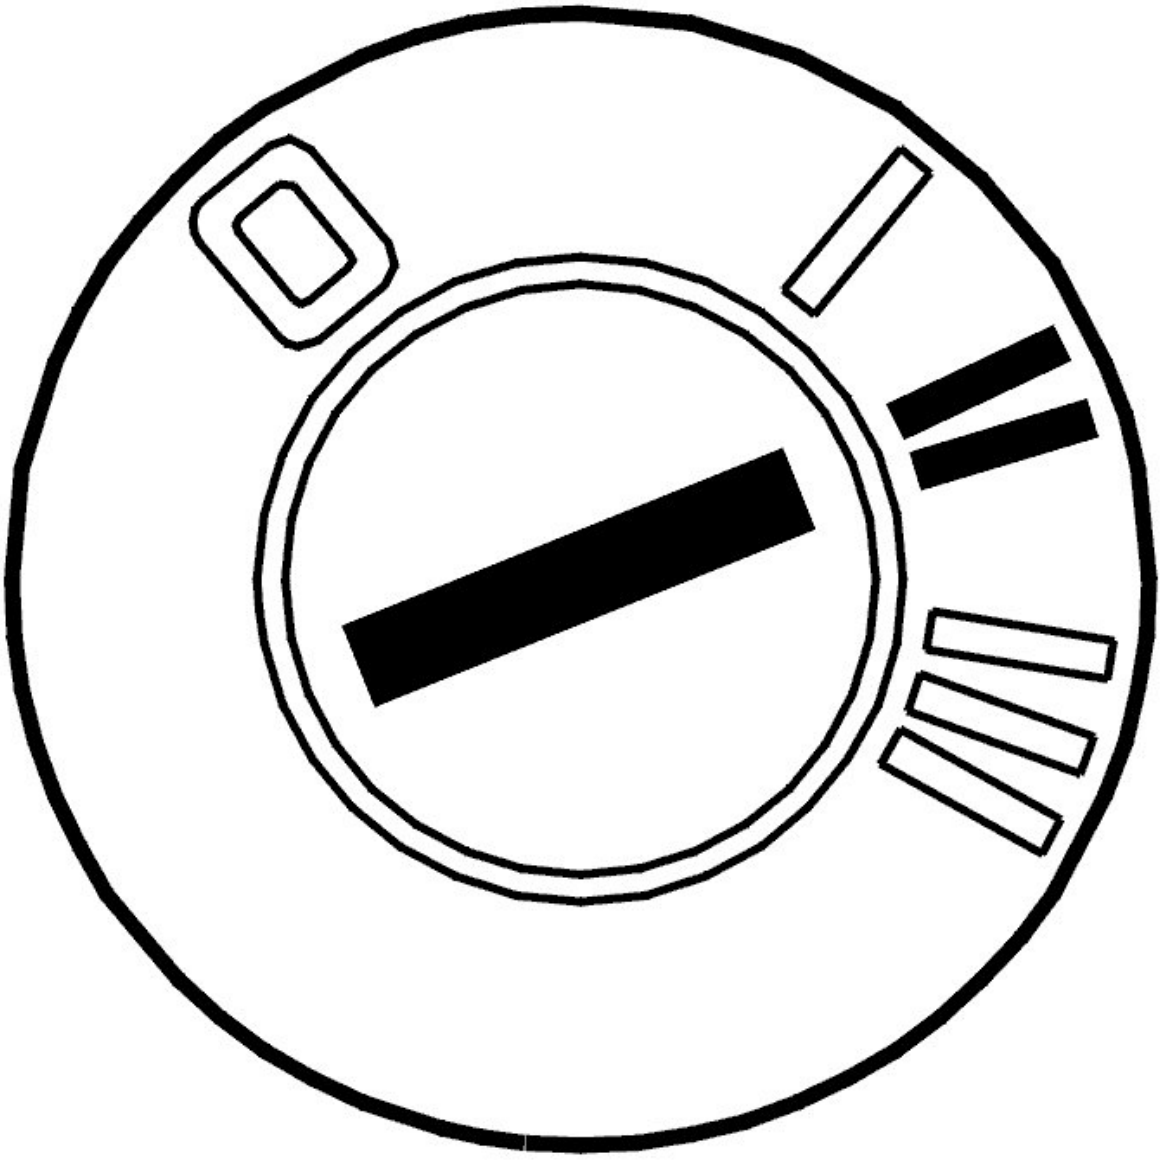
Possible source
- Open-circuit on LIN bus 2 between the climate control module (CCM) and the right-hand seat heating module (SHM)
- Contact resistance, oxidation or loose connections in the connectors.

Fault symptom[s]
- The front seat heating does not function.

No Communication

No communication

Checking the diagnostic trouble codes (DTCs)



- Ignition on.

Check that the fuse for the Seat heating module (SHM) is intact.
The diagnostic trouble code (DTC) may occur together with diagnostic trouble codes (DTCs) for other components that communicate with the climate control module (CCM) via LIN bus 2.
Check whether the diagnostic trouble code (DTC) has been stored together with other diagnostic trouble codes (DTCs) for other components on the climate control unit.
Select one of the following options:

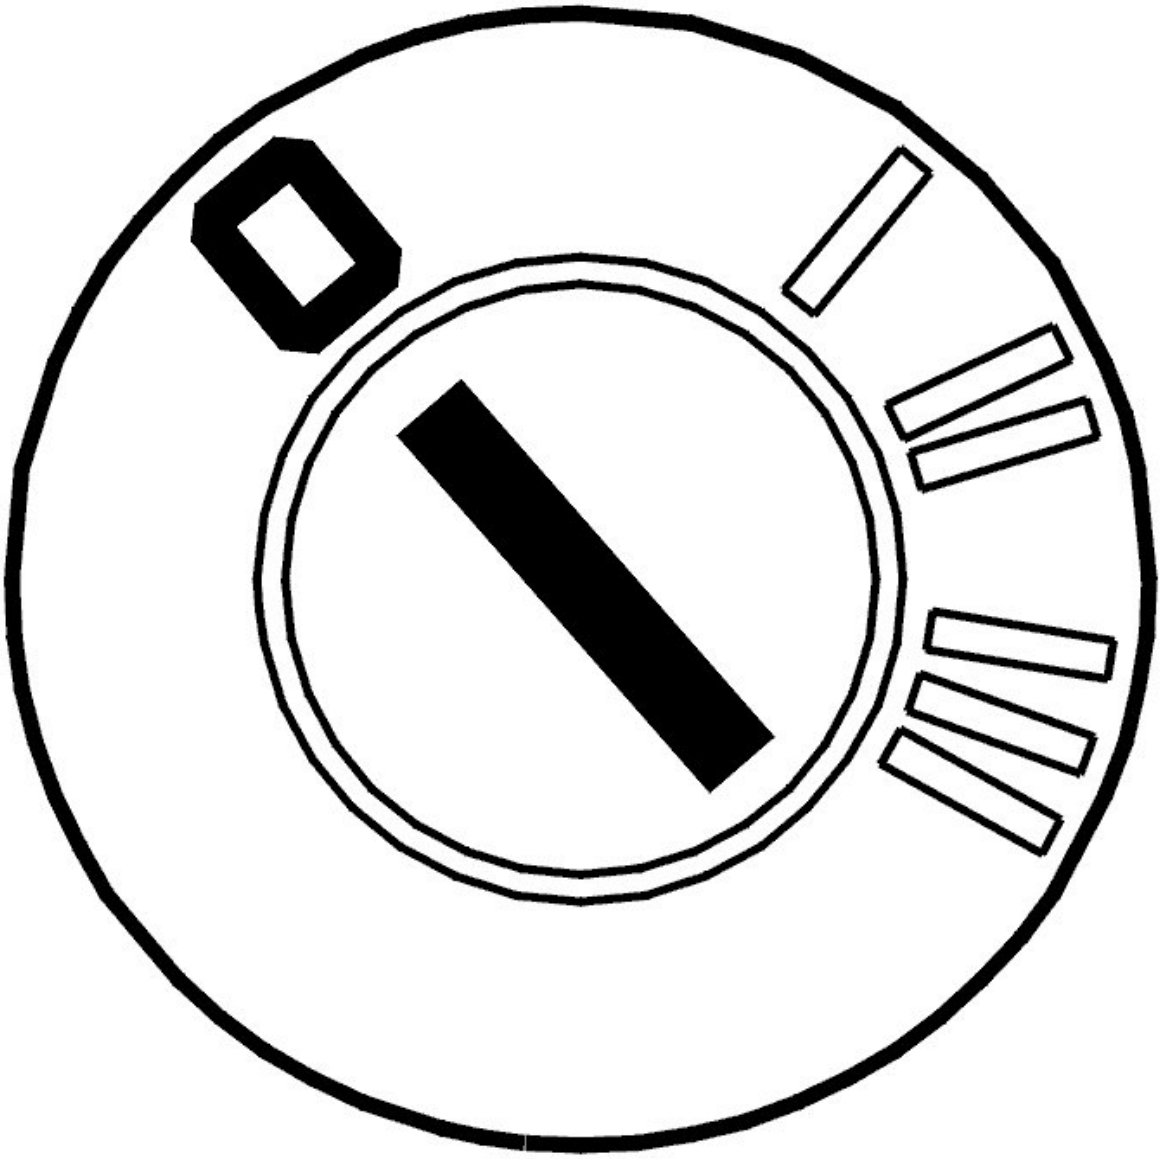
1. The diagnostic trouble code (DTC) is stored together with diagnostic trouble codes (DTCs) for components on LIN bus 2 (CCM-DD30-CCM-DD34)
2. The diagnostic trouble code (DTC) is not stored together with diagnostic trouble codes (DTCs) for other components on LIN bus 2.

Select an alternative.

1 - Checking LIN bus 2 and connector

2 - Checking the wiring and component

Checking LIN bus 2 and connector



- Ignition off
- Disconnect the connector for the climate control module (CCM).

Check the climate control module (CCM) connector. Check for contact resistance. Check for oxidation. Check for loose connections.
Check LIN bus 2 between the climate control module (CCM), the connector for the climate control unit and the seat heating module (SHM) right. Check for an open-circuit.
Take readings between:

- The connector for climate control module (CCM) terminal #7 (#31) and the connector for climate control unit terminal #5
- The connector for the climate control module (CCM) terminal #7 (#31) and connector A for the seat heating module (SHM) right terminal #2.

Remedy as necessary.

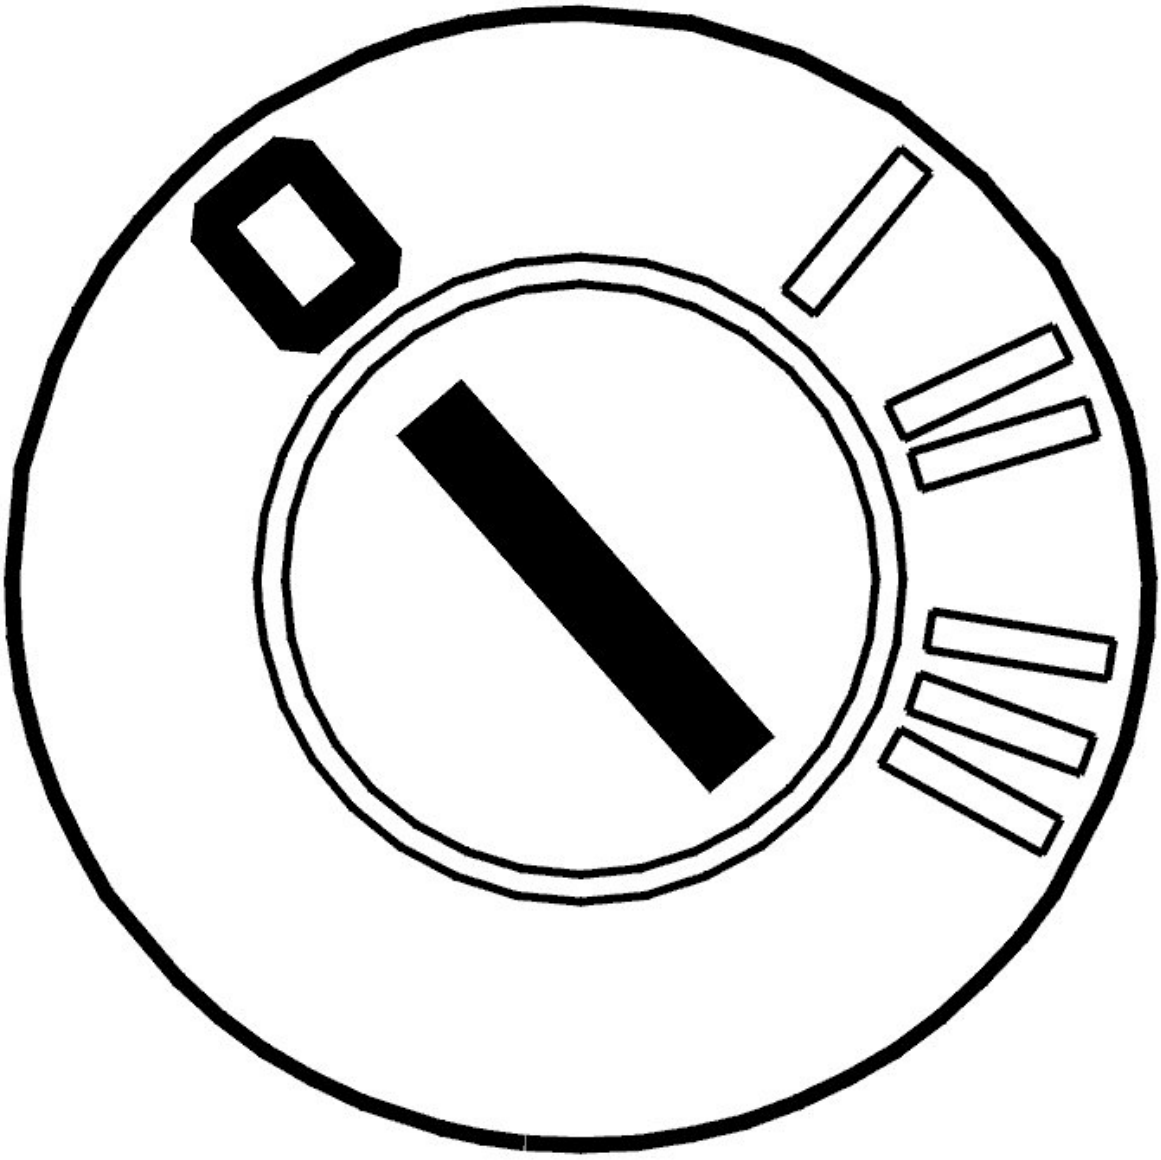
Continue - Verification

Checking the wiring and component



- Ignition off
- Disconnect connector A for the seat heating module (SHM) right.

Check connector A for the seat heating module (SHM). Check for contact resistance. Check for oxidation. Check for loose connections.
Check that the seat heating module (SHM) is connected to power supply and ground.
Measure the voltage at connector A between terminals #1 and #4.
Check LIN bus 2 by taking a reading between connector A for seat heating module (SHM) terminal #2 and the connector for climate control module (CCM) terminal A#7 (#31). Check for an open-circuit.
Try replacing the seat heating module (SHM) if no fault is found.
Remedy as necessary.

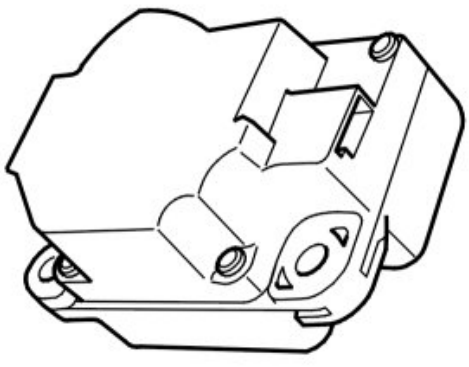
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CCM-DD31

Condition



The diagnostic trouble code (DTC) is stored if the climate control module (CCM) detects an open-circuit in the communication between the damper motor recirculation and the climate control module (CCM) on LIN bus 2.
The diagnostic trouble code (DTC) may occur together with diagnostic trouble codes (DTCs) for other components on LIN bus 2 (CCM-DD30 -

CCM-DD34) depending on where the open-circuit has occurred.
The diagnostic trouble code (DTC) can be diagnosed at ignition switch position II.

Substitute value
- None.

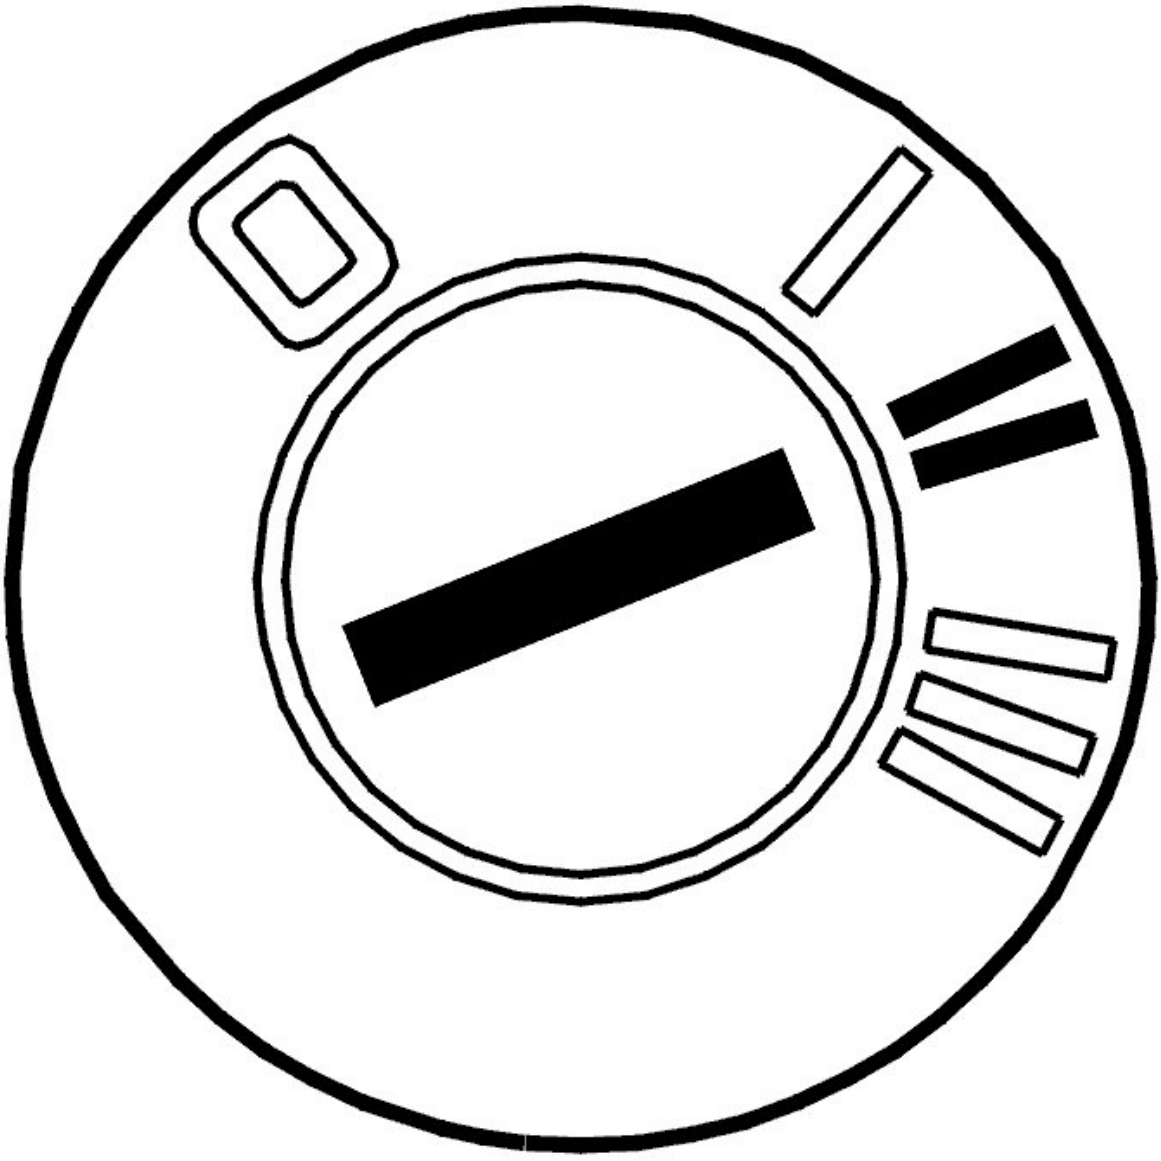
Possible source
- Open-circuit on LIN bus 2 between the climate control module (CCM) and the damper motor module (DMM) recirculation
- Contact resistance, oxidation or loose connections in the connectors.

Fault symptom[s]
- No recirculation.

No Communication

No communication

Checking the diagnostic trouble codes (DTCs)



- Ignition on.

The diagnostic trouble code (DTC) may occur together with diagnostic trouble codes (DTCs) for other components that communicate with the climate control module (CCM) via LIN bus 1 and LIN bus 2.
Check whether the diagnostic trouble code (DTC) has been stored together with other diagnostic trouble codes (DTCs) for other components on the climate control unit.
Select one of the following options:

1. The diagnostic trouble code (DTC) is stored together with diagnostic trouble codes (DTCs) for components in both LIN bus 1 and LIN bus 2 (CCM-DD10 - CCM-DD16, CCM-DD30 - CCM-DD34)
2. The diagnostic trouble code (DTC) is together with diagnostic trouble codes (DTCs) for components only on LIN bus 2 (CCM-DD30-CCM-DD34)
3. The diagnostic trouble code (DTC) is not together with diagnostic trouble codes (DTCs) for other components on LIN bus 1 and LIN bus 2.

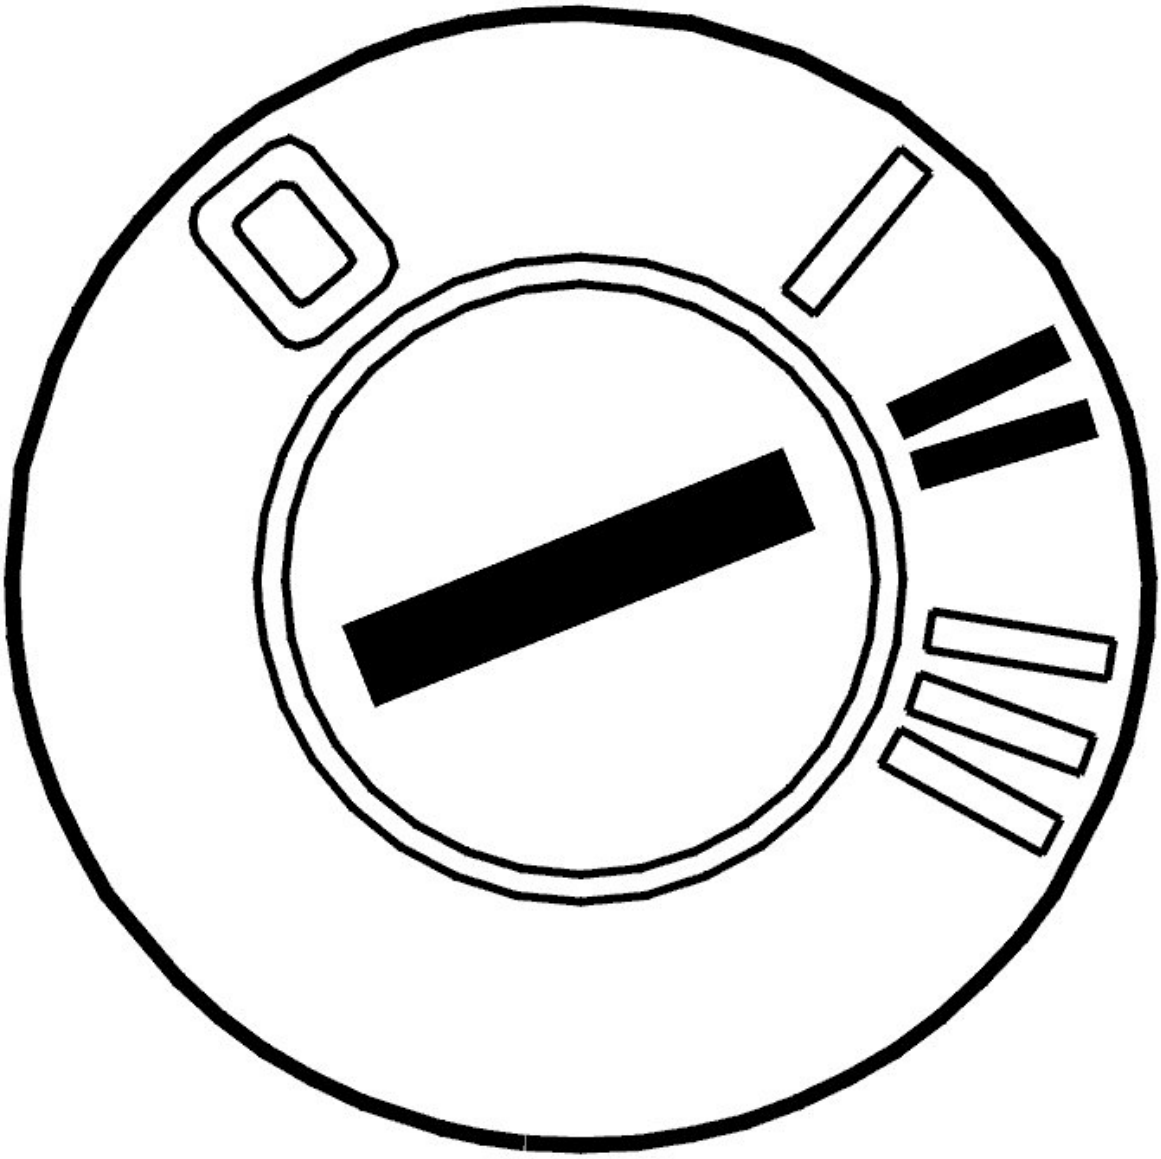
Select an alternative.

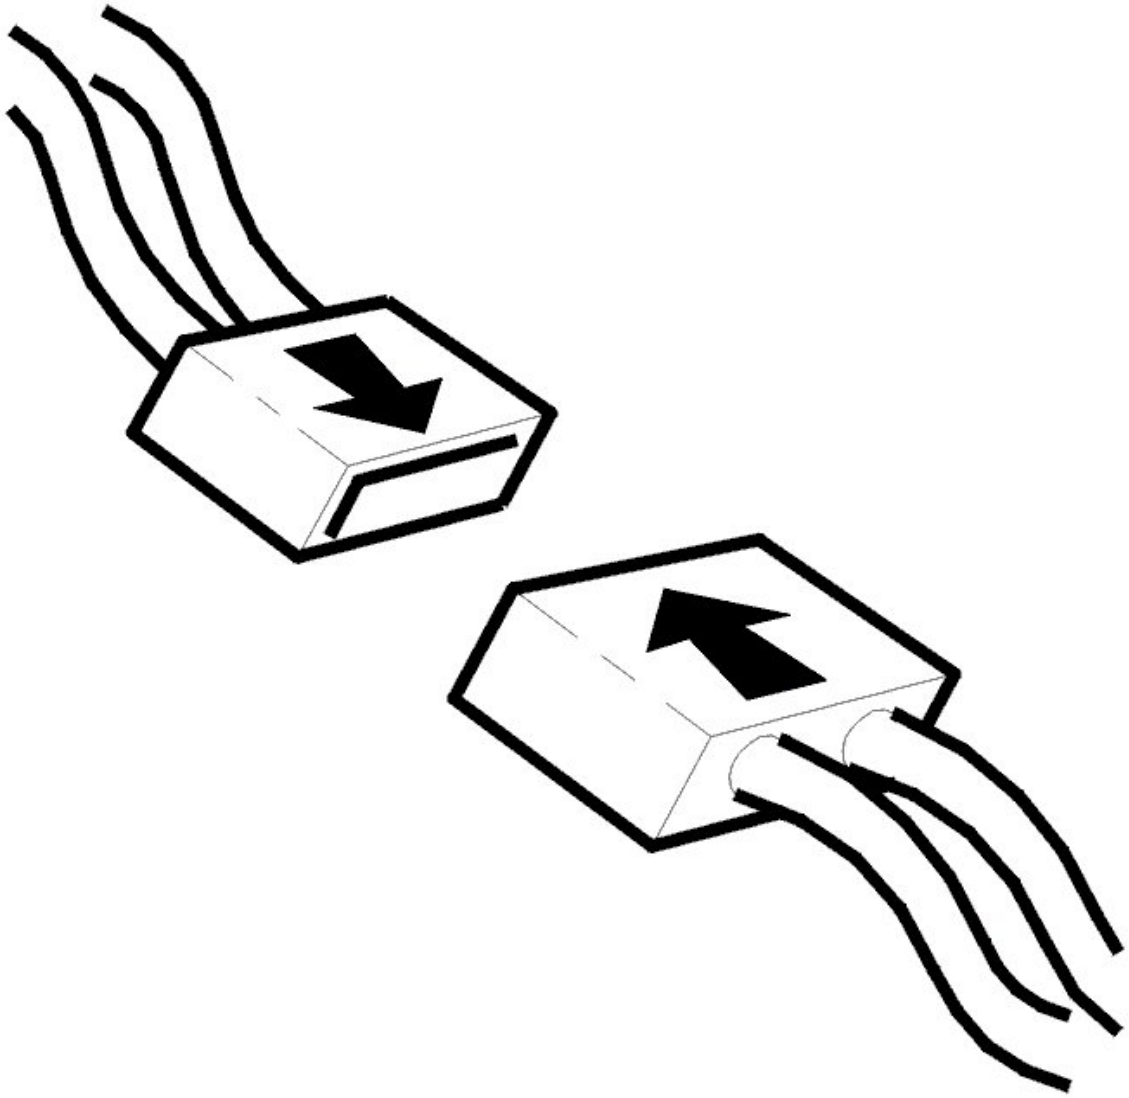
1 - Checking the connectors and wiring

2 - Checking LIN bus 2 and connector

3 - Checking the wiring and component

Checking the connectors and wiring





- Ignition off
- Disconnect the connector for the climate control module (CCM)
- Disconnect the connector for the central electronic module (CEM)
- Ignition on.

Checking the power supply and ground terminals

The following applies to components on the climate control unit that communicate with the climate control module (CCM) via LIN bus 1 and LIN bus 2:

- All components are jointly powered via a fuse from the central electronic module (CEM)
- All components are grounded via a common ground terminal.

Check the power supply to the components on the climate control unit by taking a reading on connector A for the central electronic module (CEM) between terminal #A44 (C44) and chassis ground.
Also check the fuse on the central electronic module (CEM).
Check the power supply cable between the central electronic module (CEM) and the connector for the climate control unit. Check for an open-circuit. Measure between terminal #1 on the connector for the climate control unit and chassis ground.
Check the ground terminal for the components on the climate control unit. Measure between the connector for climate control unit terminal #6 and chassis ground.
Check the connector for the climate control unit and connector A for the central electronic module (CEM). Check for contact resistance. Check for oxidation. Check for loose connections.

Checking LIN bus

Check both LIN bus 1 and LIN bus 2. Check for an open-circuit.
Take readings between:

- The connector for climate control module (CCM) terminal #12 (#36) and the connector for climate control unit terminal #2
- The connector for climate control module (CCM) terminal #7 (#31) and the connector for climate control unit terminal #5.

Check the wiring between the connector and the components on the climate control unit. Check for an open-circuit.
Remedy as necessary.

- Ignition on.

Checking the power supply and ground terminals

The following applies to components on the climate control unit that communicate with the climate control module (CCM) via LIN bus 1 and LIN bus 2:

- All components are jointly powered via a fuse from the central electronic module (CEM)
- All components are grounded via a common ground terminal.

Check the power supply to the components on the climate control unit by taking a reading on connector A for the central electronic module (CEM) between terminal #A44 (C44) and chassis ground.
Also check the fuse on the central electronic module (CEM).
Check the power supply cable between the central electronic module (CEM) and the connector for the climate control unit. Check for an open-circuit. Measure between terminal #1 on the connector for the climate control unit and chassis ground.
Check the ground terminal for the components on the climate control unit. Measure between the connector for climate control unit terminal #6 and chassis ground.
Check the connector for the climate control unit and connector A for the central electronic module (CEM). Check for contact resistance. Check for oxidation. Check for loose connections.

Checking LIN bus

Check both LIN bus 1 and LIN bus 2. Check for an open-circuit.
Take readings between:

- The connector for climate control module (CCM) terminal #12 (#36) and the connector for climate control unit terminal #2
- The connector for climate control module (CCM) terminal #7 (#31) and the connector for climate control unit terminal #5.

Check the wiring between the connector and the components on the climate control unit. Check for an open-circuit.
Remedy as necessary.

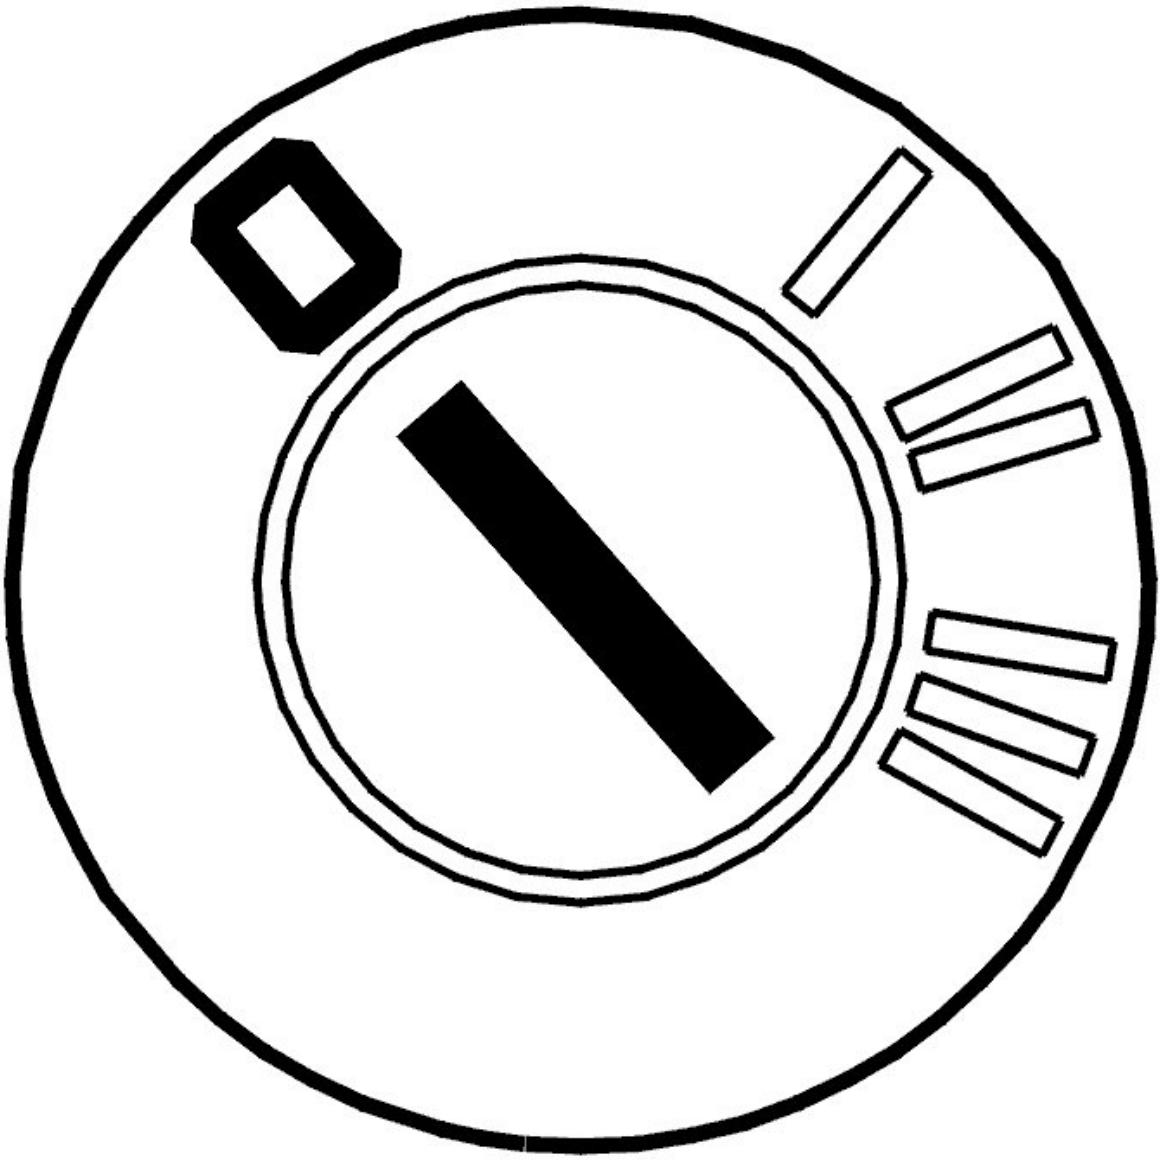
Continue - Verification

Checking LIN bus 2 and connector



- Ignition off
- Disconnect the connector for the climate control module (CCM).

Check the climate control module (CCM) connector. Check for contact resistance. Check for oxidation. Check for loose connections.
Check LIN bus 2 between the climate control module (CCM), the connector for the climate control unit and the seat heating module (SHM) right. Check for an open-circuit.
Take readings between:

- The connector for climate control module (CCM) terminal #7 (#31) and the connector for climate control unit terminal #5
- The connector for the climate control module (CCM) terminal #7 (#31) and connector A for the seat heating module (SHM) right terminal #2.

Check LIN bus 2 between the components (the damper motors and the air quality sensor (AQS)) and the connector for the climate control unit. Check for an open-circuit.
Check the connector for the climate control unit. Check for contact resistance. Check for oxidation. Check for loose connections.
Remedy as necessary.

Other information:

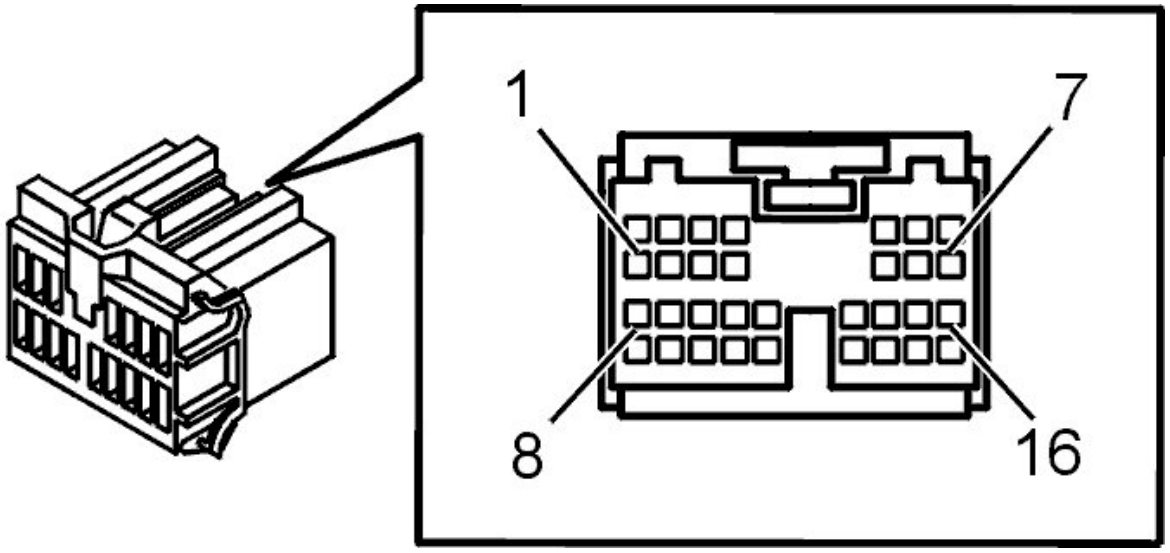
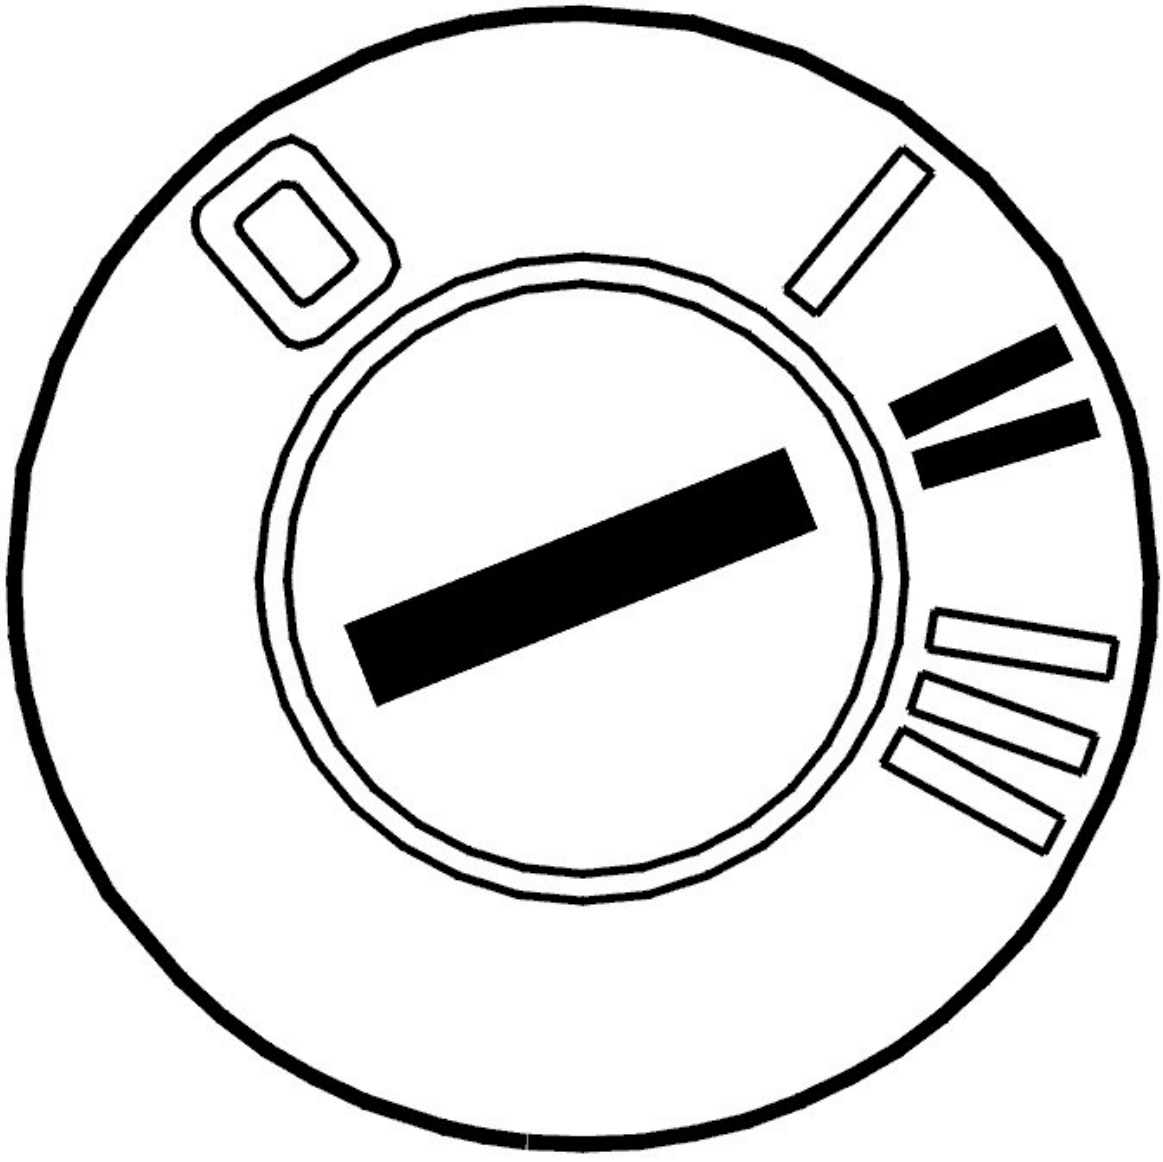
- Seat heating module (SHM), replacing See: Body and Frame/Relays and Modules - Body and Frame/Seat Heater Control Module/Service and Repair
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals



Continue - Verification

Checking the wiring and component



- Ignition off
- Disconnect the connector for the damper motor module (DMM) defroster
- Ignition on.

Check the connector. Check for contact resistance. Check for oxidation. Check for loose connections.
Check that the damper motor module (DMM) is connected to power supply and ground.

Measure the voltage on the connector for the damper motor module (DMM) between terminals #1 and #3.
Check LIN bus 2 by taking a reading between the damper motor module (DMM) connector terminal #2 and the connector for the climate control unit terminal #5. Check for an open-circuit.
Try replacing the damper motor module (DMM) if no fault is found.
Remedy as necessary.

Other information:

- For further information about the connectors, fuses and relays, see the relevant section in the Wiring Diagram

Identifying the Damper Motor Module (DMM)

Information

- The control module must be identified after replacing the Damper Motor Module (DMM).

Note! Identification must only be carried out when replacing the Damper Motor Module (DMM).

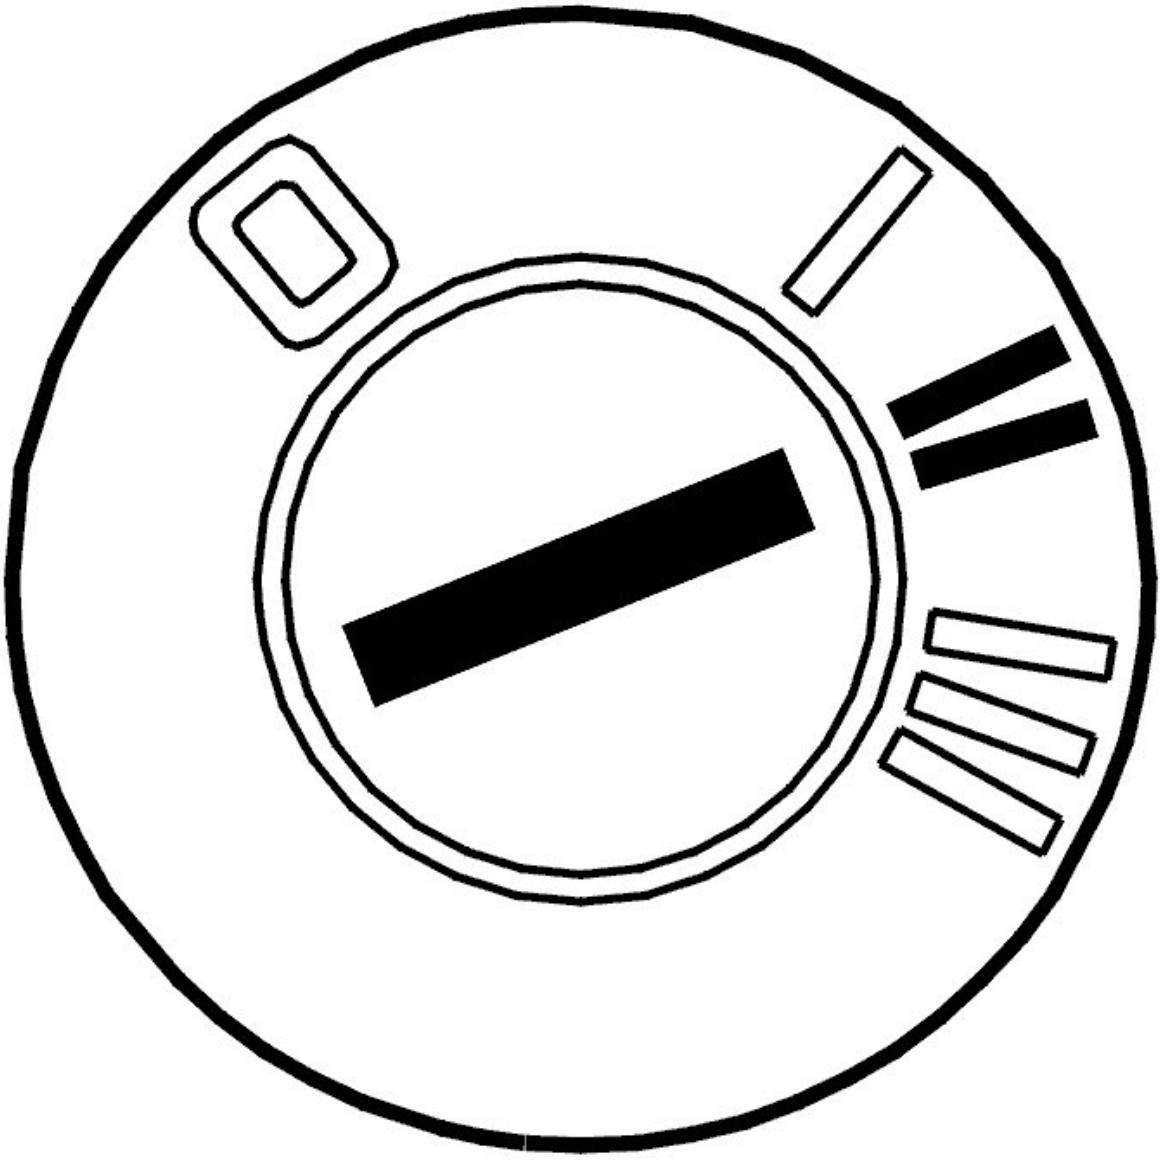
Have any damper motors been replaced?

Yes - Identifying the Damper Motor Module (DMM)

No - DONE

Identifying the Damper Motor Module (DMM)

Hint: When identifying damper motors, each damper motor must be run to its limit position. These operations can take up to 30 seconds. When identifying the damper motors it is important that a battery charger is connected.



- Ignition off
- Reinstall the connectors, components etc.

Note! Climate Control Module (CCM) and damper motors can be affected by the temperature. The vehicle should have normal room temperature when performing this service.

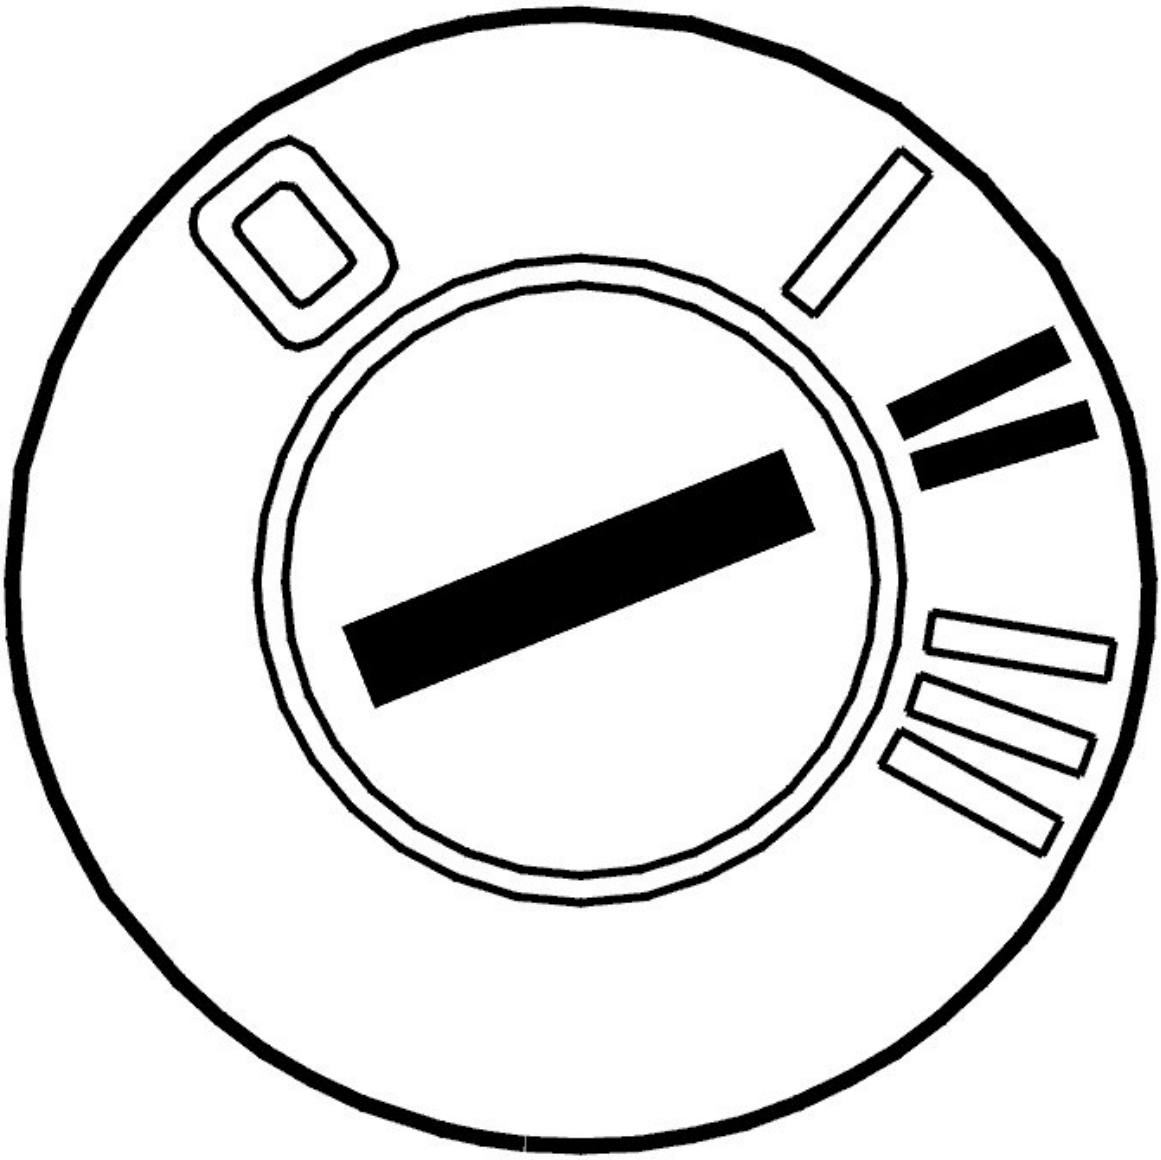
Carry out identification as follows:
- Ignition on.
- Click on the VCT2000 symbol. Wait until identification has been carried out.
- Ignition off.

Continue - Calibrating the Climate Control Module (CCM)

Calibrating the Climate Control Module (CCM)

Caution! When activating this function, calibration of the Climate Control Module (CCM) starts. After carrying out calibration read off of the diagnostic trouble codes (DTCs) starts. To ensure that diagnostics for the Climate Control Module (CCM) have been carried out, delay for 30 seconds before reading out diagnostic trouble codes (DTCs) after calibration.

Note! Climate Control Module (CCM) and damper motors can be affected by the temperature. The vehicle should have normal room temperature when performing this service.



Carry out calibration as follows:

- Ignition on.
- Click on the VCT2000 symbol. Wait until calibration has been carried out and diagnostic trouble codes (DTCs) read out.
- Ignition off.

This function controls the components that communicate with the Climate Control Module (CCM) via LIN bus 1 and LIN bus 2. In the event of a fault in any of the LIN buses, diagnostic trouble codes (DTCs) CCM-0070 to CCM-0071 will be stored depending on the fault. These diagnostic trouble codes (DTCs) can only be stored in conjunction with this diagnostic function.
If any of these diagnostic trouble codes (DTCs) recur, recalibrate to check if the problem was overcome. If the diagnostic trouble code (DTC) recurs, fault-trace the relevant diagnostic trouble code (DTC).

Continue - DONE

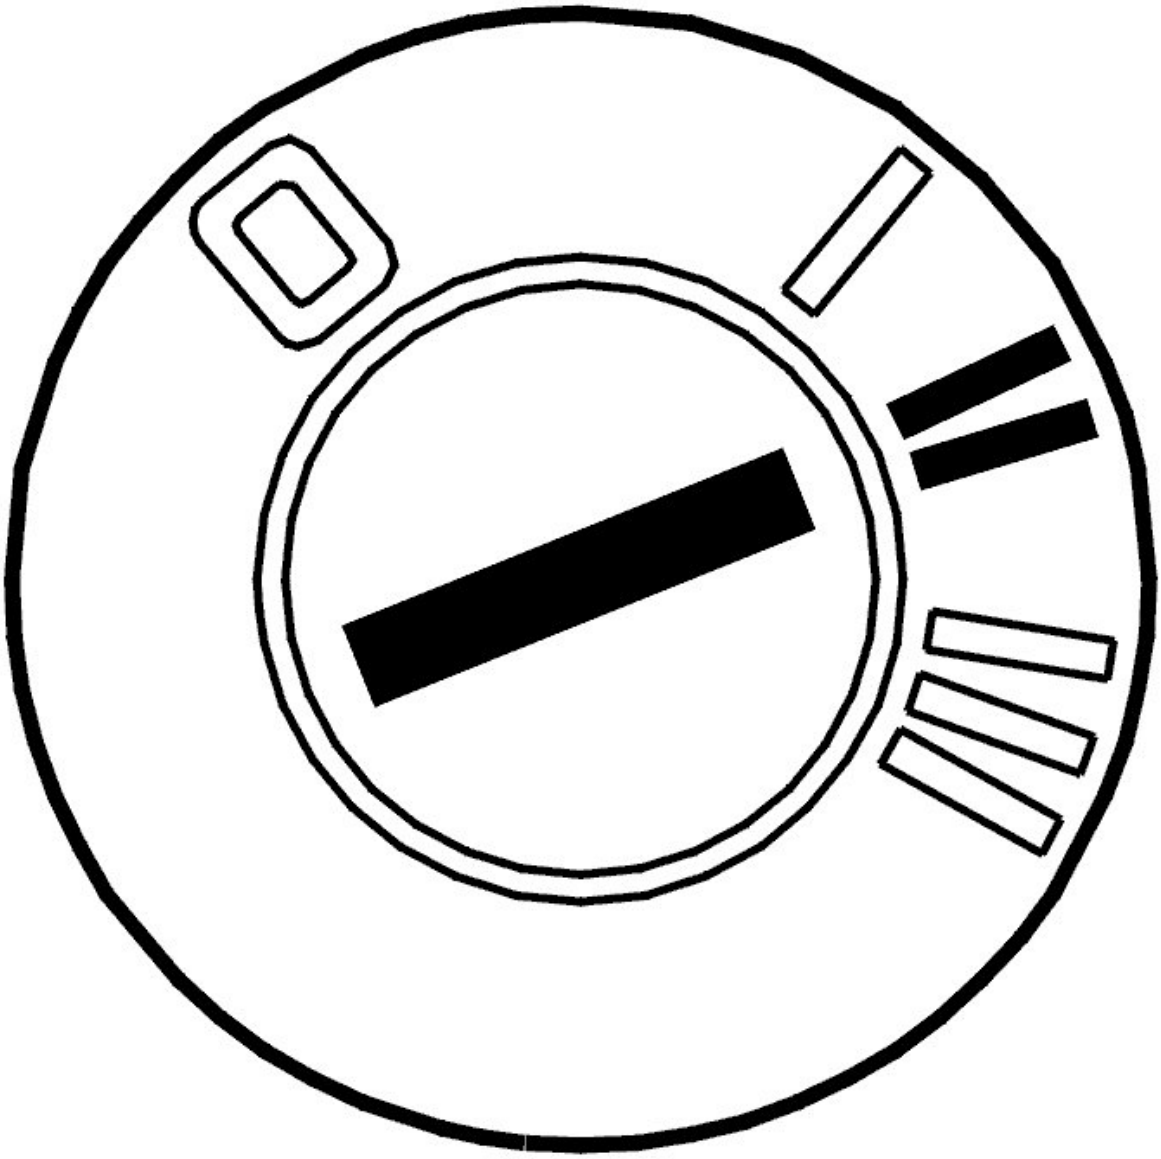
DONE - Verification

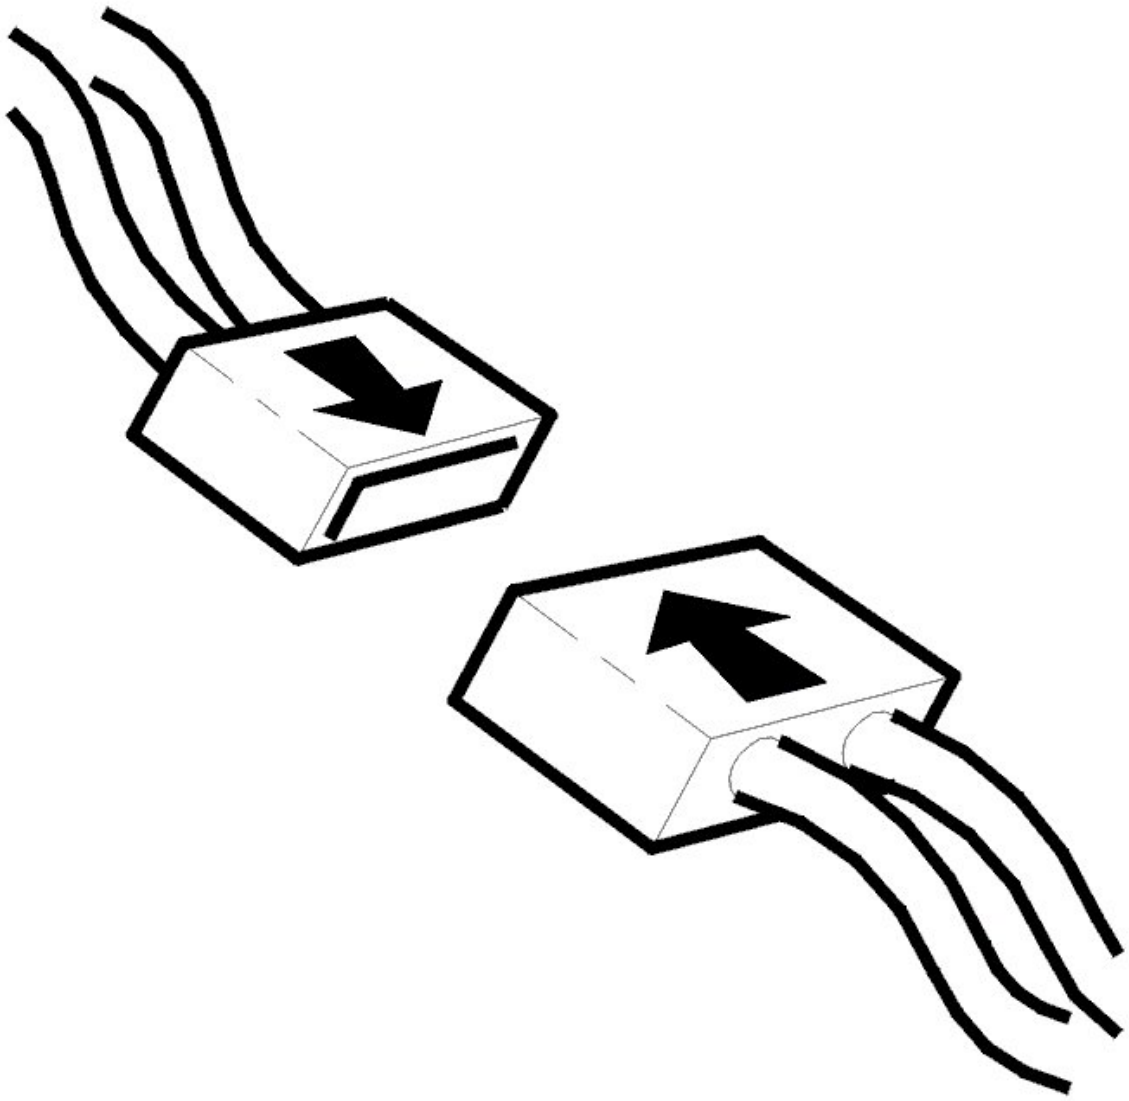
Verification

Verification

Verification

Hint: After carrying out the repair, check that the fault has been remedied.





- Ignition off
- Reinstall the connectors, components etc.
- Ignition on.

Check that the relevant diagnostic trouble code (DTC) has switched status from permanent to intermittent fault.
Check also that diagnostic trouble code (DTC) CCM-0070, CCM-0071 CCM-0072 or CCM-0073 has not been stored during identification of the damper motors.
These diagnostic trouble codes (DTCs) can only be stored when identifying damper motors. They mean that the identification has failed for some reason.
Remedy by correctly identifying the damper motor. Fault-trace according to the relevant information.

Has the status of the diagnostic trouble code (DTC) changed?

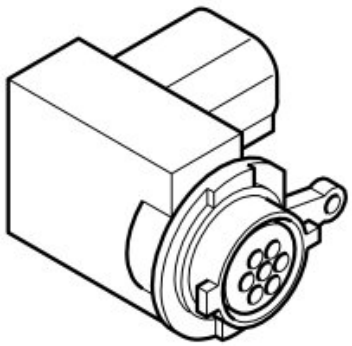
FAULT FOUND - Fault Found

Attempt New Test - Checking the diagnostic trouble codes (DTCs)

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CCM-DD34

Condition



The diagnostic trouble code (DTC) is stored if the climate control module (CCM) detects an open-circuit in the communication between the air quality sensor (AQS) and the climate control module (CCM) on LIN bus 2.
The diagnostic trouble code (DTC) may occur together with diagnostic trouble codes (DTCs) for other components on LIN bus 2 (CCM-DD30 -

CCM-DD34) depending on where the open-circuit has occurred
The diagnostic trouble code (DTC) can be diagnosed at ignition switch position II.
The diagnostic trouble code (DTC) can only be diagnosed for the electronic climate control module (CCM) (ECC).

Substitute value
- None.

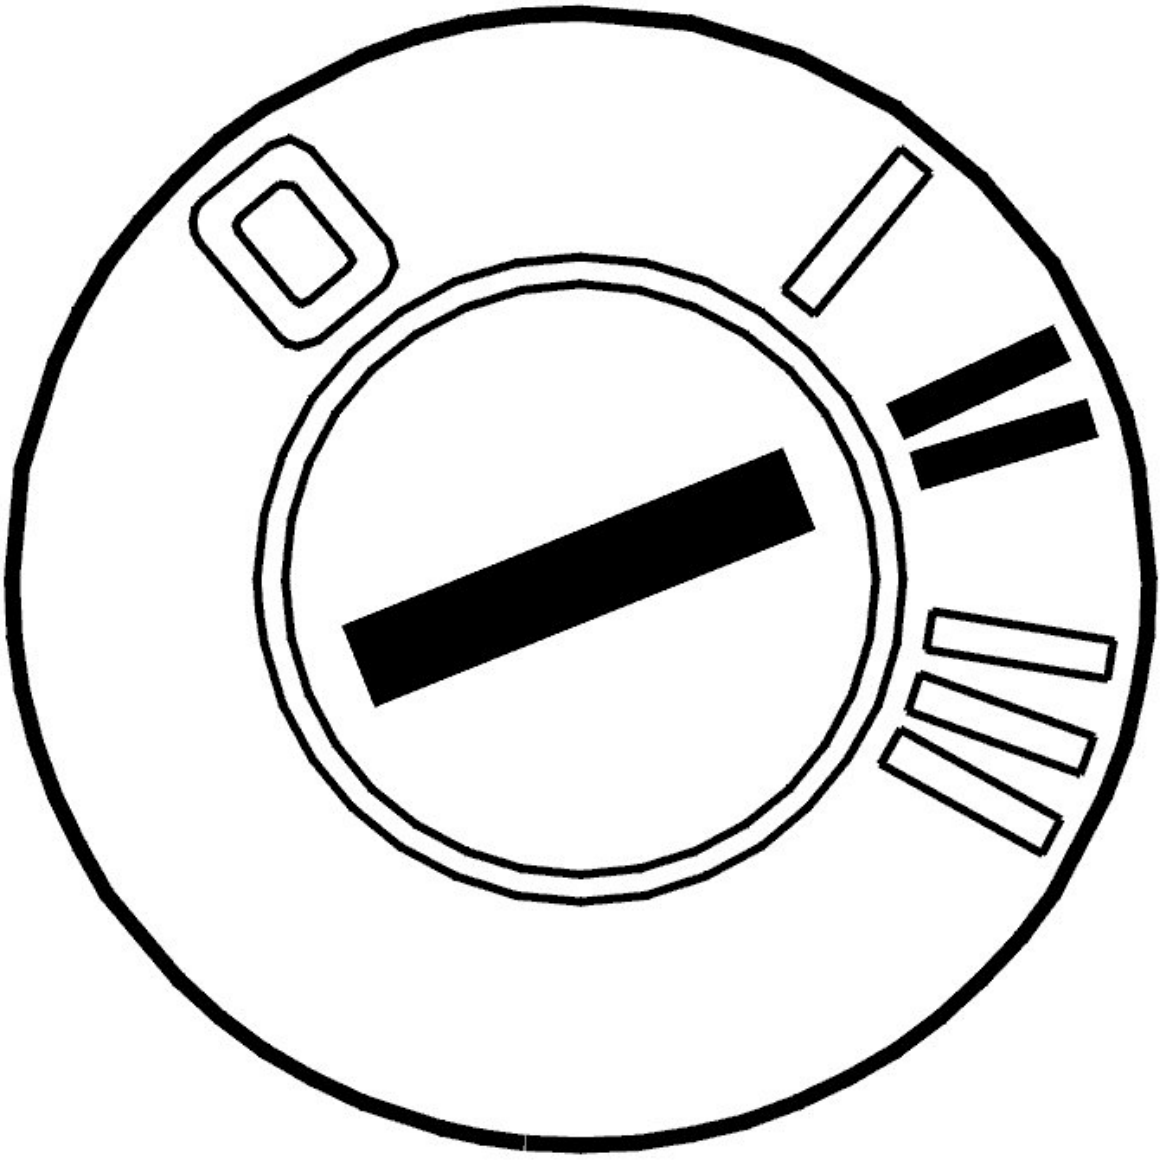
Possible source
- Open-circuit on LIN bus 2 between the climate control module (CCM) and the air quality sensor (AQS)
- Contact resistance, oxidation or loose connections in the connectors.

Fault symptom[s]
- Poor air quality in the passenger compartment.

No Communication

No communication

Checking the diagnostic trouble codes (DTCs)



- Ignition on.

The diagnostic trouble code (DTC) may occur together with diagnostic trouble codes (DTCs) for other components that communicate with the climate control module (CCM) via LIN bus 1 and LIN bus 2.
Check whether the diagnostic trouble code (DTC) has been stored together with other diagnostic trouble codes (DTCs) for other components on the climate control unit.
Select one of the following options:

1. The diagnostic trouble code (DTC) is stored together with diagnostic trouble codes (DTCs) for components in both LIN bus 1 and LIN bus 2 (CCM-DD10 - CCM-DD16, CCM-DD30 - CCM-DD34)
2. The diagnostic trouble code (DTC) is together with diagnostic trouble codes (DTCs) for components only on LIN bus 1 (CCM-DD31-CCM-DD34)

3. The diagnostic trouble code (DTC) is not together with diagnostic trouble codes (DTCs) for other components on LIN bus 1 and LIN bus 2.

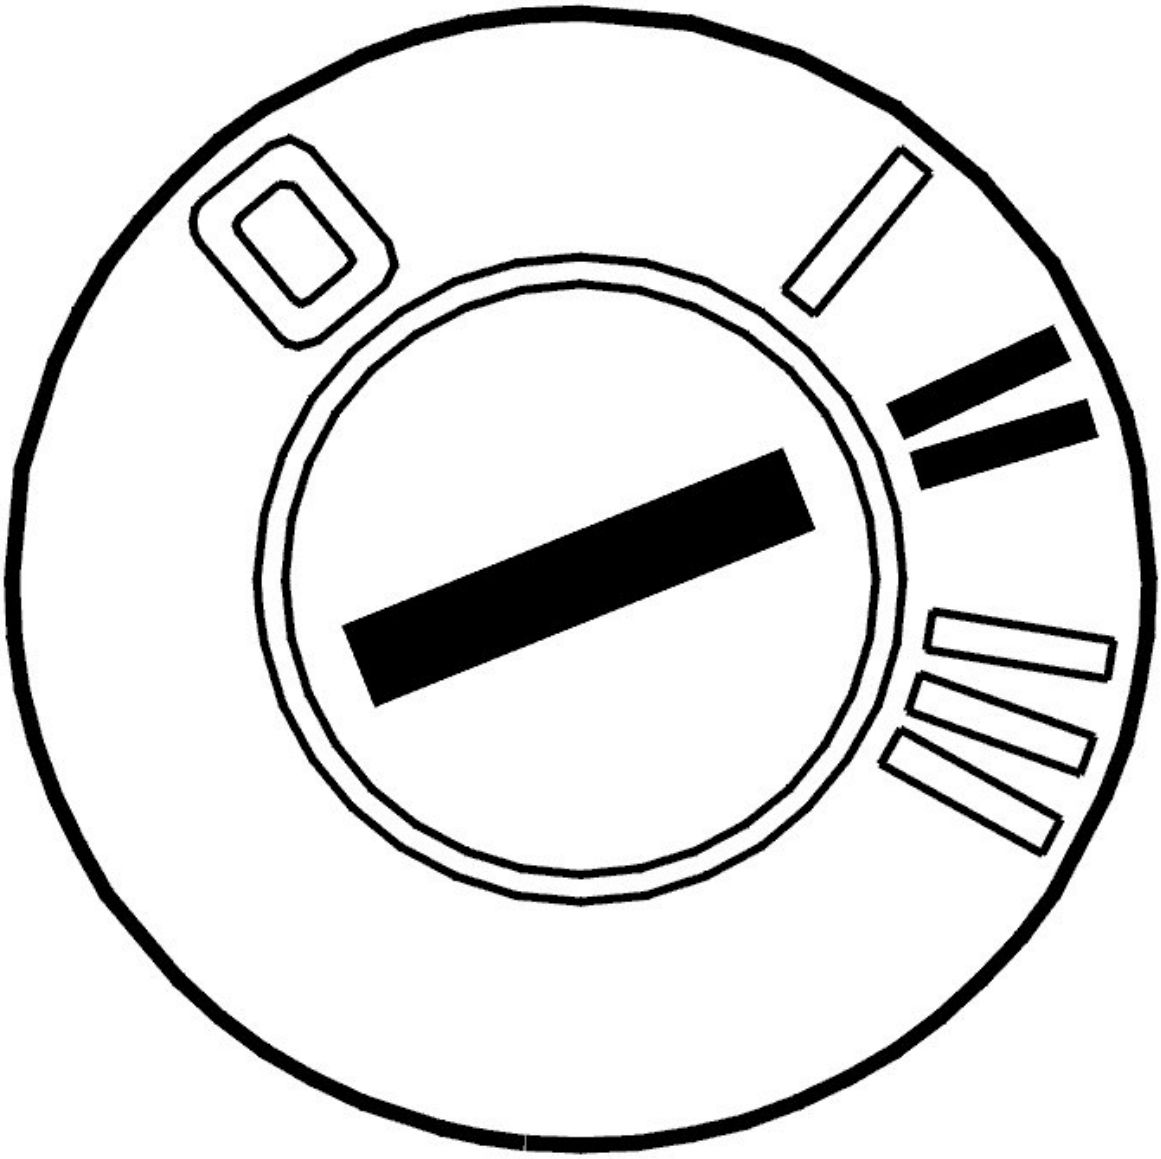
Select an alternative.

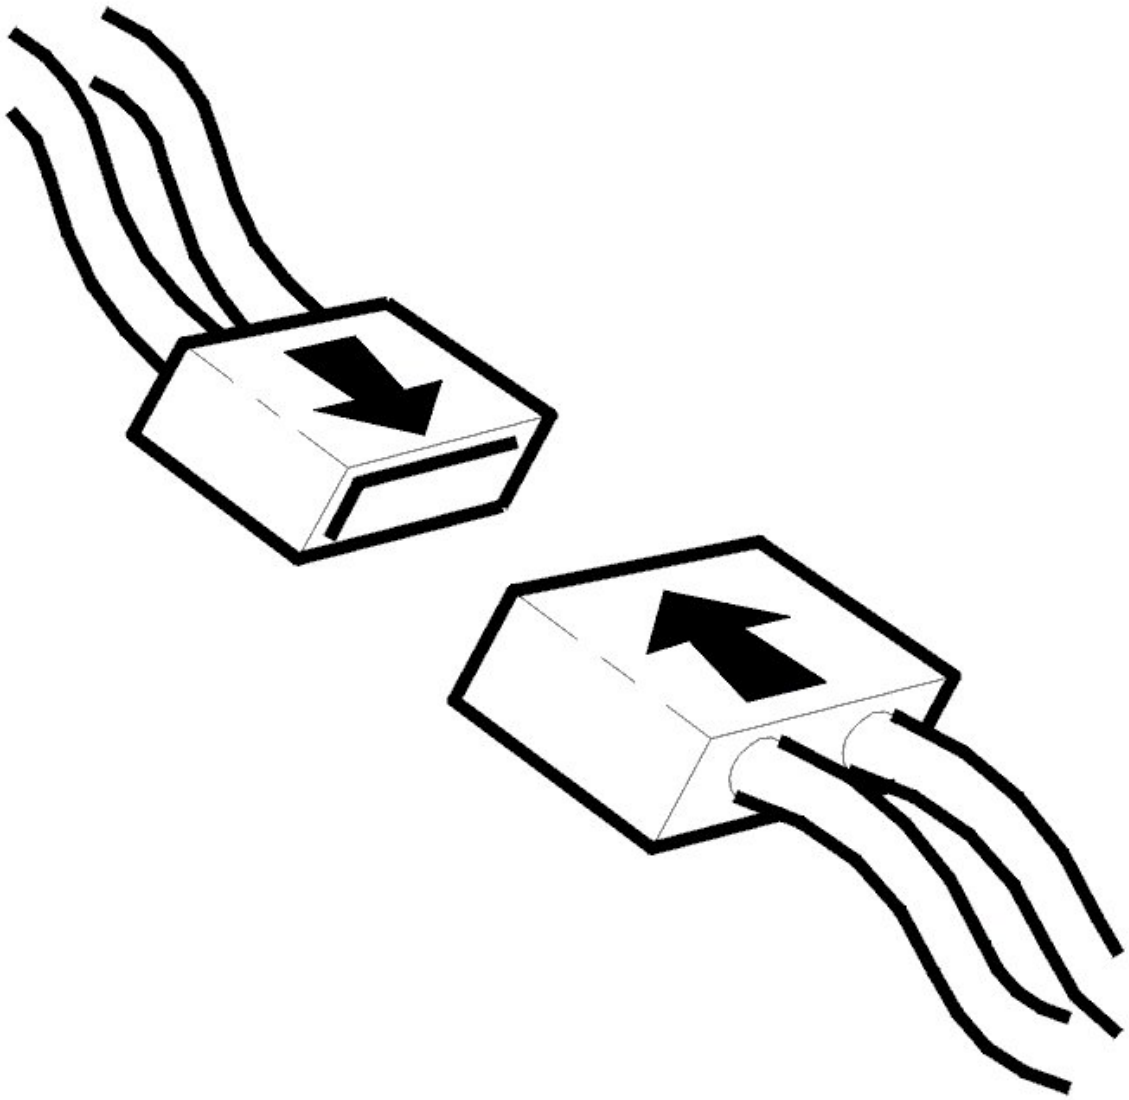
1 - Checking the connectors and wiring

2 - Checking LIN bus 2 and connector

3 - Checking the wiring and component

Checking the connectors and wiring





- Ignition off
- Disconnect the connector for the climate control module (CCM)
- Disconnect the connector for the central electronic module (CEM)
- Ignition on.

Checking the power supply and ground terminals

The following applies to components on the climate control unit that communicate with the climate control module (CCM) via LIN bus 1 and LIN bus 2:

- All components are jointly powered via a fuse from the central electronic module (CEM)
- All components are grounded via a common ground terminal.

Check the power supply to the components on the climate control unit by taking a reading on connector A for the central electronic module (CEM) between terminal #A44 (C44) and chassis ground.
Also check the fuse on the central electronic module (CEM).
Check the power supply cable between the central electronic module (CEM) and the connector for the climate control unit. Check for an open-circuit. Measure between terminal #1 on the connector for the climate control unit and chassis ground.
Check the ground terminal for the components on the climate control unit. Measure between the connector for climate control unit terminal #6 and chassis ground.
Check the connector for the climate control unit and connector A for the central electronic module (CEM). Check for contact resistance. Check for oxidation. Check for loose connections.

Checking LIN bus

Check both LIN bus 1 and LIN bus 2. Check for an open-circuit.
Take readings between:

- The connector for climate control module (CCM) terminal #12 (#36) and the connector for climate control unit terminal #2
- The connector for climate control module (CCM) terminal #7 (#31) and the connector for climate control unit terminal #5.

Check the wiring between the connector and the components on the climate control unit. Check for an open-circuit.
Remedy as necessary.

Other information:

- For further information about the connectors, fuses and relays, see the relevant section in the Wiring Diagram

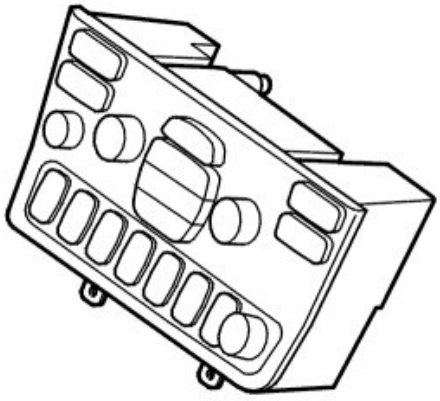
FAULT FOUND - Fault Found

Attempt New Test - Checking the diagnostic trouble codes (DTCs)

CCM-E001

Diagnostic trouble code (DTC) information CCM-E001

Condition



The control modules transmit and receive information via a standardized serial communication method - CAN (Control Area Network). The diagnostic trouble code (DTC) is stored if the control module registers serious interference on the low speed network (CAN communication blocked).

Note! In the event of system communication problems, it is not possible to communicate with the control module. Therefore it will only be possible to read off the diagnostic trouble code (DTC) if the fault is intermittent.

Substitute value
- The control module shuts itself off ("bus-off").

Hint: The control module will remain shut off until the power supply is broken (15, 30, X). When the power supply is connected the control module will make a new attempt to communicate.

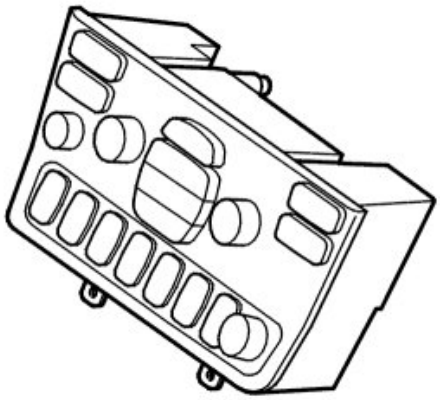
Possible source
- Short-circuit between the control area network (CAN) wiring
- Open-circuit in the control area network (CAN) wiring
- Internal fault in the control module
- Internal fault in another control module in the same part of the control area network (CAN).

Fault symptom[s]
- Misting on the windows and/or door mirrors.
- The function button is not working.
- Blower fan not operating.
- The front seat heating does not function.
- Functions in the infotainment system do not work.

CCM-E003

Diagnostic trouble code (DTC) information CCM-E003

Condition



The control module compares its configuration ID with the signal configuration transmitted on the control area network (CAN) by the central electronic module (CEM). If the configuration IDs do not correspond the fault code is stored. The diagnostic trouble code (DTC) is also stored if the communication between the control module and the central electronic module (CEM) is interrupted.

Note! In the event of an open-circuit in both the control area network (CAN) cables, it is not possible to communicate with the control module. Therefore it will only be possible to read off the diagnostic trouble code (DTC) if this type of fault is intermittent. When the diagnostic trouble code (DTC) is stored, the control module responds to the diagnostic commands. However normal control area network (CAN) communication does not work ("Expulsion mode").

Substitute value
- None.

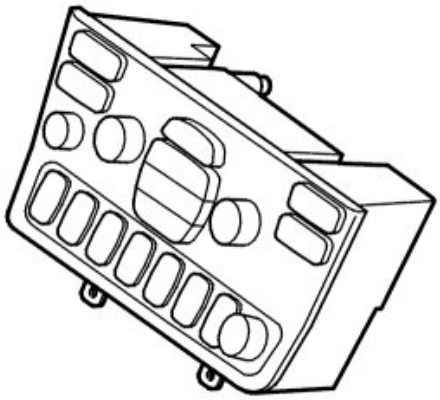
Possible source
- Faulty control area network (CAN) configuration ID. (The control module is not intended for this vehicle, for example, a used control module with different software/hardware)
- Open-circuit in the control area network (CAN) wiring between the control module and the central electrical module (CEM).

Fault symptom[s]
- Misting on the windows and/or door mirrors.
- The function button is not working.
- Blower fan not operating.
- The front seat heating does not function.
- Functions in the infotainment system do not work.

CCM-E010

Diagnostic trouble code (DTC) information CCM-E010

Condition



The diagnostic trouble code (DTC) is stored if the supply voltage to the climate control module (CCM) differs by more than 2 V from the supply voltage to the central electronic module (CEM).
The climate control module (CCM) receives information about supply voltage from the central electronic module (CEM) via the CAN network.
The diagnostic trouble code (DTC) can be diagnosed in ignition positions I and II.

Substitute value
- None.

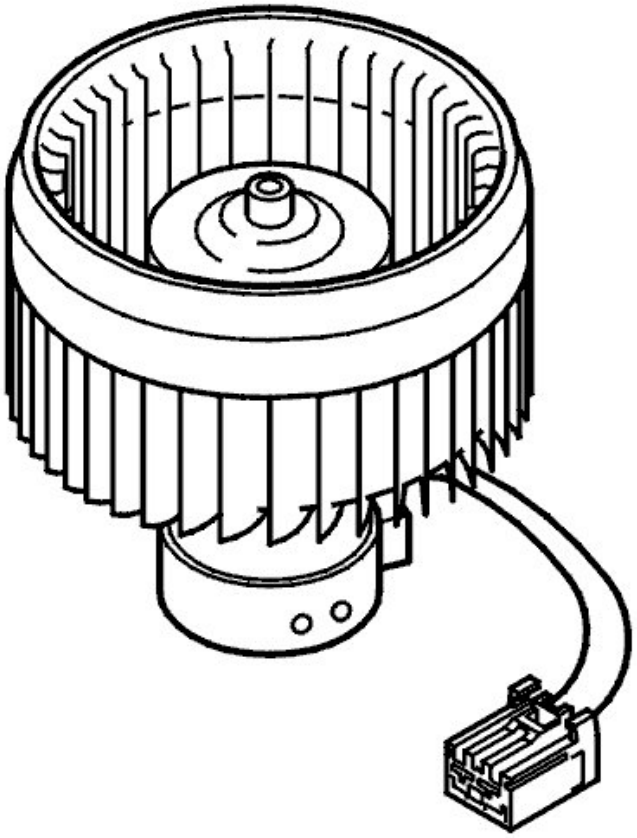
Possible source
- Short-circuit to ground in the cable harness
- Open-circuit in the cable harness
- Contact resistance
- Half-burned fuse to the climate control module (CCM).

Fault symptom[s]
- Misting on the windows and/or door mirrors.
- The function button is not working.
- Blower fan not operating.
- The front seat heating does not function.
- Functions in the infotainment system do not work.

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CCM-00A0

Condition



Diagnostic trouble code (DTC) is stored if the climate control module (CCM) registers that the diagnostic signal from the blower fan power unit is below 1.28 V and the control current to the blower fan power unit is below 0.42 mA.

Substitute value

- The control module will not allow the blower fan motor to start while the fault persists
- The air conditioning (A/C) compressor is not allowed to start.

Possible source

- Short-circuit to ground in the motor signal cable
- Short-circuit to supply voltage in the signal cable
- Open-circuit in the diagnostic signal cable
- Short-circuit to ground in the diagnostic signal cable
- Defective blower fan motor or power unit.

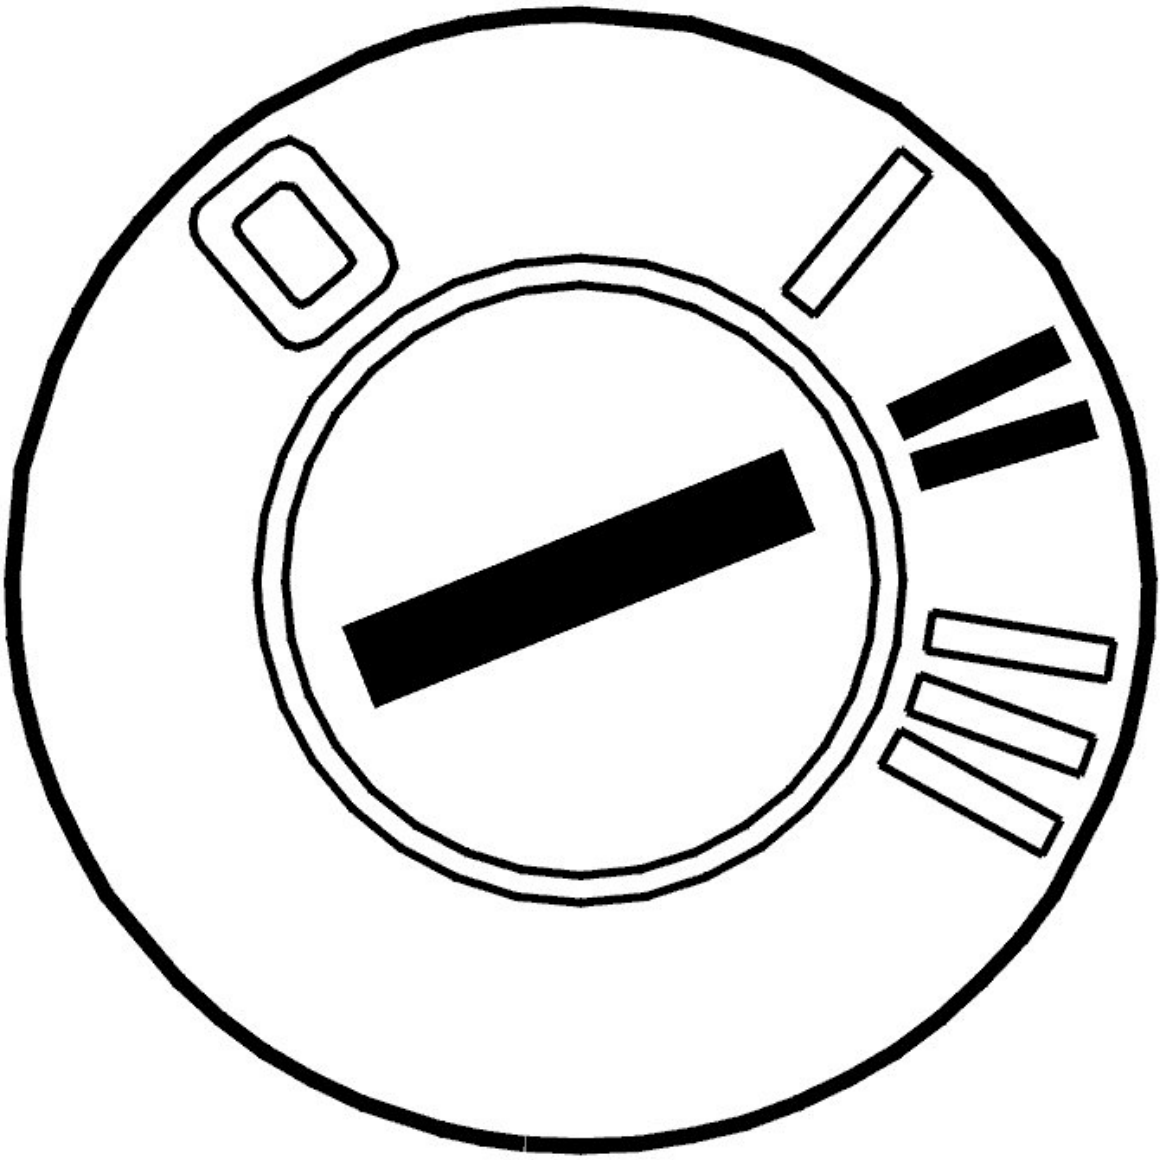
Fault symptom[s]

- Blower fan not operating.
- Air flow problem.
- No cooling from the air conditioning (A/C) system.

Signal Too Low

Signal too low

Checking the blower fan



- Ignition on.

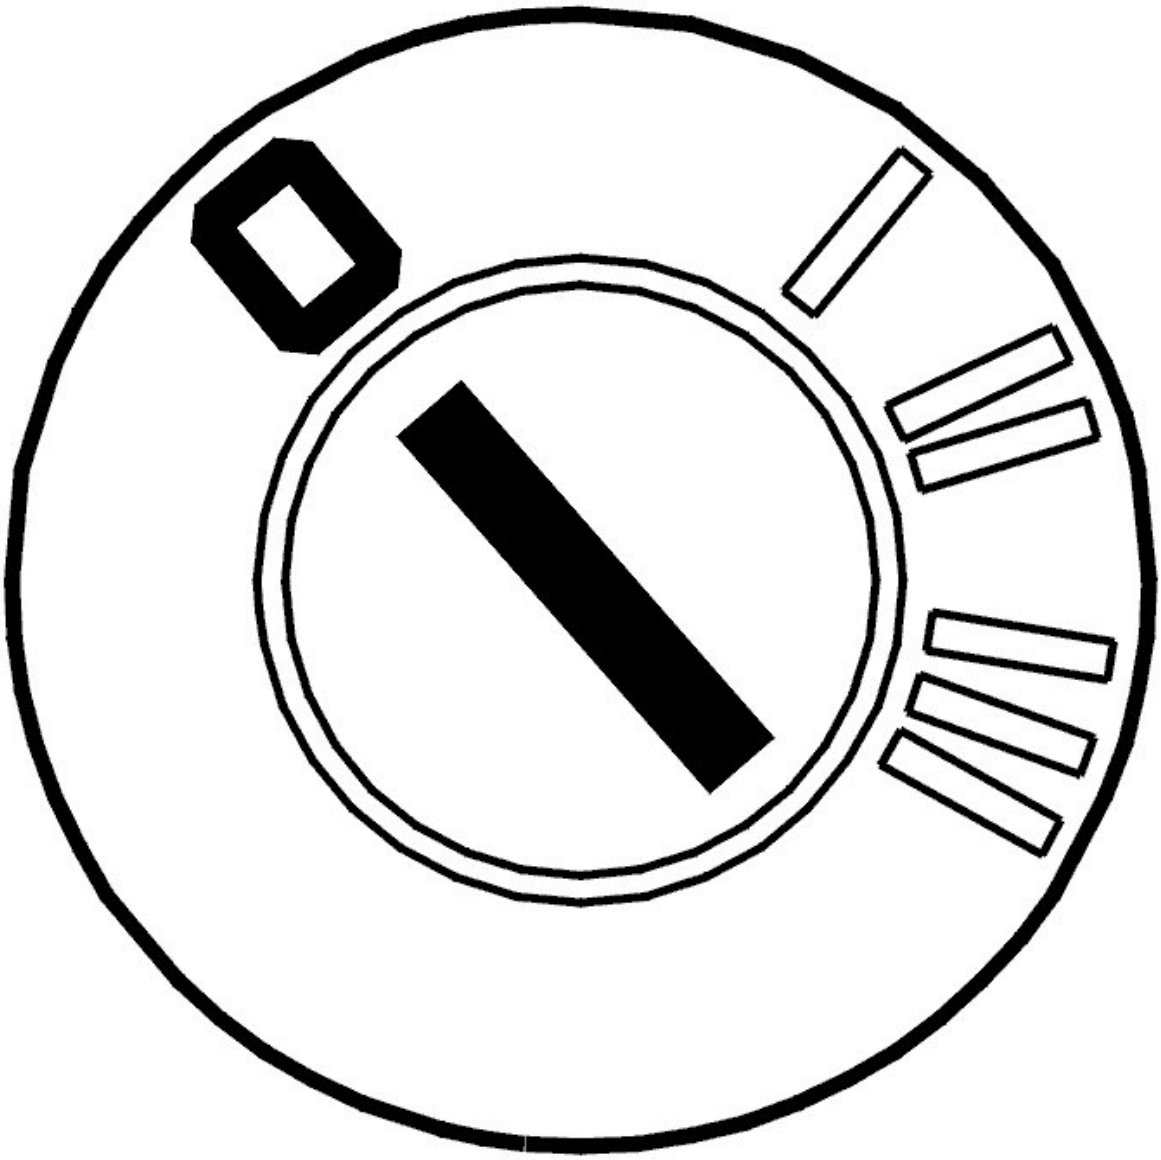
Check that the blower fan functions by turning the blower fan knob to maximum fan speed.

Is the blower fan working?

Yes - Checking the wiring

No - Checking the component and wiring

Checking the component and wiring



- Ignition off.

Caution! The blower fan motor power unit is very sensitive to short-circuits and excess current. Do not damage the power unit when taking readings.Take readings with the power unit connector disconnected when checking the wiring.

Check if the fuse for the climate control module (CCM) is defective. If the fuse is defective, check:
- the signal cable between the fuse and the power unit terminal #A2. Check for a short-circuit to ground
- the signal cable between the power unit terminal #B2 and the blower fan motor positive terminal. Check for a short-circuit to ground.

Check the control signal cable between control module terminal #A3 and power unit terminal #A1. Check for a short-circuit to supply voltage.
Check the diagnostic signal cable between control module terminal #A2 and power unit terminal #A3. Check for an open-circuit. Check for a short-circuit to ground.
Remedy as necessary.

Other information:
- To access and replace the control module, see Climate control module (CCM), replacing See: Heating and Air Conditioning/Control Module HVAC/Service and Repair

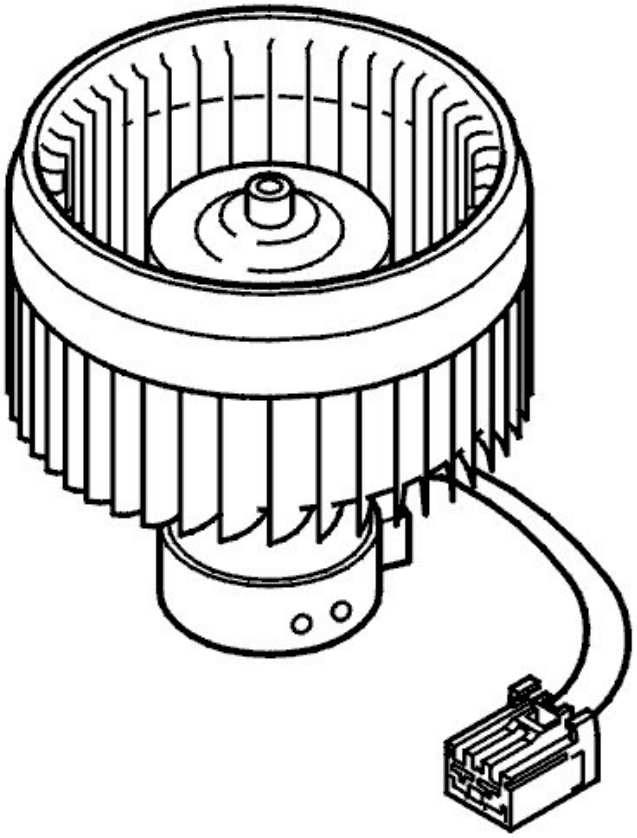
FAULT FOUND - DONE

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CCM-00A1

Condition



The diagnostic trouble code (DTC) is stored if the climate control module (CCM) registers that the diagnostic signal from the blower fan power unit is in excess of 10 V and the control current to the blower fan power unit is above 8.56 mA.

Substitute value
- The blower fan cannot start while the fault persists
- The air conditioning (A/C) compressor is not allowed to start.

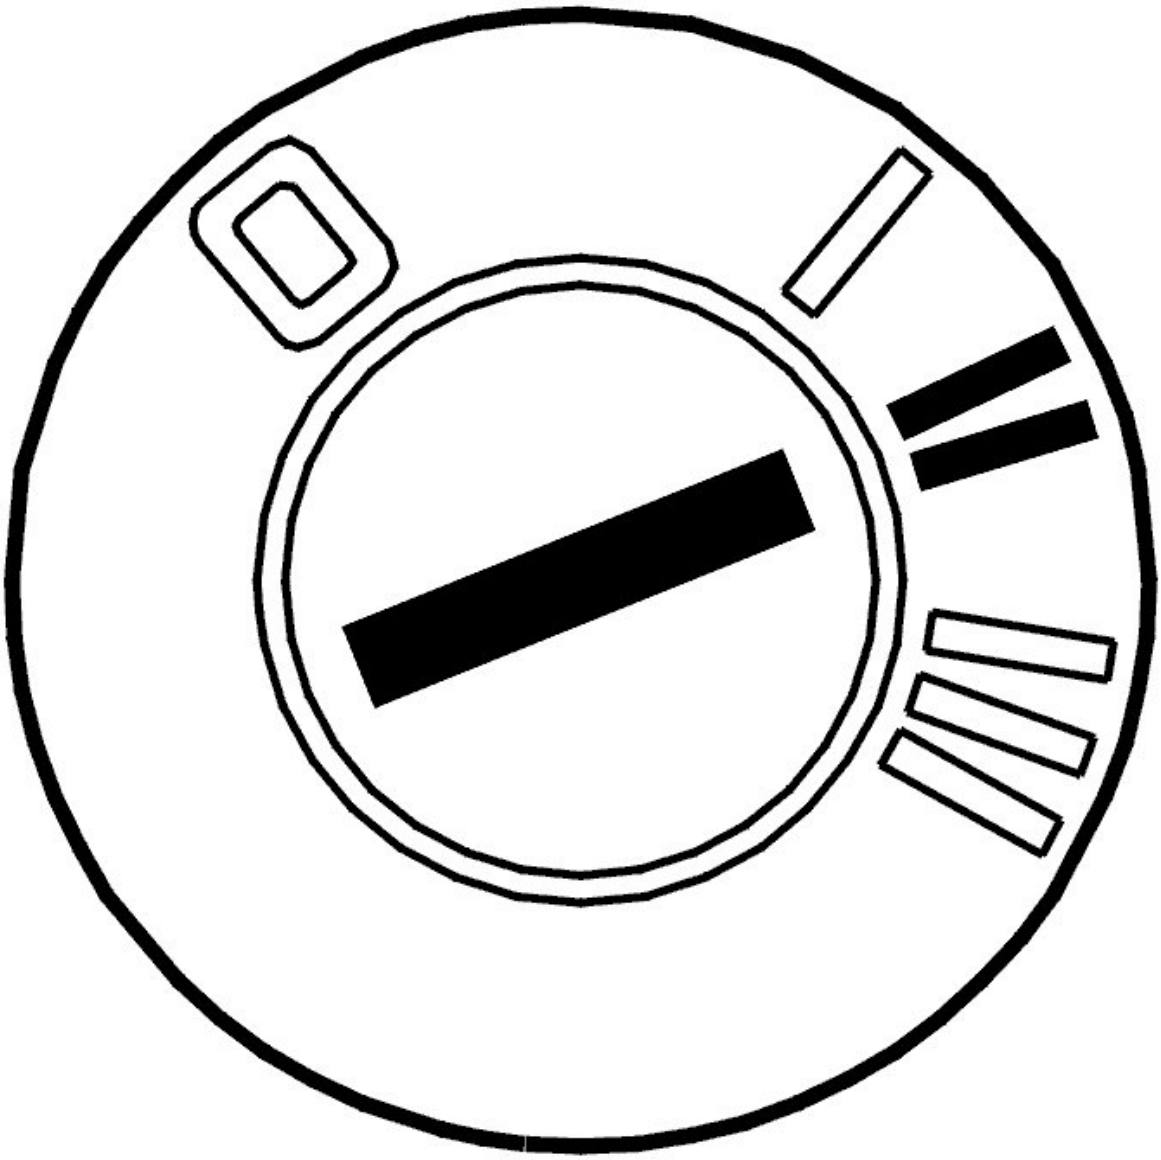
Possible source
- Blocked blower fan motor
- Open-circuit in the signal cable
- Open-circuit in the ground lead for the blower fan motor
- Short-circuit to supply voltage in the ground lead for the blower fan motor
- Short-circuit to ground in the control signal cable
- Open-circuit in the control signal cable
- Short-circuit to supply voltage in the diagnostic signal cable
- Defective blower fan motor or power unit
- Contact resistance.

Fault symptom[s]
- Blower fan not operating.
- Air flow problem.
- No cooling from the air conditioning (A/C) system.

Signal Too High

Signal too high

Checking the blower fan



- Ignition on.

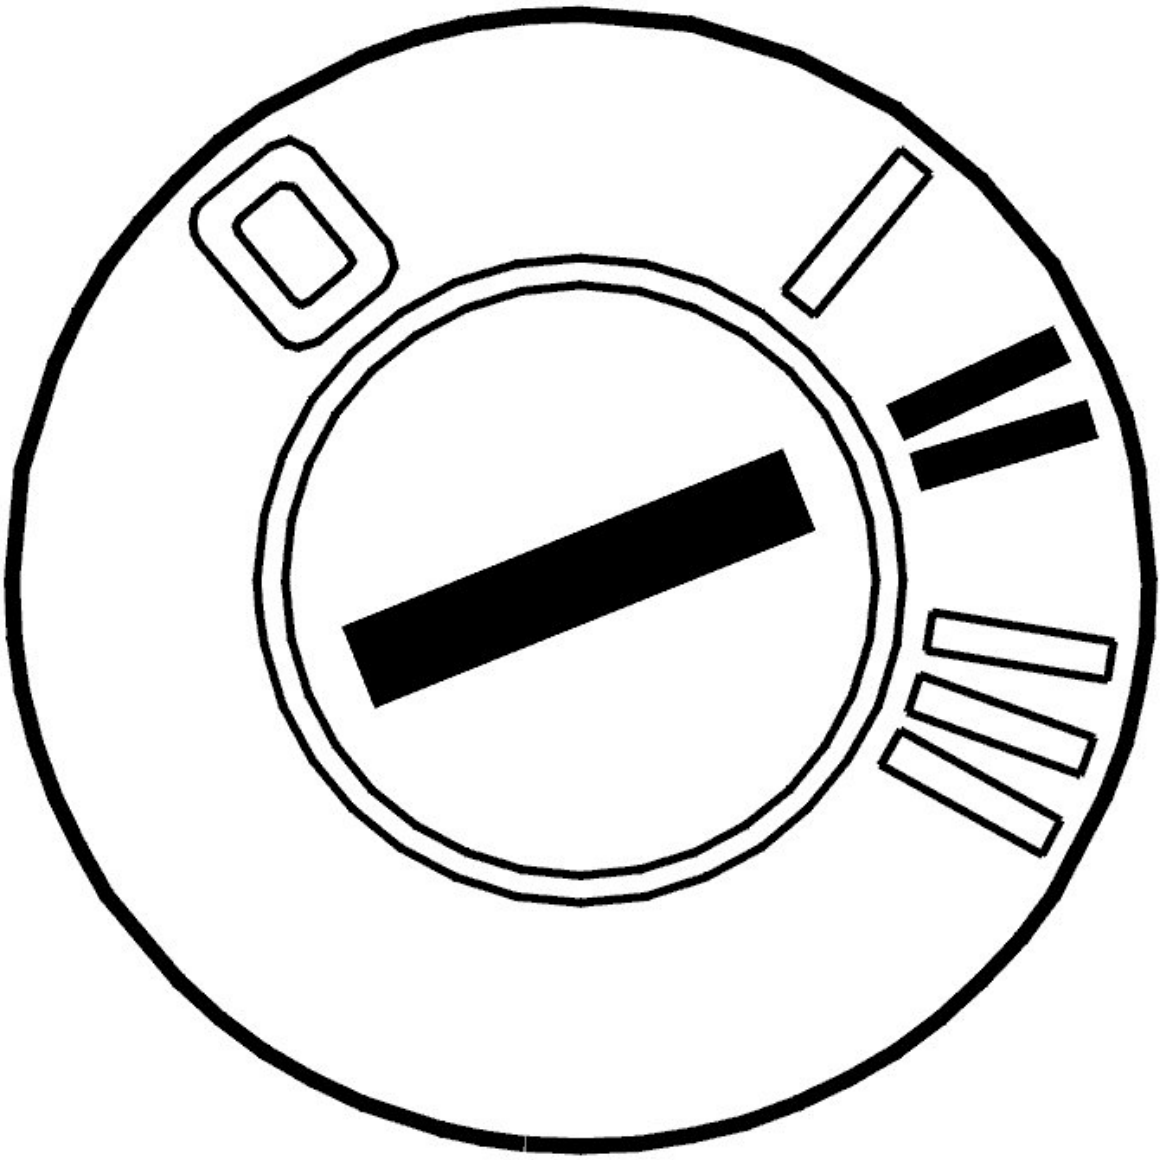
Check that the blower fan functions by turning the blower fan knob to maximum fan speed.

Is the blower fan working?

Yes - Checking the connectors and cables

No - Checking the connectors

Checking the connectors



- Ignition off
- Check the connectors on the climate control module (CCM) (terminals #A2, #A3) and the power unit. Check for contact resistance and oxidation. In particular, check for any damage
- Reinstall the components, reconnect the connectors etc.
- Ignition on.

Note! If the battery voltage has been interrupted, the blower fan speed must be calibrated. First turn the blower fan speed control to maximum speed and then to minimum speed.

Check that the blower fan motor functions: Turn the blower fan speed switch.
If the blower fan is now working the cause of the fault was loose connections in the connectors.

Checking the connectors and cables

Caution! The blower fan motor power unit is very sensitive to short-circuits and excess current. Do not damage the power unit when taking readings.Take readings with the power unit connector disconnected when checking the wiring.

Check the connectors on the control module (terminals #A2, #A3) and the power unit. Check for contact resistance and oxidation. Check for loose connections.
Check the ground lead between the power unit terminal #A4 and the ground terminal. Check for an intermittent short-circuit to supply voltage.
Check the control signal cable between the control module terminal #A3 and power unit terminal #A1. Check for an intermittent open-circuit. Check for an intermittent short-circuit to ground.
Check the diagnostic signal cable between control module terminal #A2 and power unit terminal #A3. Check for an intermittent short-circuit to supply voltage.

Note! If the battery voltage has been interrupted, the blower fan speed must be calibrated. First turn the blower fan speed control to maximum speed and then to minimum speed.

Remedy as necessary.

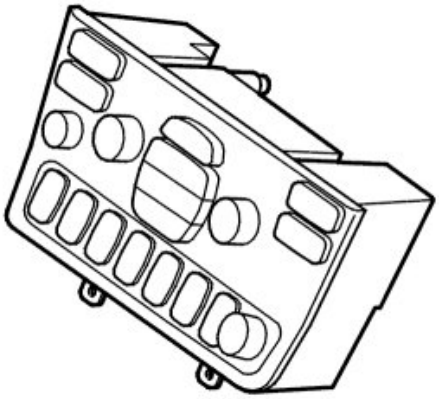
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CCM-0001

Condition



The diagnostic trouble code (DTC) is stored if the climate control module (CCM) detects an incorrect configuration parameter in the Car Configuration File.
The diagnostic trouble code (DTC) can be diagnosed in ignition positions I and II.

Substitute value

- None.

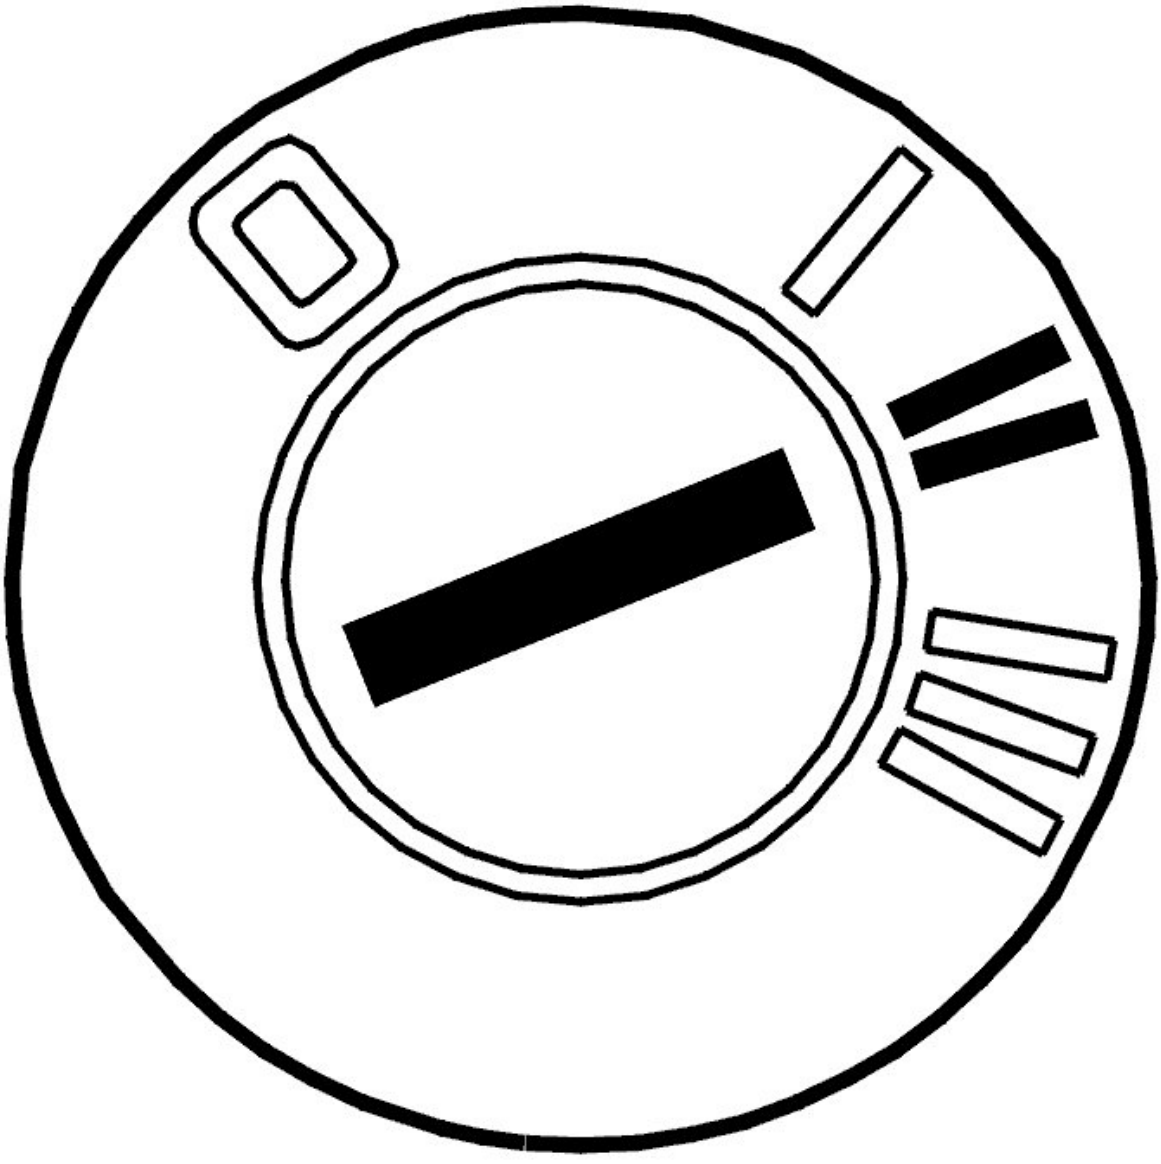
Possible source
- Incorrect configuration parameter.

Fault symptom[s]
- Misting on the windows and/or door mirrors.
- The function button is not working.
- Blower fan not operating.
- The front seat heating does not function.
- Functions in the infotainment system do not work.

Non-Approved Value

Non-approved value

Checking data for car configuration



- Ignition on.

The climate control module (CCM) has registered that a parameter in the data for car configuration is incorrect.
Check which parameter is incorrect by clicking on the VCT2000 symbol.
The reason for the parameter being incorrect may be that the climate control module (CCM) has been replaced incorrectly.
Switching the climate control module (CCM) between different cars can result in the data in the car configuration being incorrectly adapted.
If this is the case, remedy by replacing the climate control module (CCM) in the correct way.

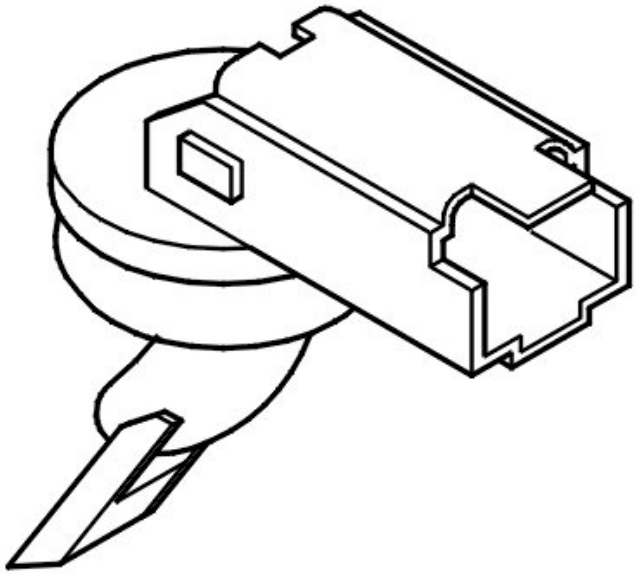
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CCM-0002

Condition



The diagnostic trouble code (DTC) is stored if the climate control module (CCM) detects a short-circuit to supply voltage in the signal, or an open-circuit in the signal between the control module and the evaporator temperature sensor.
The climate control module (CCM) uses the signal to control the A/C compressor.
At temperatures below 5.5 °C the compressor is not permitted to operate because of the risk of freezing.
In normal operation (engine running and A/C selected) the control module can regulate the compressor in the following way based on the evaporator temperature:

- 10 °C air conditioning (A/C) compressor on
- 5.5 °C air conditioning (A/C) compressor off.

The diagnostic trouble code (DTC) can be diagnosed in ignition positions I and II.

Substitute value

- The control module assumes a replacement value equivalent to 0 °C. The compressor will not then be permitted to operate
- The normal value during operation (engine running and A/C selected) is 5.5-10 °C. If the climate control system has not been operating and the engine has cooled, the temperature must correspond to the ambient temperature.

Possible source

- There is a short-circuit to supply voltage in the signal between the evaporator temperature sensor and the climate control module (CCM)
- Open-circuit in the signal between the evaporator temperature sensor and the climate control module (CCM)
- Contact resistance, oxidation or loose connections in the connectors
- The evaporator temperature sensor does not function.

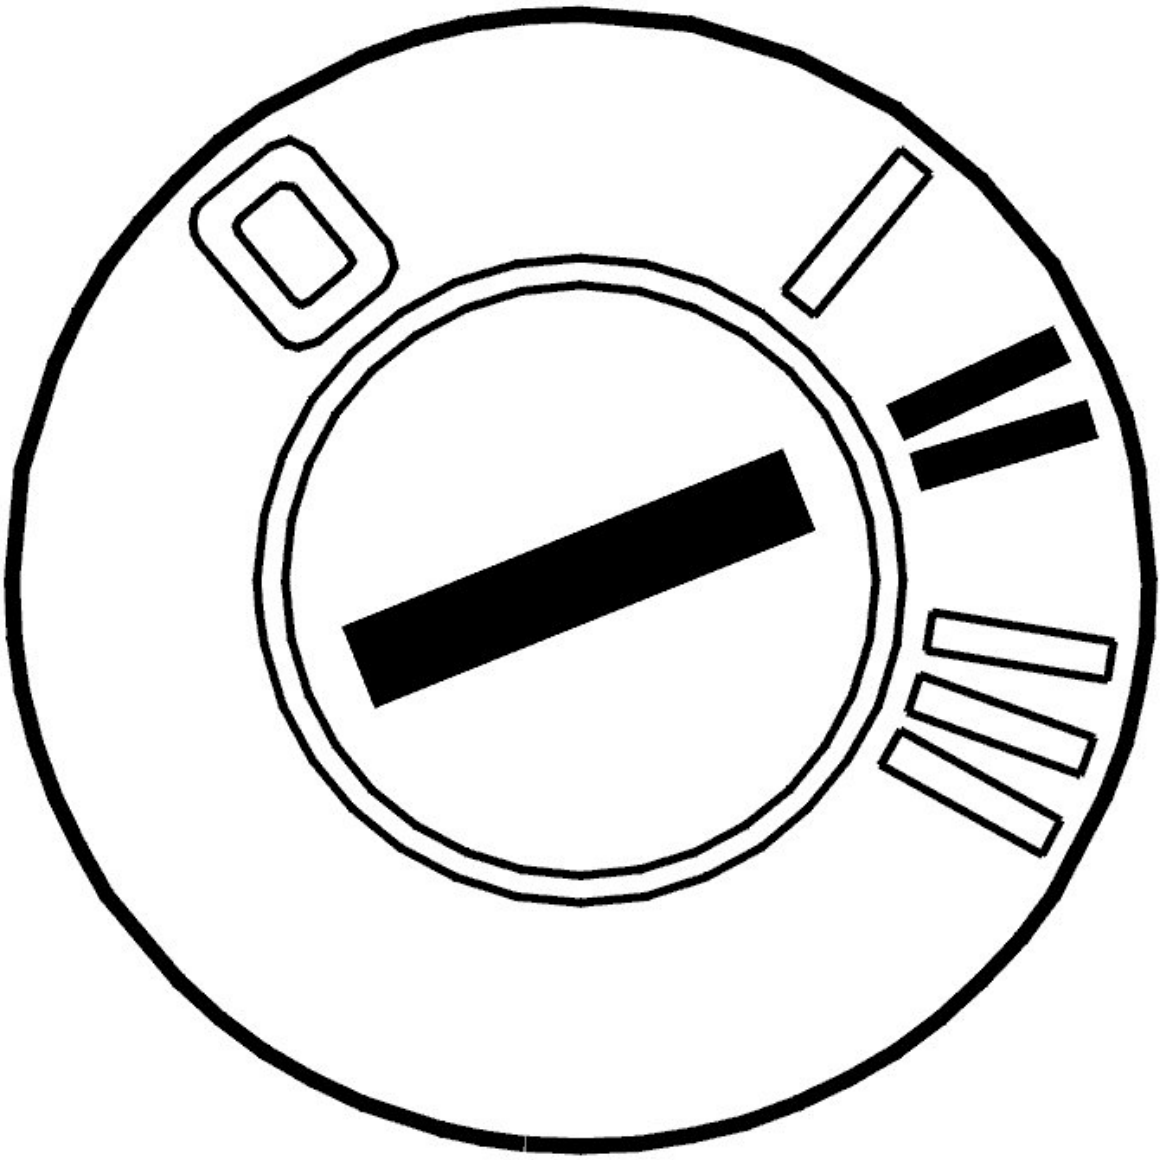
Fault symptom[s]

- No cooling from the air conditioning (A/C) system.
- Irregular cooling from the air conditioning (A/C) system.
- The air conditioning (A/C) compressor does not start, or runs sporadically.

Signal Too High / Signal Missing

Signal too high / Signal missing

Checking the evaporator temperature



- Ignition on.

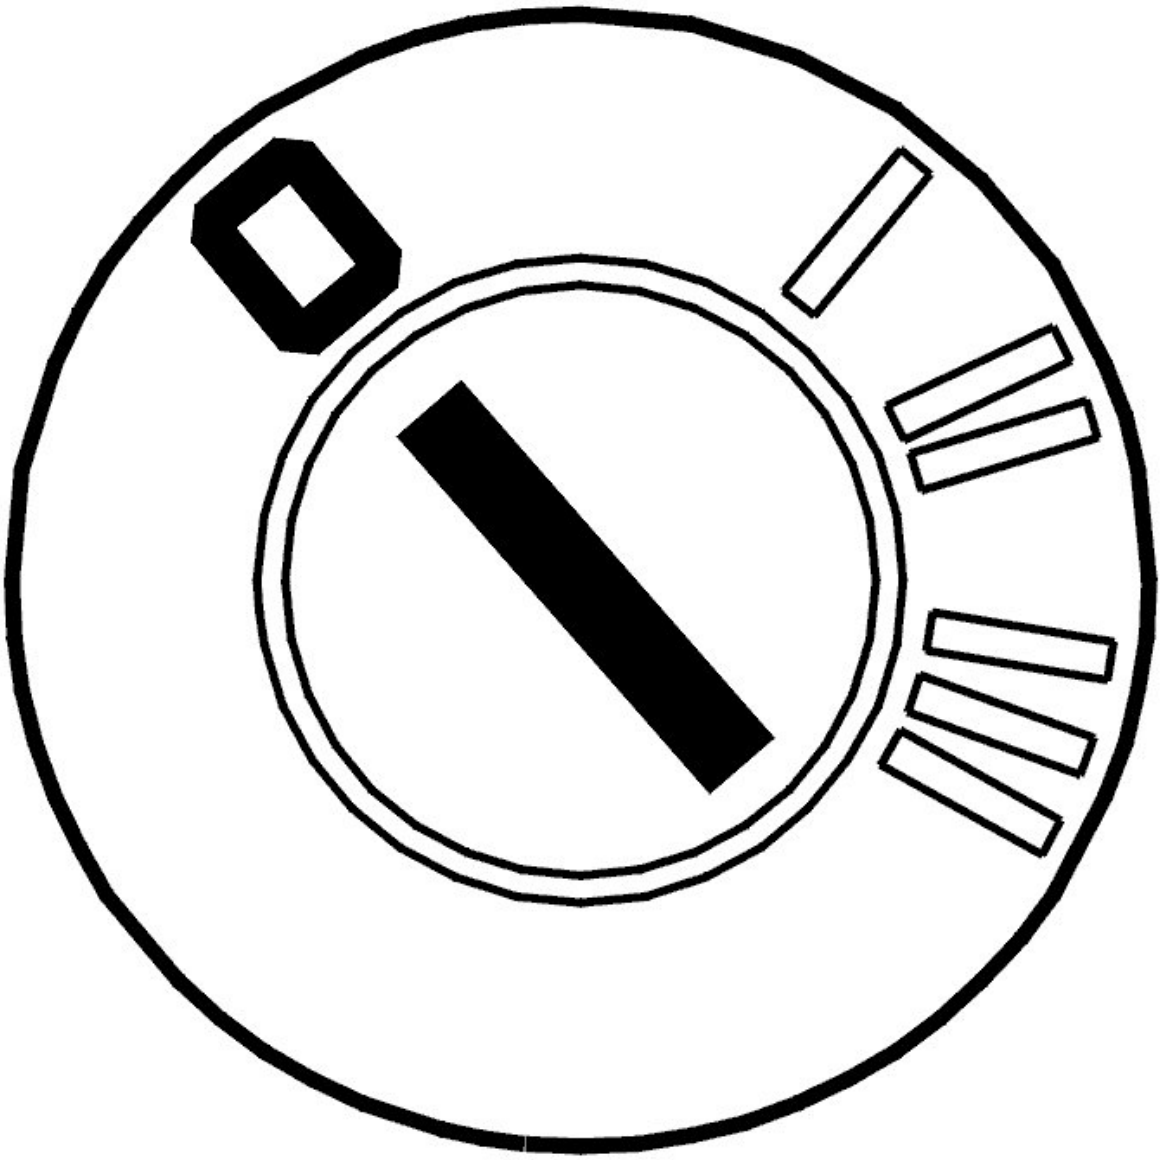
Check that the evaporator temperature is within its permitted range. If the climate control system has not been running and the engine has cooled down, the temperature must be the same as the outside temperature.
If the temperature is now OK, the fault was caused by contact resistance or loose connections.
Read off the evaporator temperature by clicking on the VCT2000 symbol.

Are the temperatures correct?

Yes - Checking the connectors and wiring

No - Checking the component and wiring

Checking the connectors and wiring



- Ignition off
- Disconnect the connector for the climate control module (CCM).

Check the signal cable between the climate control module (CCM) and the evaporator temperature sensor. Check for a short-circuit to supply voltage.
Take a reading on the connector for the climate control module (CCM) between terminals #5 (#29) and #16 (#40).
Check the ground lead between the climate control module (CCM) and the evaporator temperature sensor. Check for a short-circuit to supply voltage.
Take a reading on the connector for the climate control module (CCM) between terminals #13 (#37) and #16 (#40).
The voltage must be approximately 0 V.
Check the signal and ground cables between the climate control module (CCM) and the evaporator temperature sensor. Check for an intermittent open-circuit.
Take a reading between terminals #5 (#29) and #13 (#37) on the connector for the climate control module (CCM).
Check the connectors for contact resistance and oxidation.
Remedy as necessary.

Diagnostic Trouble Code (DTC) Information

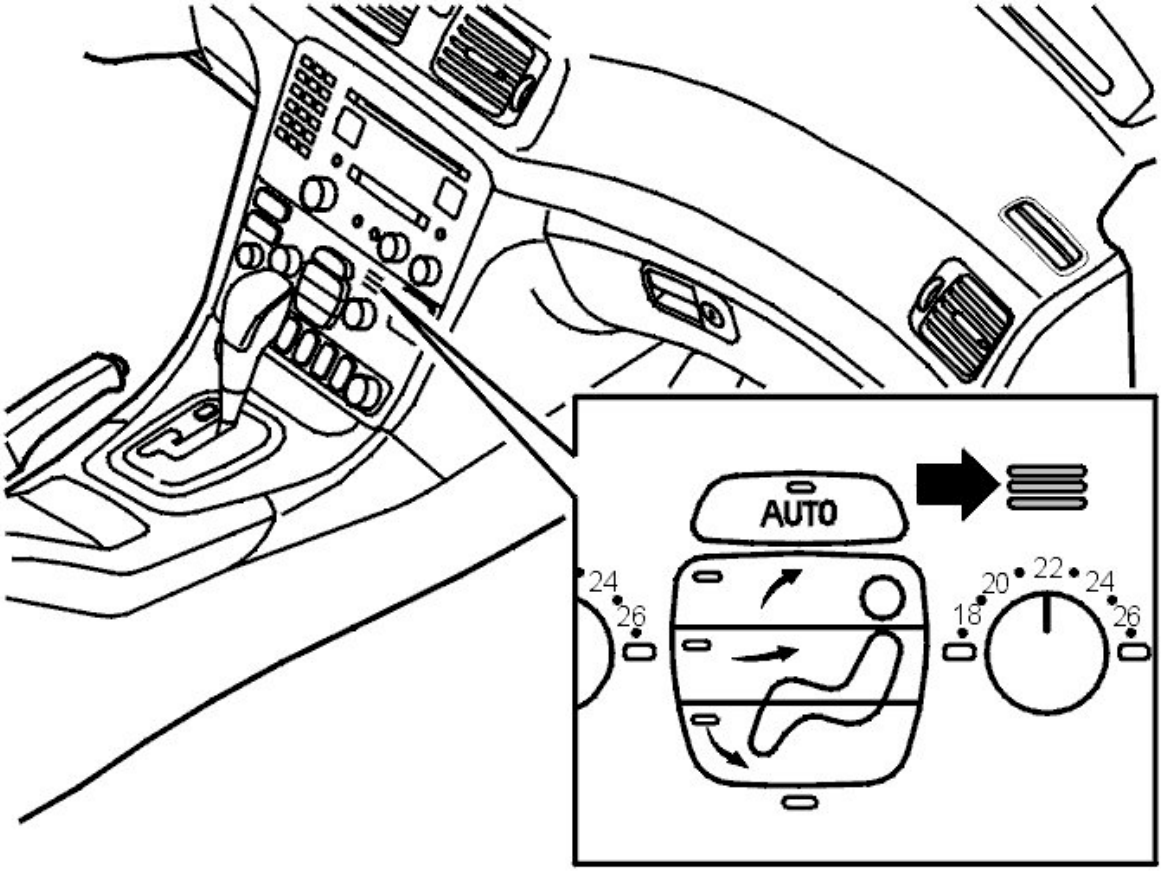
Diagnostic trouble code (DTC) information CCM-0006

Condition



The diagnostic trouble code (DTC) is stored if the climate control module (CCM) detects an open-circuit in the power supply cable to the blower fan for the passenger compartment temperature sensor, or an open-circuit in the ground lead from the blower fan to the control module.
The function of the blower fan is to supply the passenger compartment temperature sensor with air from the passenger compartment. This prevents the sensor reading from being affected by heat from the surrounding electronics.
The diagnostic trouble code (DTC) can be diagnosed in ignition positions I and II.
The diagnostic trouble code (DTC) can only be diagnosed for the electronic climate control module (CCM) (ECC).

Substitute value
- None.

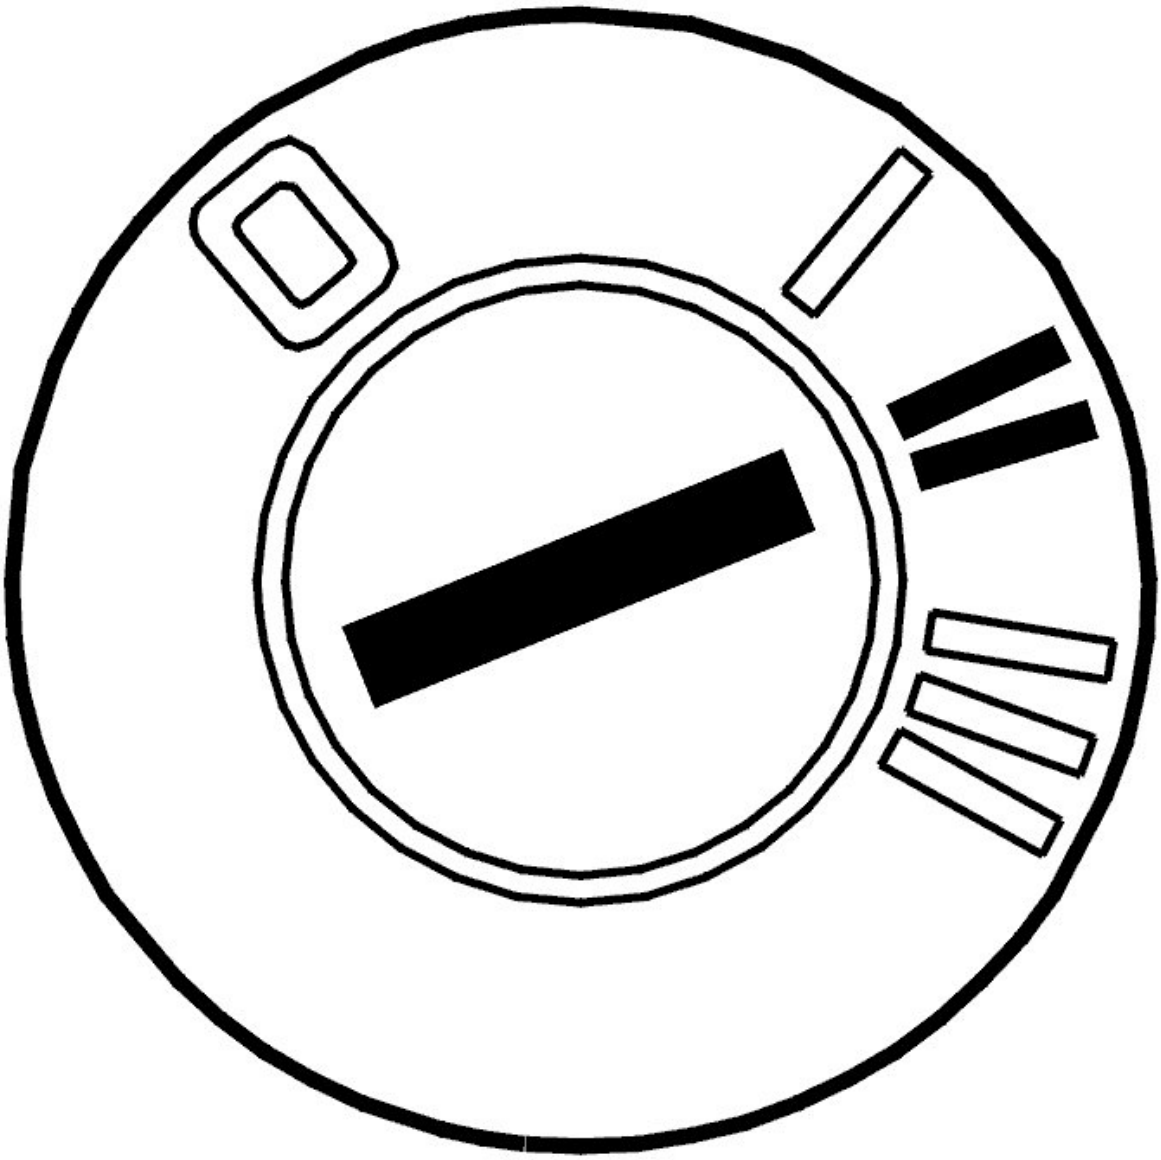
Possible source
- Open-circuit in the power supply cable between the climate control module (CCM) and the blower fan for the passenger compartment temperature sensor
- Open-circuit in the ground lead between the blower fan for the passenger compartment temperature sensor and the climate control module (CCM)
- Contact resistance, oxidation or loose connections in the connectors
- The blower fan for the passenger compartment temperature sensor is not functioning.

Fault symptom[s]
- The passenger compartment temperature does not correspond to the set position.
- Poor heating in the passenger compartment.

Signal Too High / Signal Missing

Signal too high / Signal missing

Checking the fan motor and the passenger compartment temperature sensor



- Ignition on
- Check that the fan is functioning. Place a small, thin piece of paper in front of the ventilation grille for the passenger compartment temperature sensor.

If the paper is sucked against the grille, the fan is working.

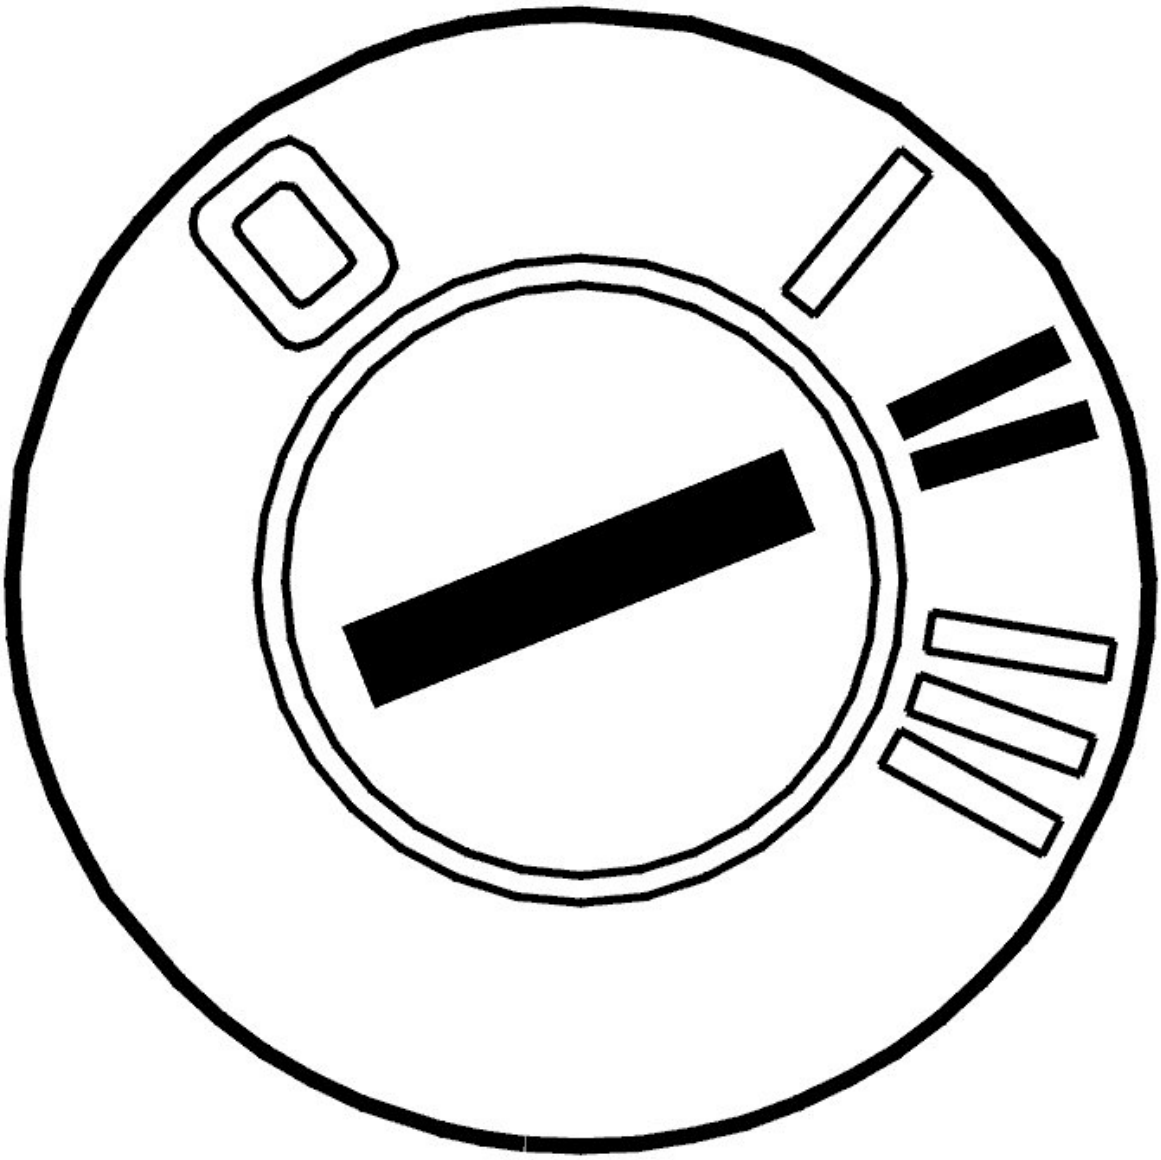
Note! The fan is only activated at passenger compartment temperatures in excess of -10 °C (14 °F).

Is the fan working?

Yes - Checking connectors and wiring

No - Checking components and connectors

Checking components and connectors



- Ignition off
- Disconnect the climate control module (CCM).

Check that the fan rotates freely and is not blocked by any objects.
Check the fan connector. Check for contact resistance and oxidation.

Note! From and including w50 2001, the fan is connected directly to connector C with no wiring in-between.

Try replacing the fan if no other fault is found.
Remedy as necessary.

Other information:

- To access and replace the control module, see Climate control module (CCM), replacing See: Heating and Air Conditioning/Control Module HVAC/Service and Repair
- To access or replace the blower fan motor, see Blower fan motor passenger compartment temperature sensor, replacing See: Heating and Air Conditioning/Cabin Temperature Sensor / Switch/Service and Repair
- For other values, see

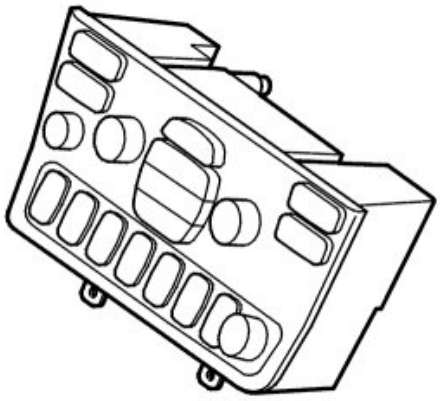
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CCM-0011

Condition



The diagnostic trouble code (DTC) is stored if the climate control module (CCM) detects an internal memory fault.
The diagnostic trouble code (DTC) can be diagnosed in ignition positions I and II.

Substitute value
- None.

Possible source
- Internal memory fault in the climate control module (CCM).

Fault symptom[s]
- The customer settings for the climate disappear.

Internal Fault

Internal fault

Replacing the component

The climate control module (CCM) has registered an internal fault.
If the fault is intermittent, it has been registered previously but is no longer present. Intermittent faults may be caused by interference at start up of the climate control module (CCM). Intermittent faults may also be caused by other types of intermittent faults. The fault is evaluated depending on how it occurs. If the fault recurs, replace the climate control module (CCM).
Replace the climate control module (CCM) in the event of a permanent fault:
Climate control module (CCM), replacing See: Heating and Air Conditioning/Control Module HVAC/Service and Repair
Remedy as necessary.

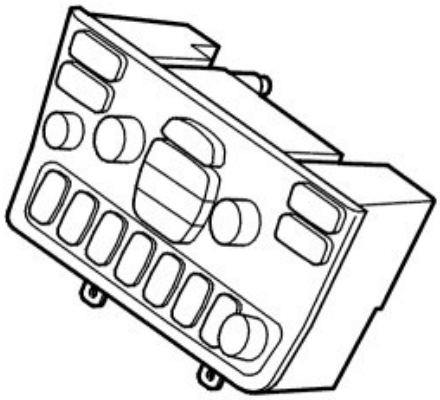
FAULT FOUND - DONE

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CCM-0020

Condition



The diagnostic trouble code (DTC) is stored if the climate control module (CCM) detects that a function button on the dashboard environment panel has been activated for longer than two minutes.
The climate control module (CCM) can detect a maximum of two buttons being pressed simultaneously. If more than two buttons are activated for too long simultaneously, the functionality for all the buttons may be lost.
The diagnostic trouble code (DTC) can be diagnosed in ignition positions I and II.

Substitute value
- The climate control module (CCM) does not permit the button function to be activated before the button has returned to the normal position.

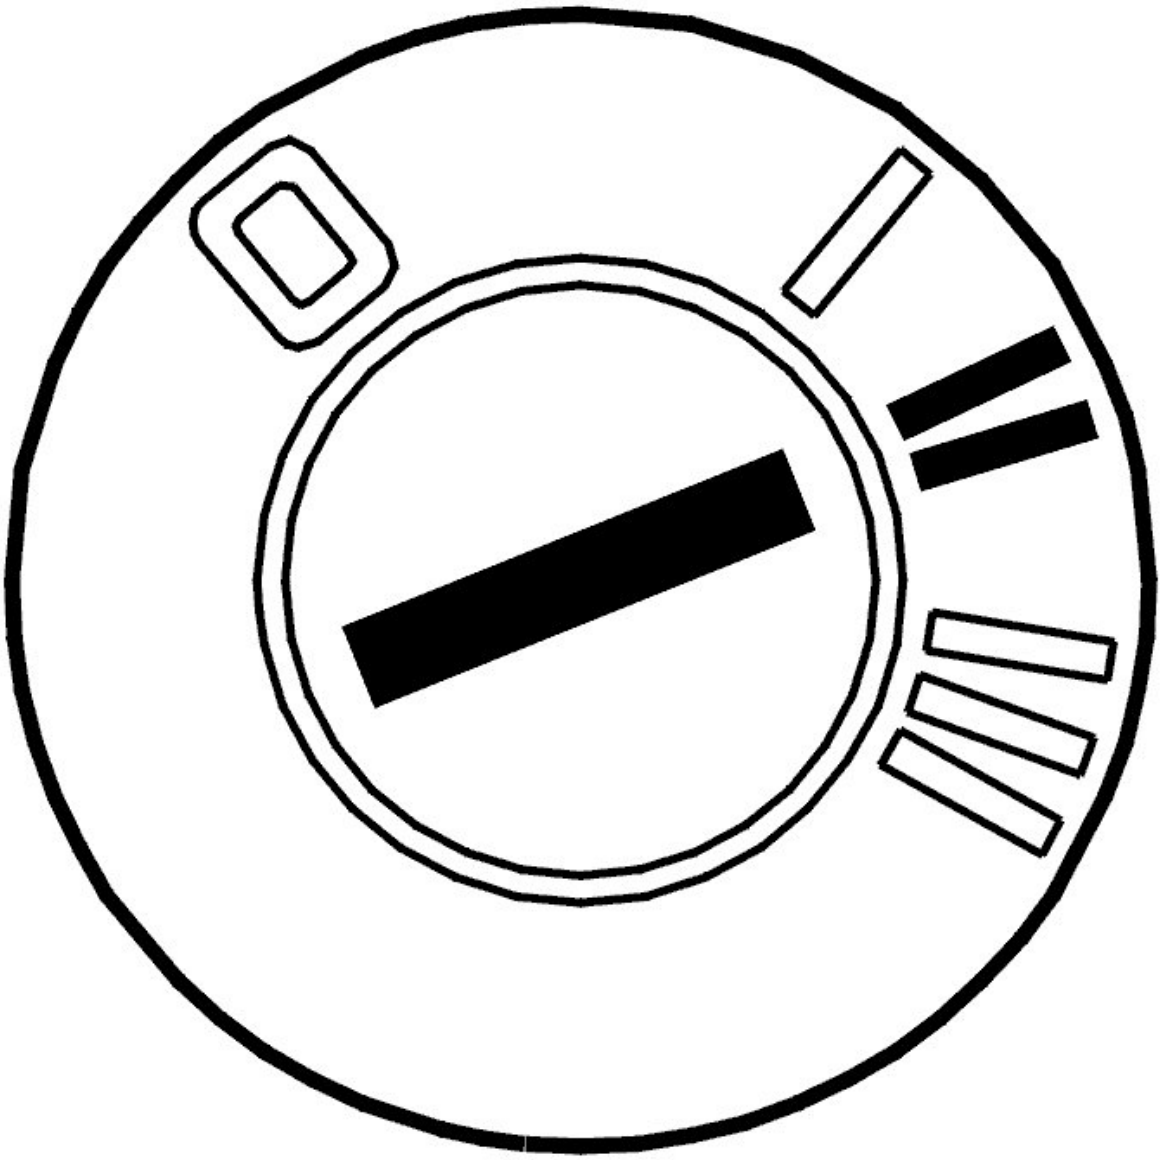
Possible source
- One or more function buttons are stuck in the pressed-in position
- Unintentionally long activation of the function button.

Fault symptom[s]
- The function button is not working.

Activated Too Long

Activated too long

Checking the component



- Ignition on.

Read off which switch was activated when the diagnostic trouble code (DTC) was set by clicking on the VCT2000 symbol.
Check if the switch is sticking due to dirt. Check if there is an obstruction preventing the switch from returning.
Check that the functions that can be controlled via the switch on the climate control module (CCM) are working.
Also check that the LEDs in the switches light and go out when the buttons are pressed.
The keypad must be replaced if the switch does not spring back and the fault is not due to dirt or an external object.

Other information:

- Climate control module (CCM), replacing See: Heating and Air Conditioning/Control Module HVAC/Service and Repair

Was a fault detected?

Yes - Verification

No - Fault-tracing information

Fault-tracing information

The fault is probably because a switch has been activated for too long during individual operating cycles. No further corrective action is required if the diagnostic trouble code (DTC) does not recur.

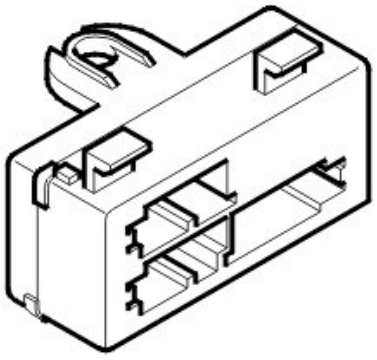
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CCM-0030

Condition



The diagnostic trouble code (DTC) is stored if the climate control module (CCM) detects a fault in the heater pad for the left seat heating module (SHM).
The climate control module (CCM) communicates with the left seat heating module (SHM) via LIN bus 1.

The seat heating module (SHM) transmits information to the climate control module (CCM) about status and current temperature.
The diagnostic trouble code (DTC) can be diagnosed at ignition switch position II.

Substitute value
- The climate control module (CCM) does not allow activation of the seat heater.

Possible source
- Open-circuit in the cable between the seat heating module (SHM) and the heater pad
- There is a short-circuit to supply voltage in the cable between the seat heating module (SHM) and the heater pad
- There is a short-circuit to ground in the cable between the seat heating module (SHM) and the heater pad.

Fault symptom[s]
- The front seat heating does not function.

Diagnostic Trouble Code (DTC) Information

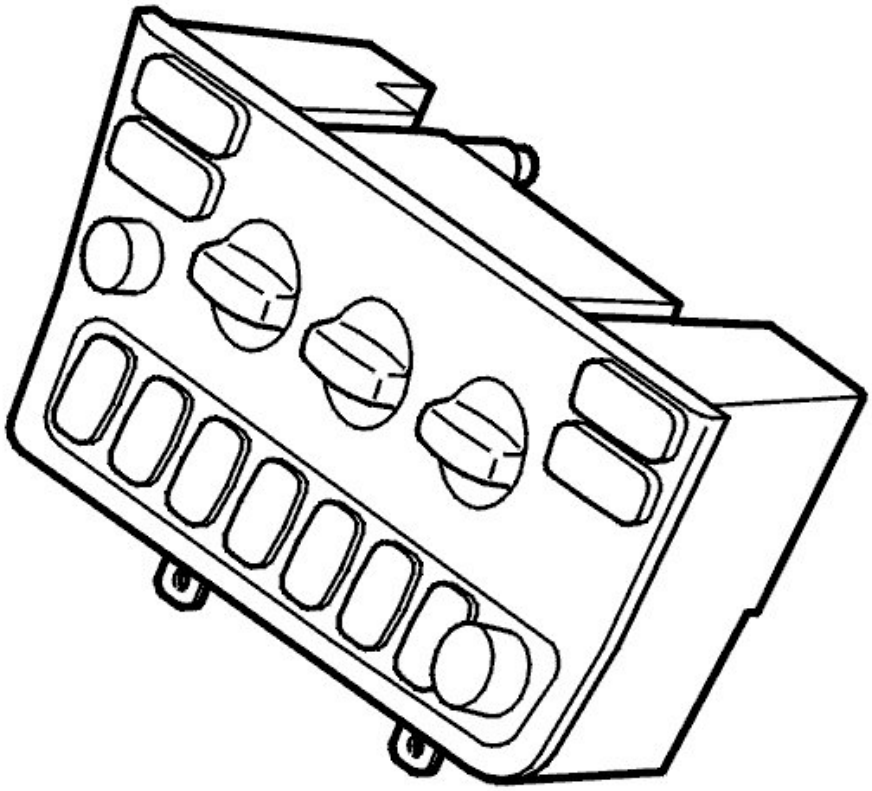
Diagnostic trouble code (DTC) information CCM-0050

Condition



The diagnostic trouble code (DTC) is stored if the climate control module (CCM) registers that the signal from the fan knob exceeds 99%, or is less than 1% of supply voltage (approximately 5 V).
The diagnostic trouble code (DTC) can be diagnosed in ignition positions I and II.

Substitute value
- The climate control module (CCM) adopts a value corresponding to half of the maximum fan knob output.

Possible source
- Defective potentiometer
- Short-circuit to supply voltage or ground in the potentiometer.

Fault symptom[s]
- The blower fan only runs at one speed.

Faulty Signal

Faulty signal

Replacing the component

The fault has probably occurred as a result of a defective potentiometer or a short-circuit in the potentiometer. If the fault is intermittent, it has been registered previously but is no longer present. Intermittent faults may be caused by interference at start up of the control module. Intermittent faults may also be caused by other types of intermittent faults. The fault is evaluated depending on how it occurs. If the fault recurs, replace the control module.
If the fault persists, replace the climate control module (CCM). The potentiometer cannot be replaced as a separate part.

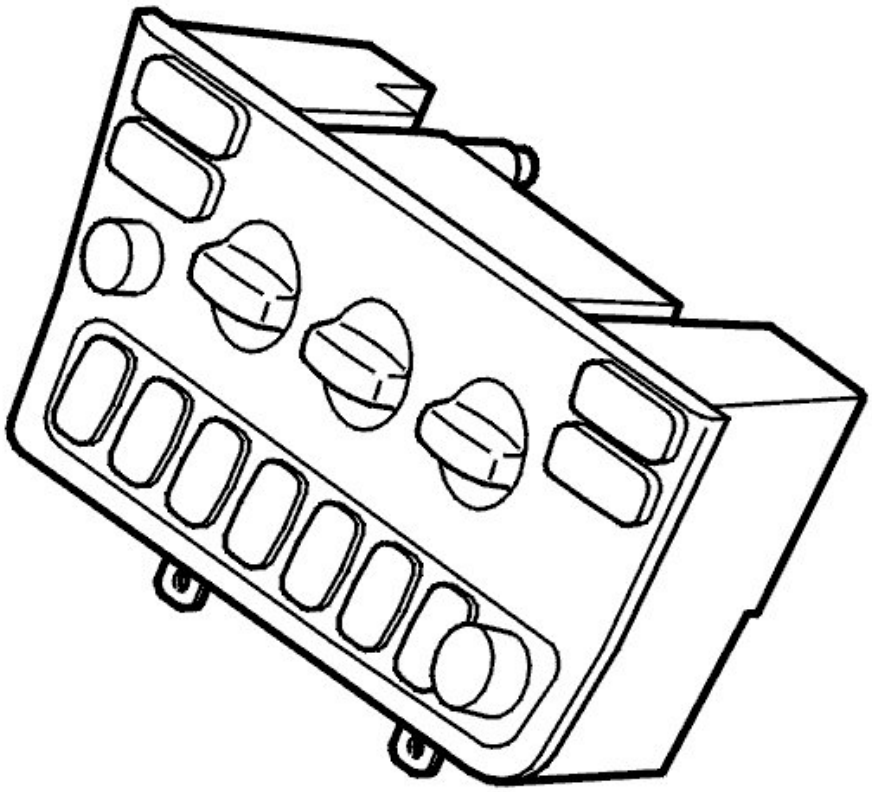
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CCM-0051

Condition



The diagnostic trouble code (DTC) is stored if the climate control module (CCM) registers that the signal from the temperature control for the left-hand side exceeds 99%, or is less than 1% of supply voltage (approximately 5 V).
The diagnostic trouble code (DTC) can be diagnosed in ignition positions I and II.

Substitute value
- The climate control module (CCM) adopts a value corresponding to half of the maximum output of the temperature control.

Possible source
- Defective potentiometer
- Short-circuit to supply voltage or ground in the potentiometer.

Fault symptom[s]
- The passenger compartment temperature does not correspond to the set value.

Faulty Signal

Faulty signal

Replacing the component

The fault has probably occurred as a result of a defective potentiometer or a short-circuit in the potentiometer. If the fault is intermittent, it has been registered previously but is no longer present. Intermittent faults may be caused by interference at start up of the control module. Intermittent faults

may also be caused by other types of intermittent faults. The fault is evaluated depending on how it occurs. If the fault recurs, replace the control module.
If the fault persists, replace the climate control module (CCM). The potentiometer cannot be replaced as a separate part.

The climate control module (CCM) communicates with the damper motor module (DMM) air distribution via LIN bus 1.
The damper motor module (DMM) transmits information to the climate control module (CCM) about status.
The diagnostic trouble code (DTC) can be diagnosed in ignition positions I and II.

Substitute value
- None.

Possible source
- Internal fault in the damper motor module (DMM) air distribution
- Incorrect calibration due to loss of power.

Fault symptom[s]
- Misting on the windows and/or door mirrors.
- Air flow problem.

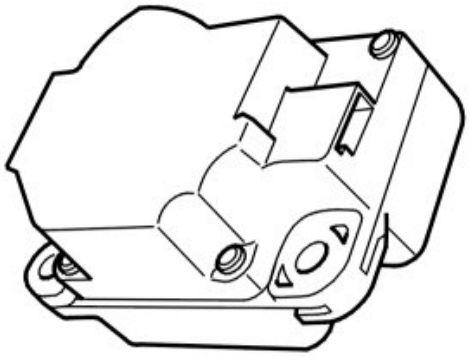
Internal Fault

Internal fault

Replacing the component

The climate control module (CCM) has registered an internal fault in the damper motor module (DMM) for air distribution.

If the fault is intermittent, it has been registered previously but is no longer present. Intermittent faults may be caused by interference at start up of the damper motor module (DMM). Intermittent faults may also be caused by other types of intermittent faults. The fault is evaluated depending on how it occurs. Replace the damper motor module (DMM) if the fault recurs.
Replace the damper motor module (DMM) for air distribution if the fault is permanent:
Damper motor air distribution, replacing See: Heating and Air Conditioning/Air Door/Air Door Actuator / Motor/Service and Repair
Remedy as necessary.



Continue - Identifying the Damper Motor Module (DMM)

Identifying the Damper Motor Module (DMM)

Information
- The control module must be identified after replacing the Damper Motor Module (DMM).

Note! Identification must only be carried out when replacing the Damper Motor Module (DMM).

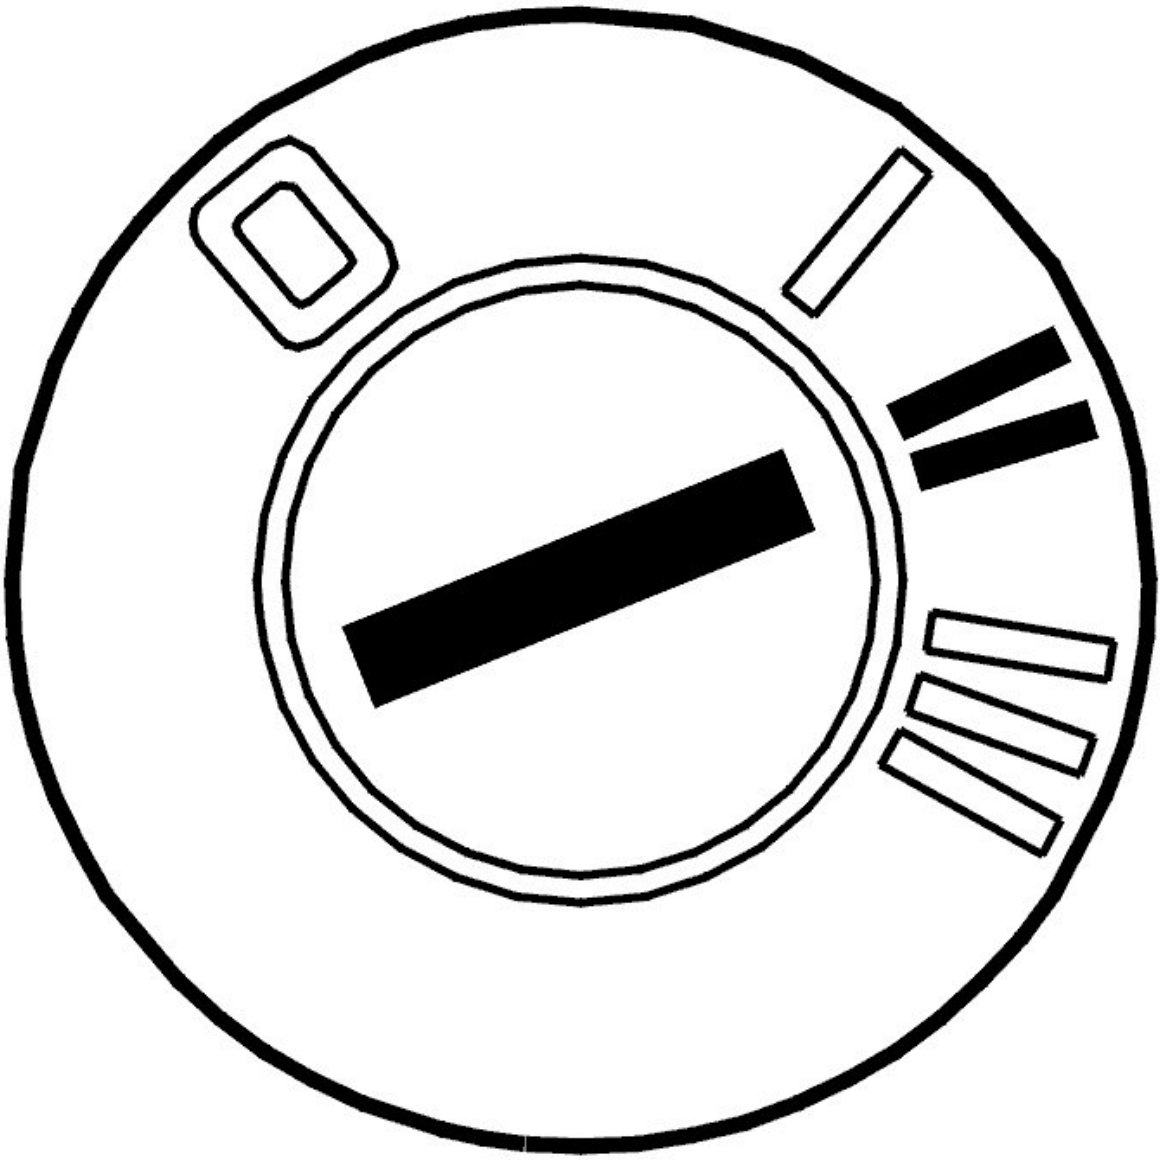
Have any damper motors been replaced?

Yes - Identifying the Damper Motor Module (DMM)

No - DONE

Identifying the Damper Motor Module (DMM)

Hint: When identifying damper motors, each damper motor must be run to its limit position. These operations can take up to 30 seconds. When identifying the damper motors it is important that a battery charger is connected.



- Ignition off
- Reinstall the connectors, components etc.

Note! Climate Control Module (CCM) and damper motors can be affected by the temperature. The vehicle should have normal room temperature when performing this service.

Carry out identification as follows:

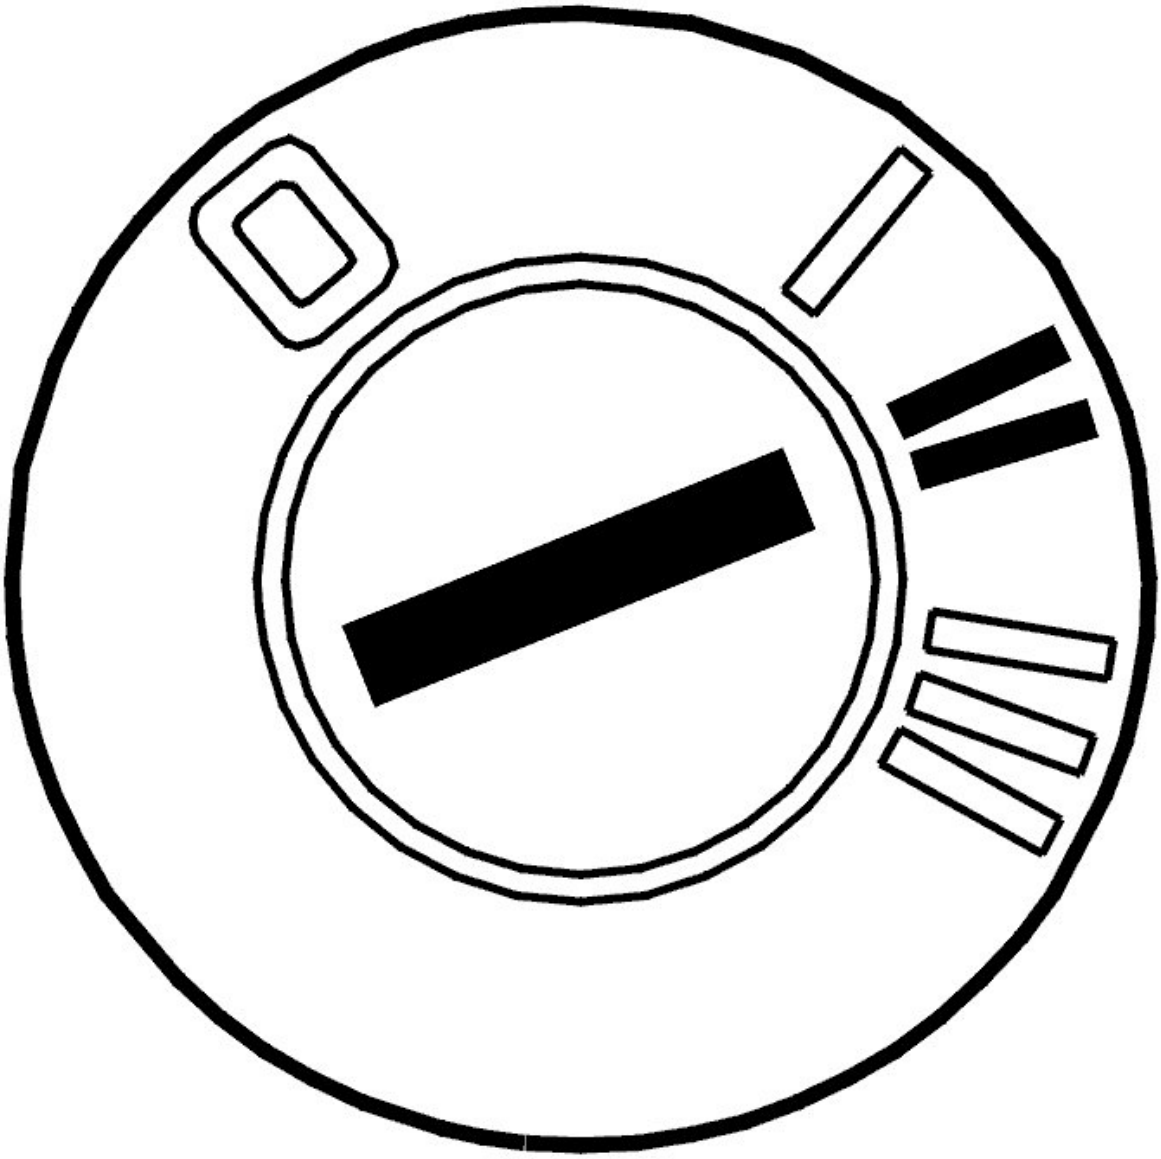
- Ignition on.
- Click on the VCT2000 symbol. Wait until identification has been carried out.
- Ignition off.

Continue - Calibrating the Climate Control Module (CCM)

Calibrating the Climate Control Module (CCM)

Caution! When activating this function, calibration of the Climate Control Module (CCM) starts. After carrying out calibration read off of the diagnostic trouble codes (DTCs) starts. To ensure that diagnostics for the Climate Control Module (CCM) have been carried out, delay for 30 seconds before reading out diagnostic trouble codes (DTCs) after calibration.

Note! Climate Control Module (CCM) and damper motors can be affected by the temperature. The vehicle should have normal room temperature when performing this service.



Carry out calibration as follows:

- Ignition on.
- Click on the VCT2000 symbol. Wait until calibration has been carried out and diagnostic trouble codes (DTCs) read out.
- Ignition off.

This function controls the components that communicate with the Climate Control Module (CCM) via LIN bus 1 and LIN bus 2. In the event of a fault in any of the LIN buses, diagnostic trouble codes (DTCs) CCM-0070 to CCM-0071 will be stored depending on the fault. These diagnostic trouble codes (DTCs) can only be stored in conjunction with this diagnostic function.
If any of these diagnostic trouble codes (DTCs) recur, recalibrate to check if the problem was overcome. If the diagnostic trouble code (DTC) recurs, fault-trace the relevant diagnostic trouble code (DTC).

Continue - DONE

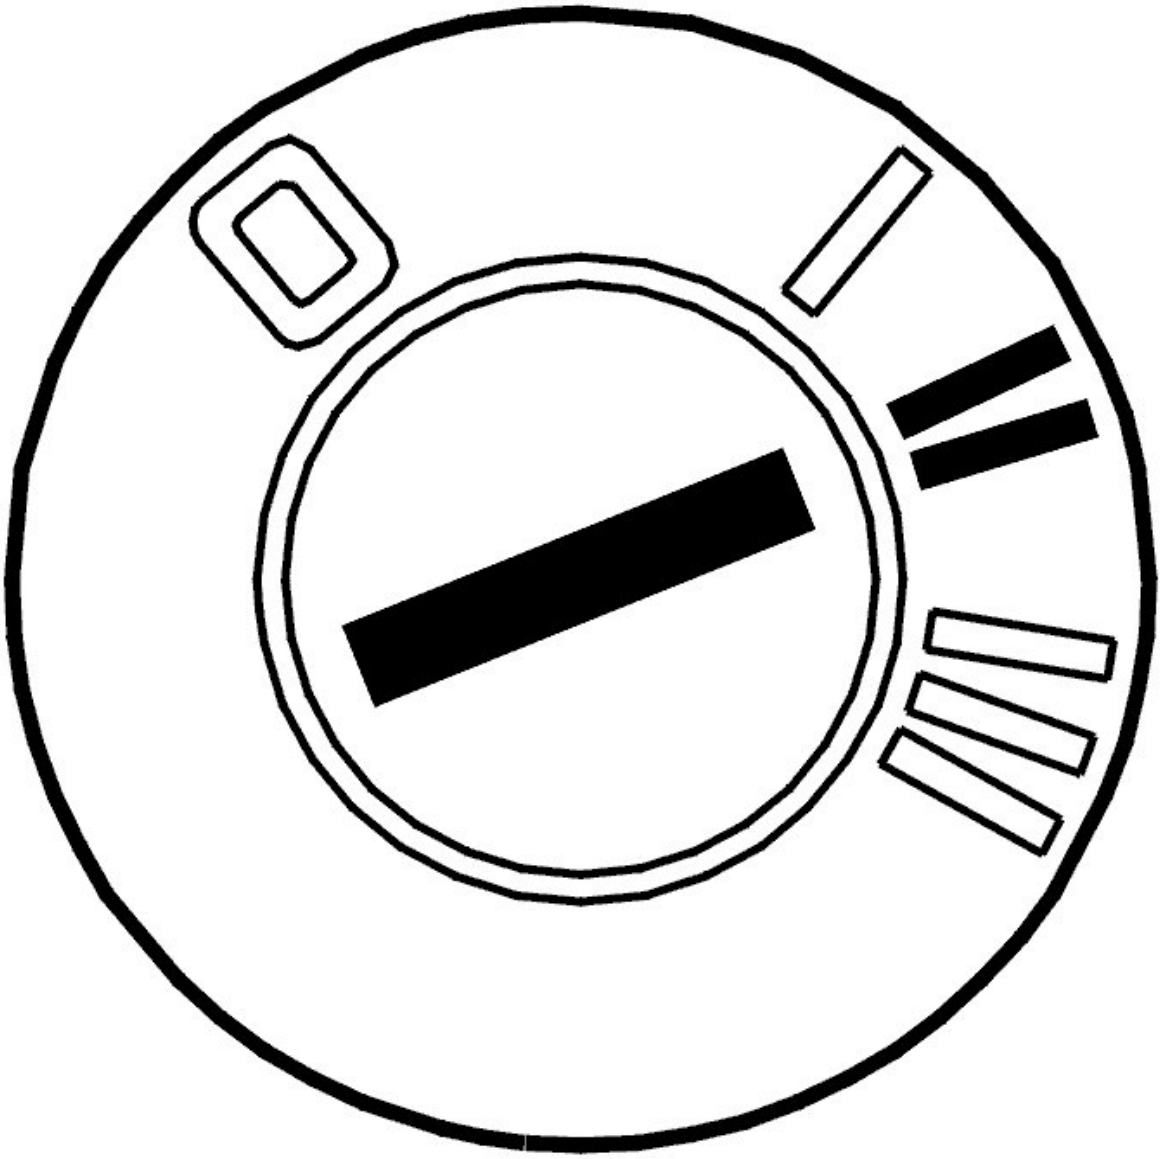
DONE - Verification

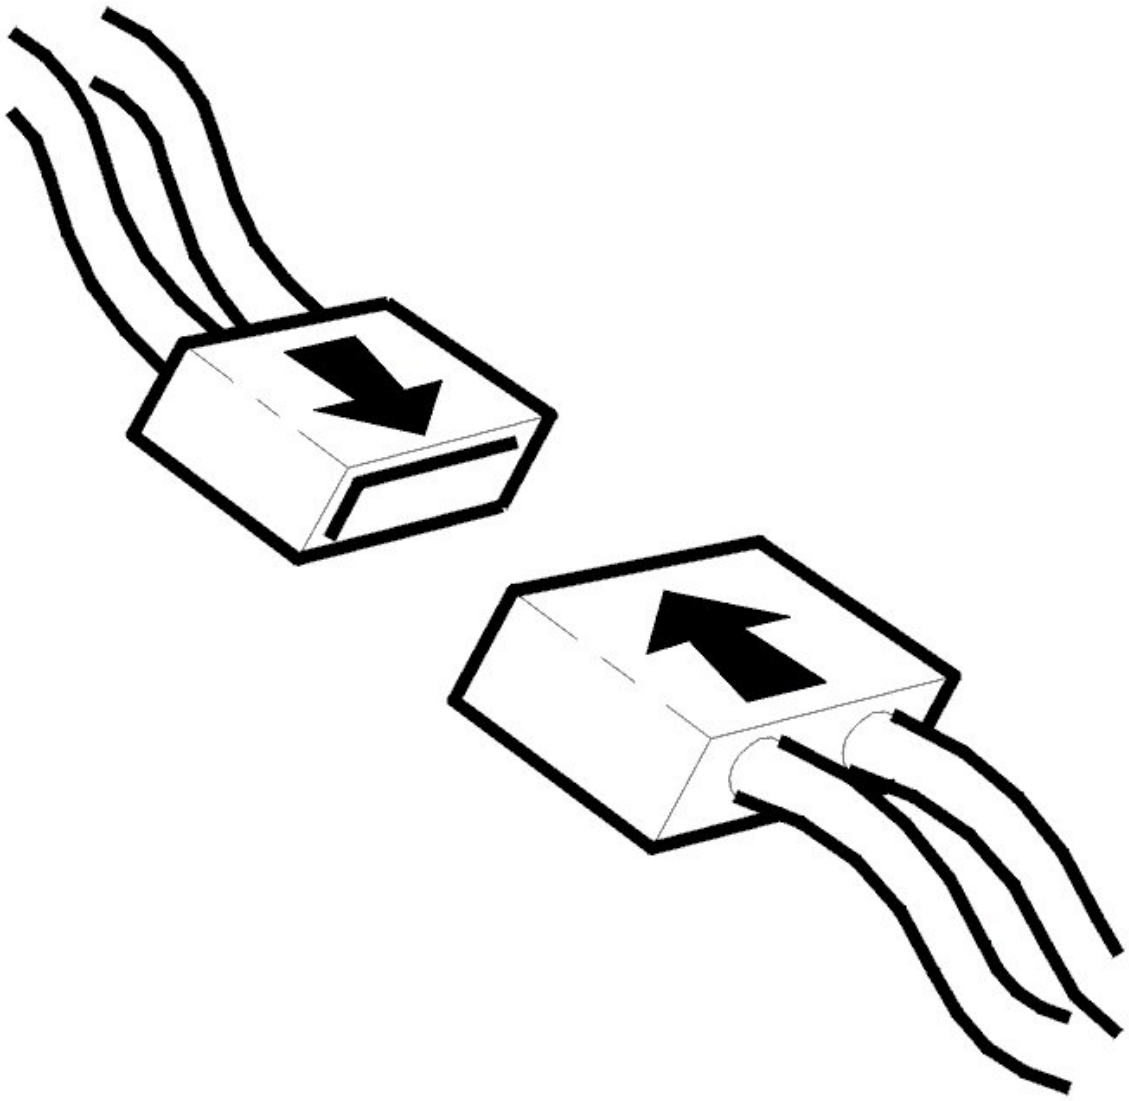
Verification

Verification

Verification

Hint: After carrying out the repair, check that the fault has been remedied.





- Ignition off
- Reinstall the connectors, components etc.
- Ignition on.

Check that the relevant diagnostic trouble code (DTC) has switched status from permanent to intermittent fault.
Check also that diagnostic trouble code (DTC) CCM-0070, CCM-0071 CCM-0072 or CCM-0073 has not been stored during identification of the damper motors.
These diagnostic trouble codes (DTCs) can only be stored when identifying damper motors. They mean that the identification has failed for some reason.
Remedy by correctly identifying the damper motor. Fault-trace according to the relevant information.

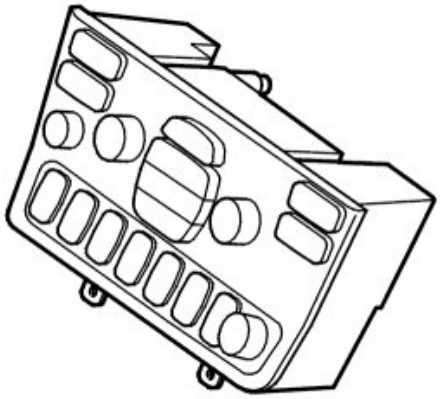
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CCM-0070

Condition



The diagnostic trouble code (DTC) is stored if the climate control module (CCM) detects that components on LIN bus 1 and LIN bus 2 do not correspond with the components included in the Car Config File.
The climate control module (CCM) receives information about the Car Config File from the central electronic module (CEM) via the CAN network.
The diagnostic trouble code (DTC) can be diagnosed in ignition positions I and II.
The diagnostic trouble code (DTC) can only be diagnosed in conjunction with activation of a diagnostic function.

Substitute value
- None.

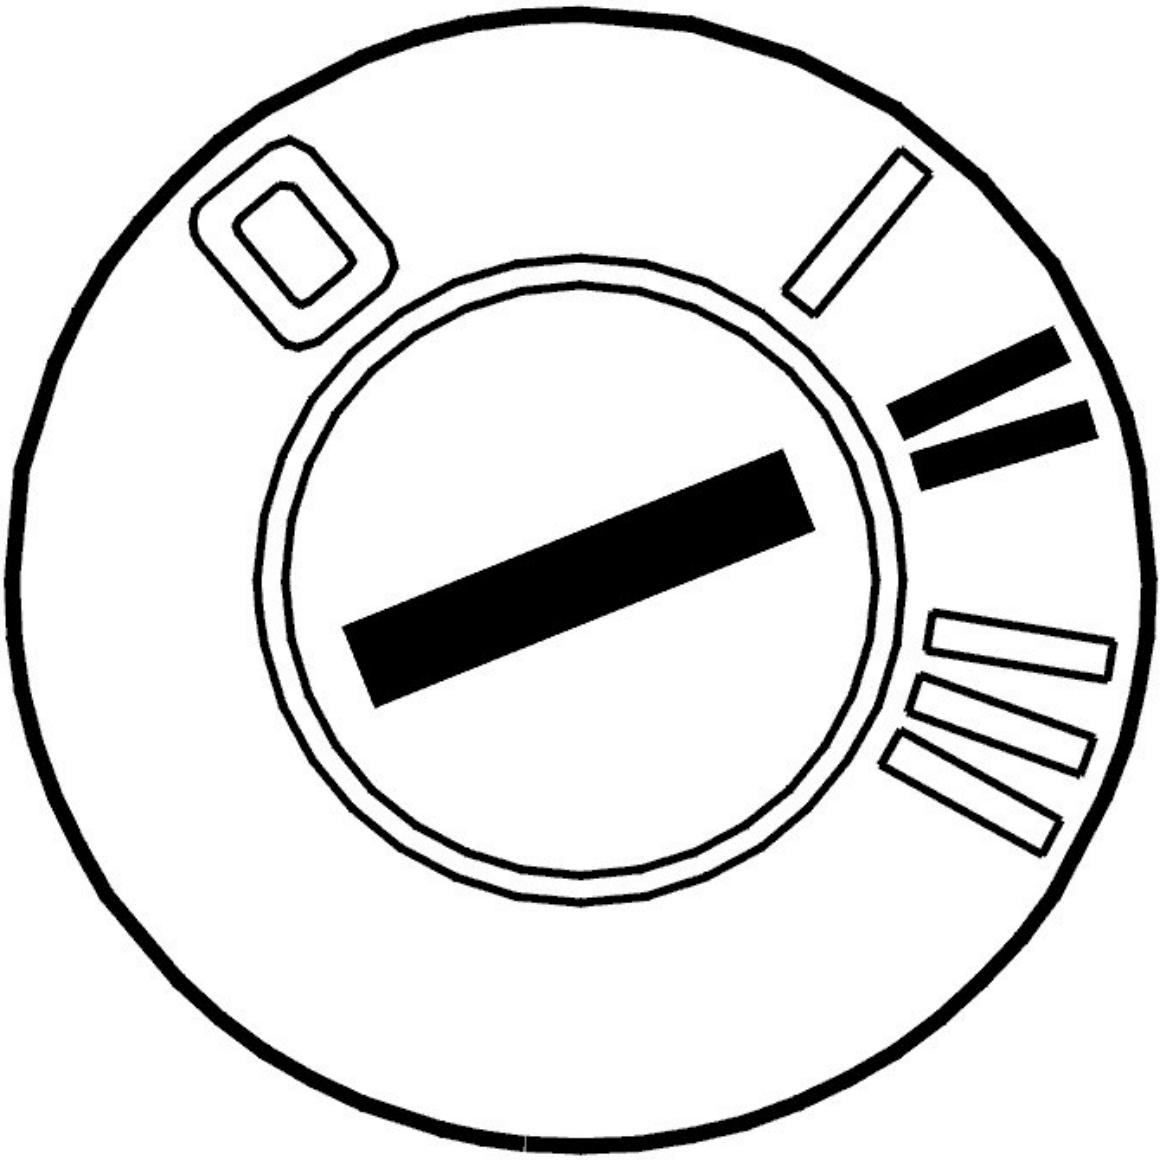
Possible source
- Components on LIN bus 1 or LIN bus 2 are missing
- Components on LIN bus 1 or LIN bus 2 are incorrectly installed.

Fault symptom[s]
- Misting on the windows and/or door mirrors.
- Air flow problem.
- Temperature control/Uneven temperature
- The passenger compartment temperature does not correspond to the set position.
- No recirculation.

Faulty Identification

Faulty identification

Checking components on LIN bus



- Ignition on.

The climate control module (CCM) has registered that the number of control modules on LIN bus 1 or 2 does not correspond with the number of control modules occupied in the car configuration.
If a control module is missing according to the car configuration, check that the control module is installed and correctly connected.
Check also whether any control modules are connected that are not occupied in the car configuration.
If the diagnostic trouble code (DTC) is stored together with CCM-0072, the fault can be due to several damper motor modules (DMM) having the same identity. In such cases, remedy by identifying the damper motor.
Read out which control modules/sensors are on LIN bus 1 and 2 and compare this to the car configuration. Which control modules and sensors are to be found and which alternatives can be presented in the car configuration can be read in the tables below.

LIN bus 1

Control module/sensor	On LIN bus 1
Damper Motor Position Sensor recirculation	Always
Damper motor, temperature left	Always
Damper motor recirculation (REC/OSA).	If the vehicle is right-hand drive
Left seat heating	If the vehicle is equipped with seat heating
Air quality sensor (AQS)	If the vehicle is right-hand drive and equipped with an air quality sensor (AQS)

LIN bus 2

Control module/sensor	On LIN bus 2
Damper motor, temperature, right	Always
Defroster damper motor	If the vehicle is equipped with ECC
Damper motor recirculation (REC/OSA).	If the vehicle is left-hand drive
Seat heater, right.	If the vehicle is equipped with seat heating
Air quality sensor (AQS)	If the vehicle is left-hand drive and equipped with an air quality sensor (AQS)

Car configuration

Parameter	Alternative
Steering	Left-hand drive Right-hand drive
Climate control system	ECC ECC/AQS ECC, rear AC MCC
Seat heating calibration	No Low 28C/82F-High 35C/95F Low 30C/86F-High 36C/97F Low 31C/88F-High 37C/99F Low 32C/90F-High 38C/100F Low 33C/91F-High 39C/102F Low 34C/93F-High 40C/104F Low 35C/95F-High 41C/106F Low 36C/97F-High 43C/109F
Cabin filter	Pollen filter Air Quality System, AQS

Click the VCT2000 symbol to check which control module/sensor does not correspond to the car configuration.
Remedy as necessary.

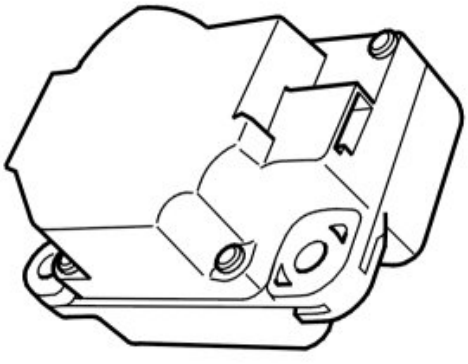
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CCM-0071

Condition



The diagnostic trouble code (DTC) is stored if the climate control module (CCM) detects that the limit positions for a damper motor module (DMM) do not correspond to the anticipated limit positions.
The diagnostic trouble code (DTC) can be diagnosed in ignition positions I and II.

The diagnostic trouble code (DTC) can only be diagnosed in conjunction with activation of a diagnostic function.

Substitute value
- None.

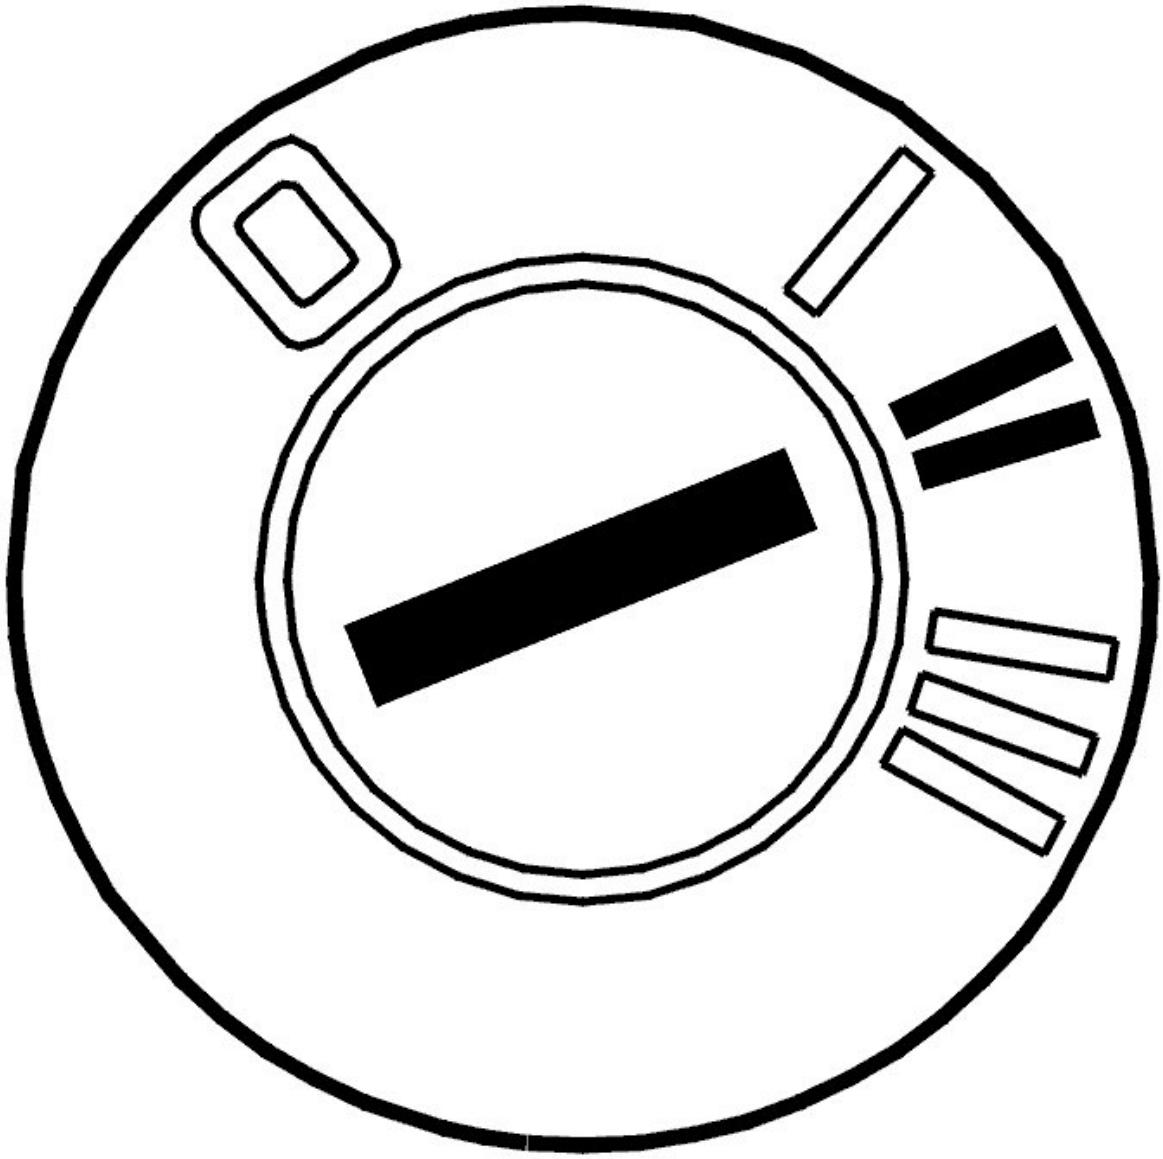
Possible source
- Blocked damper.
- Climate control unit calibrated at incorrect temperature.
- Internal fault in the Damper motor module (DMM).

Fault symptom[s]
- Misting on the windows and/or door mirrors.
- Air flow problem.
- The passenger compartment temperature does not correspond to the set position.
- No recirculation.

Incorrect position

Incorrect position

Checking the component



- Ignition on.

The climate control module (CCM) has registered that one or more damper motor modules (DMM) have an incorrect number of steps between the end positions during damper regulation.
Check which damper motor has an incorrect number of steps between the end positions by:
- Read out the actual range to identify the number of stages between the upper and lower end positions measured by the damper motor module (DMM).
- Read out the preset range to identify the number of stages between the upper and lower end positions stored by the damper motor module (DMM).

- Compare these values to check the tolerances.

The defective damper motor has been identified if the actual range of any of the damper motors is outside the preset range by more than the tolerance.
Check that the damper motor is correctly installed.
Check that the damper is not blocked and that is has not become stuck. Look, for example, for a screw, cable or foam rubber gasket.

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CCM-0074

Condition

The climate control module (CCM) communicates with the damper motor module (DMM) defroster via the LIN bus 2.
The diagnostic trouble code (DTC) is stored if the control module detects that:

- Damper motor module (DMM) defroster does not go to desired position.

Substitute value

- None.

Possible source

- Internal fault in Damper motor module (DMM) defroster.

Fault symptom[s]

- Defog/defrost/Windshield defog/defrost/Slow to clear/uneven clearing
- Defog/defrost/Windshield defog/defrost/Does not work

L.H.D.

Fault-tracing

Fault-tracing information

Use the following information and general checks during fault-tracing.

Note! Check that the fuses are intact. For locations, see the instruction manual, cover for fuse box, fuse ratings or similar.

1. Check, if possible, relevant functions in the vehicle using buttons/controls/test drives to determine the status of the fault.

   Note! If the vehicle does not show any of the given symptoms in the diagnostic trouble code information (DTC), this may mean that the fault is intermittent or that the control module is not detecting the fault at this moment.

2. Use the diagnostic trouble code's **frozen values**, **status identifiers** and **counter** to determine the operating conditions when the fault was detected, the fault's current status and any degree of intermittence of the fault.
3. Check and fault-trace according to **the fault causes** that are specified in the **diagnostic trouble code (DTC) information**.
4. Use **VIDA Vehicle communication**. Read off the parameters, activate components and functions, carry out quick tests and checking routines for the diagnostic trouble codes to identify the fault.
5. Check relevant components according to **Component specifications**.
6. Check relevant signals using **wiring diagram**, **signal specification** and **breakout box**.

Note! More information is available in Design and function.

Remedy as necessary.

   Note! If the vehicle does not show any of the given symptoms in the diagnostic trouble code information (DTC), this may mean that the fault is intermittent or that the control module is not detecting the fault at this moment.

2. Use the diagnostic trouble code's **frozen values**, **status identifiers** and **counter** to determine the operating conditions when the fault was detected, the fault's current status and any degree of intermittence of the fault.
3. Check and fault-trace according to **the fault causes** that are specified in the **diagnostic trouble code (DTC) information**.
4. Use **VIDA Vehicle communication**. Read off the parameters, activate components and functions, carry out quick tests and checking routines for the diagnostic trouble codes to identify the fault.
5. Check relevant components according to **Component specifications**.
6. Check relevant signals using **wiring diagram**, **signal specification** and **breakout box**.

Note! More information is available in Design and function.

Remedy as necessary.

Diagnostic Trouble Code (DTC) Information

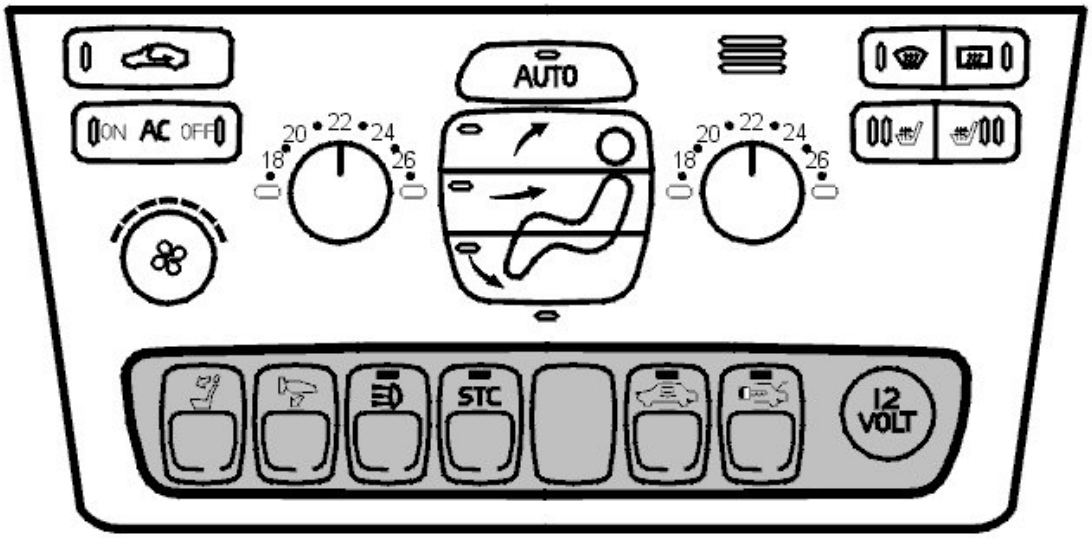
Diagnostic trouble code (DTC) information CCM-0090

Condition



The diagnostic trouble code (DTC) is stored if the climate control module (CCM) registers a non-permissible switch identity compared to the permitted switch identities included in the Car Config File.
The diagnostic trouble code (DTC) can be diagnosed in ignition positions I and II.

Substitute value
- None.

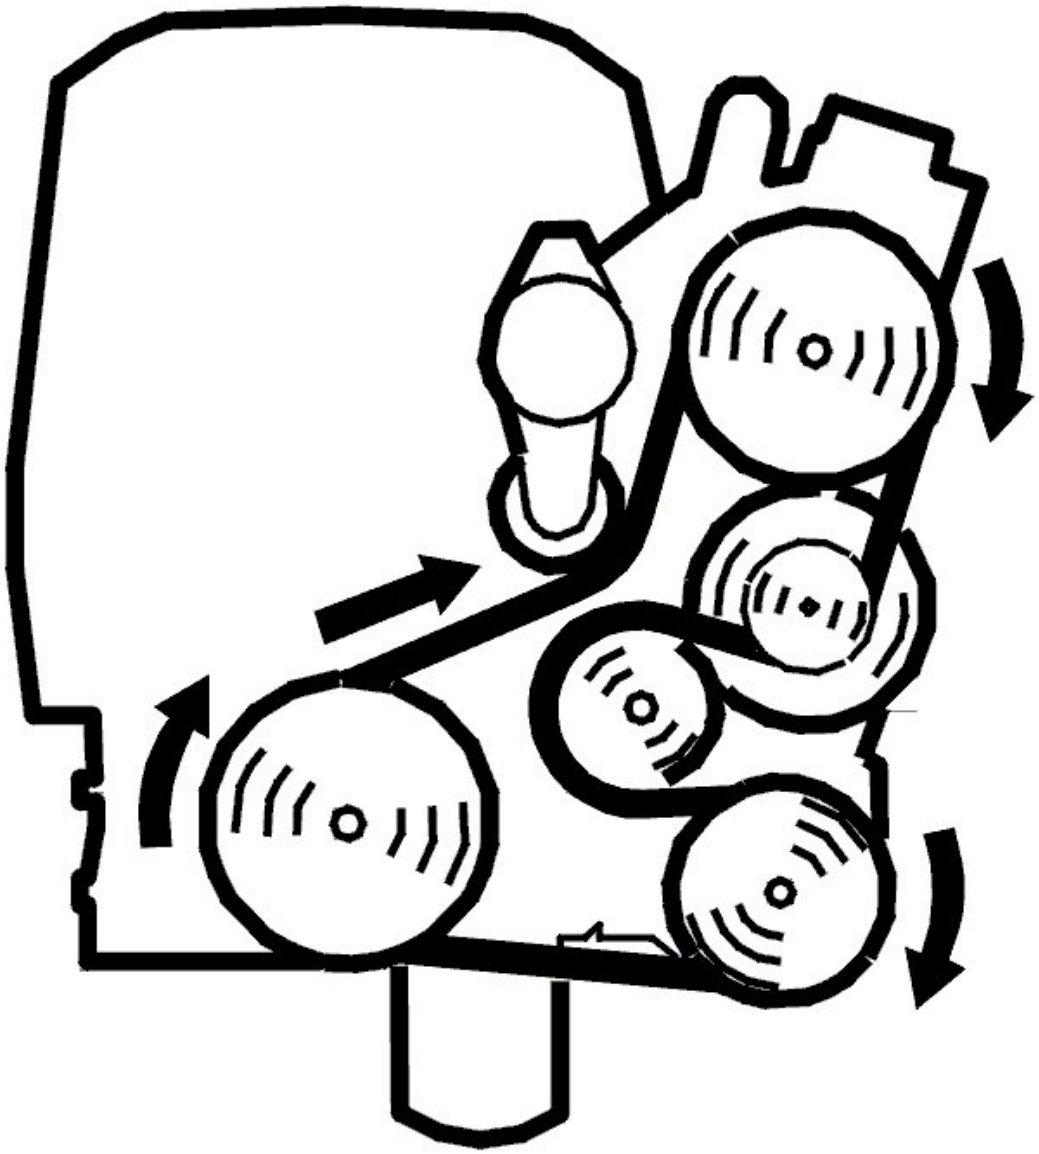
Possible source
- Switch replaced with a switch with incorrect identity
- Defective switch
- Fault in the Car Configuration File
- Two or more switches with the same ID.

Fault symptom[s]
- The function button is not working.

Faulty ID

Faulty ID

Checking the function



- Engine running.

Check that all the functions can be activated via the lower switch.

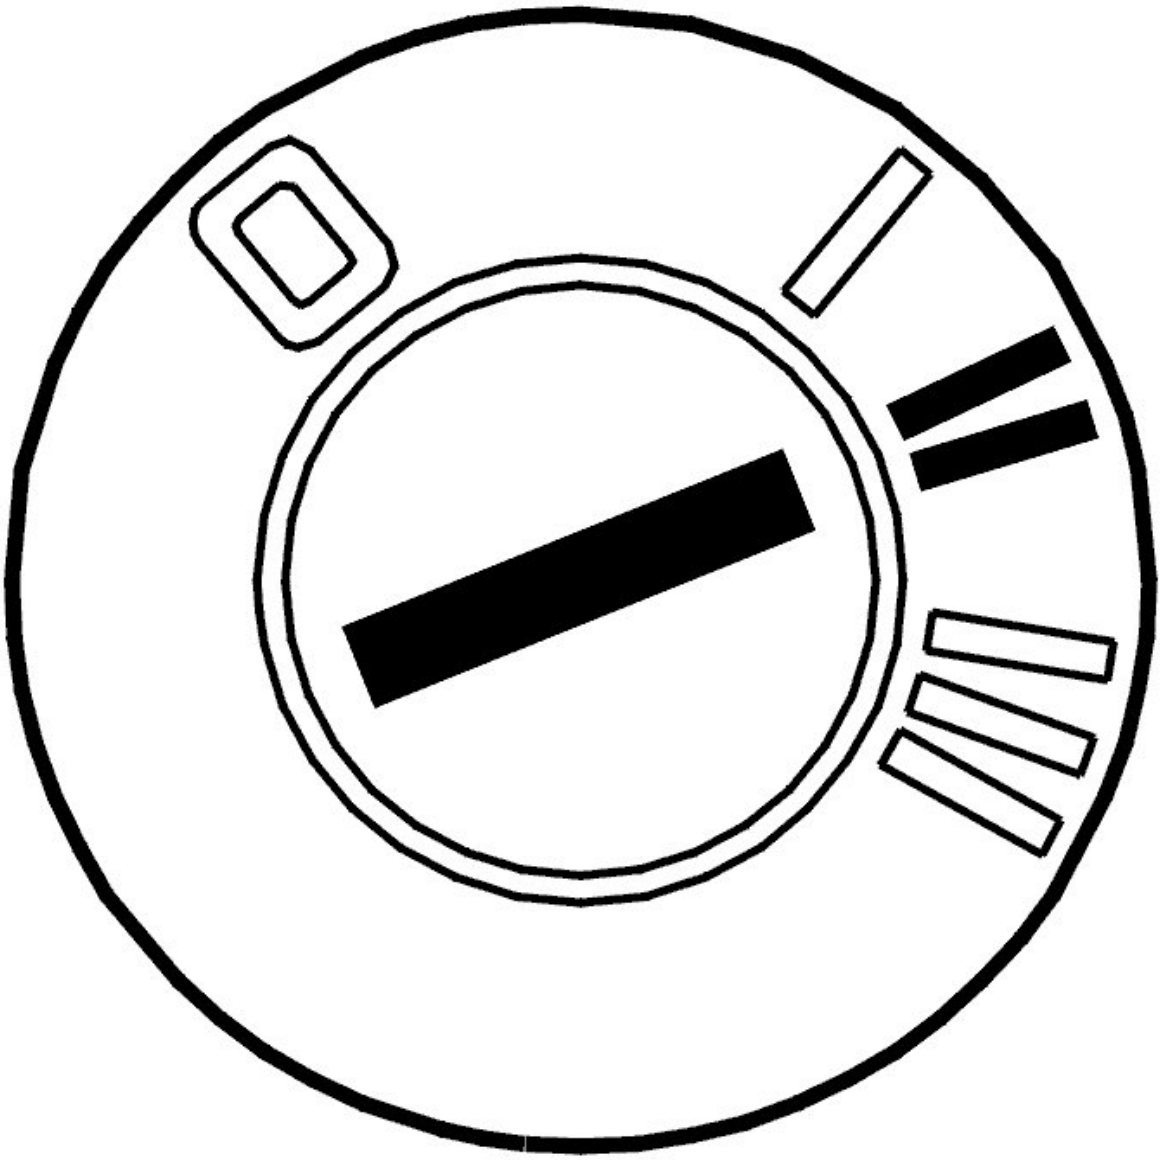
Hint: Where applicable, the LED on the lower switch must be lit when the function is activated.

Are all functions activated?

Yes - Fault-tracing information

No - Checking the switch identity

Checking the switch identity



- Ignition on.

Note! The switches can be placed in any position in the climate control assembly (without internal order). The position of the switches must be taken into account when fault-tracing with VCT2000.The switch furthest to the left in the climate control assembly corresponds to no. 1 in VCT2000. VCT2000 then follows the numbering in order to the switch furthest to the right, which is designated no. 7.

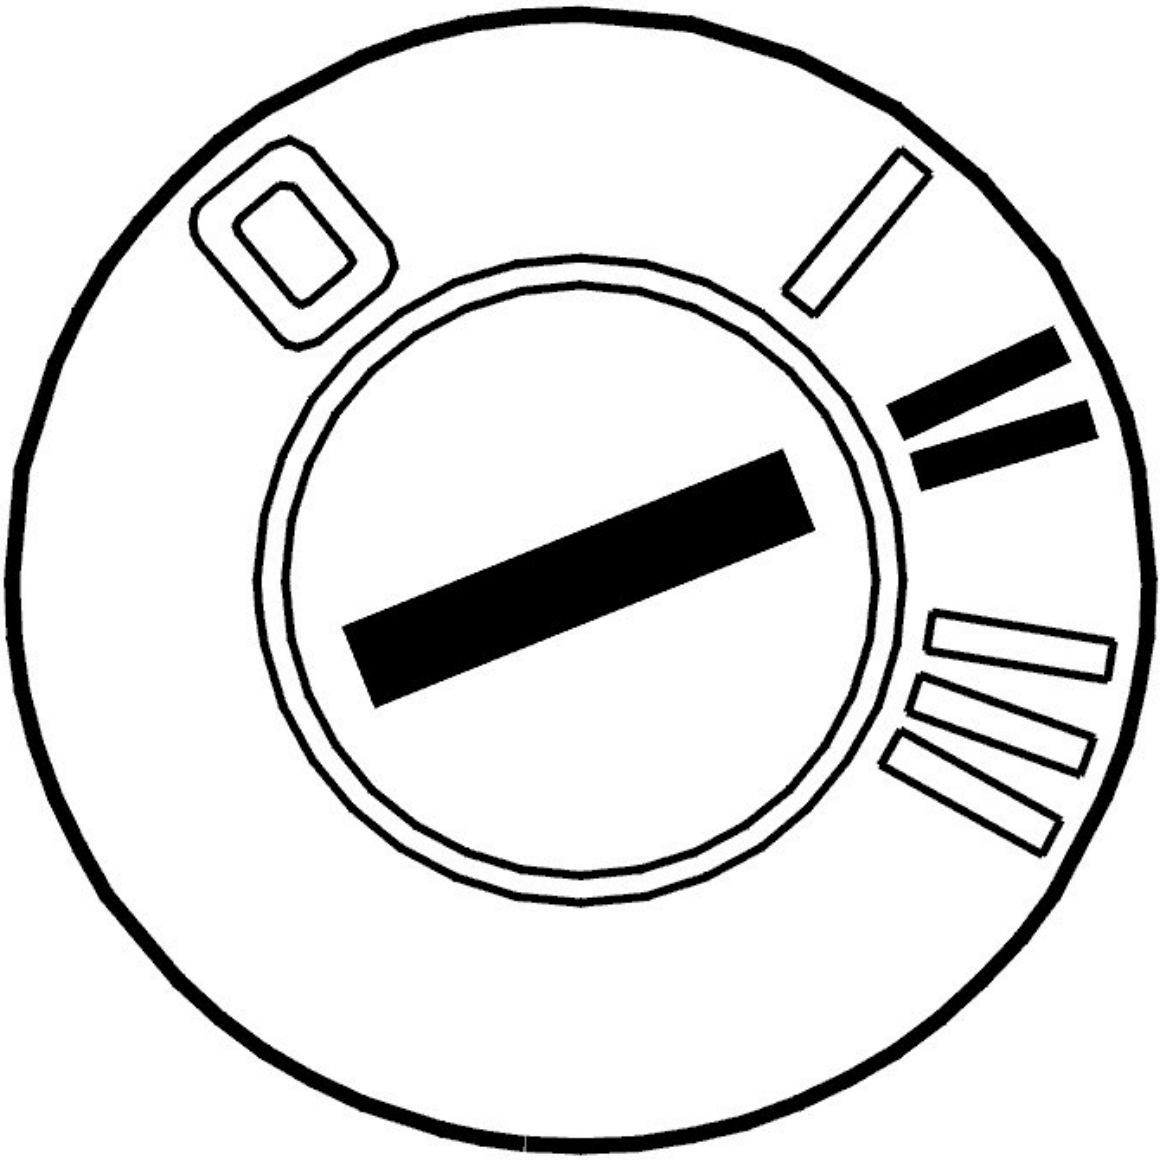
Read off the identities of the switches. Check that the read off identity corresponds to the switch marking for its position in the dashboard environment panel. If the identity does not correspond to the marking, this indicates a defective switch.
Remedy as necessary.

Was a fault detected?

Yes - Verification

No - Checking the switch status

Checking the switch status



- Ignition on.

Note! The switches can be placed in any position in the climate control assembly (without internal order). The position of the switches must be taken into account when fault-tracing with VCT2000.The switch furthest to the left in the climate control assembly corresponds to no. 1 in VCT2000. VCT2000 then follows the numbering in order to the switch furthest to the right, which is designated no. 7.

Read off the status of the switches. Check that the read off status is OK for each switch. If the status is not OK, this indicates that the function of the switch is not in the Car Configuration.

Was a fault detected?

Yes - Information

No - No Fault Found

Information

The fault is probably because the functionality of the button is not in Car Configuration. This is remedied by ordering and downloading the missing functionality.

Continue - Verification

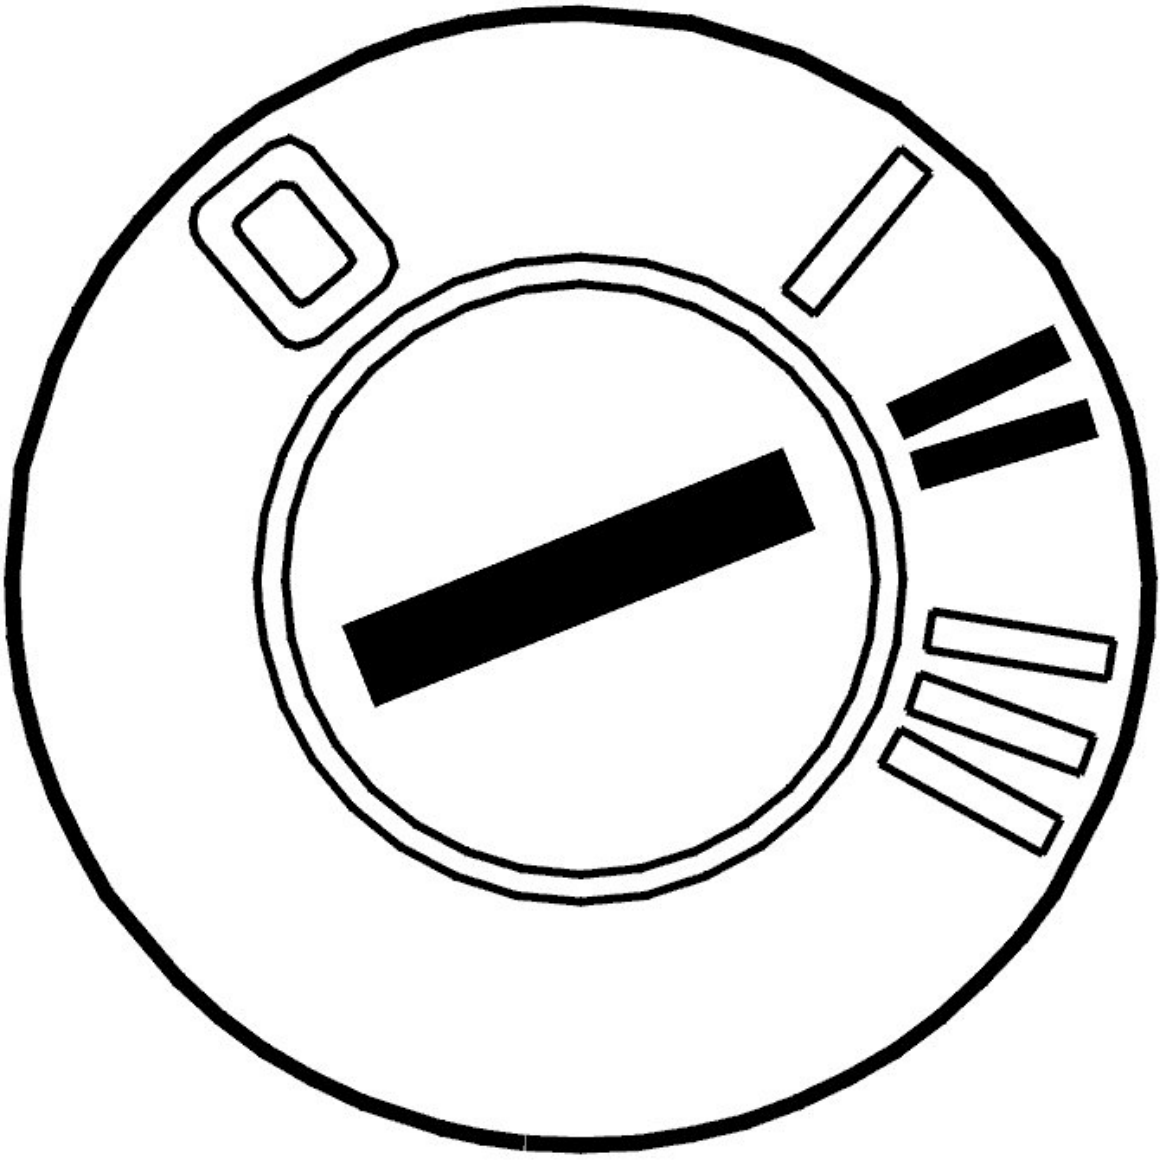
Fault-tracing information

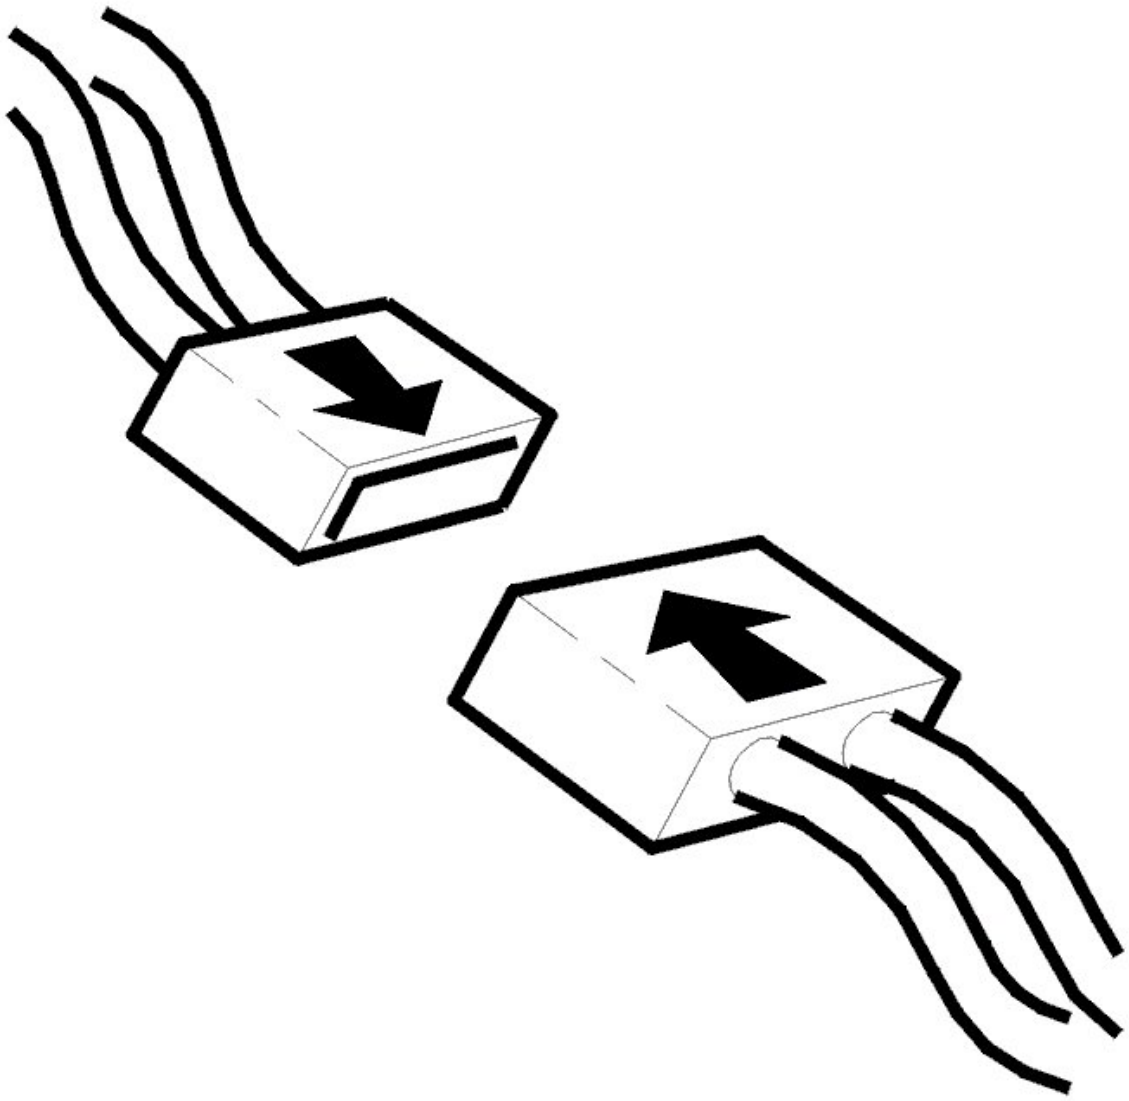
The fault is probably the result of a damaged, intermittently defective or missing switch. If the fault is intermittent, it has been registered previously but is no longer present.
Intermittent faults may be caused by interference at start up of the control module. Intermittent faults may also be caused by other types of intermittent faults. The fault is evaluated depending on how it occurs.

Continue - Information

Verification

Hint: After carrying out the repair, check that the fault has been remedied.





- Ignition off.

Note! Wait at least 1 minute before "Ignition on". This is to allow the climate control module (CCM) to carry out a new diagnostic.

- Reinstall the connectors, components etc.
- Ignition on
- Read off diagnostic trouble codes (DTCs).

The fault is no longer present if the status of the diagnostic trouble code (DTC) has changed to intermittent.

Does the status change?

Yes - VERIFIED

No - VERIFICATION FAILED

VERIFIED - Fault Found

VERIFICATION FAILED - Information

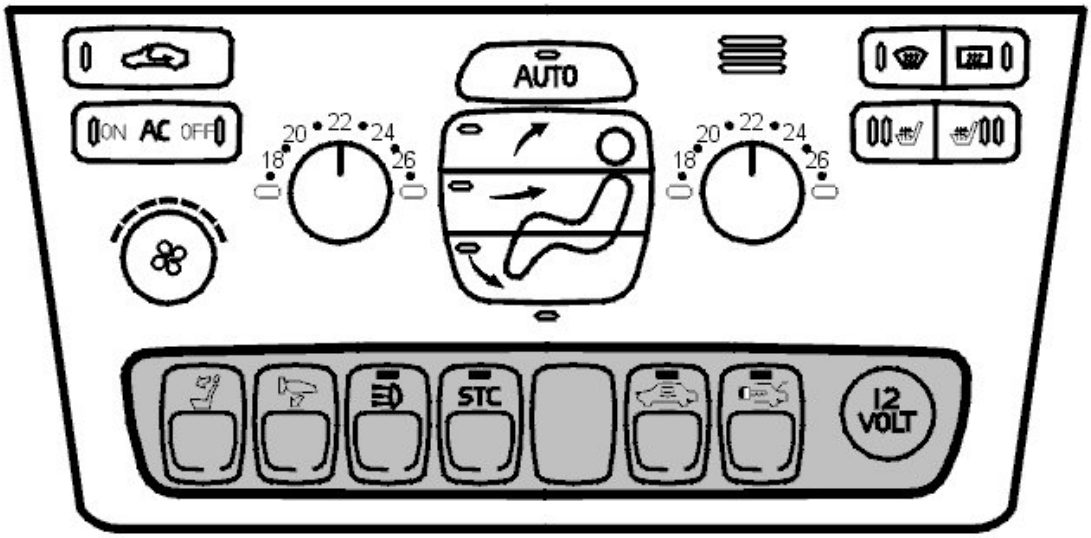
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CCM-0091

Condition



The diagnostic trouble code (DTC) is stored if the climate control module (CCM) registers that the identity of a lower switch is missing compared to the switch identities included in the Car Config File.
The diagnostic trouble code (DTC) can be diagnosed in ignition positions I and II.

Substitute value
- The climate control module (CCM) assumes different values depending on which switch identity is missing.

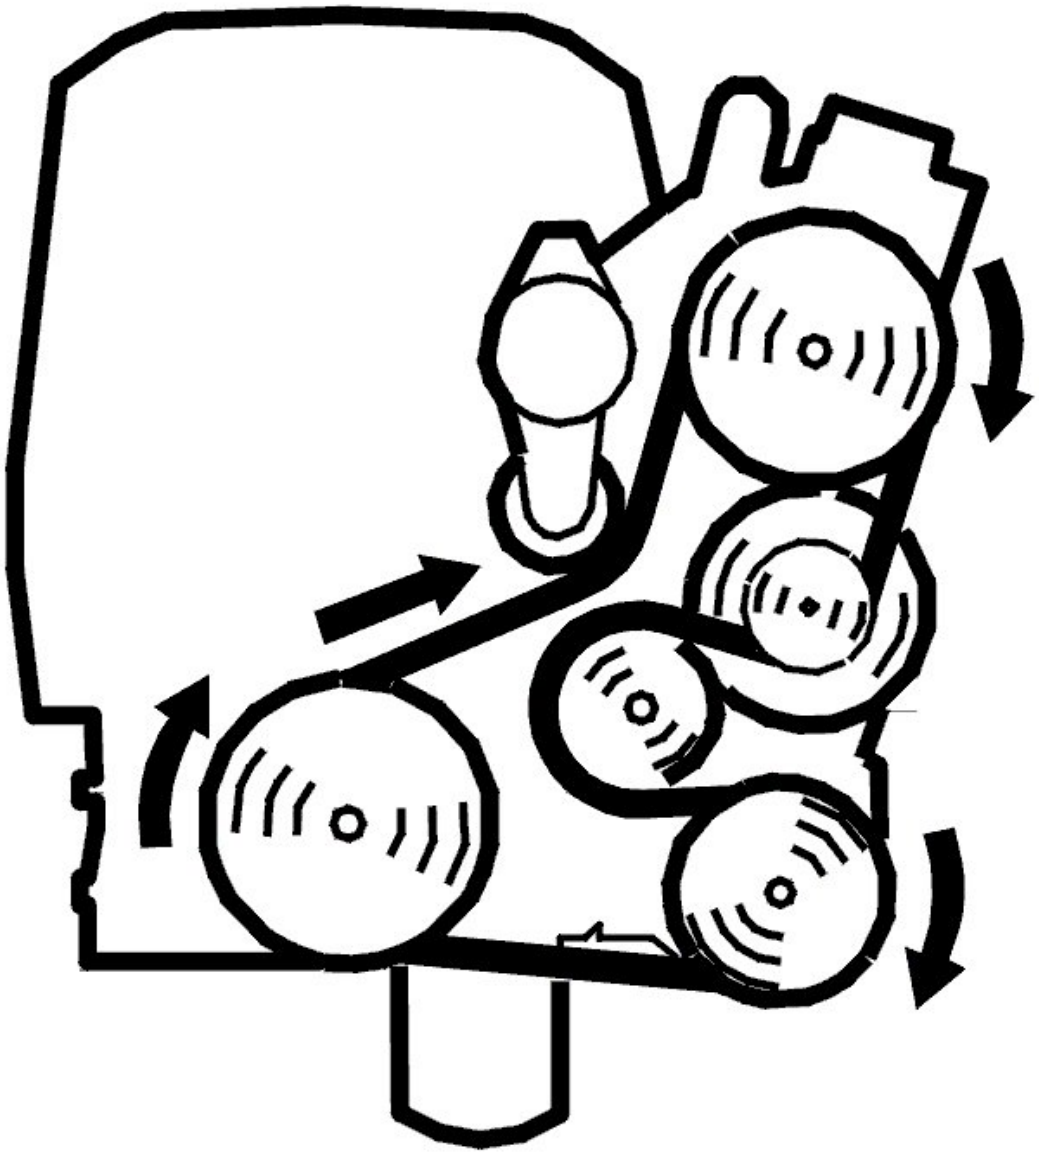
Possible source
- Defective switch
- Switch missing
- Fault in the Car Configuration File.

Fault symptom[s]
- The function button is not working.

ID Missing

ID missing

Checking the function



- Engine running.

Check that all the functions can be activated via the lower switch.

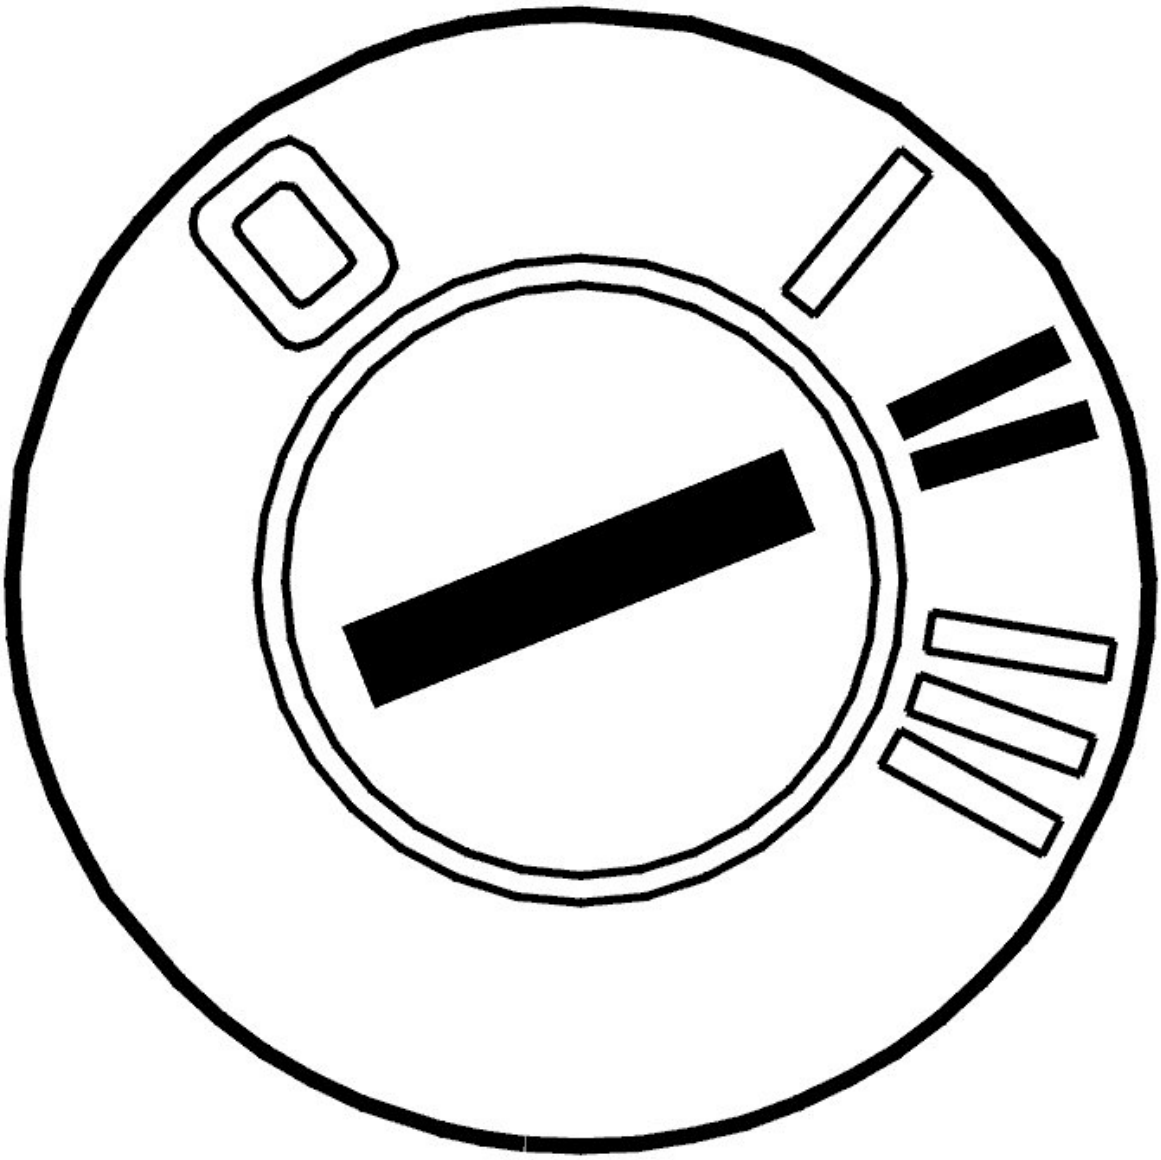
Hint: Where applicable, the LED on the lower switch must be lit when the function is activated.

Are all functions activated?

Yes - Fault-tracing information

No - Checking the component

Checking the component



- Ignition on.

Note! The switches can be placed in any position in the climate control assembly (without internal order). The position of the switches must be taken into account when fault-tracing with VCT2000.The switch furthest to the left in the climate control assembly corresponds to no. 1 in VCT2000. VCT2000 then follows the numbering in order to the switch furthest to the right, which is designated no. 7.

Read off the identities of the switches. Check that the read off identity corresponds to the switch marking for its position in the dashboard environment panel. The switch is defective or missing if the identity does not correspond.

Continue - Verification

Fault-tracing information

The fault has probably occurred as a result of a defect or intermittent defect or a missing switch. If the fault is intermittent, it has been registered previously but is no longer present.
Intermittent faults may be caused by interference at start up of the control module. Intermittent faults may also be caused by other types of intermittent faults. The fault is evaluated depending on how it occurs. If the fault recurs, replace the switch.

Continue - Information

Verification

Hint: After carrying out the repair, check that the fault has been remedied.

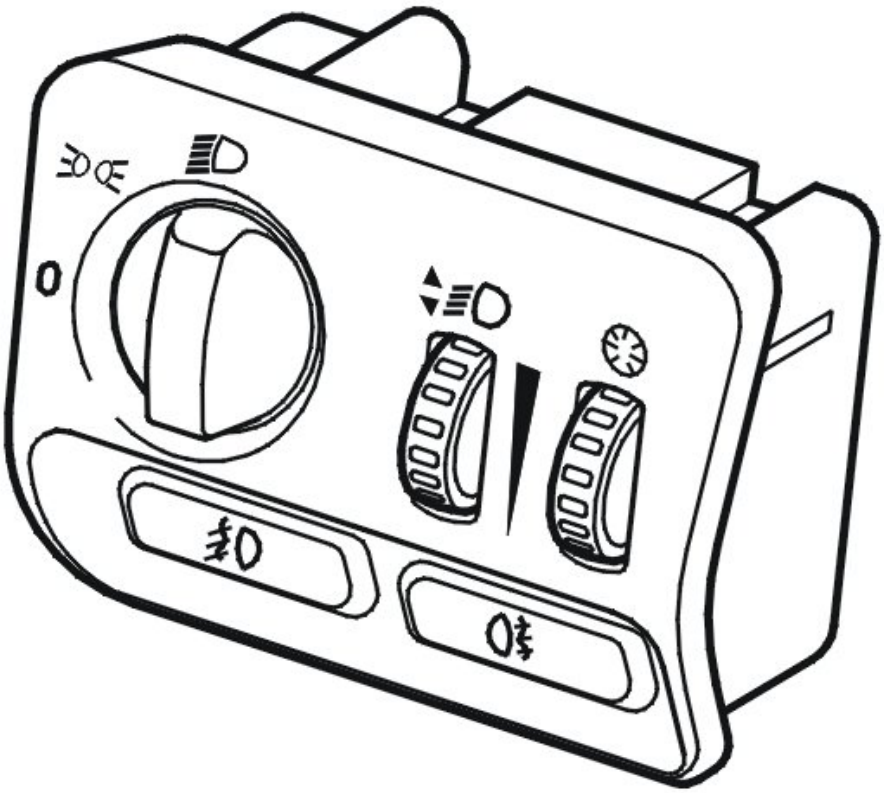
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CEM-DD00

Condition



The central electronic module (CEM) sends and receives information via a standardized serial communication system. This system is called Volcano Lite (VOLvo CAN based distributed real time Operative environment). The diagnostic trouble code (DTC) is stored if the control module registers serious interference such as blocked communication with the light switch module (LSM) or combustion preheater module (CPM). The diagnostic trouble code (DTC) can be diagnosed when the ignition key is in position II for at least 10 seconds and with the battery voltage above 10.5 V.

Note! In the event of CEM-DDxx diagnostic trouble codes (DTCs), the central electronic module (CEM) must not be replaced as the diagnostic trouble code (DTC) indicates a short-circuit in one or more conductors. The central electronic module (CEM) is the only control module that monitors the voltage level in the signal cables. The central electronic module (CEM) is therefore the only control module that can store a diagnostic trouble code (DTC) for a short-circuit in one of the cables to ground or supply voltage. Do not replace the central electronic module (CEM) in the event of this type of fault unless VIDA fault-tracing has indicated that the central electronic module (CEM) has an internal fault.

Substitute value

- None.

Possible source

- Short-circuit to supply voltage in the signal cable
- Short-circuit to ground in the signal cable
- Internal fault in another control module in the same part of the network.

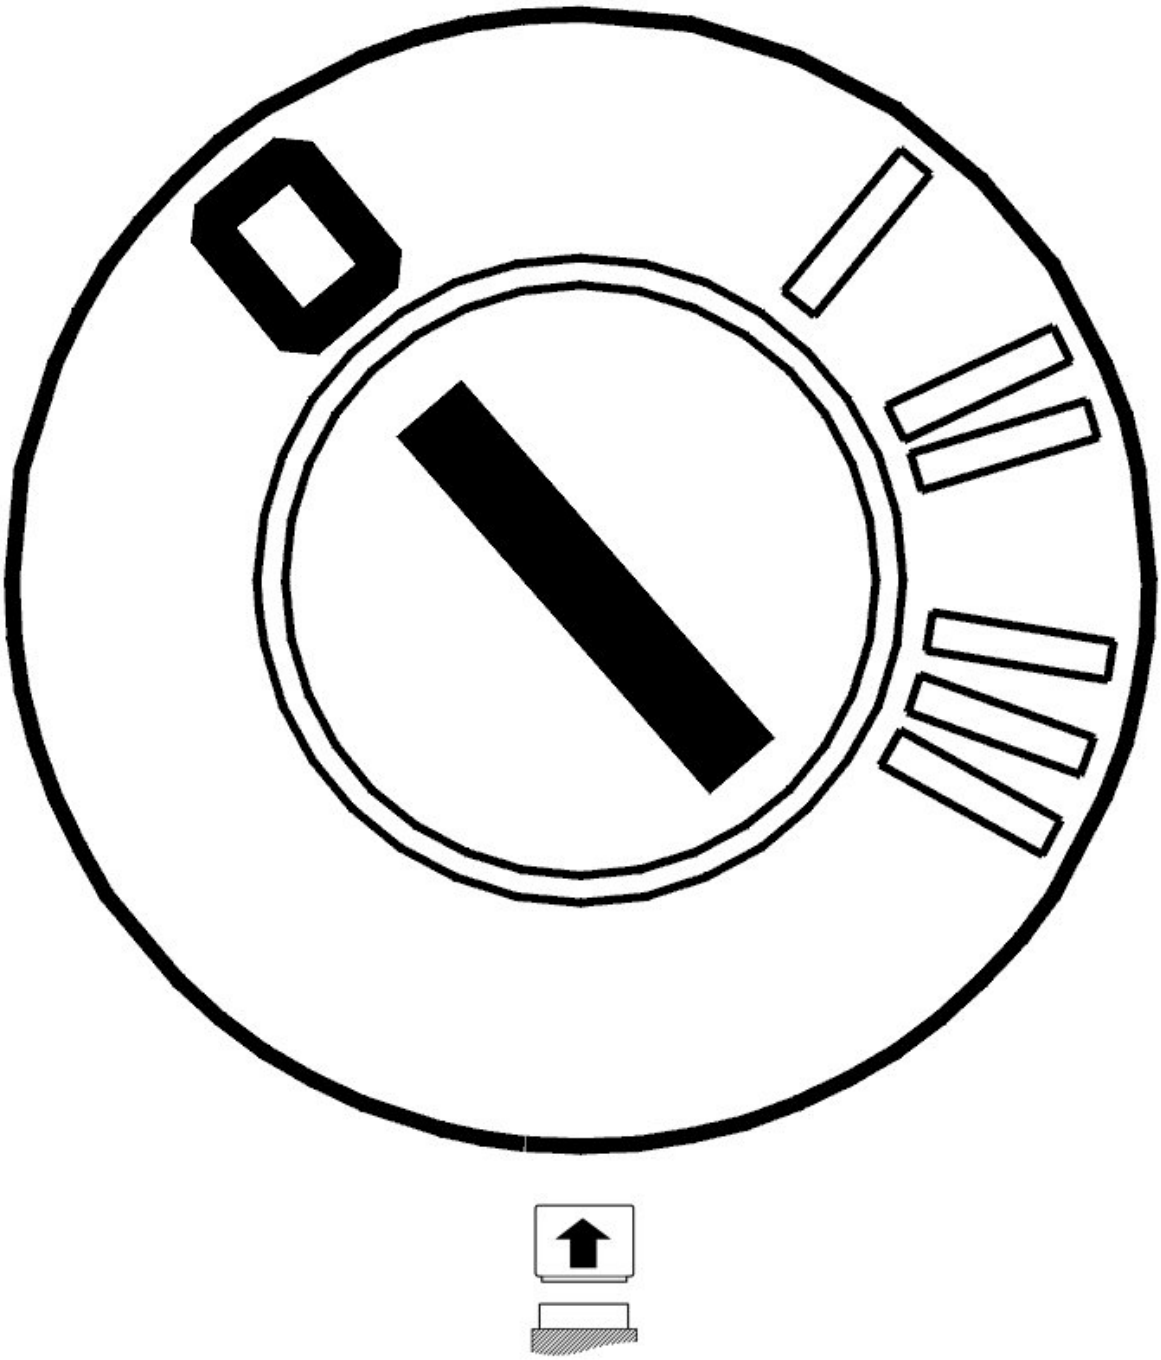
Fault symptom[s]

- The light switch does not operate
- Beam height control does not function
- The parking heater does not operate.

Communication Fault

Communication fault

Checking the wiring



- Ignition off
- Disconnect connectors D and C from the central electronic module (CEM).

The diagnostic trouble code (DTC) indicates that the communication between the light switch module (LSM), central electronic module (CEM) and combustion preheater module (CPM) is not working. This may be due to a fault in the signal cable between the control modules or a damaged communication device in one or all of the control modules.
Check the signal cable. Check for a short-circuit to supply voltage. Check for a short-circuit to ground.
Take readings between:

- Central electronic module (CEM) terminal #D41 (#41) and light switch module (LSM) terminal #3
- Central electronic module (CEM) terminal #C32 (#32) and combustion preheater module (CPM) terminal #6.

Remedy as necessary.

Diagnostic Trouble Code (DTC) Information

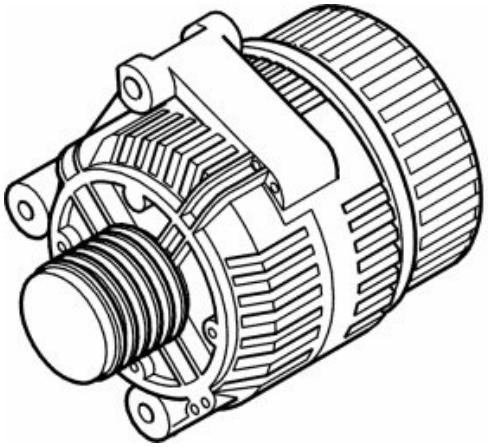
Diagnostic trouble code (DTC) information CEM-DD20

Condition



The central electronic module (CEM) transmits and receives information via a standardized serial communication method - LIN (Local Interconnect Network). The diagnostic trouble code (DTC) is generated if the control module registers serious interference such as blocked LIN communication. The diagnostic trouble code (DTC) can be detected when the ignition key is in position II for at least 10 seconds and with the battery voltage above 10.5 V.
Note: In the event of CEM-DDxx diagnostic trouble codes (DTCs), the central electronic module (CEM) must not be replaced as the diagnostic trouble code (DTC) indicates a short-circuit in one or more conductors in the LIN network. The central electronic module (CEM) is the only control module that monitors the voltage level in the LIN wiring. The central electronic module (CEM) is therefore the only control module that can generate diagnostic trouble codes (DTC) for a short-circuit in one of the cables to ground or supply voltage. Do not replace the central electronic module (CEM) in the event of a LIN fault unless fault-tracing has indicated that the central electronic module (CEM) has an internal fault.

Substitute value
- None.

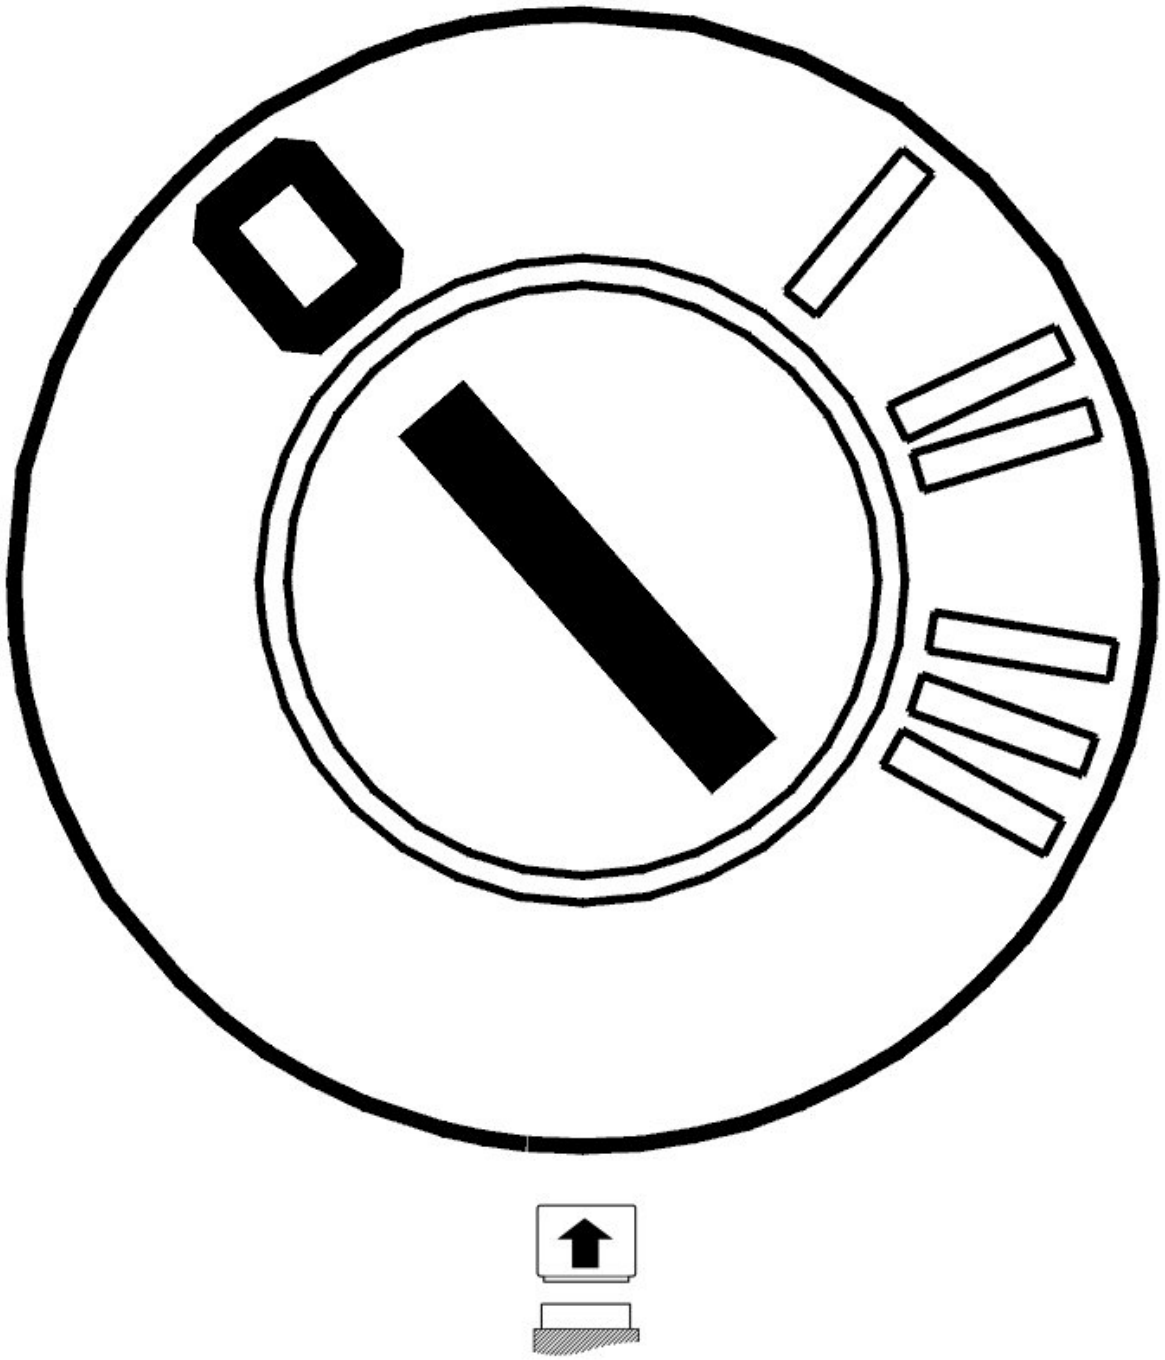
Possible source
- Short-circuit between the LIN wiring
- Open-circuit in the LIN wiring
- Internal fault in another control module in the same part of the LIN network.

Fault symptom[s]
- The battery electrolyte boils when the engine is running. (Not vehicles with a V8 engine.)
- The battery discharges. (Not vehicles with a V8 engine.)
- The LED does not come on. (Only vehicles with Blind Spot Indication System, BLIS.)

Communication Fault

Communication fault

Checking the wiring



The diagnostic trouble code indicates that communication between the central electronic module (CEM) and the alternator control module (ACM) (not vehicles with a V8 engine), the left camera module (LCM) (optional extra) and the right camera module (RCM) (optional extra) is inoperative. This could be due to a fault in the signal lead between the control modules or a damaged communication unit in one or all of the control modules.

Note! All vehicles from and including model year 2005 are equipped with a signal cable to the Left Camera Module (LCM) / Right Camera Module (RCM) even if the vehicle is not equipped with BLIS system. This means that measurements must always be carried out up to the 12-pin connector in the external doors when the diagnostic trouble code (DTC) has been detected on LIN bus 2.

Check the signal lead between the central electronic module (CEM) and the alternator control module (ACM) for an open circuit or shorting to ground.
Take readings between:

- Central electronic module (CEM) #C16 (#16) and alternator control module (ACM) #B1.

For vehicles without the Blind Spot Indication System (BLIS)

Check the signal cable between the Central Electronic Module (CEM) and the 12-pin connector in the outer doors. Check for an open-circuit.
Check for a short-circuit to ground.
Check the connector in both doors.
Take readings between:

- Central Electronic Module (CEM) D24 (#24) and the 12 pin connector in the external doors terminal #12.

For vehicles equipped with the Blind Spot Indication System (BLIS)

Check the signal lead between the central electronic module (CEM) and the left camera module (LCM) for an open circuit or shorting to ground.
Take readings between:
- Central electronic module (CEM) #D24 (#24) and left camera module (LCM) #5.

Check the signal lead between the central electronic module (CEM) and the right camera module (RCM) for an open circuit or shorting to ground.
Take readings between:
- Central electronic module (CEM) #D24 (#24) and right camera module (RCM) #5.

Also check intermediate connectors.
Remedy as necessary.

Diagnostic Trouble Code (DTC) Information

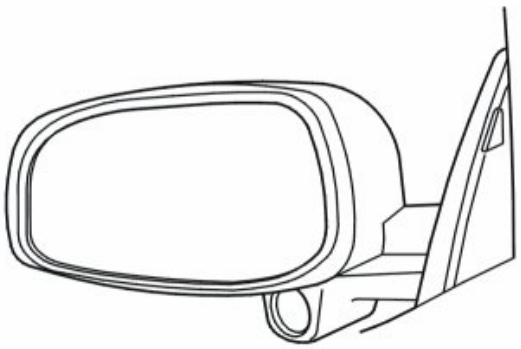
Diagnostic trouble code (DTC) information CEM-DD31

Condition



The central electronic module (CEM) transmits and receives information via a standardized serial communication method - LIN (Local Interconnect Network). The diagnostic trouble code (DTC) is generated if the control module registers serious interference (LIN communication blocked) with the left camera module (LCM).
The diagnostic trouble code (DTC) can be detected when the ignition switch in position II for at least 10 seconds if battery voltage is above 10.5 V.
Note: In the event of CEM-DDxx diagnostic trouble codes (DTCs), the central electronic module (CEM) must not be replaced as the diagnostic trouble code (DTC) indicates a short-circuit in one or more conductors in the LIN network. The central electronic module (CEM) is the only control module that monitors the voltage level in the LIN wiring. The central electronic module (CEM) is therefore the only control module that can generate a diagnostic trouble code (DTC) for a short-circuit in one of the cables to ground or supply voltage. Do not replace the central electronic module (CEM) in the event of a LIN fault unless fault-tracing has indicated that the central electronic module (CEM) has an internal fault.

Substitute value
- Nothing.

Possible source
- Short-circuit between the LIN wiring
- Open-circuit in the LIN wiring
- Internal fault in another control module in the same part of the LIN network.

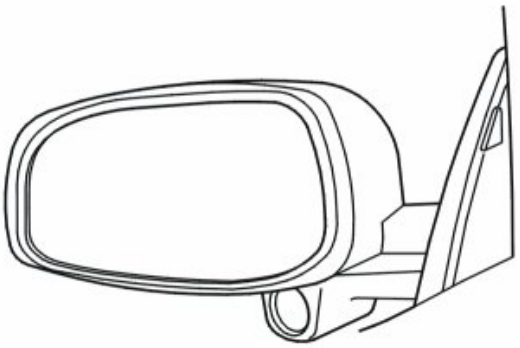
Fault symptom[s]
- The LED does not come on.

Signal Missing

Signal missing

Checking the function

The LEDs should flash three times whenever the Blind Spot Indication System (BLIS) is activated.
Switch on the ignition to check the functionality of the left camera module (LCM).

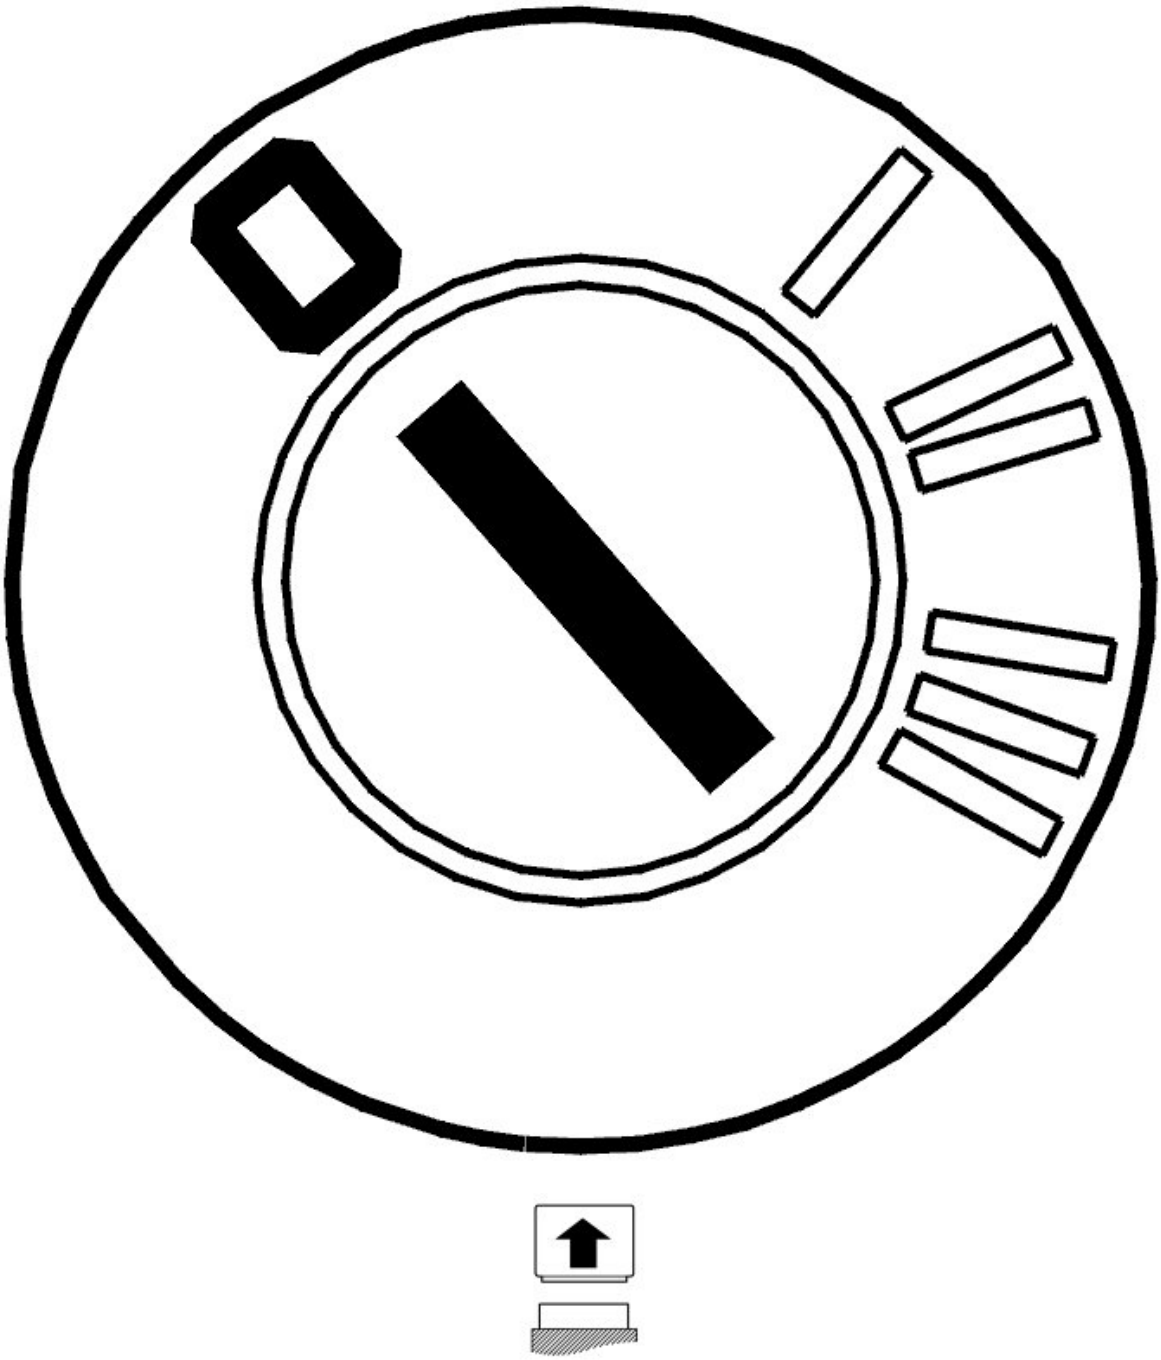


Did the LED flash three times?

Yes - Fault-tracing information

No - Checking the wiring

Checking the wiring



- Ignition off
- Unplug the central electronic module (CEM) D connector.

The diagnostic trouble code indicates that communication between the central electronic module (CEM) and the left camera module (LCM) is inoperative. This could be due to a fault in the signal lead between the control modules or a damaged communication unit in one or all of the control modules.

Check the signal lead between the central electronic module (CEM) and the left camera module (LCM) for an open circuit or short circuit. Also check intermediate connectors.

Measure between:

- Central electronic module (CEM) #D41 (41) and left camera module (LCM) #5.

Remedy as necessary.

The central electronic module (CEM) transmits and receives information via a standardized serial communication method - LIN (Local Interconnect Network). The diagnostic trouble code (DTC) is generated if the control module registers serious interference (LIN communication blocked) with the right camera module (LCM).
The diagnostic trouble code (DTC) can be detected when the ignition switch in position II for at least 10 seconds if battery voltage is above 10.5 V.
Note: In the event of CEM-DDxx diagnostic trouble codes (DTCs), the central electronic module (CEM) must not be replaced as the diagnostic trouble code (DTC) indicates a short-circuit in one or more conductors in the LIN network. The central electronic module (CEM) is the only control module that monitors the voltage level in the LIN wiring. The central electronic module (CEM) is therefore the only control module that can generate a diagnostic trouble code (DTC) for a short-circuit in one of the cables to ground or supply voltage. Do not replace the central electronic module (CEM) in the event of a LIN fault unless fault-tracing has indicated that the central electronic module (CEM) has an internal fault.

Substitute value
- Nothing.

Possible source
- Short-circuit between the LIN wiring
- Open-circuit in the LIN wiring
- Internal fault in another control module in the same part of the LIN network.

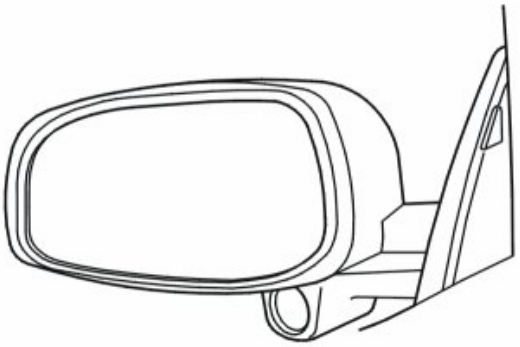
Fault symptom[s]
- The LED does not come on.

Signal Missing

Signal missing

Checking the function

The LEDs should flash three times whenever the Blind Spot Indication System (BLIS) is activated.
Switch on the ignition to check the functionality of the right camera module (RCM).

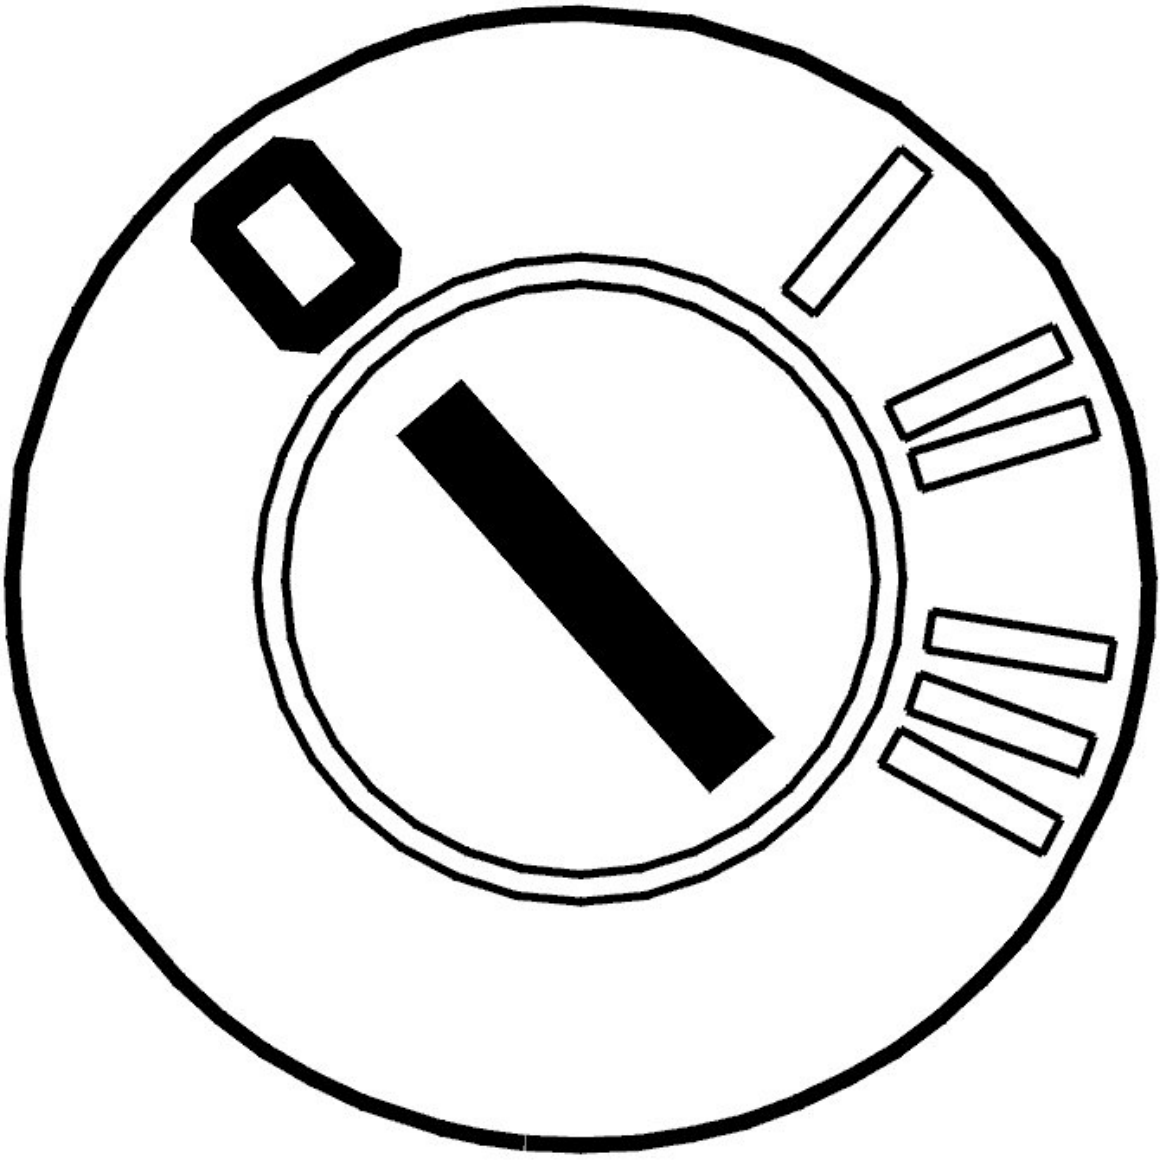


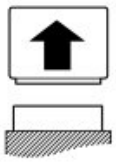
Did the LED flash three times?

Yes - Fault-tracing information

No - Checking the wiring

Checking the wiring





- Ignition off
- Unplug the central electronic module (CEM) D connector.

The diagnostic trouble code indicates that communication between the central electronic module (CEM) and the right camera module (RCM) is inoperative. This could be due to a fault in the signal lead between the control modules or a damaged communication unit in one or all of the control modules.
Check the signal lead between the central electronic module (CEM) and the right camera module (RCM) for an open circuit or short circuit. Also check intermediate connectors.
Measure between:

- Central electronic module (CEM) #D41 (#41) and right camera module (RCM) #5.

Remedy as necessary.

Was a fault detected?

Yes - Verification

No - Replacing the control module

Replacing the control module

Try changing the right camera module (RCM).
Remedy as necessary.

Other information

- Change the right camera module (RCM), see: Door mirror, replacing See: Body and Frame/Mirrors/Service and Repair

Continue - Verification

Fault-tracing information

The right camera module (RCM) has previously registered a fault but the fault no longer exists. The diagnostic trouble code (DTC) was probably generated by an intermittent fault. If the fault persists, fault-tracing according to this diagnostic trouble code (DTC) should be carried out even though no fault symptom can be detected. The seriousness of the fault is determined from case to case.
You can choose between continuing fault-tracing or ending it.

Would you like to continue?

Yes - Checking the wiring

No - No Fault Found

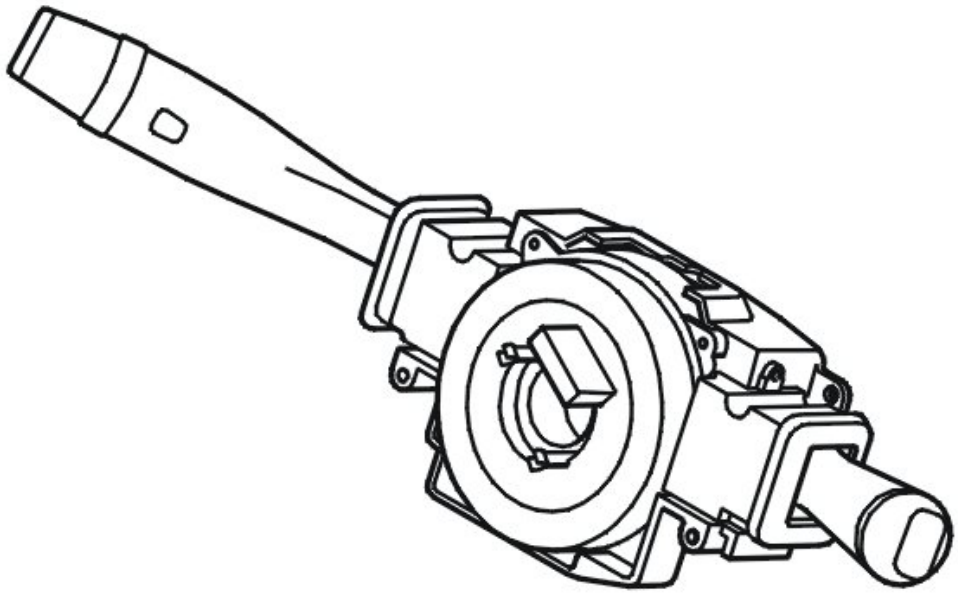
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CEM-DD40

Condition



The central electronic module (CEM) transmits and receives information via a standardized serial communication method - LIN (Local Interconnect Network). The diagnostic trouble code (DTC) is stored if the control module registers serious interference such as blocked LIN communication with the steering wheel module (SWM).
The diagnostic trouble code (DTC) can be detected when the ignition key is in position II for at least 10 seconds and the battery voltage exceeds 10.5 V.
Note! In the event of CEM-DDxx diagnostic trouble codes (DTCs), the central electronic module (CEM) must not be replaced as the diagnostic trouble code (DTC) indicates a short-circuit in one or more conductors in the LIN network. The central electronic module (CEM) is the only control module that monitors the voltage level in the LIN wiring. The central electronic module (CEM) is therefore the only control module that can store a diagnostic trouble code (DTC) for a short-circuit in one of the cables to ground or supply voltage. Do not replace the central electronic module (CEM) in the event of a LIN fault unless VIDA fault-tracing has indicated that the central electronic module (CEM) has an internal fault.

Substitute value
- None.

Possible source
- Short-circuit between the LIN wiring
- Open-circuit in the LIN wiring
- Internal fault in another control module in the same part of the LIN network.

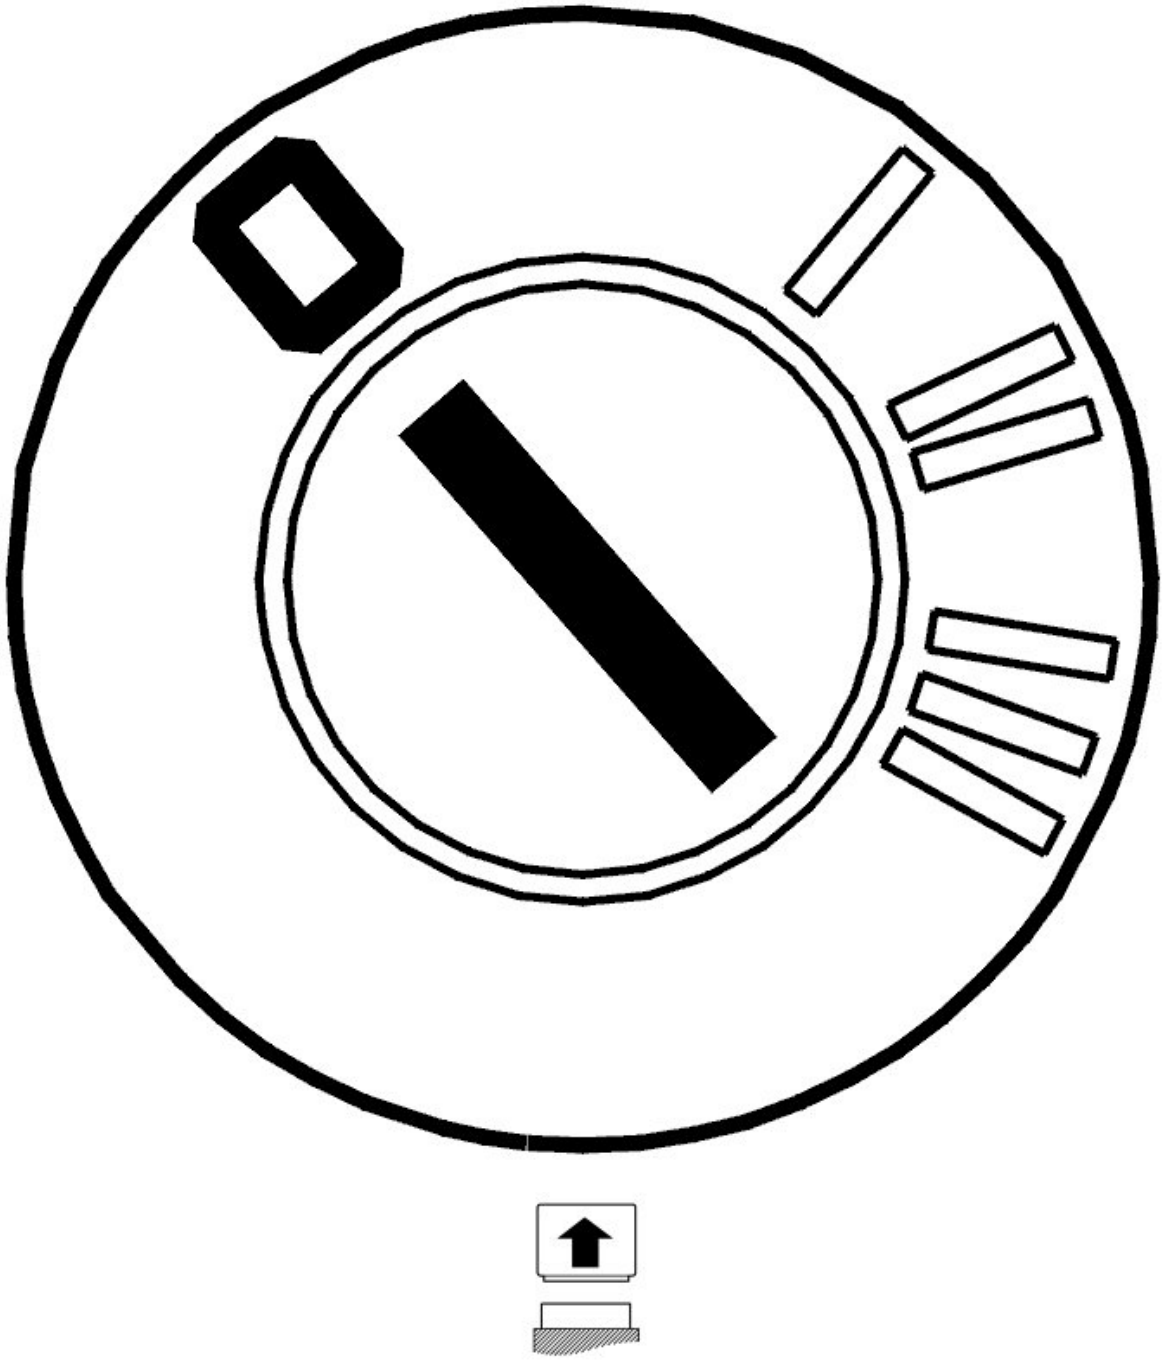
Fault symptom[s]
- The windshield wipers only operate at lowest speed

- Front windshield washing does not work
- Rear windshield washing does not work
- The turn signal lamp switch does not work
- Cruise control does not work at all
- The turn signal lamps are not operating
- The radio buttons on the steering wheel do not function
- The phone buttons on the steering wheel do not work.

Communication Fault

Communication fault

Checking the wiring



- Ignition off
- Disconnect central electronic module (CEM) connector D.

The diagnostic trouble code (DTC) indicates that the communication between the steering wheel module (SWM) and central electronic module (CEM) is not working. This may be due to a fault in the signal cable between the control modules or a damaged communication device in one or both of the control modules.

Check the signal cable. Check for an open-circuit. Check for a short-circuit to ground.

Take readings between:

- Central electronic module (CEM) #D58 (#58) and steering wheel module (SWM) #7.

Remedy as necessary.

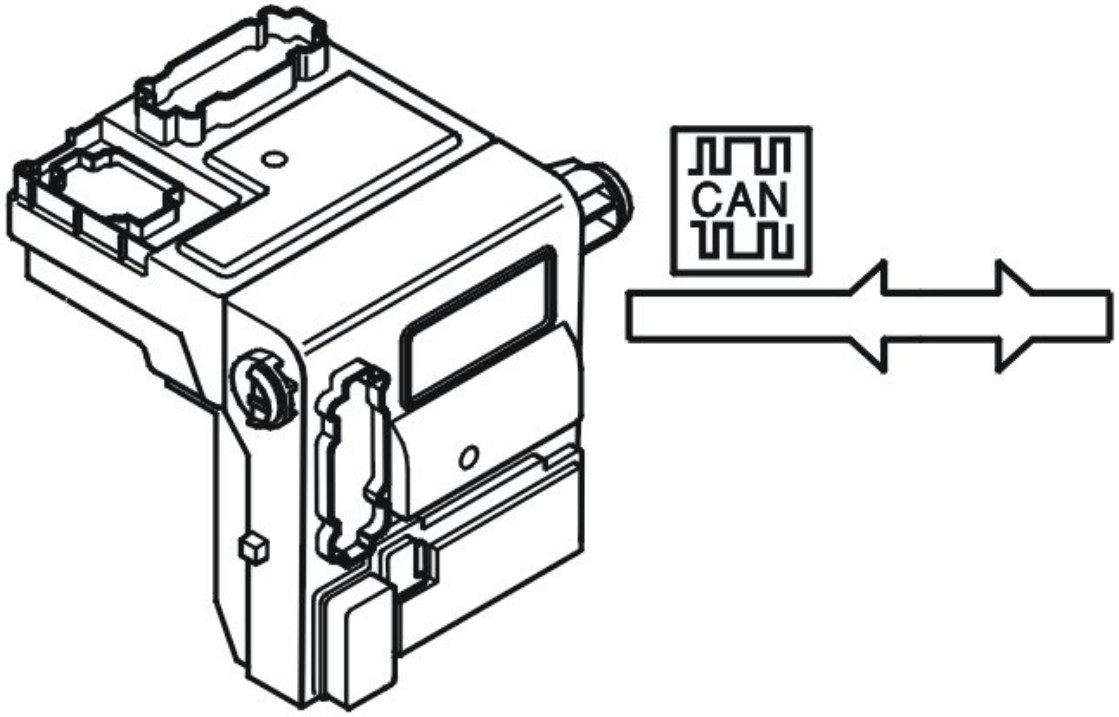
CEM-DF01

Diagnostic trouble code (DTC) information CEM-DF01

Condition



The central electronic module (CEM) checks the voltage in the CAN wiring in the low speed network. The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers an open-circuit in CAN H or CAN L in the low speed network.

Note! The central electronic module (CEM) is the only control module that monitors the voltage level in the Control area network wiring. The central electronic module (CEM) is the only control module that can directly store diagnostic trouble codes (DTCs) for an open-circuit in these conductors. However other control modules can store diagnostic trouble codes (DTCs) as a result of the open-circuit. Do not replace the central electronic module (CEM) in the event of a CAN fault unless VIDA fault-tracing has indicated that the central electronic module (CEM) has an internal fault.

The diagnostic trouble code (DTC) can be diagnosed when the ignition has been on for more than 10 seconds.

Substitute value
- None.

Possible source
- Open-circuit in one of the control area network (CAN) cables on the low speed network
- Contact resistance in the terminals.

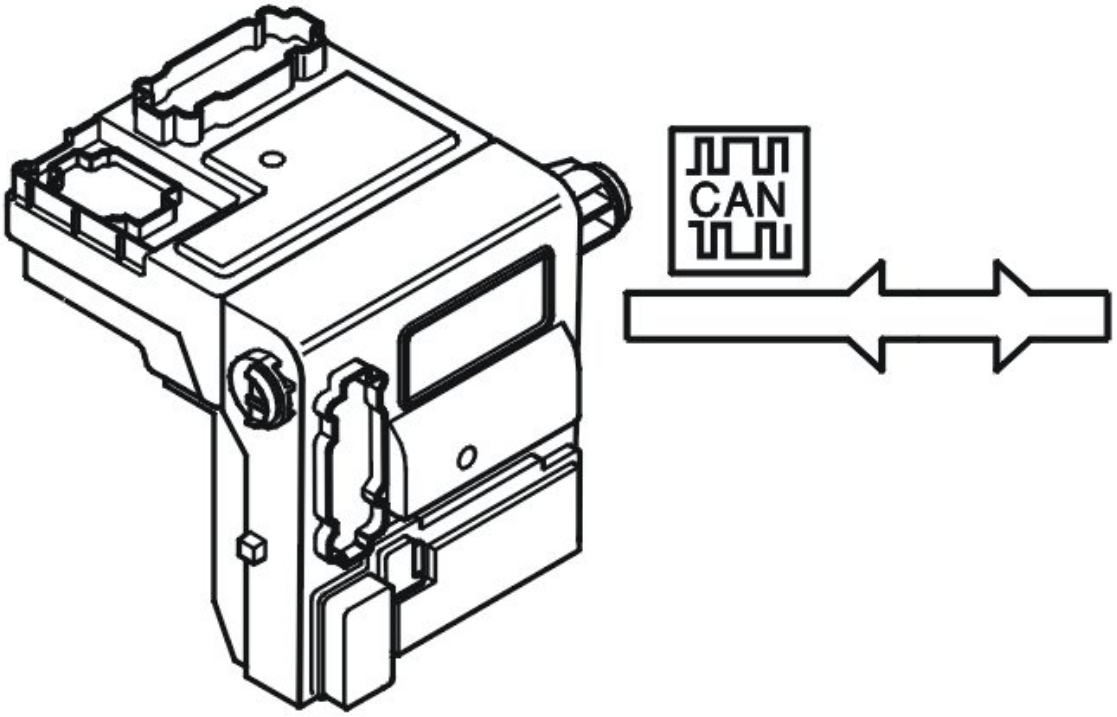
Fault symptom[s]
- No gauges working.

- The lighting in the instrument panel does not function.
- The central locking system does not function at all.

CEM-DF03

Diagnostic trouble code (DTC) information CEM-DF03

Condition



The central electronic module (CEM) checks the voltage in the CAN wiring in the low speed network. The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers a short-circuit to supply voltage in the CAN H in the low speed network.

Note! If DFxx diagnostic trouble codes (DTCs) are stored the central electronic module (CEM) must not be replaced as the diagnostic trouble code (DTC) indicates a short-circuit in one or more conductors in the Control area network. The central electronic module (CEM) is the only control module that monitors the voltage level in the Control area network wiring. The central electronic module (CEM) is therefore the only control module that can store a diagnostic trouble code (DTC) for a short-circuit in one of the cables to ground or supply voltage. Do not replace the central electronic module (CEM) in the event of a CAN fault unless VIDA fault-tracing has indicated that the central electronic module (CEM) has an internal fault.

The diagnostic trouble code (DTC) can be diagnosed when the ignition has been on for more than 10 seconds.

Substitute value
- None.

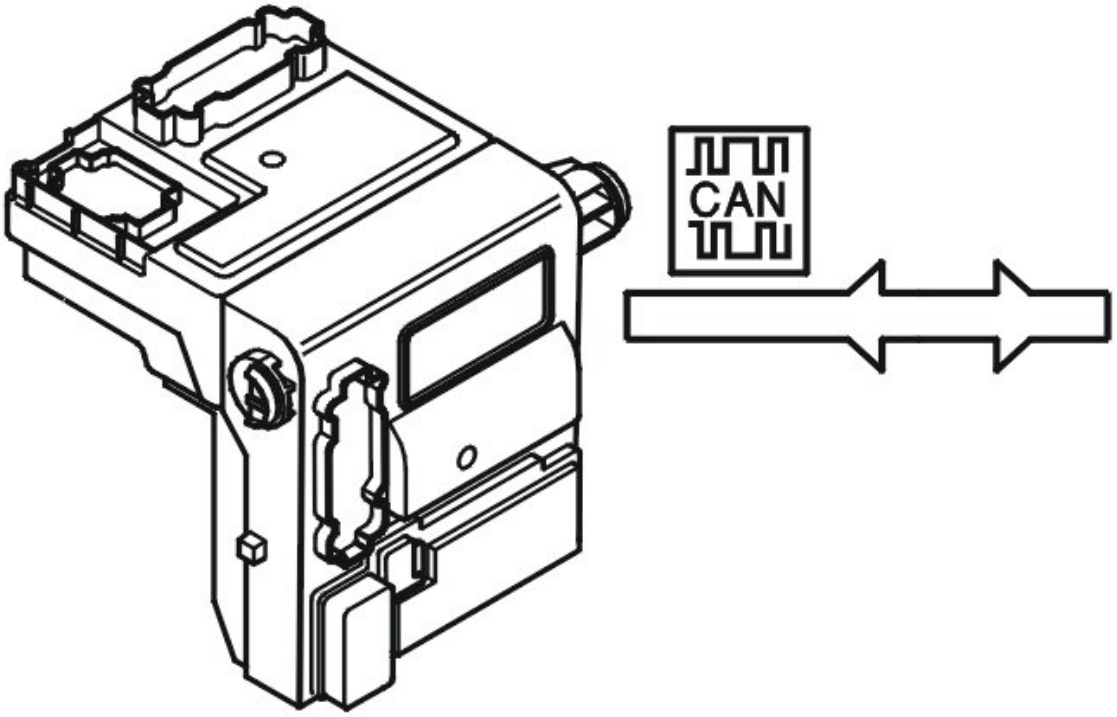
Possible source
- Short-circuit to supply voltage in the low speed network.

Fault symptom[s]
- No gauges working.
- The lighting in the instrument panel does not function.
- The central locking system does not function at all.

CEM-DF04

Diagnostic trouble code (DTC) information CEM-DF04

Condition



The central electronic module (CEM) checks the voltage in the CAN wiring in the low speed network. The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers a short-circuit to ground in the CAN L in the low speed network.

Note! If DFxx diagnostic trouble codes (DTCs) are stored the central electronic module (CEM) must not be replaced as the diagnostic trouble code (DTC) indicates a short-circuit in one or more conductors in the Control area network. The central electronic module (CEM) is the only control module that monitors the voltage level in the Control area network wiring. The central electronic module (CEM) is therefore the only control module that can store a diagnostic trouble code (DTC) for a short-circuit in one of the cables to ground or supply voltage. Do not replace the central electronic module (CEM) in the event of a CAN fault unless VIDA fault-tracing has indicated that the central electronic module (CEM) has an internal fault.

The diagnostic trouble code (DTC) can be diagnosed when the ignition has been on for more than 10 seconds.

Substitute value
- None.

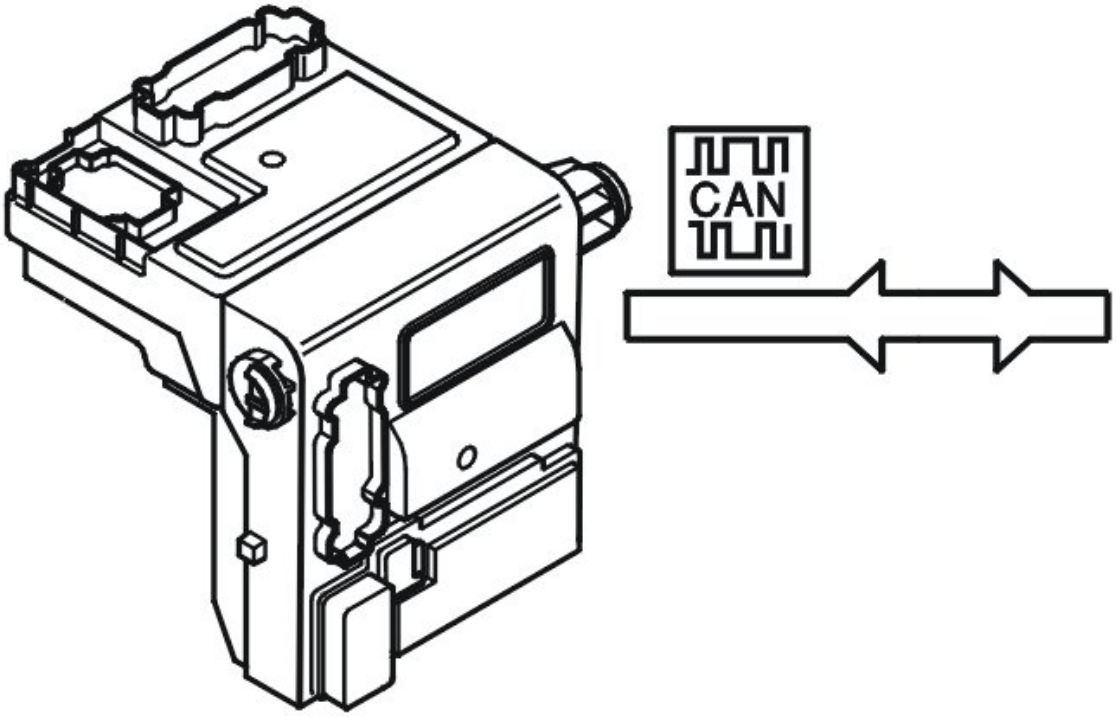
Possible source
- Short-circuit to ground in the low speed network.

Fault symptom[s]
- Radio interference.

CEM-DF05

Diagnostic trouble code (DTC) information CEM-DF05

Condition



The central electronic module (CEM) checks the voltage in the CAN wiring in the low speed network. The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers that there is a short-circuit to ground in the CAN H in the low speed network.

Note! If DFxx diagnostic trouble codes (DTCs) are stored the central electronic module (CEM) must not be replaced as the diagnostic trouble code (DTC) indicates a short-circuit in one or more conductors in the Control area network. The central electronic module (CEM) is the only control module that monitors the voltage level in the Control area network wiring. The central electronic module (CEM) is therefore the only control module that can store a diagnostic trouble code (DTC) for a short-circuit in one of the cables to ground or supply voltage. Do not replace the central electronic module (CEM) in the event of a CAN fault unless VIDA fault-tracing has indicated that the central electronic module (CEM) has an internal fault.

The diagnostic trouble code (DTC) can be diagnosed when the ignition has been on for more than 10 seconds.

Substitute value
- None.

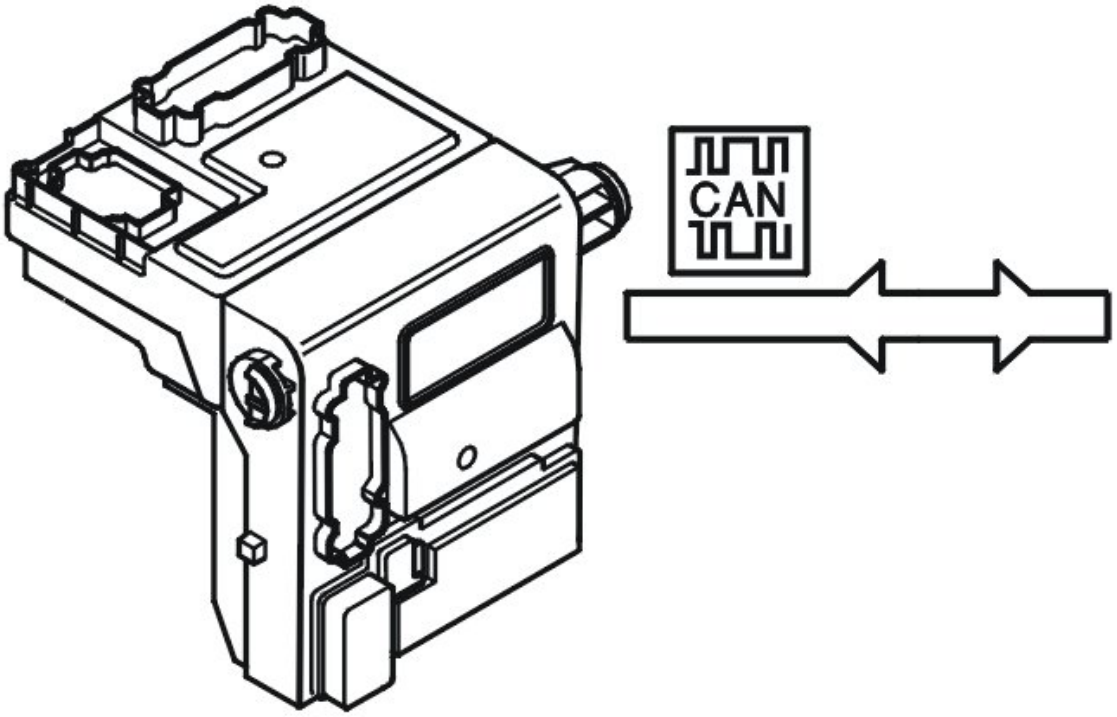
Possible source
- Short-circuit to ground in the low speed network.

Fault symptom[s]
- No gauges working.
- The instrument lighting does not operate
- The central locking system does not function at all.

CEM-DF06

Diagnostic trouble code (DTC) information CEM-DF06

Condition



The central electronic module (CEM) checks the voltage in the CAN wiring in the low speed network. The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers a short-circuit to supply voltage in the CAN L in the low speed network.

Note! If DFxx diagnostic trouble codes (DTCs) are stored the central electronic module (CEM) must not be replaced as the diagnostic trouble code (DTC) indicates a short-circuit in one or more conductors in the Control area network. The central electronic module (CEM) is the only control module that monitors the voltage level in the Control area network wiring. The central electronic module (CEM) is therefore the only control module that can store a diagnostic trouble code (DTC) for a short-circuit in one of the cables to ground or supply voltage. Do not replace the central electronic module (CEM) in the event of a CAN fault unless VIDA fault-tracing has indicated that the central electronic module (CEM) has an internal fault.

The diagnostic trouble code (DTC) can be diagnosed when the ignition has been on for more than 10 seconds.

Substitute value
- None.

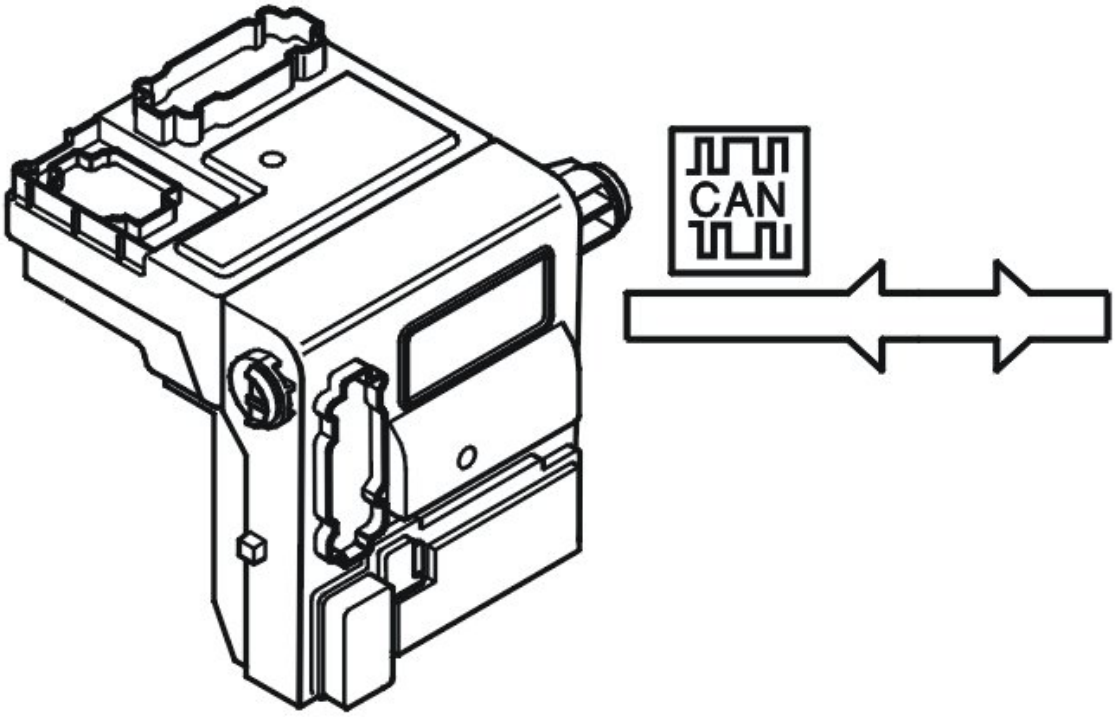
Possible source
- Short-circuit to supply voltage in the low speed network.

Fault symptom[s]
- No gauges working.
- The lighting in the instrument panel does not function.
- The central locking system does not function at all.

CEM-DF07

Diagnostic trouble code (DTC) information CEM-DF07

Condition



The central electronic module (CEM) checks the voltage in CAN L and CAN H on the low speed network. The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers a short-circuit between CAN L and CAN H in the low speed network.
The diagnostic trouble code (DTC) can be diagnosed when the ignition has been on for at least 10 seconds.

Note! If DFxx diagnostic trouble codes (DTCs) are stored the central electronic module (CEM) must not be replaced as the diagnostic trouble code (DTC) indicates a short-circuit in one or more conductors in the Control area network. The central electronic module (CEM) is the only control module that monitors the voltage level in the Control area network wiring. The central electronic module (CEM) is therefore the only control module that can store a diagnostic trouble code (DTC) for a short-circuit in one of the cables to ground or supply voltage. Do not replace the central electronic module (CEM) in the event of a CAN fault unless VIDA fault-tracing has indicated that the central electronic module (CEM) has an internal fault.

The diagnostic trouble code (DTC) can be diagnosed when the ignition has been on for more than 10 seconds.

Substitute value
- None.

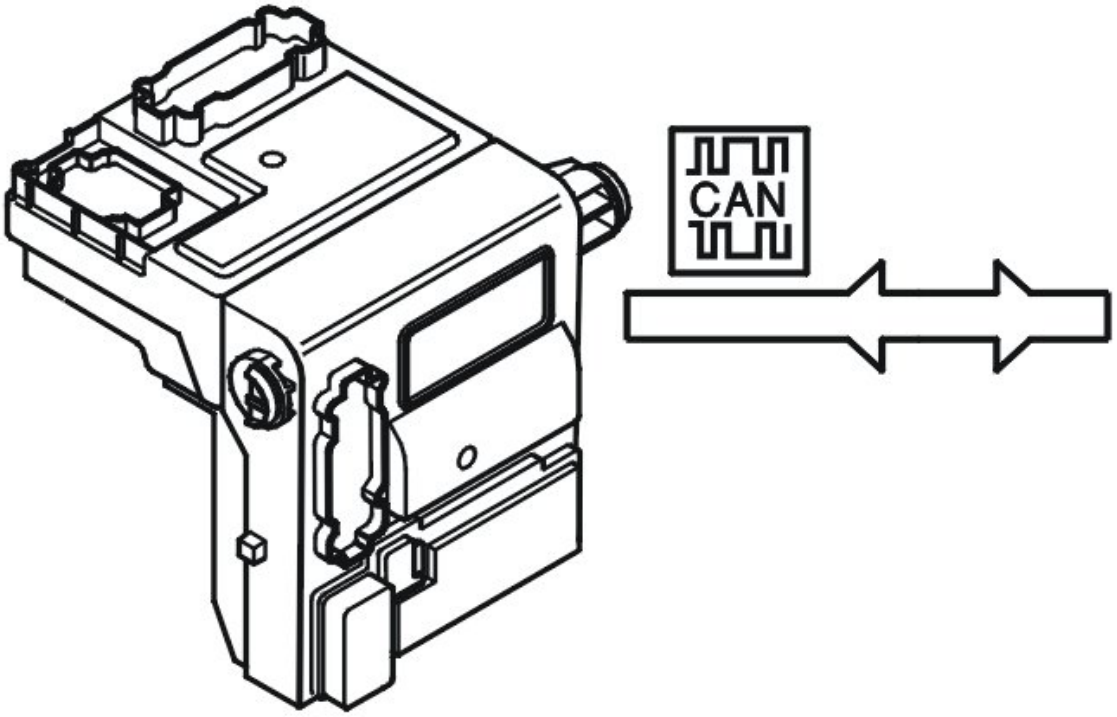
Possible source
- Short-circuit between CAN L and CAN H in the low speed network.

Fault symptom[s]
- No gauges working.
- The instrument lighting does not operate
- The central locking system does not function at all.

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CEM-DF11

Condition



The central electronic module (CEM) checks the voltage in the CAN wiring in the high speed network. The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers an open-circuit in CAN H or CAN L in the high speed network.

Note! The central electronic module (CEM) is the only control module that monitors the voltage level in the Control area network wiring. The central electronic module (CEM) is the only control module that can directly store diagnostic trouble codes (DTCs) for an open-circuit in these conductors. However other control modules can store diagnostic trouble codes (DTCs) as a result of the open-circuit. Do not replace the central electronic module (CEM) in the event of a CAN fault unless VIDA fault-tracing has indicated that the central electronic module (CEM) has an internal fault.

The diagnostic trouble code (DTC) can be diagnosed when the ignition has been on for more than 10 seconds.

Substitute value
- None.

Possible source
- Open-circuit in one of the control area network (CAN) cables on the high speed network
- Contact resistance in the terminals.

Fault symptom[s]
- The engine does not start.
- Malfunction indicator lamp (MIL) lit.
- Message in the display.

Signal Missing

Signal missing

General information

Note! Figures shown are only examples.

Hint: For general information about CAN-troubleshooting, see:
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

General about CAN-related diagnostic trouble codes.
CEM-DF01 - DF17can only be stored in Central electronic module (CEM). These diagnostic trouble codes are stored when an electric fault is detected in CAN-lines. Start with these diagnostic trouble codes first.
CEM-1AXX only stored in Central electronic module (CEM). One diagnostic trouble code for every control module on the CAN-net. These

diagnostic trouble codes indicate that Central electronic module (CEM) does not receive any reply from other control modules.
XXX-E000 (HS-CAN)/E001 (LS-CAN) can be stored in all CAN-connected control modules. These diagnostic trouble codes indicate that the control module has detected interference on the CAN-net.
XXX-E003 can be stored in all CAN-connected control modules except in Central electronic module (CEM). The control modules on the CAN-net listen for a message (identity number) that is sent out at regular intervals from Central electronic module (CEM). This diagnostic trouble code indicates that the control module has not received any identity number, or that the expected number is not correct. Interference on the CAN-net can also store this diagnostic trouble code.

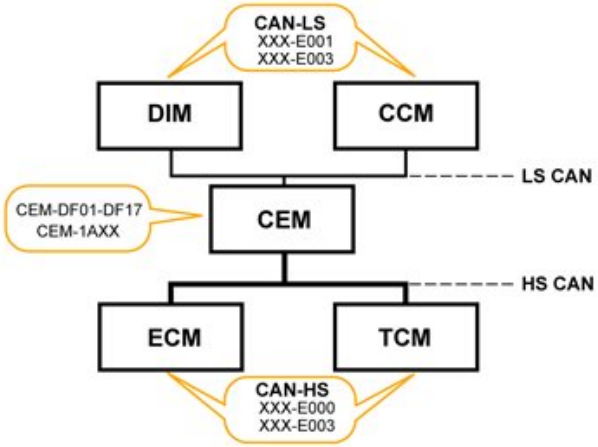
Note! In case of CAN-related faults, it is likely that a combination of above diagnostic trouble codes occur.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

If a communication diagnostic trouble code can be read from the control module, the malfunction is probably intermittent.
Intermittent fault in the voltage supply and ground to a control module on the CAN network results in the Central electronic module (CEM) storing a diagnostic trouble code (DTC) for an open-circuit in communication with the control module where the voltage supply does not work. There will probably not be a diagnostic trouble code (DTC) in the control module where the open-circuit in the voltage supply occurred as the control module cannot store a diagnostic trouble code (DTC) when it is not supplied with power.

Note! Central electronic module (CEM) should not be replaced in case of CAN-fault, unless troubleshooting reveals that Central electronic module (CEM) has an internal fault.

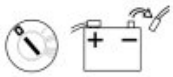
Caution! During this fault-tracing use the wiring diagram to provide support when taking readings.



Select "Continue".

Continue - Checking resistance in CAN-net

Checking resistance in CAN-net



- Ignition off
- Disconnect the battery negative lead
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #6 and #14. The resistance should be approx. 55 - 65 ohms.
- If resistance is approx. 120 ohms, this indicates open circuit in the circuit so that only one terminating resistor (120 ohms) has been measured.

- If resistance is above 1 kohms this indicates open circuit/high contact resistance somewhere in the circuit.
- If resistance is below 55 ohms this indicates short-circuiting/contact resistance between the CAN-lines somewhere in the circuit.

Hint: For HS-CAN (High Speed) the terminating resistors are located in Brake control module (BCM) and in Engine control module (ECM).

Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

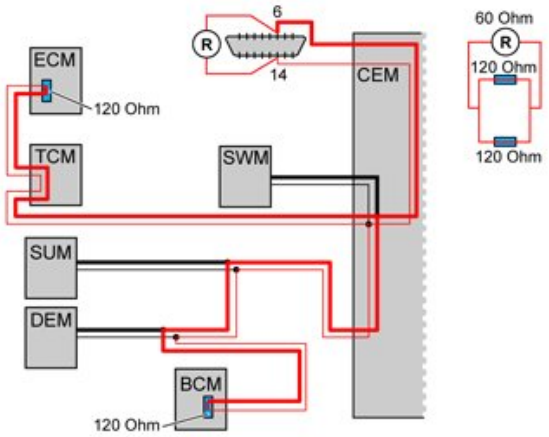
Note! Resistance measurement measures only main lines in the CAN-net (in circuit where both terminating resistors are found), not branches to certain control modules. See wiring diagram for vehicle model in question.Open circuit on branching without a terminating resistor cannot be detected with this measurement. However, short-circuiting on a branch can be detected. To measure resistance in the CAN-net to control modules located in a branching of their own, the measurement shall be done against the CAN-net at that control module. The values shall be as above.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy wiring as necessary.

Other information

- Battery, disconnecting See: Starting and Charging/Battery/Service and Repair/Procedures/Battery, Disconnecting
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

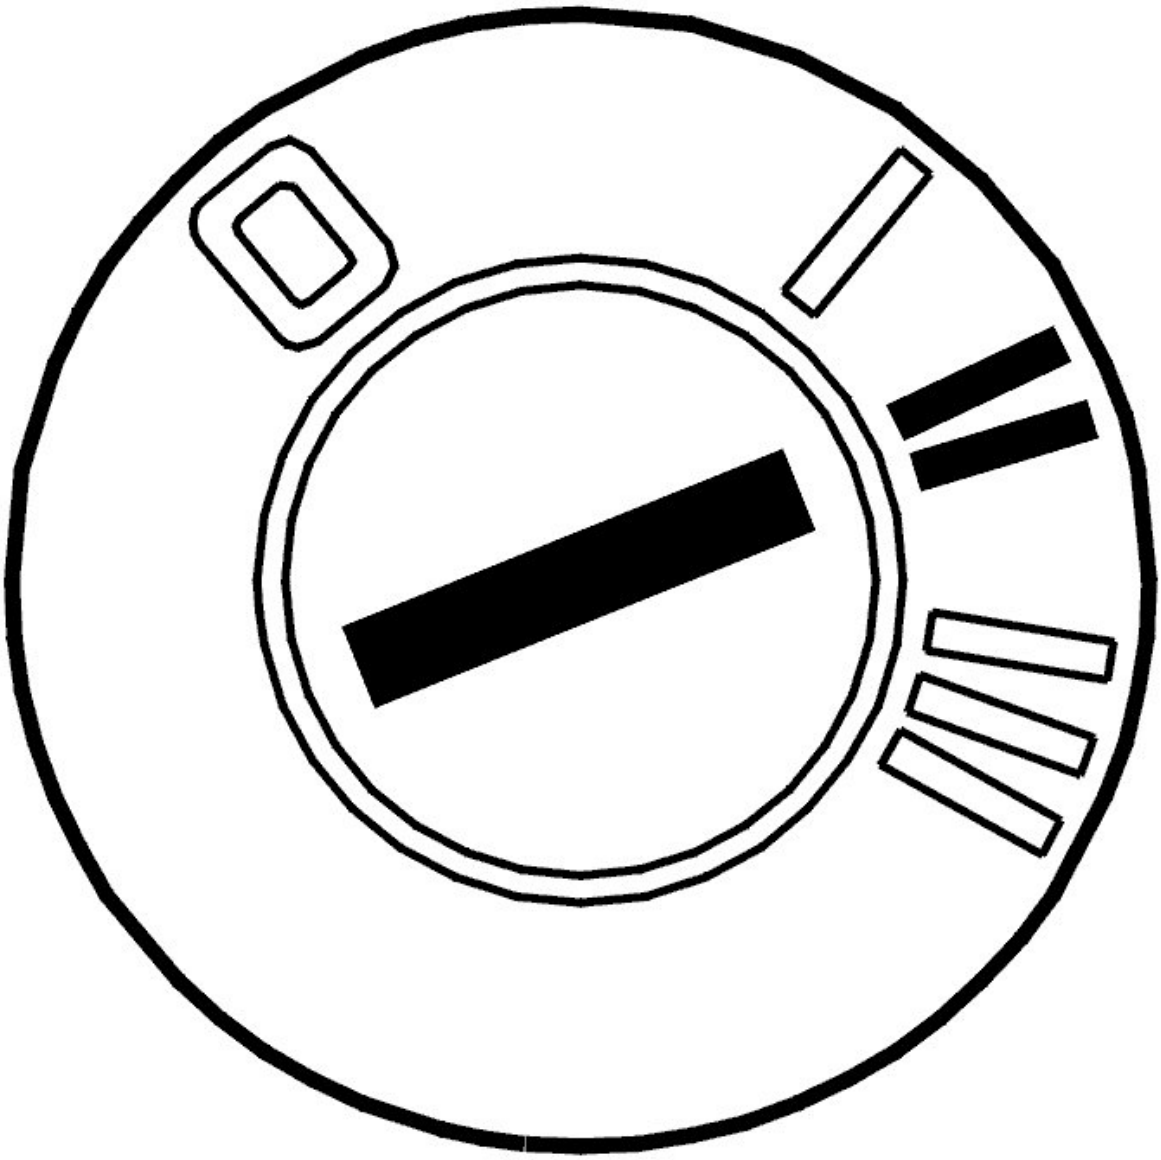


Was a fault detected?

Yes - Verification

No - Checking short-circuiting to ground/voltage in CAN-net

Checking the traffic load on the CAN cables



- Connect the battery
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Faults in the CAN network may be due to a control module sending faulty messages that disrupt normal communication. When messages are sent incorrectly, this results in a considerable increase in the amount of traffic on the CAN network. Check the load by measuring the average voltage value on the CAN cables in relation to ground.
For further information, see the wiring diagram.
Measure voltage between the following connections on the OBDII-box/diagnostics socket.
- #6 and #4 (ground). The voltage should be approx: 2,8 - 3,2 V.
- #14 and #4 (ground). The voltage should be approx: 1,8 - 2,2 V.
- #6 and #14. The voltage shall be between approx. 0.55-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Hint: DiCE Error Frame Finder can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools: **951 3010** (memory card) as well as associated TJ 20402.

- Ignition on.
- Connect DiCE Error Frame Finder to the diagnostics socket.
- Note the blue LED-indicator. The indicator flashes to show detection of fault messages.

Note! Certain interference may occur without any real fault!

Cable fault

- Shake the cables lightly and pull lightly on the connections during the check to locate any fault. Note the blue LED-indicator.

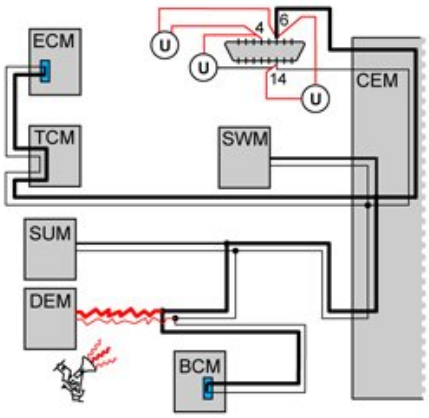
"Chatting" control modules

- "Chatting" control modules may be difficult to find and troubleshooting may take time. Let the vehicle stand with DiCE connected for an extended time period. Afterwards, activate functions to provoke a malfunction. It may take up to several hours before the fault messages are sent. When the indicator starts to flash, remove the fuse for one control module at a time until the indicator stops flashing. When the indicator stops flashing, restore the fuse for the relevant control module and check that the indicator starts to flash again. Then it is likely that the problem is identified.

Remedy wiring as necessary.

Other information

- Battery, disconnecting See: Starting and Charging/Battery/Service and Repair/Procedures/Battery, Disconnecting
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

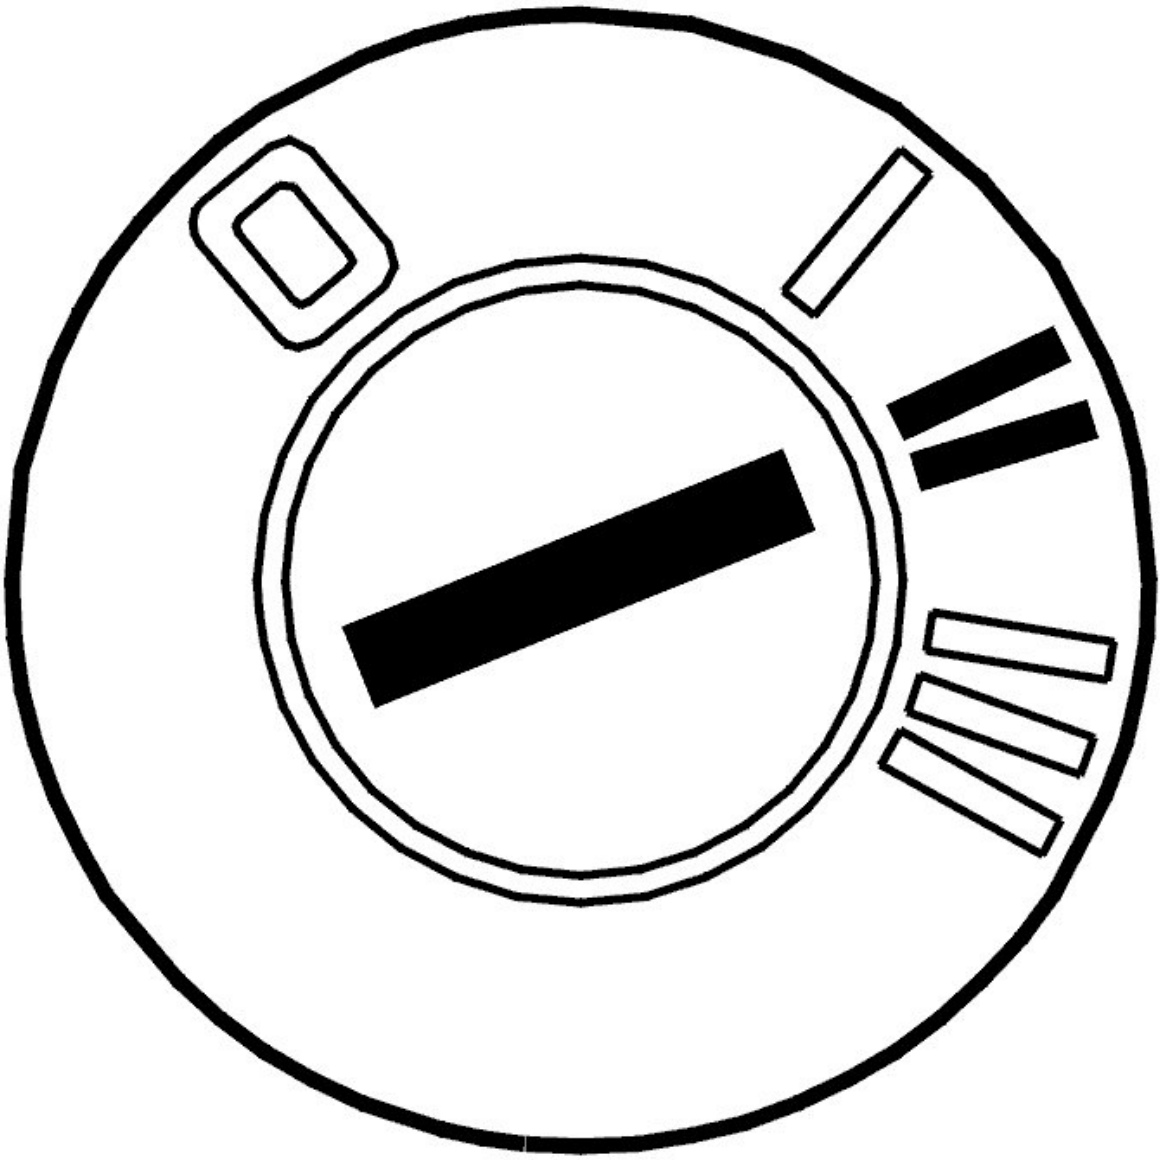


Was a fault detected?

Yes - Identifying a control module in the CAN network

No - respectively

Identifying a control module in the CAN network



Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:

- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Hint: DiCE Error Frame Finder can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools: **951 3010** (memory card) as well as associated TJ 20402.

If the load on the CAN network is too high, this may be due to a control module sending faulty messages on the CAN network (known as a disruptive control module). The fault may also be due to an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The faults can occur without a diagnostic trouble code (DTC) being stored by the control modules. The voltage can be measured between the CAN cables in order to check the load on the CAN network.

Note! It is not necessarily the control module(s) that stored the diagnostic trouble code (DTC) that is communicating faultily. Faulty messages can come from any control module in the same section of the CAN network. However, faulty communication in one network cannot affect the communication on the other network. In other words, faulty communication on the LS-CAN cannot disrupt communication on the HS-CAN and vice versa.

- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Check communication/load on CAN-net by measuring voltage between CAN-L and CAN-H. Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #6 and #14. The average value of the voltage must be approximately 0.6-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

In order to identify which control module has faulty communication, cut the power supply to one control module at a time. Check the voltage in the

CAN cables again. The easiest way to cut the power supply is to remove the fuse(s) for the relevant control module. Repeat until the voltage between the CAN wiring drops to the normal level.

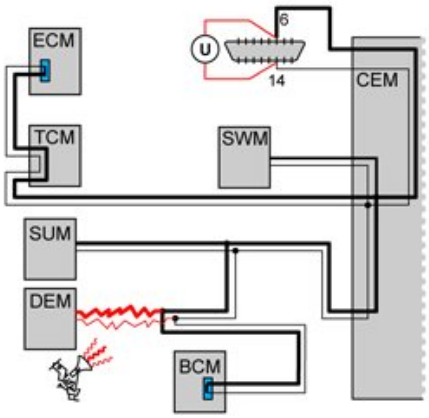
Note! When connecting and disconnecting individual control modules, other diagnostic trouble codes (DTCs) may be stored in certain control modules.

Hint: When the suspected defective control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the malfunction appears and disappears. Switch off the ignition between each check.

Note! Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.

A control module that is communicating incorrectly must be replaced. See Repairing and installing/Removing, replacing and installing.

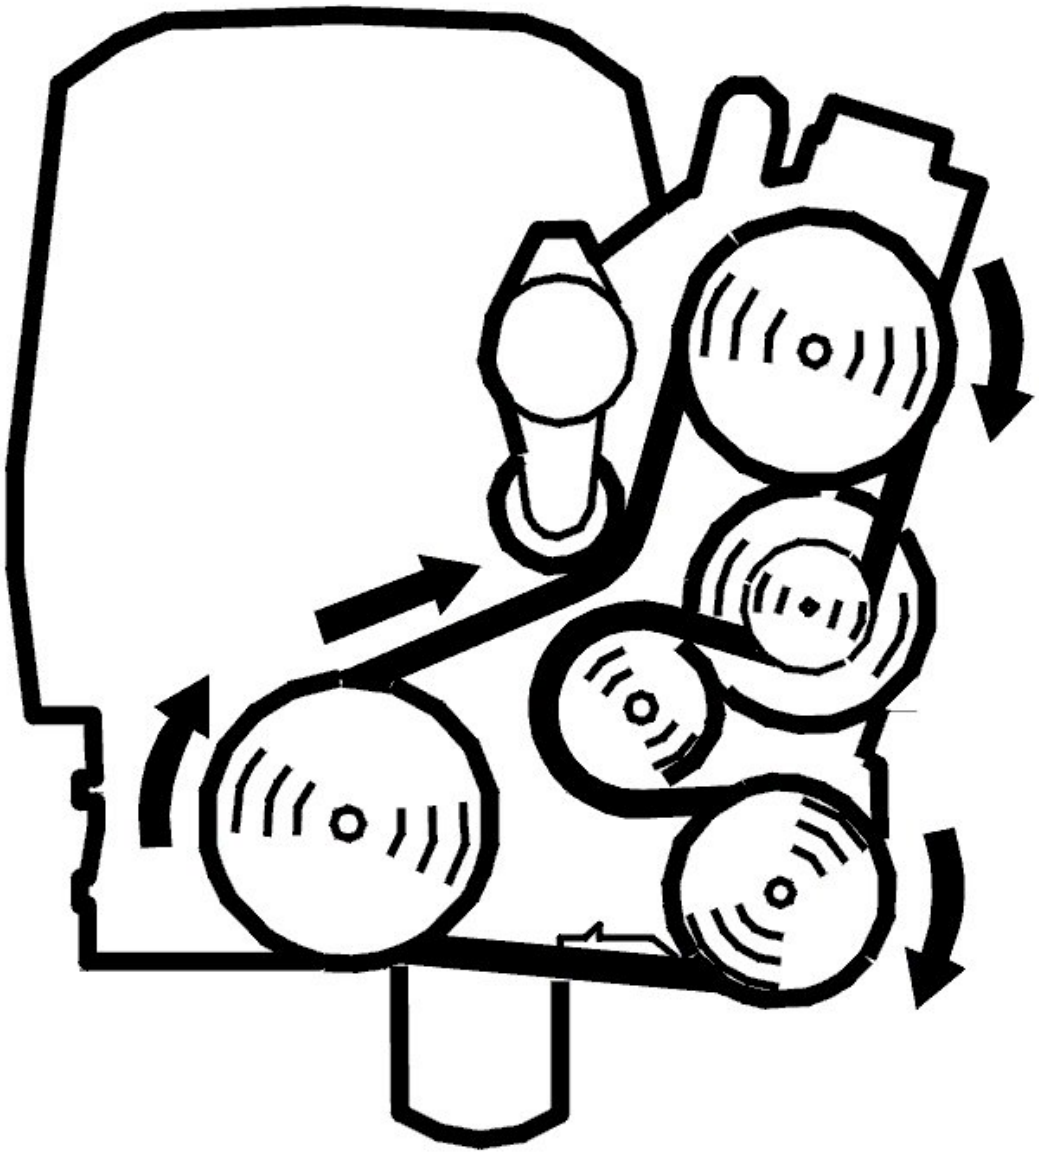
Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

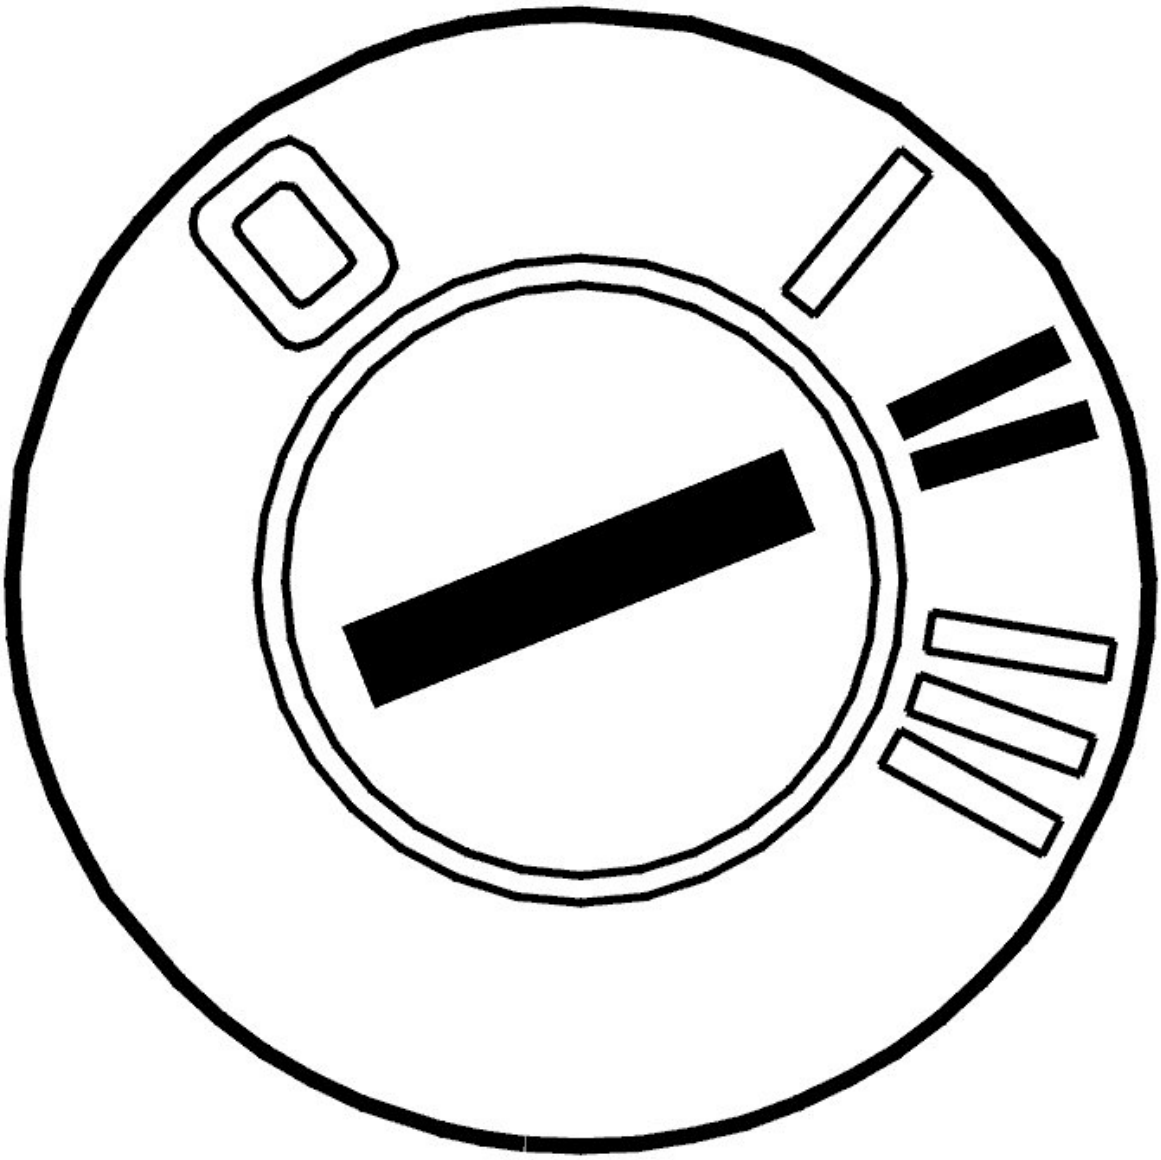


Continue - Verification

Verification

Hint: After rectifying a fault, a verification should be carried out.





- Reinstall the connectors, components etc.
- Ignition on.

Note! For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

- Erase diagnostic trouble codes (DTCs) in all control modules.
- Ignition off.
- Ignition on.
- Start the vehicle. Allow the vehicle to run for 10 minutes.
- Read out the diagnostic trouble codes in the vehicle via the DIAGNOSTICS tab.

Does the diagnostic trouble code (DTC) for faulty communication return?

Yes - Fault-tracing information

No - Fault Found

Fault-tracing information

Information

Fault-tracing information

The fault should have been detected and remedied. As this is not the case fault-tracing has failed.
Exit fault-tracing for this diagnostic trouble code (DTC) or make another attempt.

Do you want to exit fault-tracing?

Yes - FAULT-TRACING FAILED

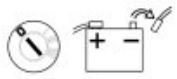
FAULT-TRACING FAILED - FAULT-TRACING FAILED

Attempt New Test - General information

Checking short-circuiting to ground/voltage in CAN-net



- Ignition off.
- Disconnect the battery negative lead.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Checking for a short-circuit to ground

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #6 and #4 (ground). Measurement is shown in the figure. The resistance should be above 1 kohms.
- #14 and #4 (ground). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and ground.

Checking for a short-circuit to voltage

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #6 and #16 (voltage). Measurement is shown in the figure. The resistance should be above 1 kohms.
- #14 and #16 (voltage). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and voltage cable.
Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

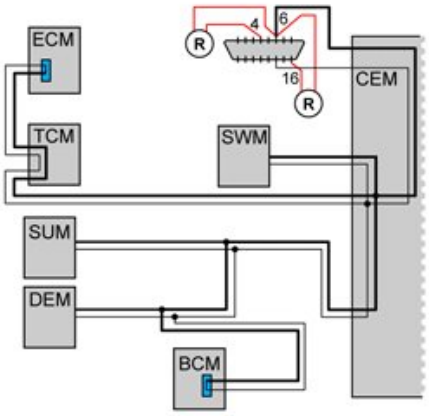
Hint: Part the CAN-net at suitable points to decide where a short-circuit may be found.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy wiring as necessary.

Other information
- Battery, disconnecting See: Starting and Charging/Battery/Service and Repair/Procedures/Battery, Disconnecting
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

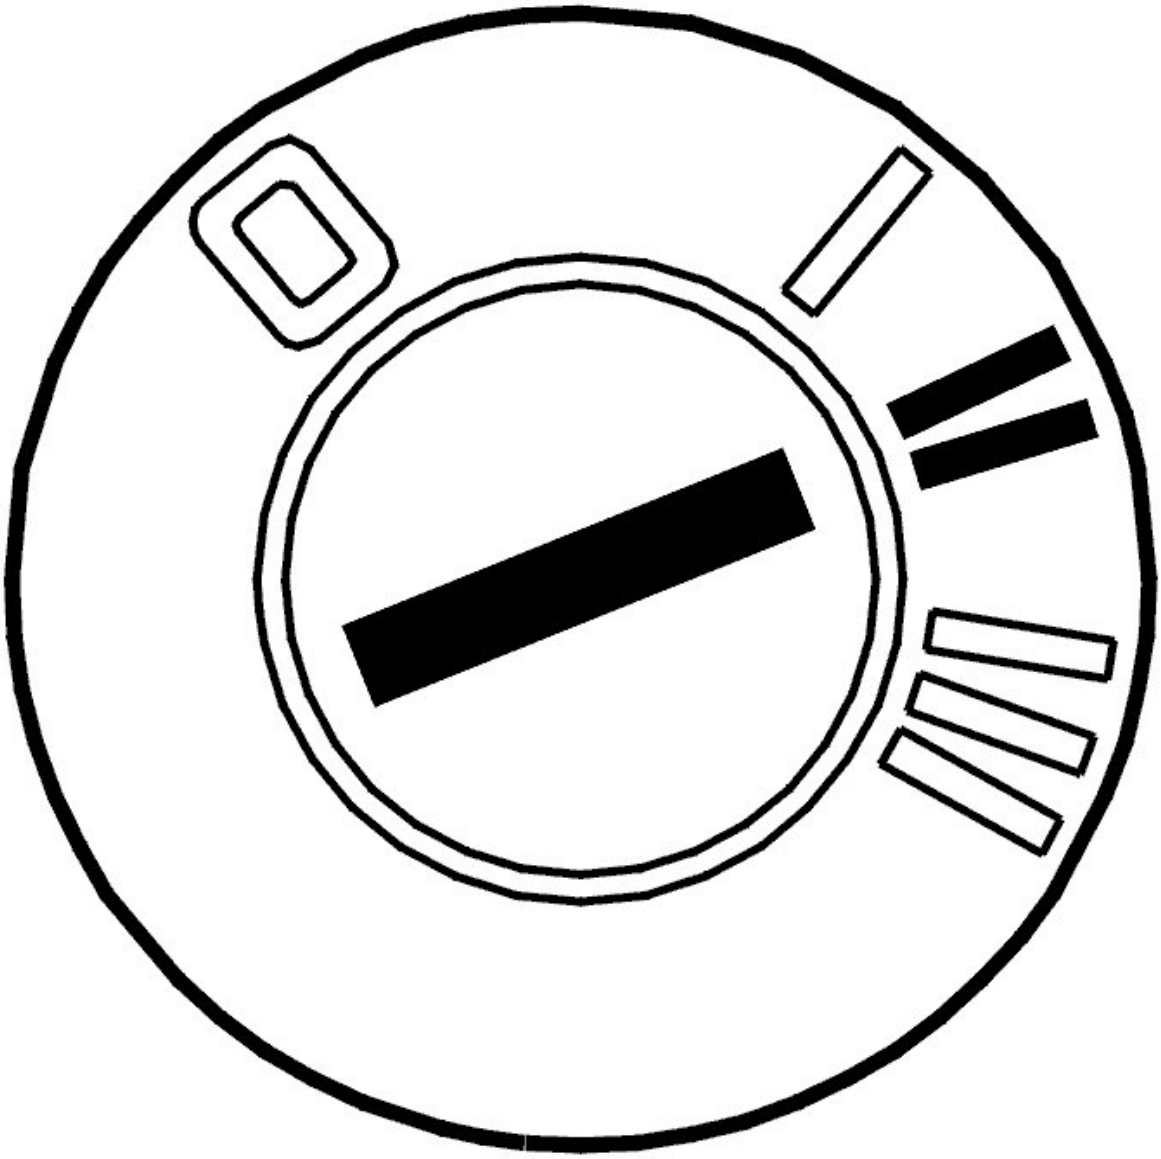


Was a fault detected?

Yes - Verification

No - Checking the traffic load on the CAN cables

Checking voltage-drop in cable for CAN-H and CAN-L, respectively



- Connect the battery.
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

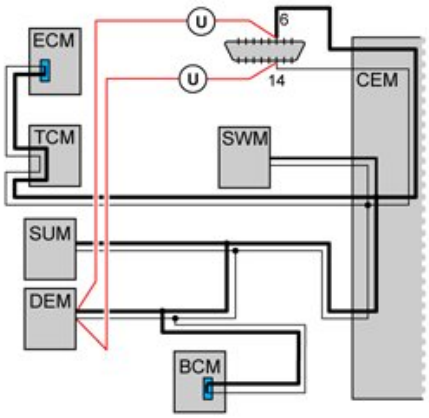
In principle, the voltage measured in each cable in the CAN-net shall be the same at each control module in the network. This means that the voltage-drop in the cable for CAN-H and CAN-L, respectively, between the control modules should be very low. If there is a voltage-difference in the CAN-lines between the diagnostics socket/Central electronic module (CEM) and a control module due to, e.g., contact resistance in a connector or branching, communication may be lost/interfered with.
Check if there is voltage-drop in the cable for CAN-H and CAN-L between the diagnostics socket/Central electronic module (CEM) and the control module where there is problem with communication.
Carry out the following:
Measure voltage between the following connections on the OBDII-box/diagnostics socket.
- #6 and corresponding connection on relevant control module for CAN-H. The voltage shall be lower than 50 mV.
- #14 and corresponding connection on relevant control module for CAN-L. The voltage shall be lower than 50 mV.

If voltage is too high, this indicates too high contact resistance in cable, connector, or branching. Check the circuit between the diagnostics socket and control module in question for contact resistance and oxidation.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy wiring as necessary.

Other information
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

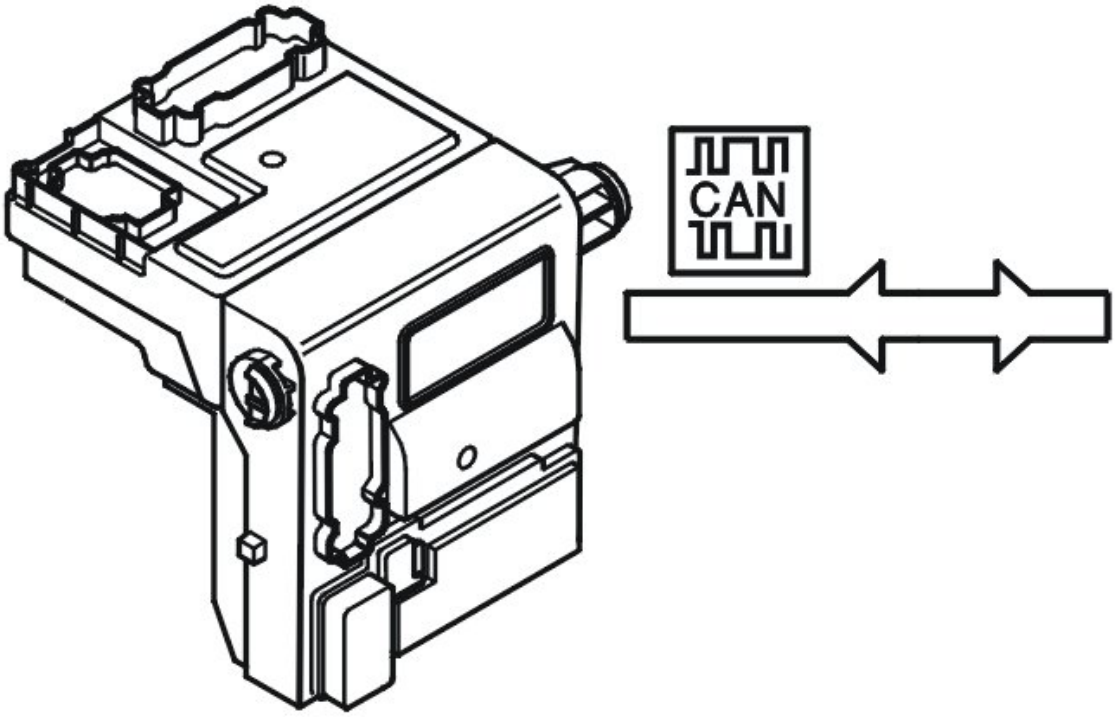


Continue - Verification

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CEM-DF13

Condition



The central electronic module (CEM) checks the voltage in the CAN wiring in the high speed network. The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers a short-circuit to supply voltage in the CAN H in the high speed network.

Note! If DFxx diagnostic trouble codes (DTCs) are stored the central electronic module (CEM) must not be replaced as the diagnostic trouble code (DTC) indicates a short-circuit in one or more conductors in the Control area network. The central electronic module (CEM) is the only control module that monitors the voltage level in the Control area network wiring. The central electronic module (CEM) is therefore the only control module that can store a diagnostic trouble code (DTC) for a short-circuit in one of the cables to ground or supply voltage. Do not replace the central electronic module (CEM) in the event of a CAN fault unless VIDA fault-tracing has indicated that the central electronic module (CEM) has an internal fault.

The diagnostic trouble code (DTC) can be diagnosed when the ignition has been on for more than 10 seconds.

Substitute value
- None.

Possible source
- Short-circuit to supply voltage in the high speed network.

Fault symptom[s]
- Poor performance.
- Poor accelerator pedal (AP) response.
- Malfunction indicator lamp (MIL) lit.
- Message in the display.

Signal Missing

Signal missing

General information

Note! Figures shown are only examples.

Hint: For general information about CAN-troubleshooting, see:
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

General about CAN-related diagnostic trouble codes.
CEM-DF01 - DF17can only be stored in Central electronic module (CEM). These diagnostic trouble codes are stored when an electric fault is detected in CAN-lines. Start with these diagnostic trouble codes first.

CEM-1AXX only stored in Central electronic module (CEM). One diagnostic trouble code for every control module on the CAN-net. These diagnostic trouble codes indicate that Central electronic module (CEM) does not receive any reply from other control modules.
XXX-E000 (HS-CAN)/E001 (LS-CAN) can be stored in all CAN-connected control modules. These diagnostic trouble codes indicate that the control module has detected interference on the CAN-net.
XXX-E003 can be stored in all CAN-connected control modules except in Central electronic module (CEM). The control modules on the CAN-net listen for a message (identity number) that is sent out at regular intervals from Central electronic module (CEM). This diagnostic trouble code indicates that the control module has not received any identity number, or that the expected number is not correct. Interference on the CAN-net can also store this diagnostic trouble code.

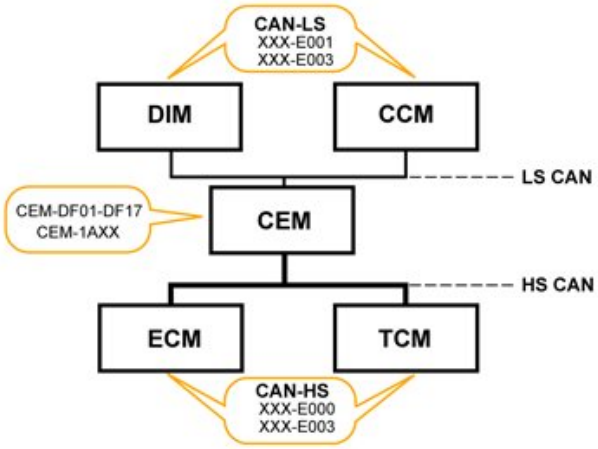
Note! In case of CAN-related faults, it is likely that a combination of above diagnostic trouble codes occur.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

If a communication diagnostic trouble code can be read from the control module, the malfunction is probably intermittent.
Intermittent fault in the voltage supply and ground to a control module on the CAN network results in the Central electronic module (CEM) storing a diagnostic trouble code (DTC) for an open-circuit in communication with the control module where the voltage supply does not work. There will probably not be a diagnostic trouble code (DTC) in the control module where the open-circuit in the voltage supply occurred as the control module cannot store a diagnostic trouble code (DTC) when it is not supplied with power.

Note! Central electronic module (CEM) should not be replaced in case of CAN-fault, unless troubleshooting reveals that Central electronic module (CEM) has an internal fault.

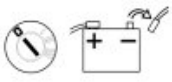
Caution! During this fault-tracing use the wiring diagram to provide support when taking readings.



Select "Continue".

Continue - Checking resistance in CAN-net

Checking resistance in CAN-net



- Ignition off
- Disconnect the battery negative lead
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #6 and #14. The resistance should be approx. 55 - 65 ohms.
- If resistance is approx. 120 ohms, this indicates open circuit in the circuit so that only one terminating resistor (120 ohms) has been

measured.

- If resistance is above 1 kohms this indicates open circuit/high contact resistance somewhere in the circuit.
- If resistance is below 55 ohms this indicates short-circuiting/contact resistance between the CAN-lines somewhere in the circuit.

Hint: For HS-CAN (High Speed) the terminating resistors are located in Brake control module (BCM) and in Engine control module (ECM).

Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

Note! Resistance measurement measures only main lines in the CAN-net (in circuit where both terminating resistors are found), not branches to certain control modules. See wiring diagram for vehicle model in question.Open circuit on branching without a terminating resistor cannot be detected with this measurement. However, short-circuiting on a branch can be detected. To measure resistance in the CAN-net to control modules located in a branching of their own, the measurement shall be done against the CAN-net at that control module. The values shall be as above.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy wiring as necessary.

Other information

- Battery, disconnecting See: Starting and Charging/Battery/Service and Repair/Procedures/Battery, Disconnecting

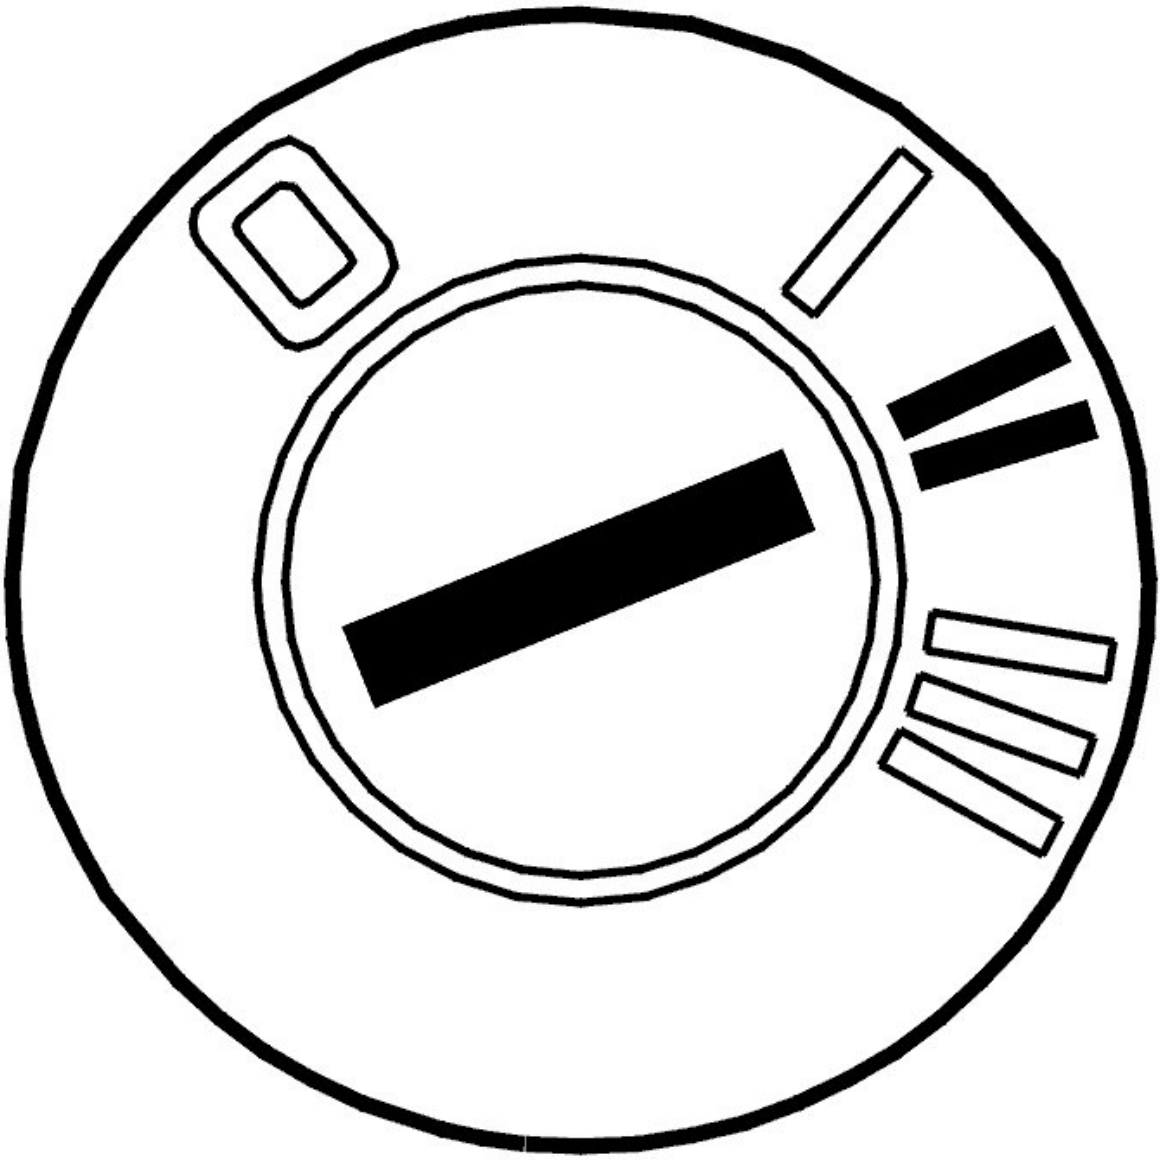
Was a fault detected?

Yes - Verification

No - Checking short-circuiting to ground/voltage in CAN-net

Checking the traffic load on the CAN cables



- Connect the battery
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Faults in the CAN network may be due to a control module sending faulty messages that disrupt normal communication. When messages are sent incorrectly, this results in a considerable increase in the amount of traffic on the CAN network. Check the load by measuring the average voltage value on the CAN cables in relation to ground.
For further information, see the wiring diagram.
Measure voltage between the following connections on the OBDII-box/diagnostics socket.
- #6 and #4 (ground). The voltage should be approx: 2,8 - 3,2 V.
- #14 and #4 (ground). The voltage should be approx: 1,8 - 2,2 V.
- #6 and #14. The voltage shall be between approx. 0.55-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Hint: DiCE Error Frame Finder can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools: **951 3010** (memory card) as well as associated TJ 20402.

- Ignition on.
- Connect DiCE Error Frame Finder to the diagnostics socket.
- Note the blue LED-indicator. The indicator flashes to show detection of fault messages.

Note! Certain interference may occur without any real fault!

Cable fault

- Shake the cables lightly and pull lightly on the connections during the check to locate any fault. Note the blue LED-indicator.

"Chatting" control modules

- "Chatting" control modules may be difficult to find and troubleshooting may take time. Let the vehicle stand with DiCE connected for an extended time period. Afterwards, activate functions to provoke a malfunction. It may take up to several hours before the fault messages are sent. When the indicator starts to flash, remove the fuse for one control module at a time until the indicator stops flashing. When the indicator stops flashing, restore the fuse for the relevant control module and check that the indicator starts to flash again. Then it is likely that the problem is identified.

Remedy wiring as necessary.

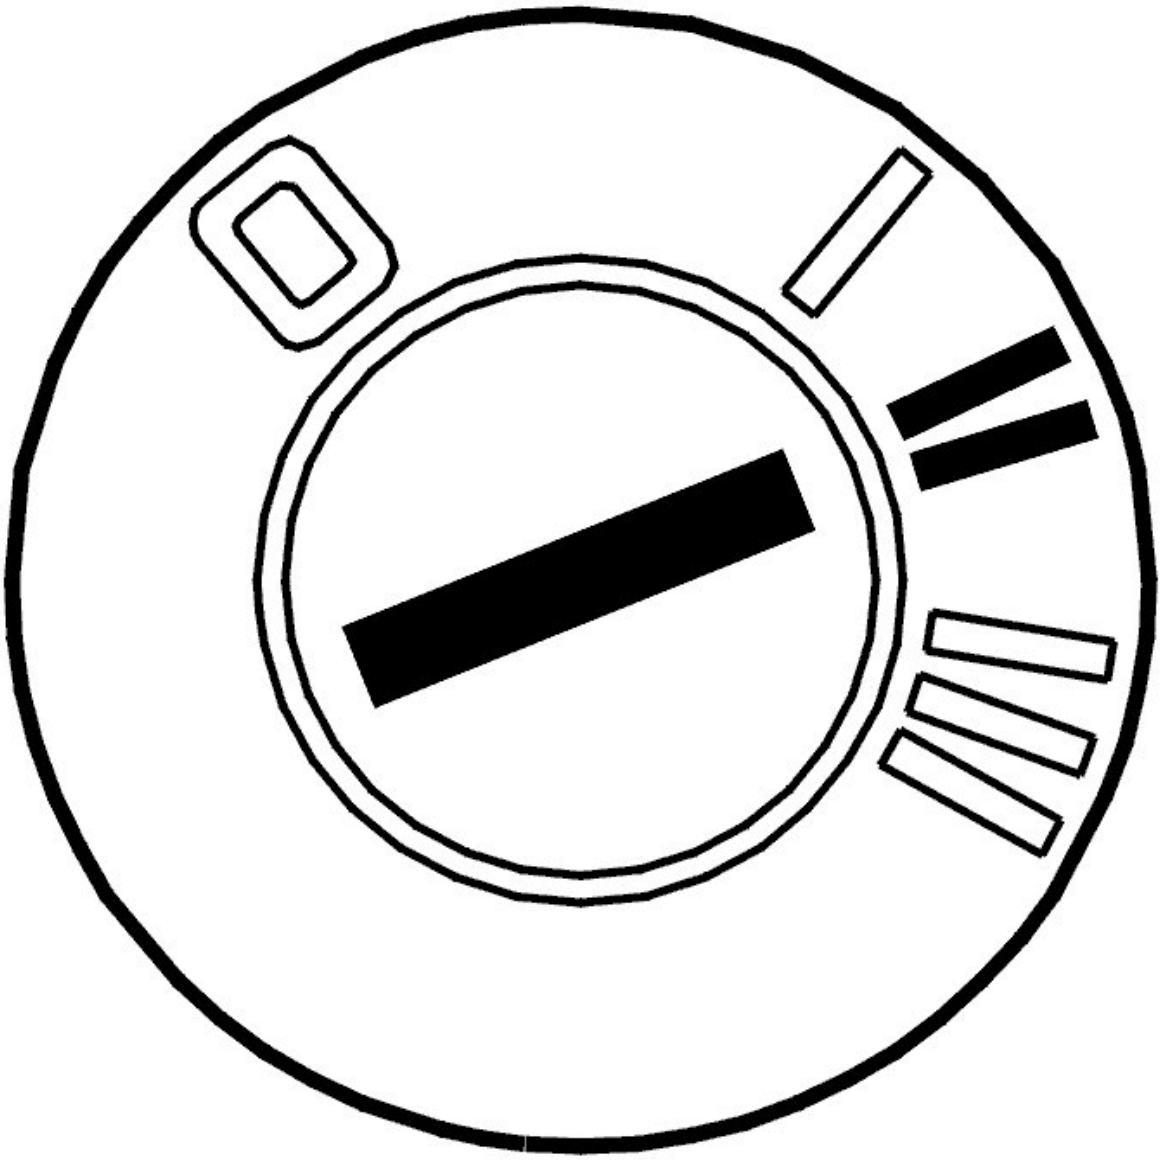
Was a fault detected?

Yes - Identifying a control module in the CAN network

No - respectively

Identifying a control module in the CAN network



Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:

- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Hint: DiCE Error Frame Finder can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools: **951 3010** (memory card) as well as associated TJ 20402.

If the load on the CAN network is too high, this may be due to a control module sending faulty messages on the CAN network (known as a disruptive control module). The fault may also be due to an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The faults can occur without a diagnostic trouble code (DTC) being stored by the control modules. The voltage can be measured between the CAN cables in order to check the load on the CAN network.

Note! It is not necessarily the control module(s) that stored the diagnostic trouble code (DTC) that is communicating faultily. Faulty messages can come from any control module in the same section of the CAN network. However, faulty communication in one network cannot affect the communication on the other network. In other words, faulty communication on the LS-CAN cannot disrupt communication on the HS-CAN and vice versa.

- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Check communication/load on CAN-net by measuring voltage between CAN-L and CAN-H. Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #6 and #14. The average value of the voltage must be approximately 0.6-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

In order to identify which control module has faulty communication, cut the power supply to one control module at a time. Check the voltage in the

CAN cables again. The easiest way to cut the power supply is to remove the fuse(s) for the relevant control module. Repeat until the voltage between the CAN wiring drops to the normal level.

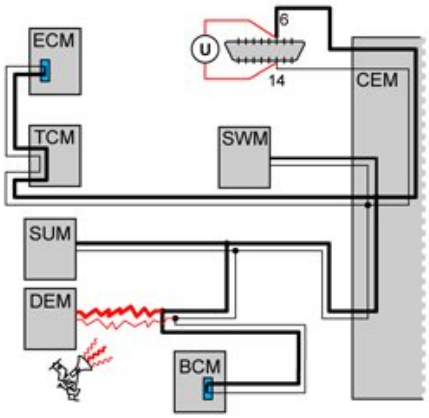
Note! When connecting and disconnecting individual control modules, other diagnostic trouble codes (DTCs) may be stored in certain control modules.

Hint: When the suspected defective control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the malfunction appears and disappears. Switch off the ignition between each check.

Note! Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.

A control module that is communicating incorrectly must be replaced. See Repairing and installing/Removing, replacing and installing.

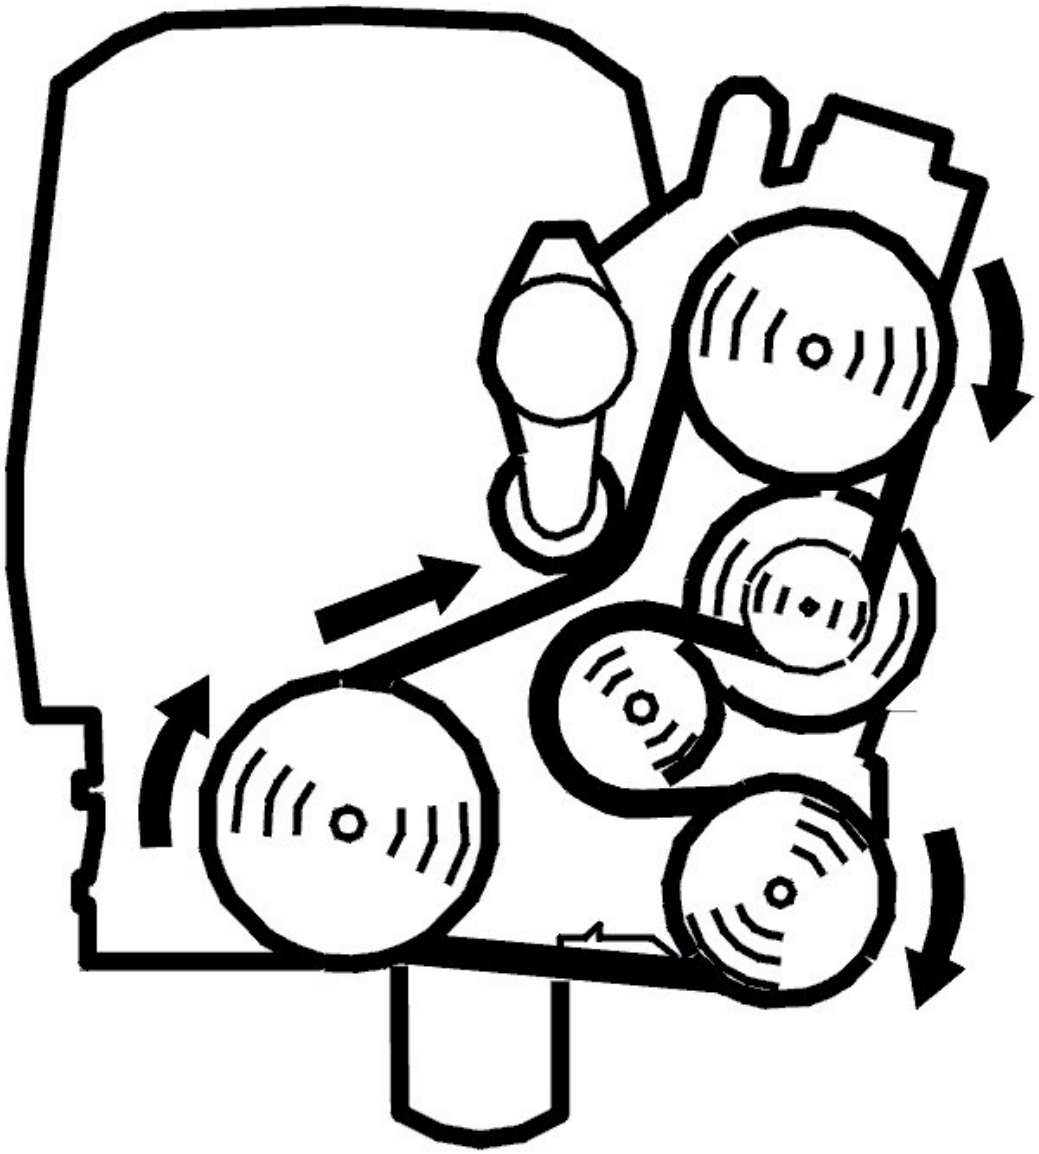
Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

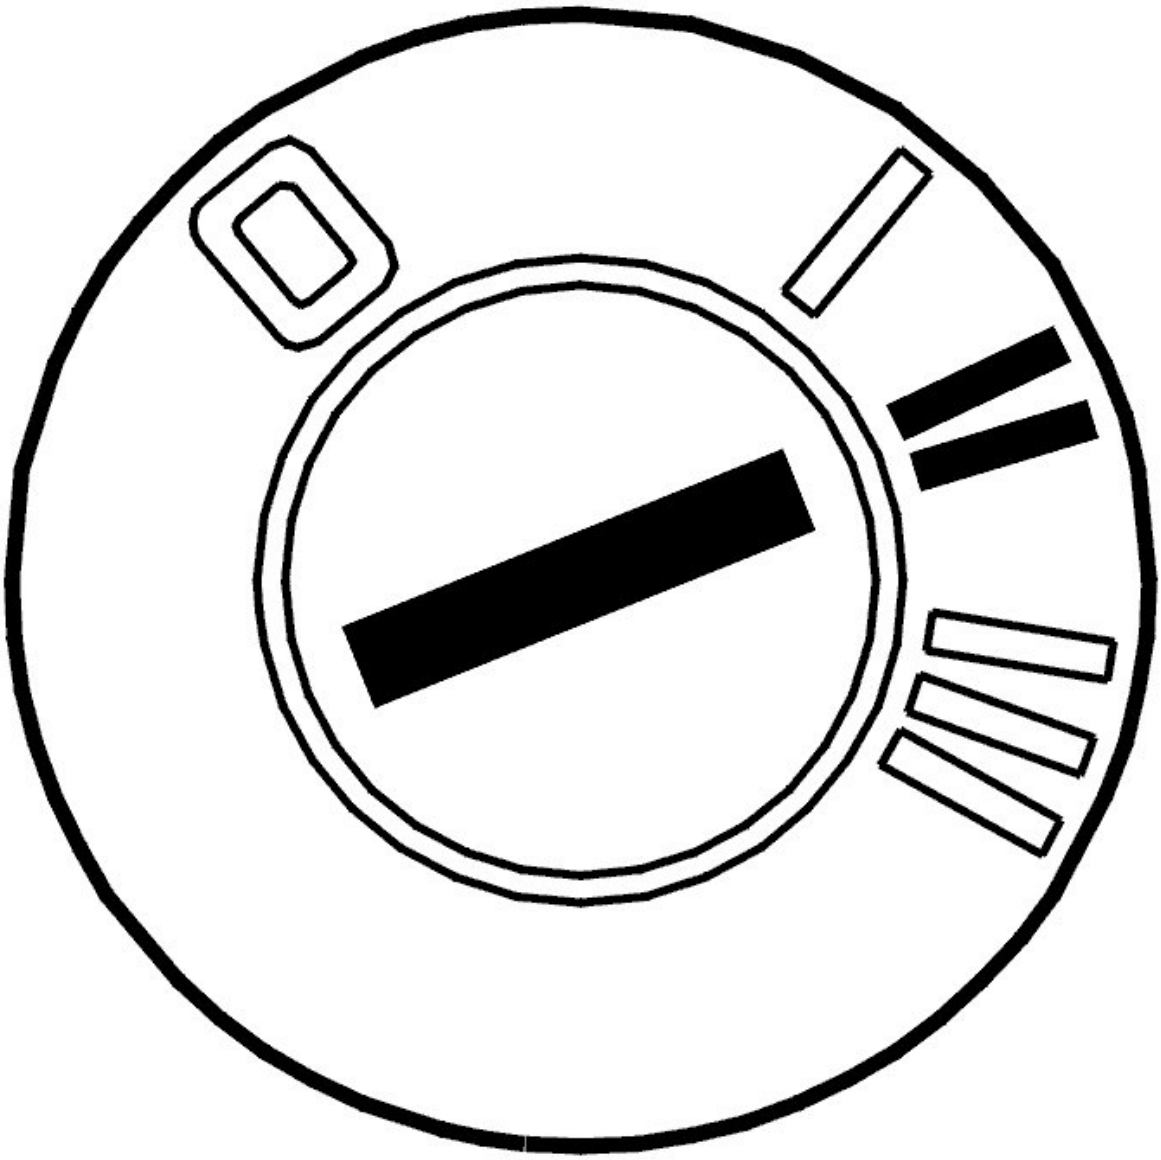


Continue - Verification

Verification

Hint: After rectifying a fault, a verification should be carried out.





- Reinstall the connectors, components etc.
- Ignition on.

Note! For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

- Erase diagnostic trouble codes (DTCs) in all control modules.
- Ignition off.
- Ignition on.
- Start the vehicle. Allow the vehicle to run for 10 minutes.
- Read out the diagnostic trouble codes in the vehicle via the DIAGNOSTICS tab.

Does the diagnostic trouble code (DTC) for faulty communication return?

Yes - Fault-tracing information

No - Fault Found

Fault-tracing information

Information

Fault-tracing information

The fault should have been detected and remedied. As this is not the case fault-tracing has failed.
Exit fault-tracing for this diagnostic trouble code (DTC) or make another attempt.

Do you want to exit fault-tracing?

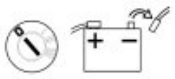
Yes - FAULT-TRACING FAILED

No - Attempt New Test

FAULT-TRACING FAILED - FAULT-TRACING FAILED

Attempt New Test - General information

Checking short-circuiting to ground/voltage in CAN-net



- Ignition off.
- Disconnect the battery negative lead.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Checking for a short-circuit to ground

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #6 and #4 (ground). Measurement is shown in the figure. The resistance should be above 1 kohms.
- #14 and #4 (ground). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and ground.

Checking for a short-circuit to voltage

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #6 and #16 (voltage). Measurement is shown in the figure. The resistance should be above 1 kohms.
- #14 and #16 (voltage). The resistance should be above 1 kohms.

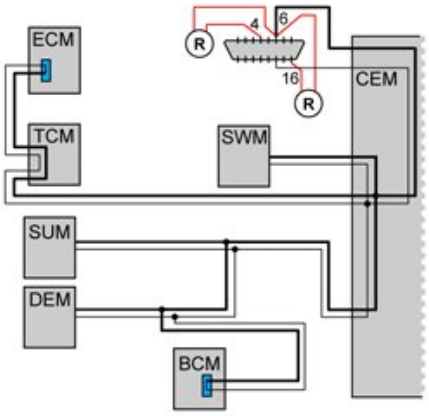
If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and voltage cable.
Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

Hint: Part the CAN-net at suitable points to decide where a short-circuit may be found.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy wiring as necessary.

Other information
- Battery, disconnecting See: Starting and Charging/Battery/Service and Repair/Procedures/Battery, Disconnecting
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

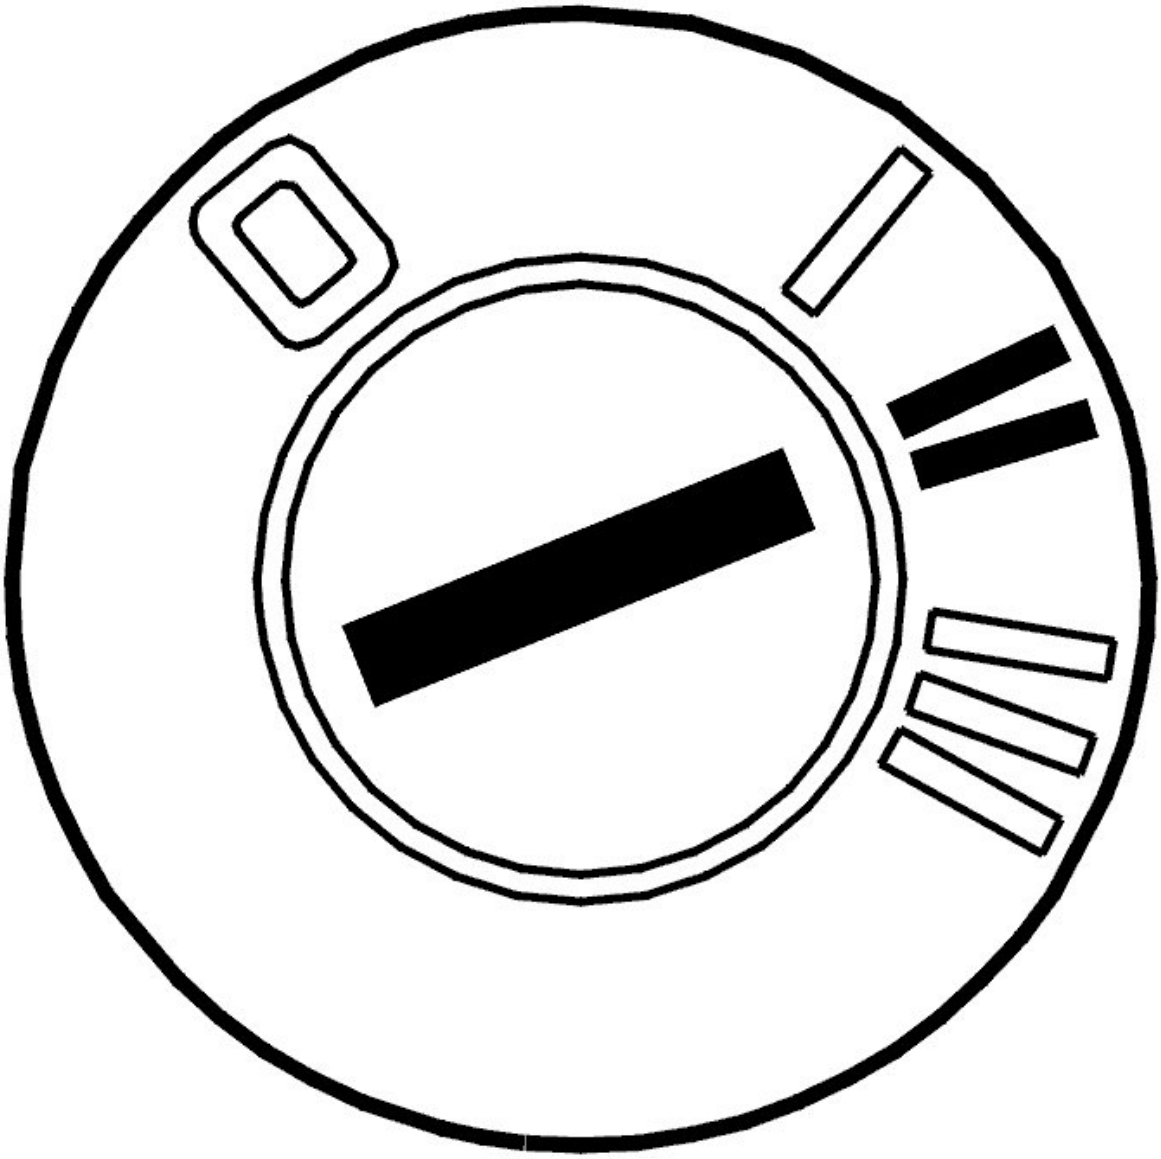


Was a fault detected?

Yes - Verification

No - Checking the traffic load on the CAN cables

Checking voltage-drop in cable for CAN-H and CAN-L, respectively



- Connect the battery.
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

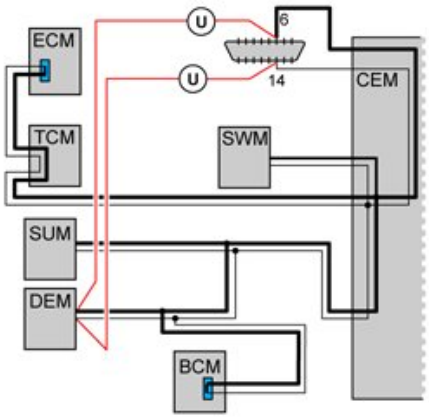
In principle, the voltage measured in each cable in the CAN-net shall be the same at each control module in the network. This means that the voltage-drop in the cable for CAN-H and CAN-L, respectively, between the control modules should be very low. If there is a voltage-difference in the CAN-lines between the diagnostics socket/Central electronic module (CEM) and a control module due to, e.g., contact resistance in a connector or branching, communication may be lost/interfered with.
Check if there is voltage-drop in the cable for CAN-H and CAN-L between the diagnostics socket/Central electronic module (CEM) and the control module where there is problem with communication.
Carry out the following:
Measure voltage between the following connections on the OBDII-box/diagnostics socket.
- #6 and corresponding connection on relevant control module for CAN-H. The voltage shall be lower than 50 mV.
- #14 and corresponding connection on relevant control module for CAN-L. The voltage shall be lower than 50 mV.

If voltage is too high, this indicates too high contact resistance in cable, connector, or branching. Check the circuit between the diagnostics socket and control module in question for contact resistance and oxidation.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy wiring as necessary.

Other information
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

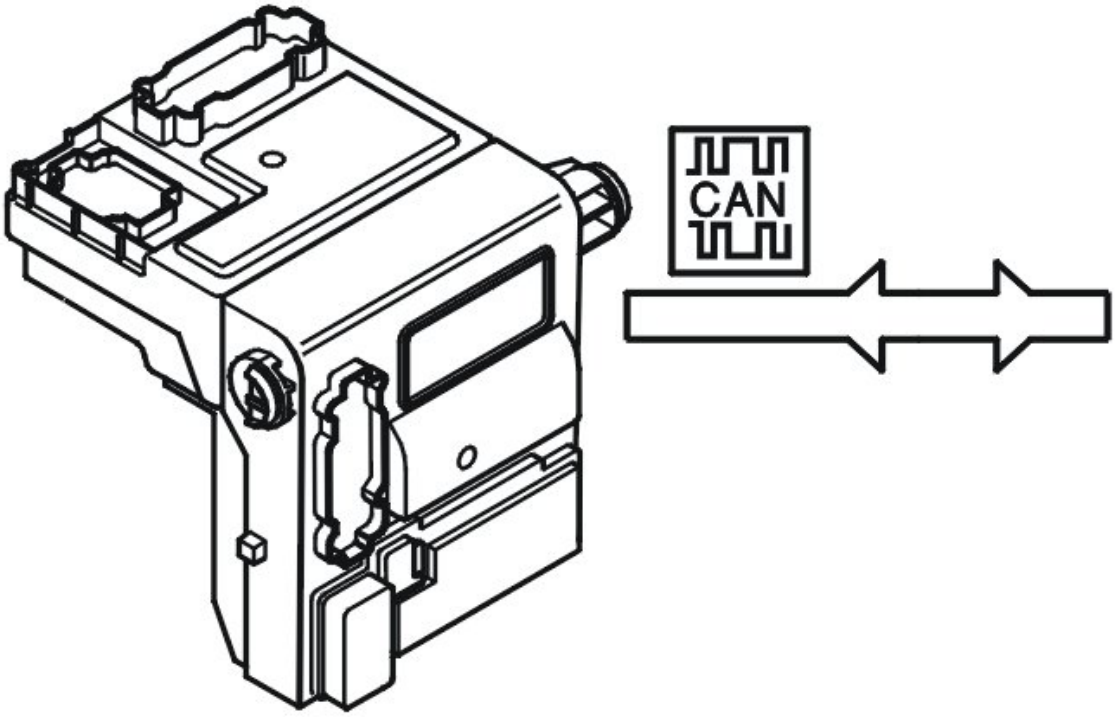


Continue - Verification

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CEM-DF14

Condition



The central electronic module (CEM) checks the voltage in the CAN wiring in the high speed network. The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers a short-circuit to ground in the CAN L in the high speed network.

Note! If DFxx diagnostic trouble codes (DTCs) are stored the central electronic module (CEM) must not be replaced as the diagnostic trouble code (DTC) indicates a short-circuit in one or more conductors in the Control area network. The central electronic module (CEM) is the only control module that monitors the voltage level in the Control area network wiring. The central electronic module (CEM) is therefore the only control module that can store a diagnostic trouble code (DTC) for a short-circuit in one of the cables to ground or supply voltage. Do not replace the central electronic module (CEM) in the event of a CAN fault unless VIDA fault-tracing has indicated that the central electronic module (CEM) has an internal fault.

The diagnostic trouble code (DTC) can be diagnosed when the ignition has been on for more than 10 seconds.

Substitute value
- None.

Possible source
- Short-circuit to ground in the high speed network.

Fault symptom[s]
- Radio interference.

Signal Missing

Signal missing

General information

Note! Figures shown are only examples.

Hint: For general information about CAN-troubleshooting, see:
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

General about CAN-related diagnostic trouble codes.
CEM-DF01 - DF17can only be stored in Central electronic module (CEM). These diagnostic trouble codes are stored when an electric fault is detected in CAN-lines. Start with these diagnostic trouble codes first.
CEM-1AXX only stored in Central electronic module (CEM). One diagnostic trouble code for every control module on the CAN-net. These diagnostic trouble codes indicate that Central electronic module (CEM) does not receive any reply from other control modules.
XXX-E000 (HS-CAN)/E001 (LS-CAN) can be stored in all CAN-connected control modules. These diagnostic trouble codes indicate that the

control module has detected interference on the CAN-net.
XXX-E003 can be stored in all CAN-connected control modules except in Central electronic module (CEM). The control modules on the CAN-net listen for a message (identity number) that is sent out at regular intervals from Central electronic module (CEM). This diagnostic trouble code indicates that the control module has not received any identity number, or that the expected number is not correct. Interference on the CAN-net can also store this diagnostic trouble code.

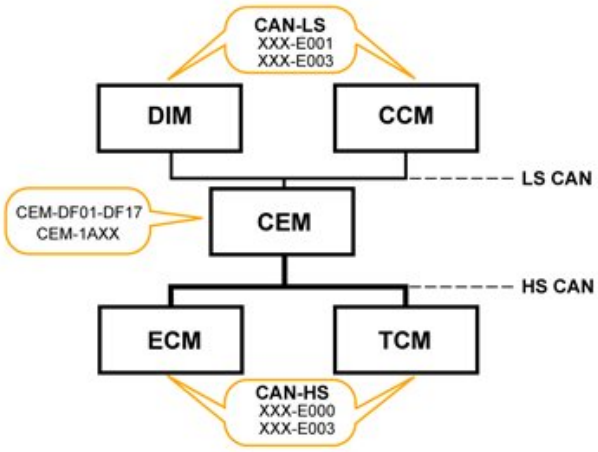
Note! In case of CAN-related faults, it is likely that a combination of above diagnostic trouble codes occur.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

If a communication diagnostic trouble code can be read from the control module, the malfunction is probably intermittent.
Intermittent fault in the voltage supply and ground to a control module on the CAN network results in the Central electronic module (CEM) storing a diagnostic trouble code (DTC) for an open-circuit in communication with the control module where the voltage supply does not work. There will probably not be a diagnostic trouble code (DTC) in the control module where the open-circuit in the voltage supply occurred as the control module cannot store a diagnostic trouble code (DTC) when it is not supplied with power.

Note! Central electronic module (CEM) should not be replaced in case of CAN-fault, unless troubleshooting reveals that Central electronic module (CEM) has an internal fault.

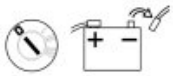
Caution! During this fault-tracing use the wiring diagram to provide support when taking readings.



Select "Continue".

Continue - Checking resistance in CAN-net

Checking resistance in CAN-net



- Ignition off
- Disconnect the battery negative lead
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #6 and #14. The resistance should be approx. 55 - 65 ohms.
- If resistance is approx. 120 ohms, this indicates open circuit in the circuit so that only one terminating resistor (120 ohms) has been measured.
- If resistance is above 1 kohms this indicates open circuit/high contact resistance somewhere in the circuit.
- If resistance is below 55 ohms this indicates short-circuiting/contact resistance between the CAN-lines somewhere in the circuit.

Hint: For HS-CAN (High Speed) the terminating resistors are located in Brake control module (BCM) and in Engine control module (ECM).

Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

Note! Resistance measurement measures only main lines in the CAN-net (in circuit where both terminating resistors are found), not branches to certain control modules. See wiring diagram for vehicle model in question.Open circuit on branching without a terminating resistor cannot be detected with this measurement. However, short-circuiting on a branch can be detected. To measure resistance in the CAN-net to control modules located in a branching of their own, the measurement shall be done against the CAN-net at that control module. The values shall be as above.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy wiring as necessary.

Other information

- Battery, disconnecting See: Starting and Charging/Battery/Service and Repair/Procedures/Battery, Disconnecting

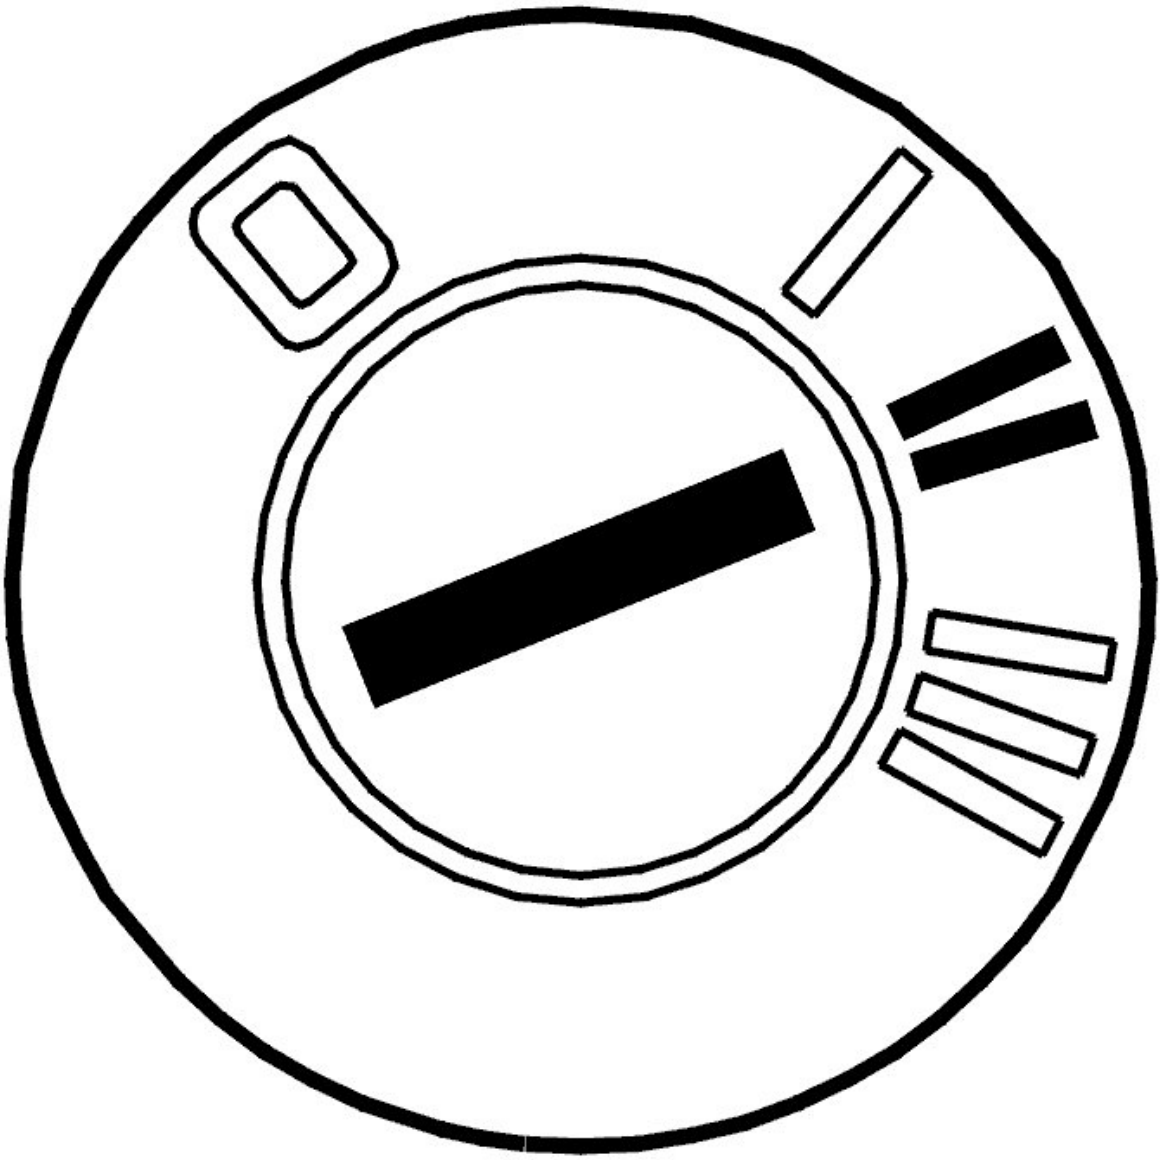
Was a fault detected?

Yes - Verification

No - Checking short-circuiting to ground/voltage in CAN-net

Checking the traffic load on the CAN cables



- Connect the battery
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Faults in the CAN network may be due to a control module sending faulty messages that disrupt normal communication. When messages are sent incorrectly, this results in a considerable increase in the amount of traffic on the CAN network. Check the load by measuring the average voltage value on the CAN cables in relation to ground.
For further information, see the wiring diagram.
Measure voltage between the following connections on the OBDII-box/diagnostics socket.
- #6 and #4 (ground). The voltage should be approx: 2,8 - 3,2 V.
- #14 and #4 (ground). The voltage should be approx: 1,8 - 2,2 V.
- #6 and #14. The voltage shall be between approx. 0.55-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Hint: DiCE Error Frame Finder can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools: **951 3010** (memory card) as well as associated TJ 20402.

- Ignition on.
- Connect DiCE Error Frame Finder to the diagnostics socket.
- Note the blue LED-indicator. The indicator flashes to show detection of fault messages.

Note! Certain interference may occur without any real fault!

Cable fault

- Shake the cables lightly and pull lightly on the connections during the check to locate any fault. Note the blue LED-indicator.

"Chatting" control modules

- "Chatting" control modules may be difficult to find and troubleshooting may take time. Let the vehicle stand with DiCE connected for an extended time period. Afterwards, activate functions to provoke a malfunction. It may take up to several hours before the fault messages are sent. When the indicator starts to flash, remove the fuse for one control module at a time until the indicator stops flashing. When the indicator stops flashing, restore the fuse for the relevant control module and check that the indicator starts to flash again. Then it is likely that the problem is identified.

Remedy wiring as necessary.

Other information

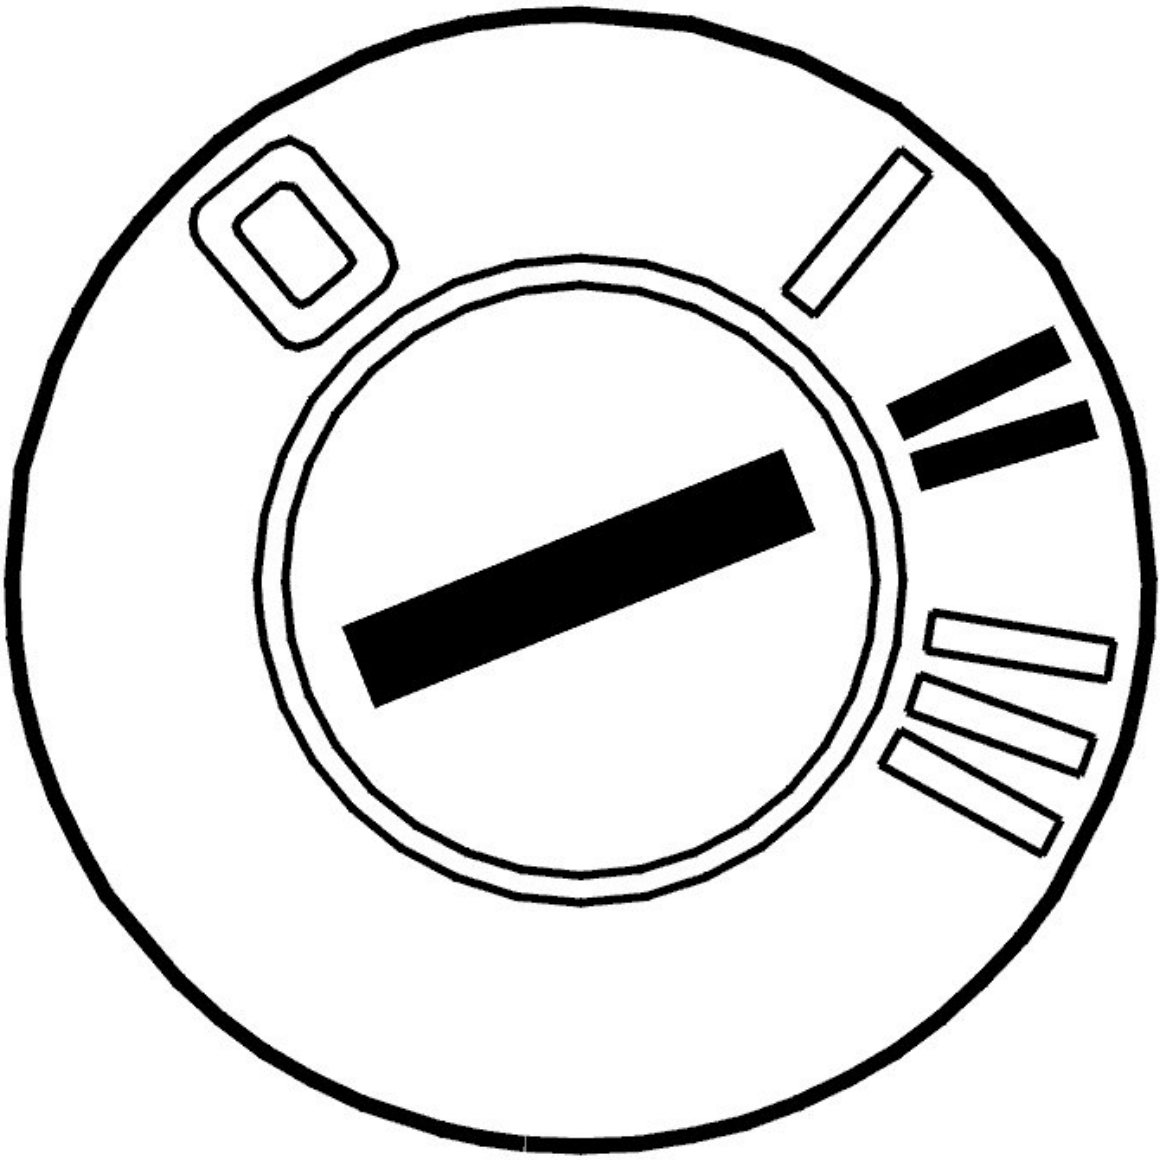
Was a fault detected?

Yes - Identifying a control module in the CAN network

No - respectively

Identifying a control module in the CAN network



Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:

- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Hint: DiCE Error Frame Finder can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools: **951 3010** (memory card) as well as associated TJ 20402.

If the load on the CAN network is too high, this may be due to a control module sending faulty messages on the CAN network (known as a disruptive control module). The fault may also be due to an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The faults can occur without a diagnostic trouble code (DTC) being stored by the control modules. The voltage can be measured between the CAN cables in order to check the load on the CAN network.

Note! It is not necessarily the control module(s) that stored the diagnostic trouble code (DTC) that is communicating faultily. Faulty messages can come from any control module in the same section of the CAN network. However, faulty communication in one network cannot affect the communication on the other network. In other words, faulty communication on the LS-CAN cannot disrupt communication on the HS-CAN and vice versa.

- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Check communication/load on CAN-net by measuring voltage between CAN-L and CAN-H. Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #6 and #14. The average value of the voltage must be approximately 0.6-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

In order to identify which control module has faulty communication, cut the power supply to one control module at a time. Check the voltage in the

CAN cables again. The easiest way to cut the power supply is to remove the fuse(s) for the relevant control module. Repeat until the voltage between the CAN wiring drops to the normal level.

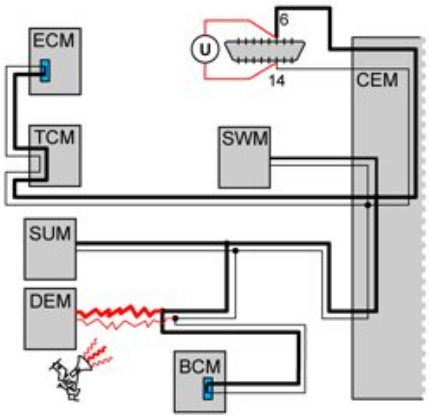
Note! When connecting and disconnecting individual control modules, other diagnostic trouble codes (DTCs) may be stored in certain control modules.

Hint: When the suspected defective control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the malfunction appears and disappears. Switch off the ignition between each check.

Note! Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.

A control module that is communicating incorrectly must be replaced. See Repairing and installing/Removing, replacing and installing.

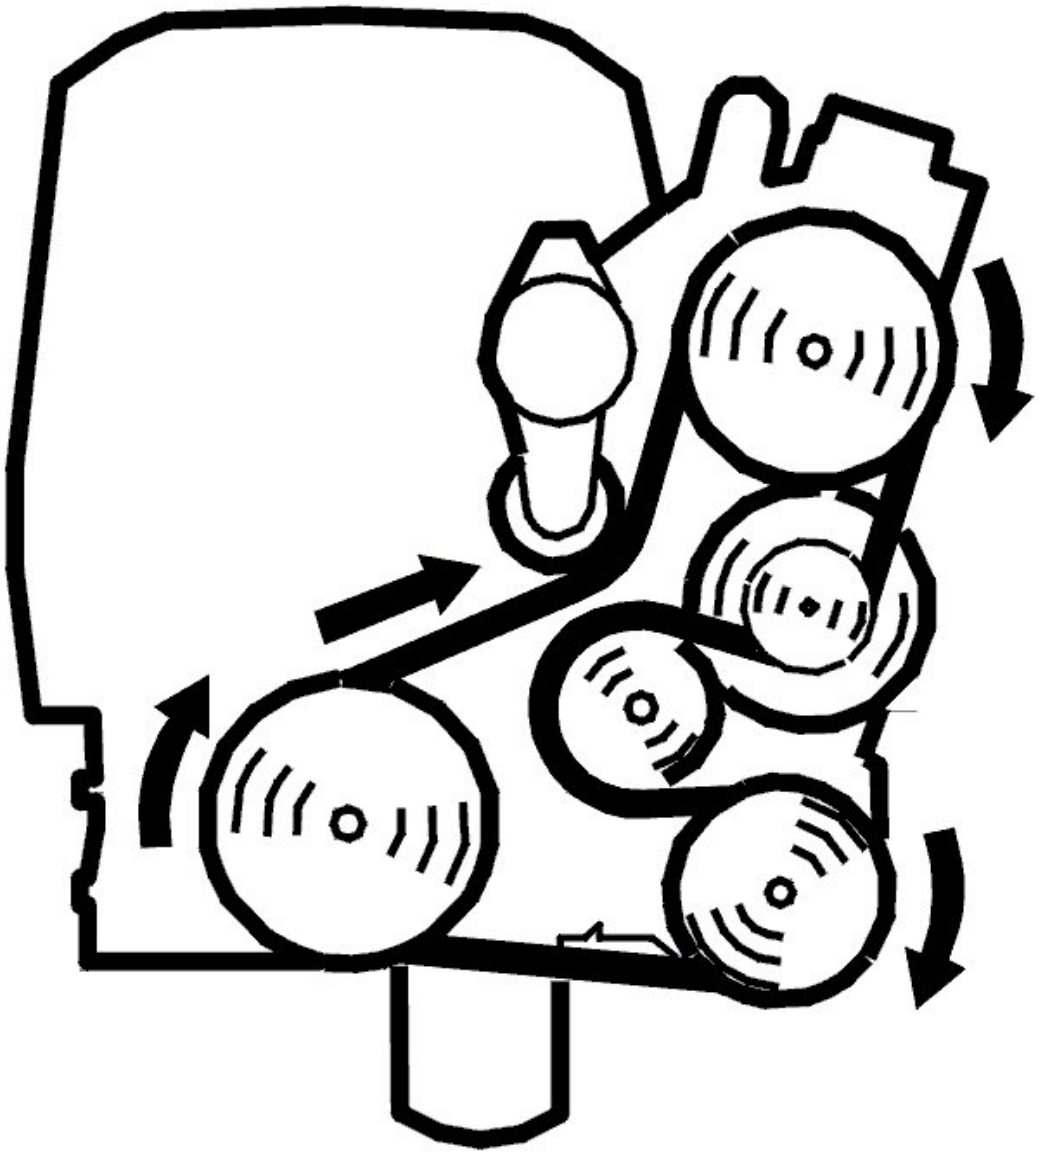
Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

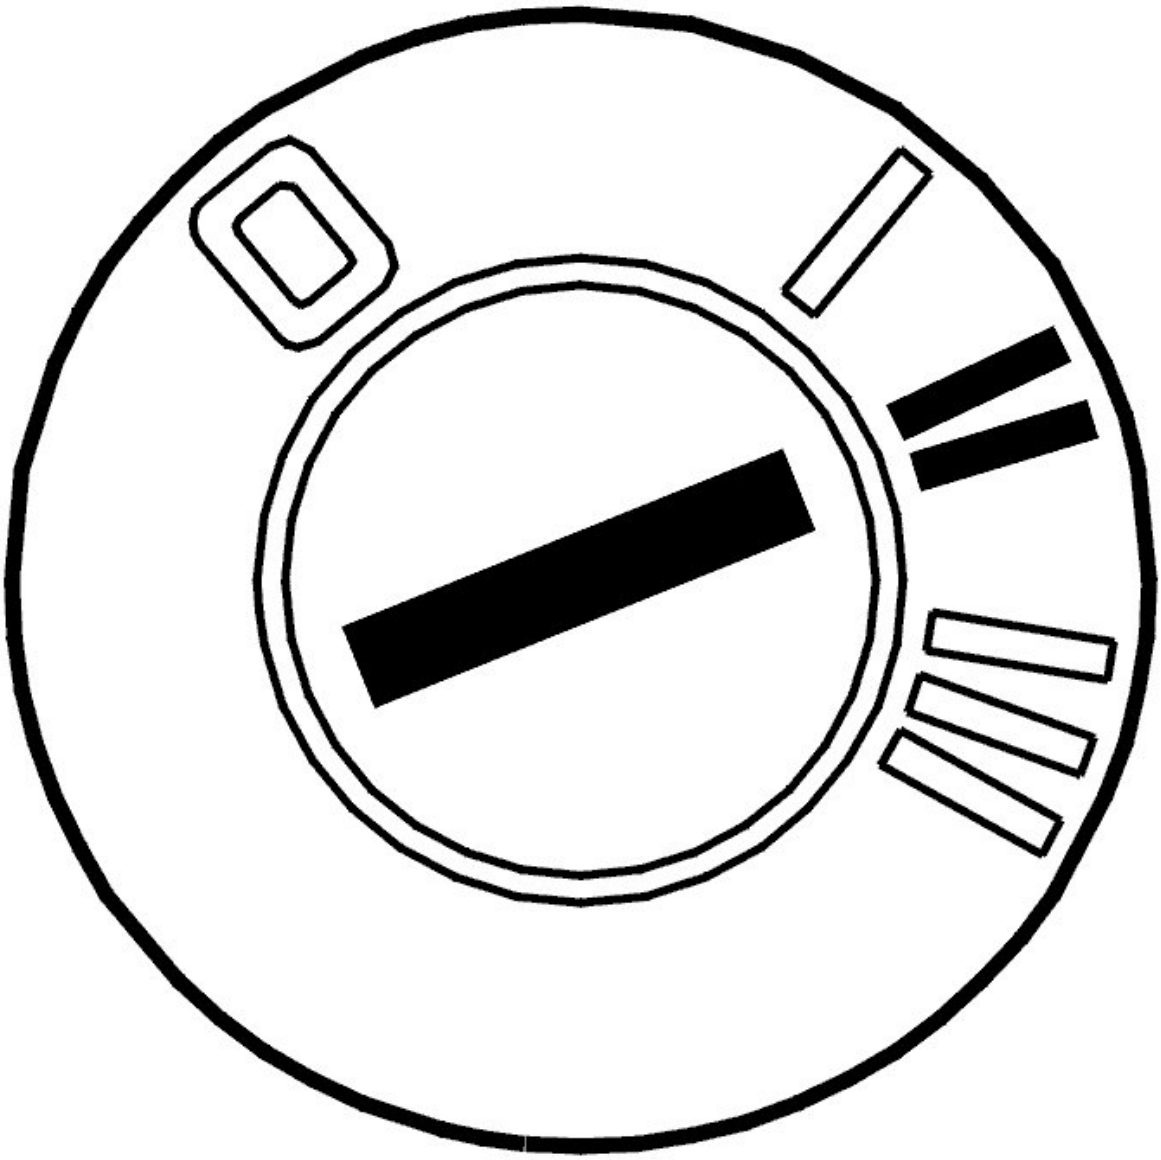


Continue - Verification

Verification

Hint: After rectifying a fault, a verification should be carried out.





- Reinstall the connectors, components etc.
- Ignition on.

Note! For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

- Erase diagnostic trouble codes (DTCs) in all control modules.
- Ignition off.
- Ignition on.
- Start the vehicle. Allow the vehicle to run for 10 minutes.
- Read out the diagnostic trouble codes in the vehicle via the DIAGNOSTICS tab.

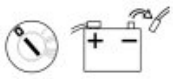
Checking short-circuiting to ground/voltage in CAN-net



- Ignition off.
- Disconnect the battery negative lead.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Checking for a short-circuit to ground

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #6 and #4 (ground). Measurement is shown in the figure. The resistance should be above 1 kohms.
- #14 and #4 (ground). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and ground.

Checking for a short-circuit to voltage

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #6 and #16 (voltage). Measurement is shown in the figure. The resistance should be above 1 kohms.
- #14 and #16 (voltage). The resistance should be above 1 kohms.

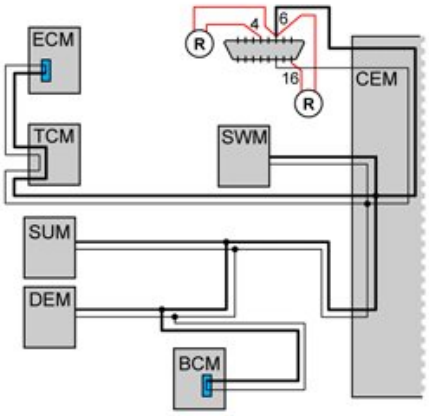
If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and voltage cable.
Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

Hint: Part the CAN-net at suitable points to decide where a short-circuit may be found.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy wiring as necessary.

Other information
- Battery, disconnecting See: Starting and Charging/Battery/Service and Repair/Procedures/Battery, Disconnecting
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

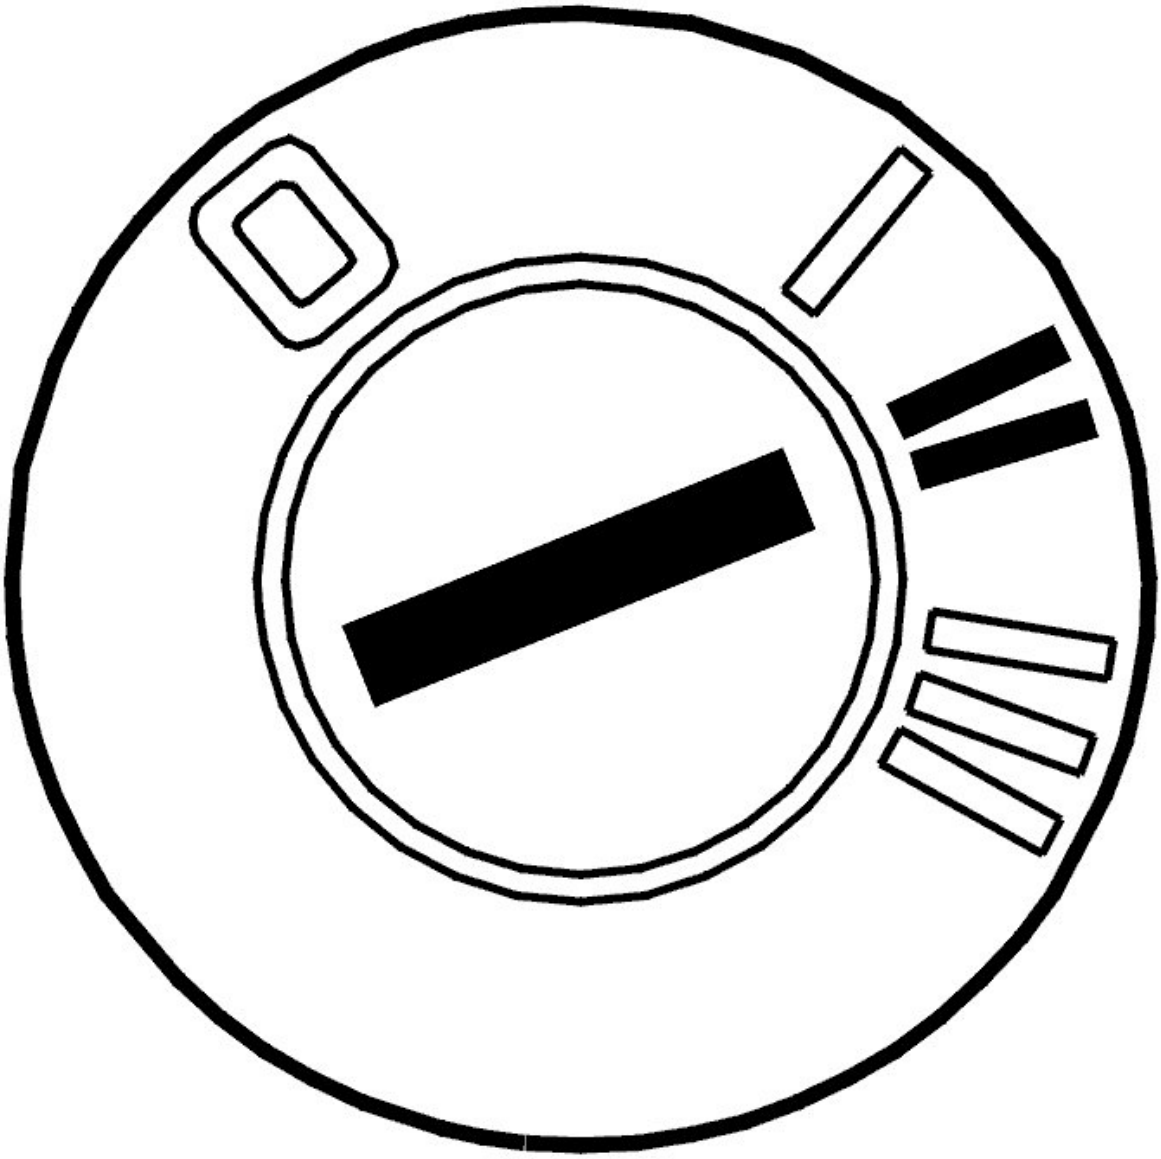


Was a fault detected?

Yes - Verification

No - Checking the traffic load on the CAN cables

Checking voltage-drop in cable for CAN-H and CAN-L, respectively



- Connect the battery.
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

In principle, the voltage measured in each cable in the CAN-net shall be the same at each control module in the network. This means that the voltage-drop in the cable for CAN-H and CAN-L, respectively, between the control modules should be very low. If there is a voltage-difference in the CAN-lines between the diagnostics socket/Central electronic module (CEM) and a control module due to, e.g., contact resistance in a connector or branching, communication may be lost/interfered with.
Check if there is voltage-drop in the cable for CAN-H and CAN-L between the diagnostics socket/Central electronic module (CEM) and the control module where there is problem with communication.
Carry out the following:
Measure voltage between the following connections on the OBDII-box/diagnostics socket.
- #6 and corresponding connection on relevant control module for CAN-H. The voltage shall be lower than 50 mV.
- #14 and corresponding connection on relevant control module for CAN-L. The voltage shall be lower than 50 mV.

If voltage is too high, this indicates too high contact resistance in cable, connector, or branching. Check the circuit between the diagnostics socket and control module in question for contact resistance and oxidation.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy wiring as necessary.

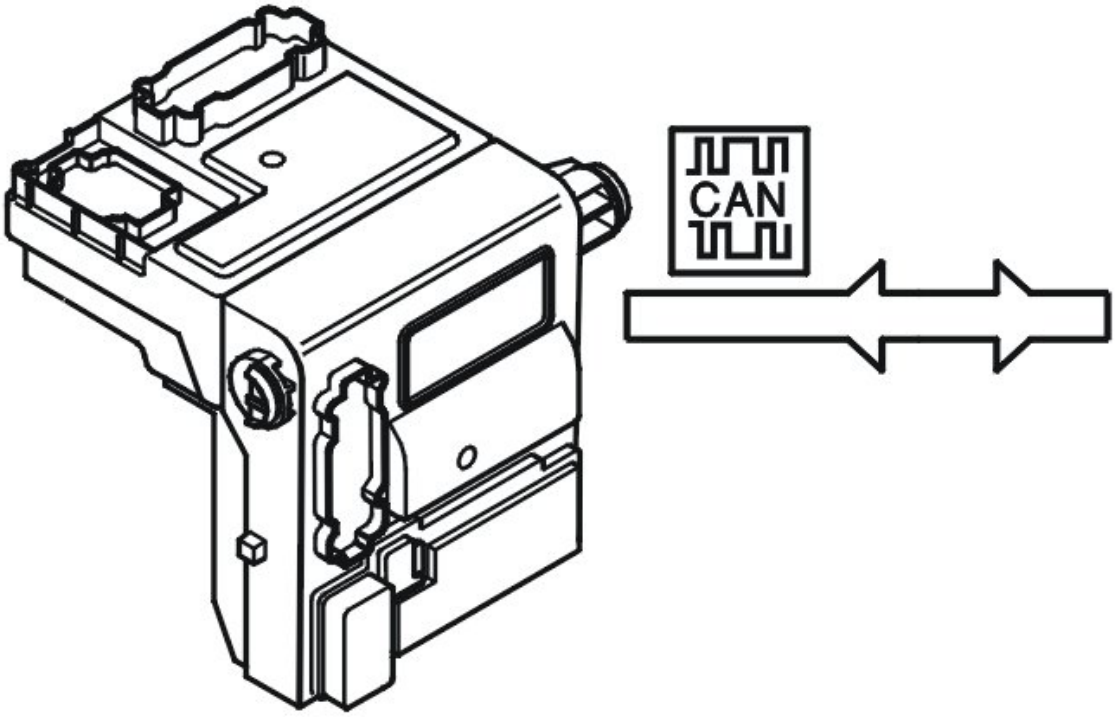
Continue - Verification

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CEM-DF15

Condition



The central electronic module (CEM) checks the voltage in the CAN wiring in the high speed network. The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers a short-circuit to ground in the CAN H in the high speed network.

Note! If DFxx diagnostic trouble codes (DTCs) are stored the central electronic module (CEM) must not be replaced as the diagnostic trouble code (DTC) indicates a short-circuit in one or more conductors in the Control area network. The central electronic module (CEM) is the only control module that monitors the voltage level in the Control area network wiring. The central electronic module (CEM) is therefore the only control module that can store a diagnostic trouble code (DTC) for a short-circuit in one of the cables to ground or supply voltage. Do not replace the central electronic module (CEM) in the event of a CAN fault unless VIDA fault-tracing has indicated that the central electronic module (CEM) has an internal fault.

The diagnostic trouble code (DTC) can be diagnosed when the ignition has been on for more than 10 seconds.

Substitute value
- None.

Possible source
- Short-circuit to ground in the high speed network.

Fault symptom[s]
- The engine does not start.
- Engine cuts out when running
- Malfunction indicator lamp (MIL) lit.
- Message in the display.

General information

Note! Figures shown are only examples.

Hint: For general information about CAN-troubleshooting, see:
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

General about CAN-related diagnostic trouble codes.
CEM-DF01 - DF17can only be stored in Central electronic module (CEM). These diagnostic trouble codes are stored when an electric fault is detected in CAN-lines. Start with these diagnostic trouble codes first.

CEM-1AXX only stored in Central electronic module (CEM). One diagnostic trouble code for every control module on the CAN-net. These diagnostic trouble codes indicate that Central electronic module (CEM) does not receive any reply from other control modules.
XXX-E000 (HS-CAN)/E001 (LS-CAN) can be stored in all CAN-connected control modules. These diagnostic trouble codes indicate that the control module has detected interference on the CAN-net.
XXX-E003 can be stored in all CAN-connected control modules except in Central electronic module (CEM). The control modules on the CAN-net listen for a message (identity number) that is sent out at regular intervals from Central electronic module (CEM). This diagnostic trouble code indicates that the control module has not received any identity number, or that the expected number is not correct. Interference on the CAN-net can also store this diagnostic trouble code.

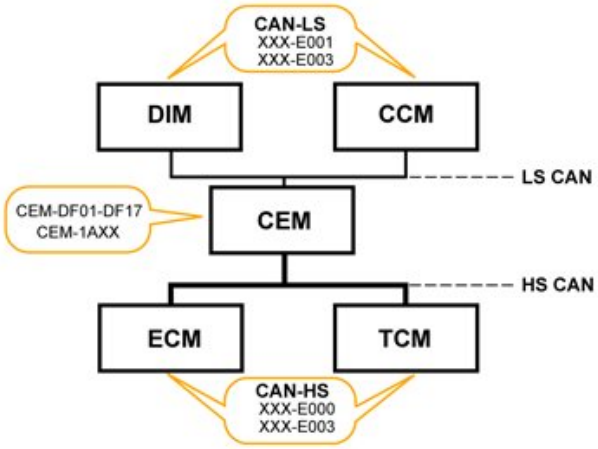
Note! In case of CAN-related faults, it is likely that a combination of above diagnostic trouble codes occur.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

If a communication diagnostic trouble code can be read from the control module, the malfunction is probably intermittent.
Intermittent fault in the voltage supply and ground to a control module on the CAN network results in the Central electronic module (CEM) storing a diagnostic trouble code (DTC) for an open-circuit in communication with the control module where the voltage supply does not work. There will probably not be a diagnostic trouble code (DTC) in the control module where the open-circuit in the voltage supply occurred as the control module cannot store a diagnostic trouble code (DTC) when it is not supplied with power.

Note! Central electronic module (CEM) should not be replaced in case of CAN-fault, unless troubleshooting reveals that Central electronic module (CEM) has an internal fault.

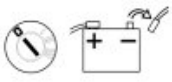
Caution! During this fault-tracing use the wiring diagram to provide support when taking readings.



Select "Continue".

Continue - Checking resistance in CAN-net

Checking resistance in CAN-net



- Ignition off
- Disconnect the battery negative lead
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #6 and #14. The resistance should be approx. 55 - 65 ohms.
- If resistance is approx. 120 ohms, this indicates open circuit in the circuit so that only one terminating resistor (120 ohms) has been

measured.

- If resistance is above 1 kohms this indicates open circuit/high contact resistance somewhere in the circuit.
- If resistance is below 55 ohms this indicates short-circuiting/contact resistance between the CAN-lines somewhere in the circuit.

Hint: For HS-CAN (High Speed) the terminating resistors are located in Brake control module (BCM) and in Engine control module (ECM).

Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

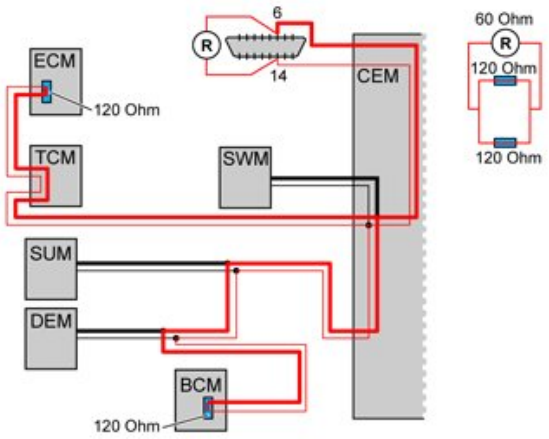
Note! Resistance measurement measures only main lines in the CAN-net (in circuit where both terminating resistors are found), not branches to certain control modules. See wiring diagram for vehicle model in question.Open circuit on branching without a terminating resistor cannot be detected with this measurement. However, short-circuiting on a branch can be detected. To measure resistance in the CAN-net to control modules located in a branching of their own, the measurement shall be done against the CAN-net at that control module. The values shall be as above.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy wiring as necessary.

Other information

- Battery, disconnecting See: Starting and Charging/Battery/Service and Repair/Procedures/Battery, Disconnecting
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

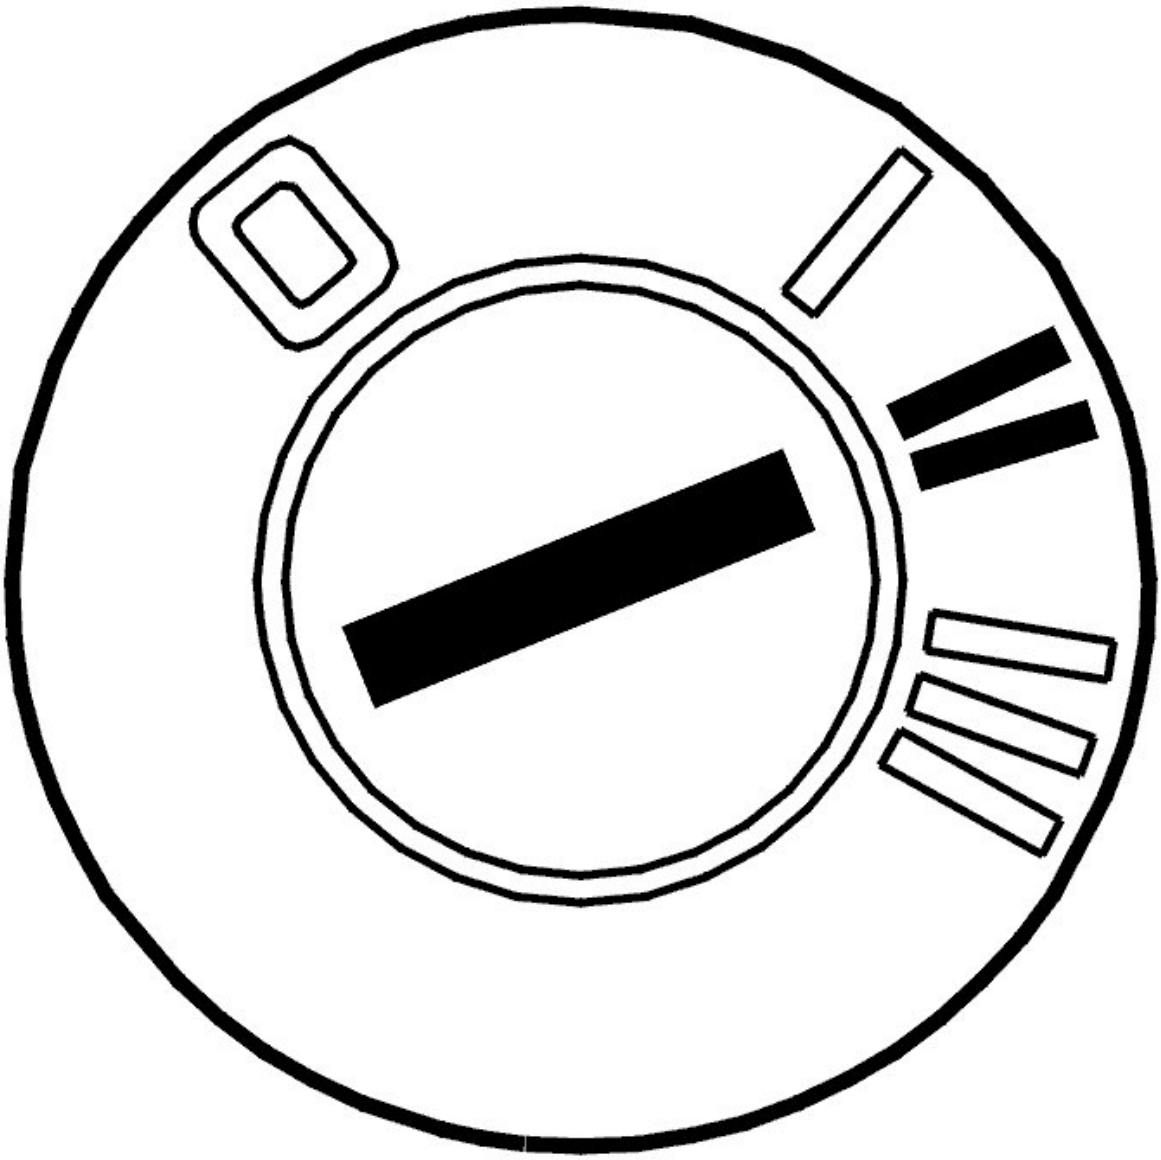


Was a fault detected?

Yes - Verification

No - Checking short-circuiting to ground/voltage in CAN-net

Checking the traffic load on the CAN cables



- Connect the battery
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Faults in the CAN network may be due to a control module sending faulty messages that disrupt normal communication. When messages are sent incorrectly, this results in a considerable increase in the amount of traffic on the CAN network. Check the load by measuring the average voltage value on the CAN cables in relation to ground.
For further information, see the wiring diagram.
Measure voltage between the following connections on the OBDII-box/diagnostics socket.
- #6 and #4 (ground). The voltage should be approx: 2,8 - 3,2 V.
- #14 and #4 (ground). The voltage should be approx: 1,8 - 2,2 V.
- #6 and #14. The voltage shall be between approx. 0.55-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Hint: DiCE Error Frame Finder can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools: **951 3010** (memory card) as well as associated TJ 20402.

- Ignition on.
- Connect DiCE Error Frame Finder to the diagnostics socket.
- Note the blue LED-indicator. The indicator flashes to show detection of fault messages.

Note! Certain interference may occur without any real fault!

Cable fault

- Shake the cables lightly and pull lightly on the connections during the check to locate any fault. Note the blue LED-indicator.

"Chatting" control modules

- "Chatting" control modules may be difficult to find and troubleshooting may take time. Let the vehicle stand with DiCE connected for an extended time period. Afterwards, activate functions to provoke a malfunction. It may take up to several hours before the fault messages are sent. When the indicator starts to flash, remove the fuse for one control module at a time until the indicator stops flashing. When the indicator stops flashing, restore the fuse for the relevant control module and check that the indicator starts to flash again. Then it is likely that the problem is identified.

Remedy wiring as necessary.

Other information

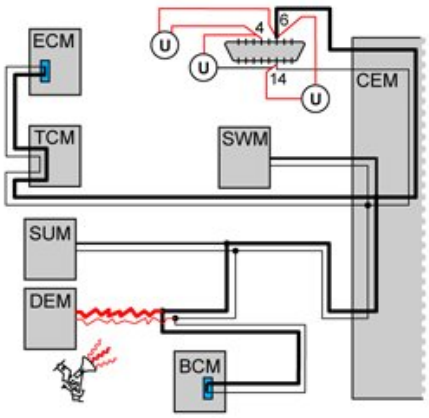
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

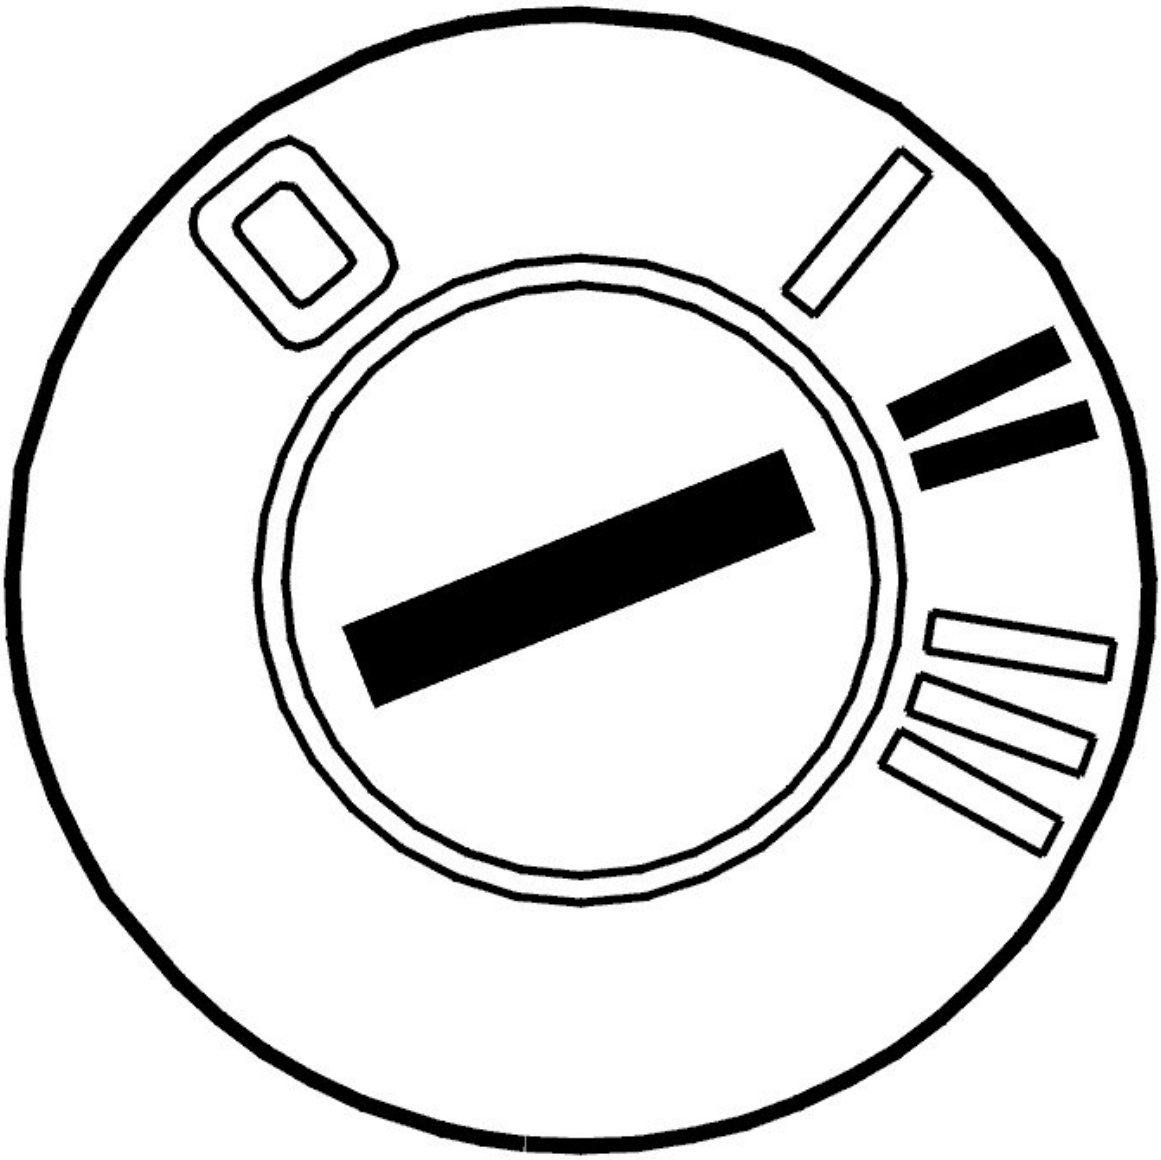


Was a fault detected?

Yes - Identifying a control module in the CAN network

No - respectively

Identifying a control module in the CAN network



Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:

- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Hint: DiCE Error Frame Finder can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools: **951 3010** (memory card) as well as associated TJ 20402.

If the load on the CAN network is too high, this may be due to a control module sending faulty messages on the CAN network (known as a disruptive control module). The fault may also be due to an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The faults can occur without a diagnostic trouble code (DTC) being stored by the control modules. The voltage can be measured between the CAN cables in order to check the load on the CAN network.

Note! It is not necessarily the control module(s) that stored the diagnostic trouble code (DTC) that is communicating faultily. Faulty messages can come from any control module in the same section of the CAN network. However, faulty communication in one network cannot affect the communication on the other network. In other words, faulty communication on the LS-CAN cannot disrupt communication on the HS-CAN and vice versa.

- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Check communication/load on CAN-net by measuring voltage between CAN-L and CAN-H. Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #6 and #14. The average value of the voltage must be approximately 0.6-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

In order to identify which control module has faulty communication, cut the power supply to one control module at a time. Check the voltage in the

CAN cables again. The easiest way to cut the power supply is to remove the fuse(s) for the relevant control module. Repeat until the voltage between the CAN wiring drops to the normal level.

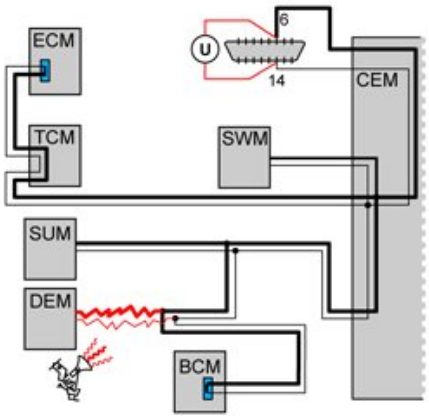
Note! When connecting and disconnecting individual control modules, other diagnostic trouble codes (DTCs) may be stored in certain control modules.

Hint: When the suspected defective control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the malfunction appears and disappears. Switch off the ignition between each check.

Note! Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.

A control module that is communicating incorrectly must be replaced. See Repairing and installing/Removing, replacing and installing.

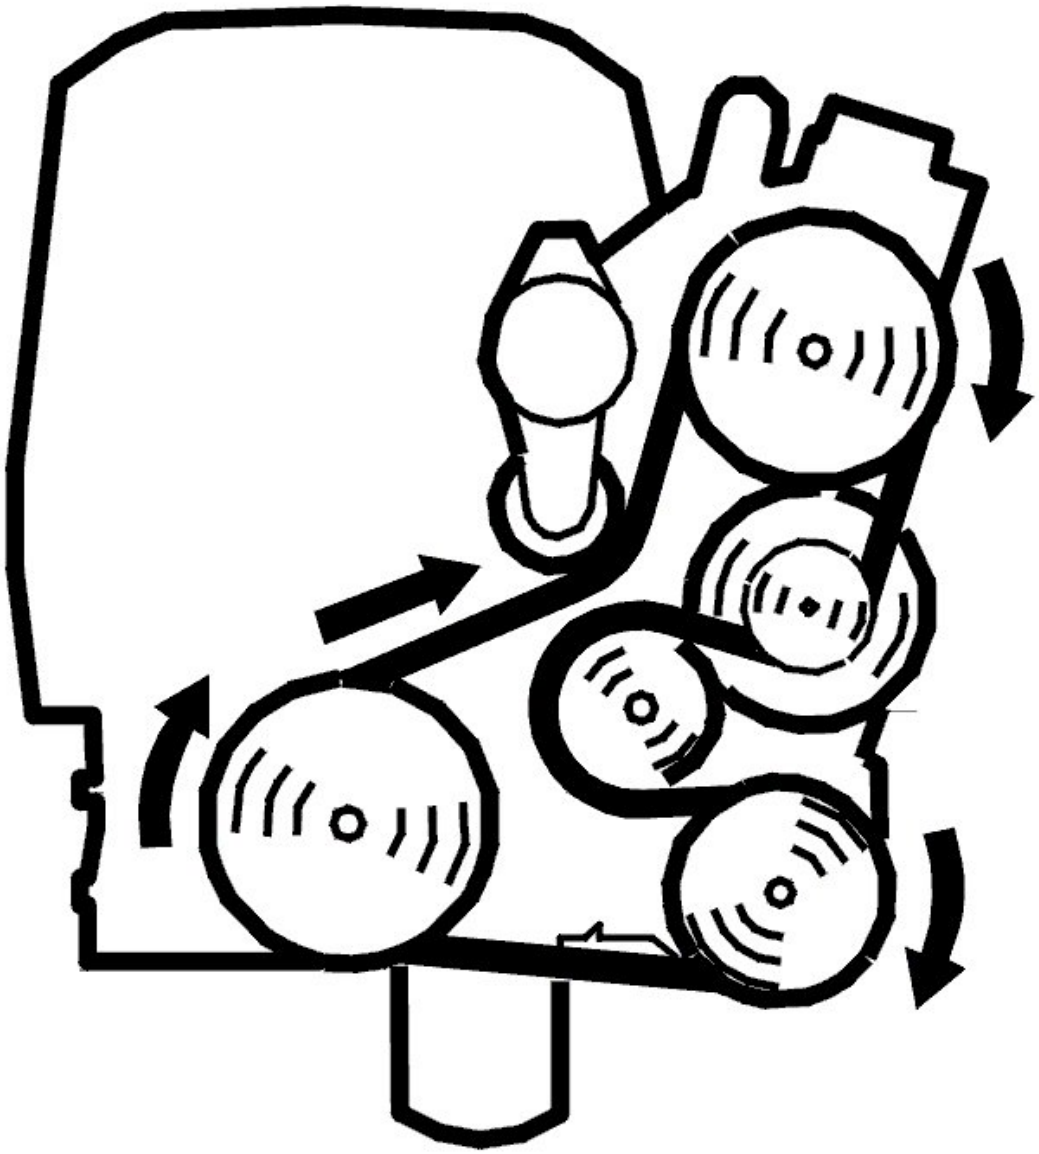
Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

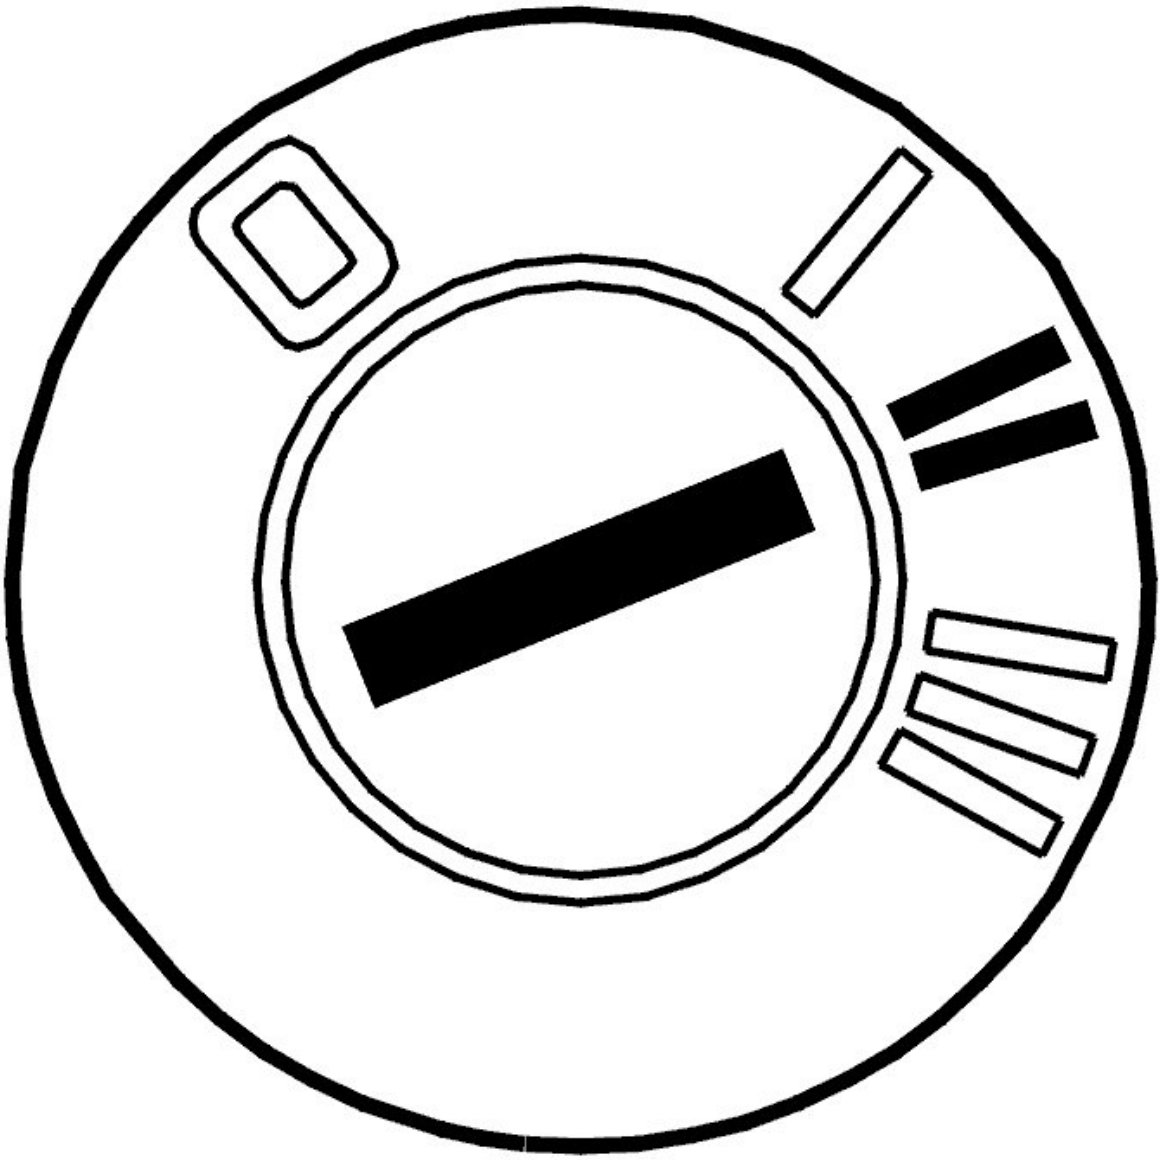


Continue - Verification

Verification

Hint: After rectifying a fault, a verification should be carried out.





- Reinstall the connectors, components etc.
- Ignition on.

Note! For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

- Erase diagnostic trouble codes (DTCs) in all control modules.
- Ignition off.
- Ignition on.
- Start the vehicle. Allow the vehicle to run for 10 minutes.
- Read out the diagnostic trouble codes in the vehicle via the DIAGNOSTICS tab.

Does the diagnostic trouble code (DTC) for faulty communication return?

Yes - Fault-tracing information

No - Fault Found

Fault-tracing information

Information

Fault-tracing information

The fault should have been detected and remedied. As this is not the case fault-tracing has failed.
Exit fault-tracing for this diagnostic trouble code (DTC) or make another attempt.

Do you want to exit fault-tracing?

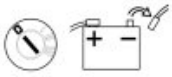
No - Attempt New Test

FAULT-TRACING FAILED - FAULT-TRACING FAILED

Attempt New Test - General information

Checking short-circuiting to ground/voltage in CAN-net



- Ignition off.
- Disconnect the battery negative lead.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Checking for a short-circuit to ground

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #6 and #4 (ground). Measurement is shown in the figure. The resistance should be above 1 kohms.
- #14 and #4 (ground). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and ground.

Checking for a short-circuit to voltage

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #6 and #16 (voltage). Measurement is shown in the figure. The resistance should be above 1 kohms.
- #14 and #16 (voltage). The resistance should be above 1 kohms.

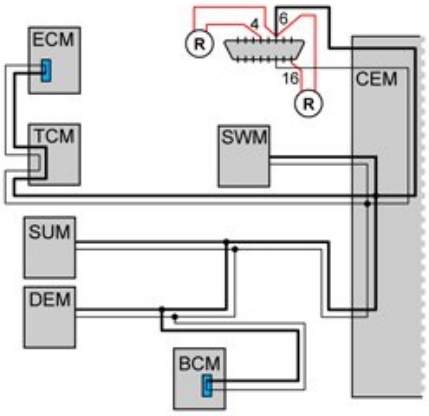
If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and voltage cable.
Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

Hint: Part the CAN-net at suitable points to decide where a short-circuit may be found.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy wiring as necessary.

Other information
- Battery, disconnecting See: Starting and Charging/Battery/Service and Repair/Procedures/Battery, Disconnecting
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

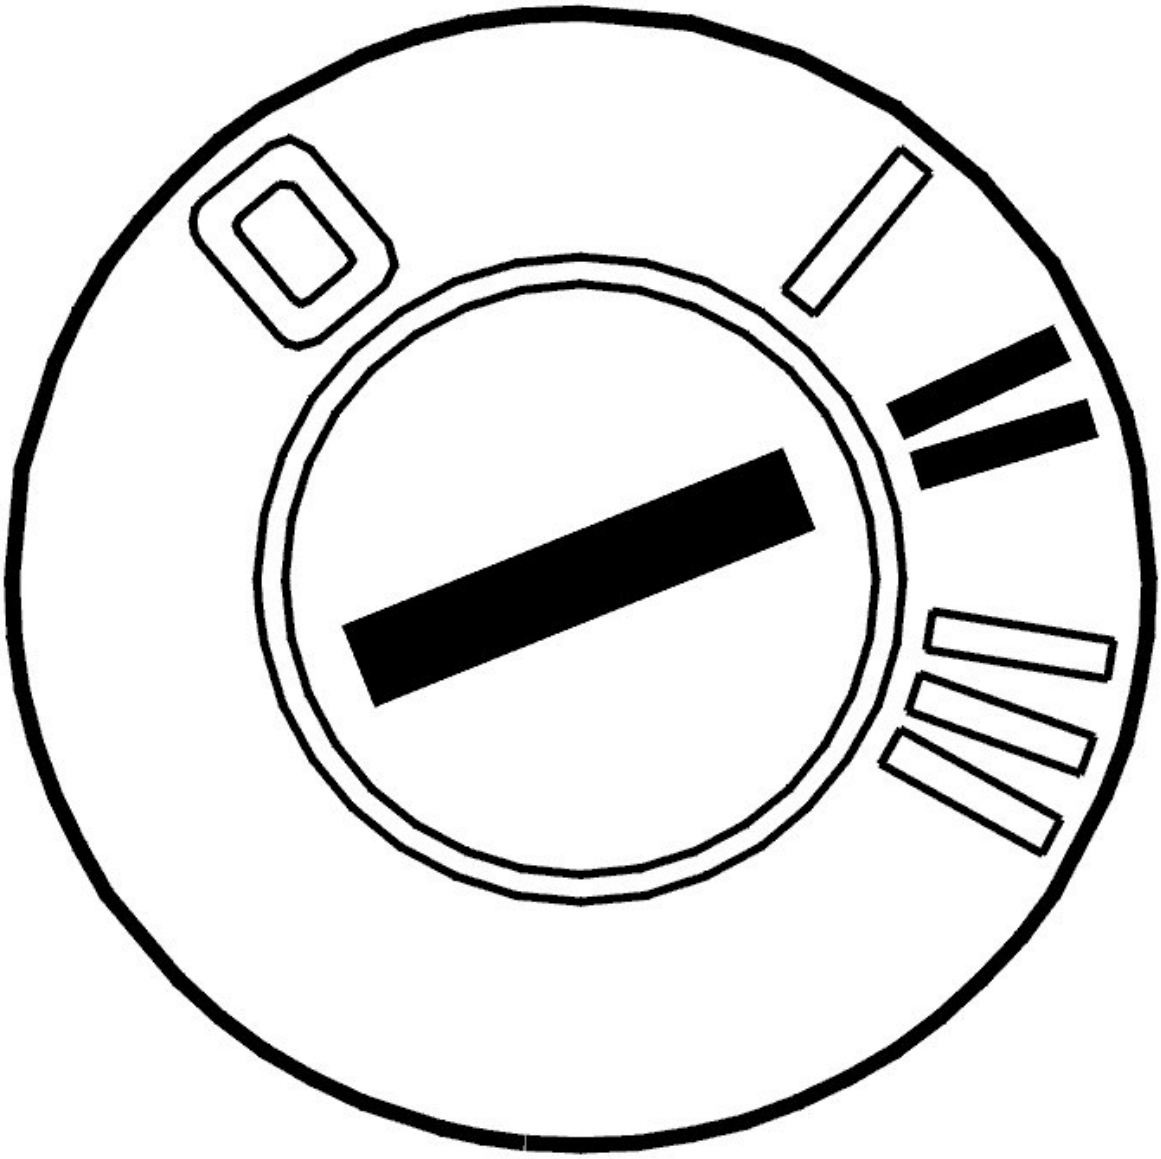


Was a fault detected?

Yes - Verification

No - Checking the traffic load on the CAN cables

Checking voltage-drop in cable for CAN-H and CAN-L, respectively



- Connect the battery.
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

In principle, the voltage measured in each cable in the CAN-net shall be the same at each control module in the network. This means that the voltage-drop in the cable for CAN-H and CAN-L, respectively, between the control modules should be very low. If there is a voltage-difference in the CAN-lines between the diagnostics socket/Central electronic module (CEM) and a control module due to, e.g., contact resistance in a connector or branching, communication may be lost/interfered with.
Check if there is voltage-drop in the cable for CAN-H and CAN-L between the diagnostics socket/Central electronic module (CEM) and the control module where there is problem with communication.
Carry out the following:
Measure voltage between the following connections on the OBDII-box/diagnostics socket.
- #6 and corresponding connection on relevant control module for CAN-H. The voltage shall be lower than 50 mV.
- #14 and corresponding connection on relevant control module for CAN-L. The voltage shall be lower than 50 mV.

If voltage is too high, this indicates too high contact resistance in cable, connector, or branching. Check the circuit between the diagnostics socket and control module in question for contact resistance and oxidation.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy wiring as necessary.

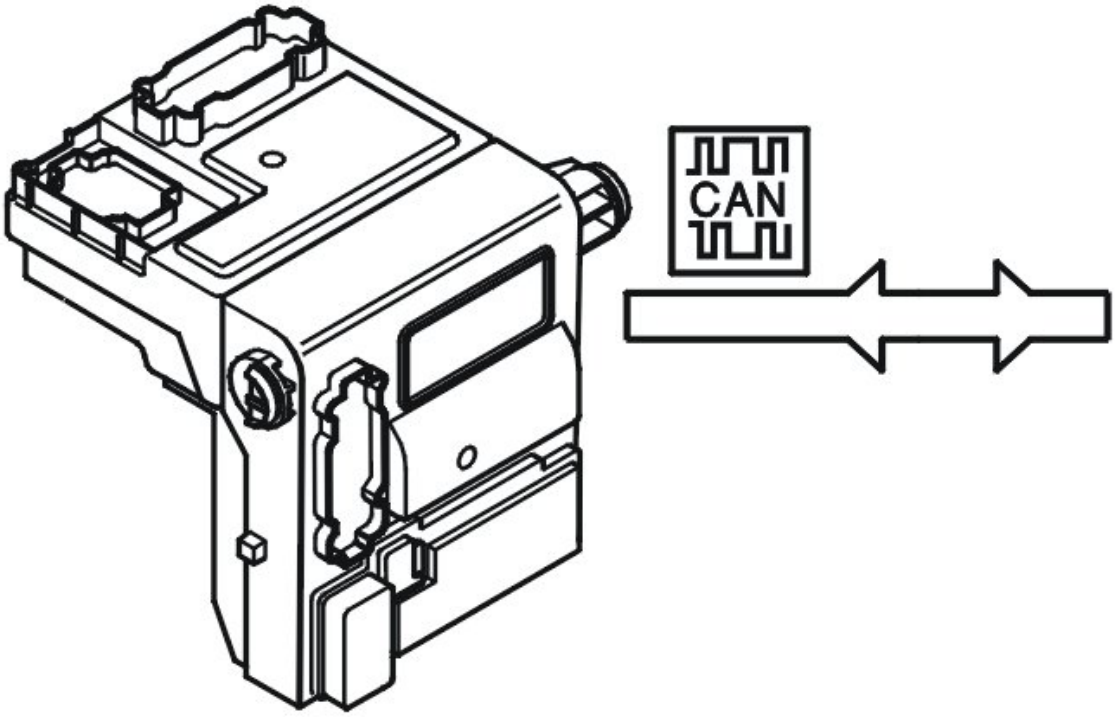
Continue - Verification

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CEM-DF16

Condition



The central electronic module (CEM) checks the voltage in the CAN wiring in the high speed network. The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers a short-circuit to supply voltage in the CAN L in the high speed network.

Note! If DFxx diagnostic trouble codes (DTCs) are stored the central electronic module (CEM) must not be replaced as the diagnostic trouble code (DTC) indicates a short-circuit in one or more conductors in the Control area network. The central electronic module (CEM) is the only control module that monitors the voltage level in the Control area network wiring. The central electronic module (CEM) is therefore the only control module that can store a diagnostic trouble code (DTC) for a short-circuit in one of the cables to ground or supply voltage. Do not replace the central electronic module (CEM) in the event of a CAN fault unless VIDA fault-tracing has indicated that the central electronic module (CEM) has an internal fault.

The diagnostic trouble code (DTC) can be diagnosed when the ignition has been on for more than 10 seconds.

Substitute value
- None.

Possible source
- Short-circuit to supply voltage in the high speed network.

Fault symptom[s]
- The engine does not start.
- Engine cuts out when running
- Malfunction indicator lamp (MIL) lit.
- Message in the display.

Signal Missing

Signal missing

General information

Note! Figures shown are only examples.

Hint: For general information about CAN-troubleshooting, see:
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

General about CAN-related diagnostic trouble codes.
CEM-DF01 - DF17can only be stored in Central electronic module (CEM). These diagnostic trouble codes are stored when an electric fault is detected in CAN-lines. Start with these diagnostic trouble codes first.

CEM-1AXX only stored in Central electronic module (CEM). One diagnostic trouble code for every control module on the CAN-net. These diagnostic trouble codes indicate that Central electronic module (CEM) does not receive any reply from other control modules.
XXX-E000 (HS-CAN)/E001 (LS-CAN) can be stored in all CAN-connected control modules. These diagnostic trouble codes indicate that the control module has detected interference on the CAN-net.
XXX-E003 can be stored in all CAN-connected control modules except in Central electronic module (CEM). The control modules on the CAN-net listen for a message (identity number) that is sent out at regular intervals from Central electronic module (CEM). This diagnostic trouble code indicates that the control module has not received any identity number, or that the expected number is not correct. Interference on the CAN-net can also store this diagnostic trouble code.

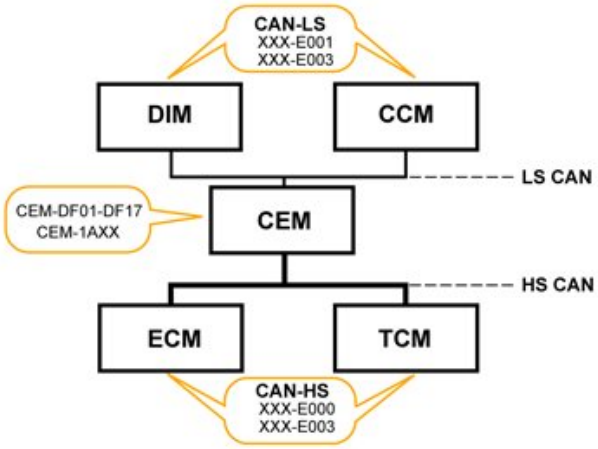
Note! In case of CAN-related faults, it is likely that a combination of above diagnostic trouble codes occur.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

If a communication diagnostic trouble code can be read from the control module, the malfunction is probably intermittent.
Intermittent fault in the voltage supply and ground to a control module on the CAN network results in the Central electronic module (CEM) storing a diagnostic trouble code (DTC) for an open-circuit in communication with the control module where the voltage supply does not work. There will probably not be a diagnostic trouble code (DTC) in the control module where the open-circuit in the voltage supply occurred as the control module cannot store a diagnostic trouble code (DTC) when it is not supplied with power.

Note! Central electronic module (CEM) should not be replaced in case of CAN-fault, unless troubleshooting reveals that Central electronic module (CEM) has an internal fault.

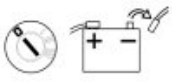
Caution! During this fault-tracing use the wiring diagram to provide support when taking readings.



Select "Continue".

Continue - Checking resistance in CAN-net

Checking resistance in CAN-net



- Ignition off
- Disconnect the battery negative lead
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #6 and #14. The resistance should be approx. 55 - 65 ohms.
- If resistance is approx. 120 ohms, this indicates open circuit in the circuit so that only one terminating resistor (120 ohms) has been

measured.

- If resistance is above 1 kohms this indicates open circuit/high contact resistance somewhere in the circuit.
- If resistance is below 55 ohms this indicates short-circuiting/contact resistance between the CAN-lines somewhere in the circuit.

Hint: For HS-CAN (High Speed) the terminating resistors are located in Brake control module (BCM) and in Engine control module (ECM).

Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

Note! Resistance measurement measures only main lines in the CAN-net (in circuit where both terminating resistors are found), not branches to certain control modules. See wiring diagram for vehicle model in question.Open circuit on branching without a terminating resistor cannot be detected with this measurement. However, short-circuiting on a branch can be detected. To measure resistance in the CAN-net to control modules located in a branching of their own, the measurement shall be done against the CAN-net at that control module. The values shall be as above.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy wiring as necessary.

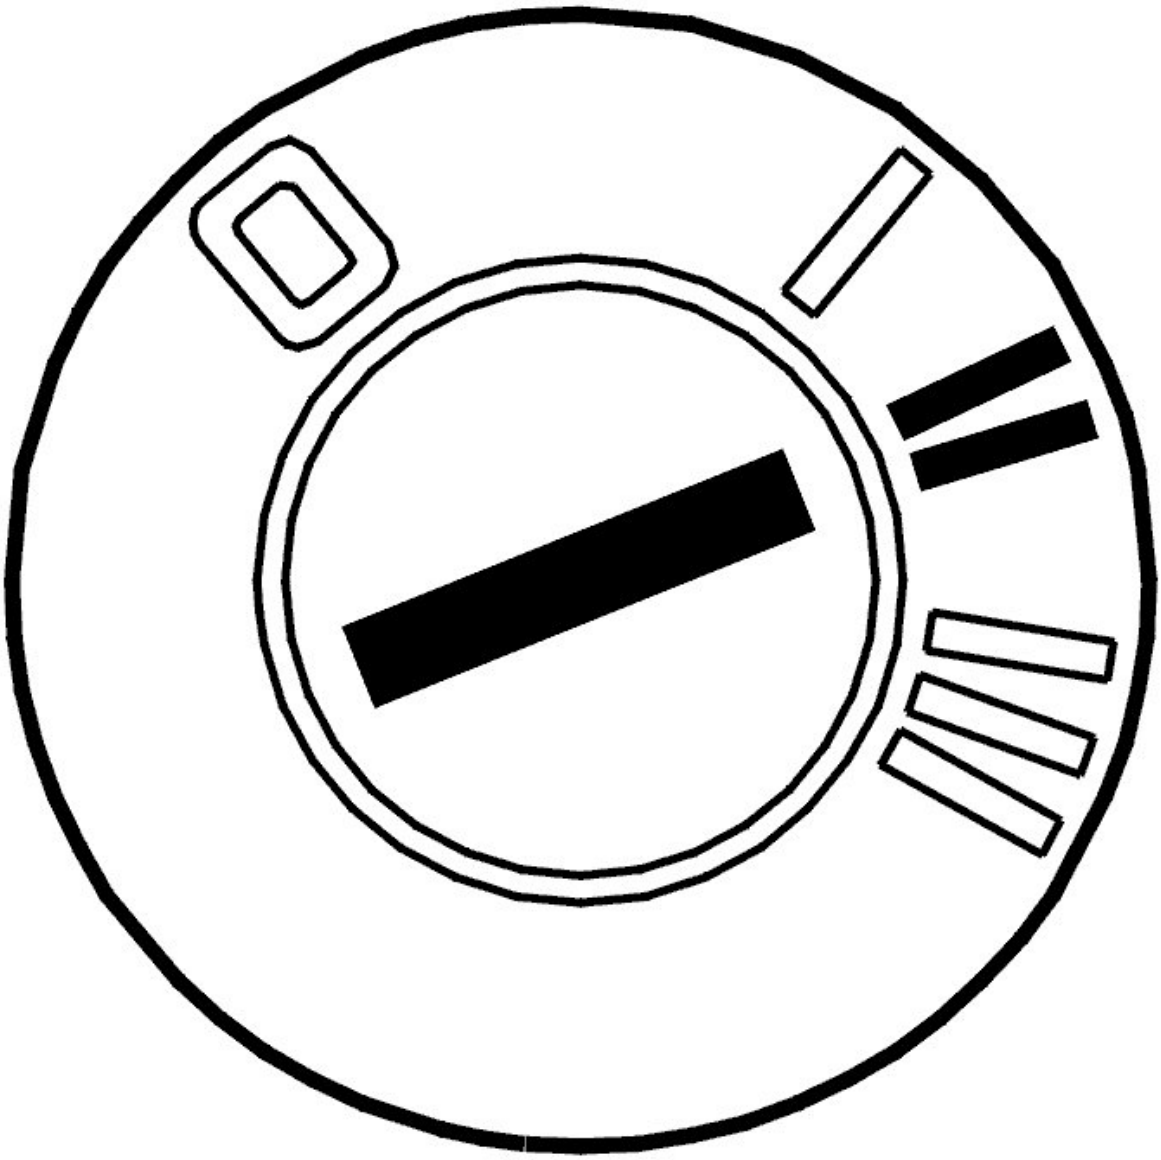
Was a fault detected?

Yes - Verification

No - Checking short-circuiting to ground/voltage in CAN-net

Checking the traffic load on the CAN cables



- Connect the battery
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Faults in the CAN network may be due to a control module sending faulty messages that disrupt normal communication. When messages are sent incorrectly, this results in a considerable increase in the amount of traffic on the CAN network. Check the load by measuring the average voltage value on the CAN cables in relation to ground.
For further information, see the wiring diagram.
Measure voltage between the following connections on the OBDII-box/diagnostics socket.
- #6 and #4 (ground). The voltage should be approx: 2,8 - 3,2 V.
- #14 and #4 (ground). The voltage should be approx: 1,8 - 2,2 V.
- #6 and #14. The voltage shall be between approx. 0.55-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Hint: DiCE Error Frame Finder can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools: **951 3010** (memory card) as well as associated TJ 20402.

- Ignition on.
- Connect DiCE Error Frame Finder to the diagnostics socket.
- Note the blue LED-indicator. The indicator flashes to show detection of fault messages.

Note! Certain interference may occur without any real fault!

Cable fault

- Shake the cables lightly and pull lightly on the connections during the check to locate any fault. Note the blue LED-indicator.

"Chatting" control modules

- "Chatting" control modules may be difficult to find and troubleshooting may take time. Let the vehicle stand with DiCE connected for an extended time period. Afterwards, activate functions to provoke a malfunction. It may take up to several hours before the fault messages are sent. When the indicator starts to flash, remove the fuse for one control module at a time until the indicator stops flashing. When the indicator stops flashing, restore the fuse for the relevant control module and check that the indicator starts to flash again. Then it is likely that the problem is identified.

Remedy wiring as necessary.

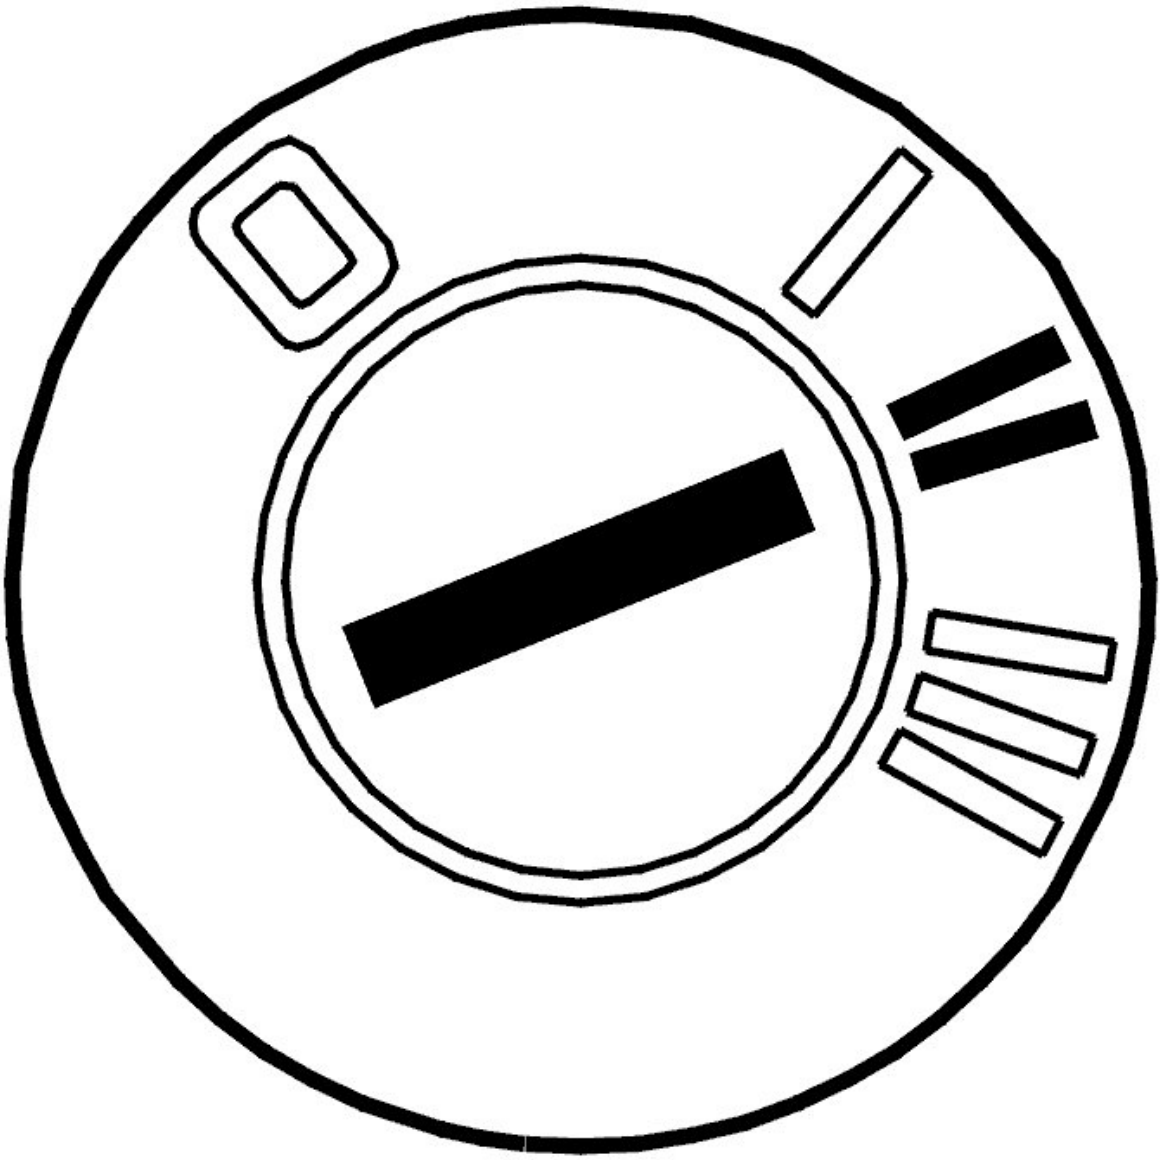
No - respectively

Identifying a control module in the CAN network



Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:

- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Hint: DiCE Error Frame Finder can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools: **951 3010** (memory card) as well as associated TJ 20402.

If the load on the CAN network is too high, this may be due to a control module sending faulty messages on the CAN network (known as a disruptive control module). The fault may also be due to an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The faults can occur without a diagnostic trouble code (DTC) being stored by the control modules. The voltage can be measured between the CAN cables in order to check the load on the CAN network.

Note! It is not necessarily the control module(s) that stored the diagnostic trouble code (DTC) that is communicating faultily. Faulty messages can come from any control module in the same section of the CAN network. However, faulty communication in one network cannot affect the communication on the other network. In other words, faulty communication on the LS-CAN cannot disrupt communication on the HS-CAN and vice versa.

- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Check communication/load on CAN-net by measuring voltage between CAN-L and CAN-H. Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #6 and #14. The average value of the voltage must be approximately 0.6-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

In order to identify which control module has faulty communication, cut the power supply to one control module at a time. Check the voltage in the

CAN cables again. The easiest way to cut the power supply is to remove the fuse(s) for the relevant control module. Repeat until the voltage between the CAN wiring drops to the normal level.

Note! When connecting and disconnecting individual control modules, other diagnostic trouble codes (DTCs) may be stored in certain control modules.

Hint: When the suspected defective control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the malfunction appears and disappears. Switch off the ignition between each check.

Note! Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.

A control module that is communicating incorrectly must be replaced. See Repairing and installing/Removing, replacing and installing.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Checking for a short-circuit to ground

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #6 and #4 (ground). Measurement is shown in the figure. The resistance should be above 1 kohms.
- #14 and #4 (ground). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and ground.

Checking for a short-circuit to voltage

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #6 and #16 (voltage). Measurement is shown in the figure. The resistance should be above 1 kohms.
- #14 and #16 (voltage). The resistance should be above 1 kohms.

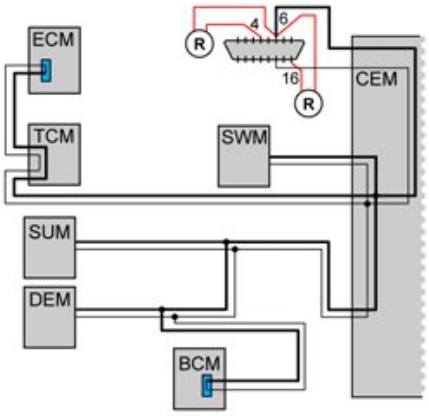
If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and voltage cable.
Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

Hint: Part the CAN-net at suitable points to decide where a short-circuit may be found.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy wiring as necessary.

Other information
- Battery, disconnecting See: Starting and Charging/Battery/Service and Repair/Procedures/Battery, Disconnecting
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

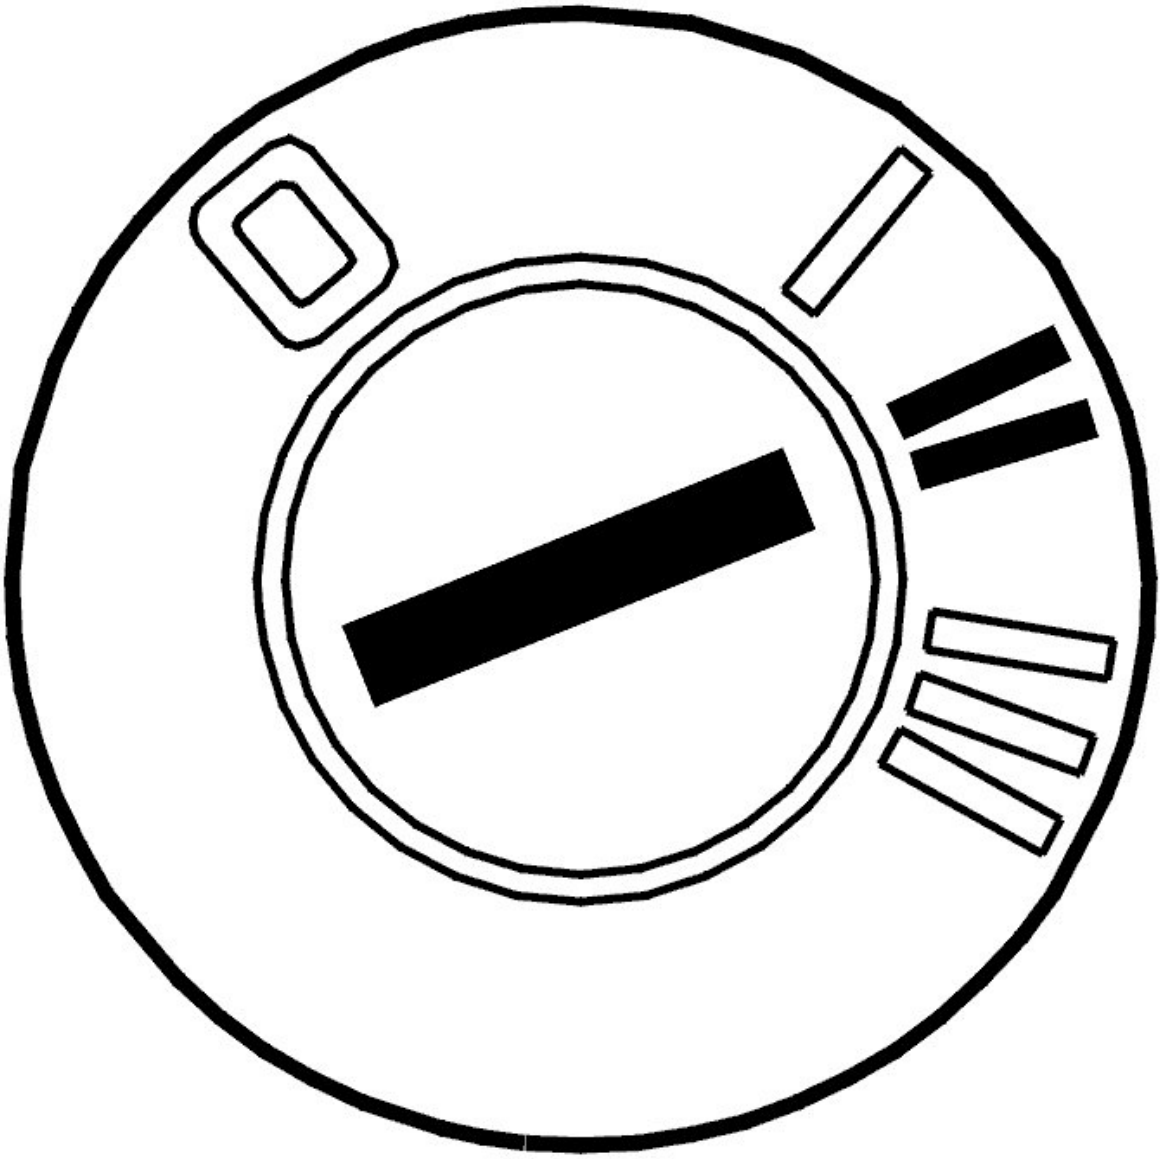


Was a fault detected?

Yes - Verification

No - Checking the traffic load on the CAN cables

Checking voltage-drop in cable for CAN-H and CAN-L, respectively



- Connect the battery.
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

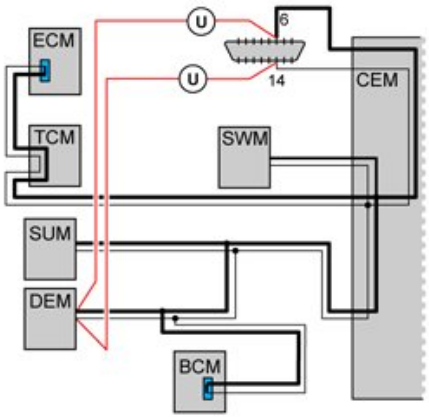
In principle, the voltage measured in each cable in the CAN-net shall be the same at each control module in the network. This means that the voltage-drop in the cable for CAN-H and CAN-L, respectively, between the control modules should be very low. If there is a voltage-difference in the CAN-lines between the diagnostics socket/Central electronic module (CEM) and a control module due to, e.g., contact resistance in a connector or branching, communication may be lost/interfered with.
Check if there is voltage-drop in the cable for CAN-H and CAN-L between the diagnostics socket/Central electronic module (CEM) and the control module where there is problem with communication.
Carry out the following:
Measure voltage between the following connections on the OBDII-box/diagnostics socket.
- #6 and corresponding connection on relevant control module for CAN-H. The voltage shall be lower than 50 mV.
- #14 and corresponding connection on relevant control module for CAN-L. The voltage shall be lower than 50 mV.

If voltage is too high, this indicates too high contact resistance in cable, connector, or branching. Check the circuit between the diagnostics socket and control module in question for contact resistance and oxidation.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy wiring as necessary.

Other information
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

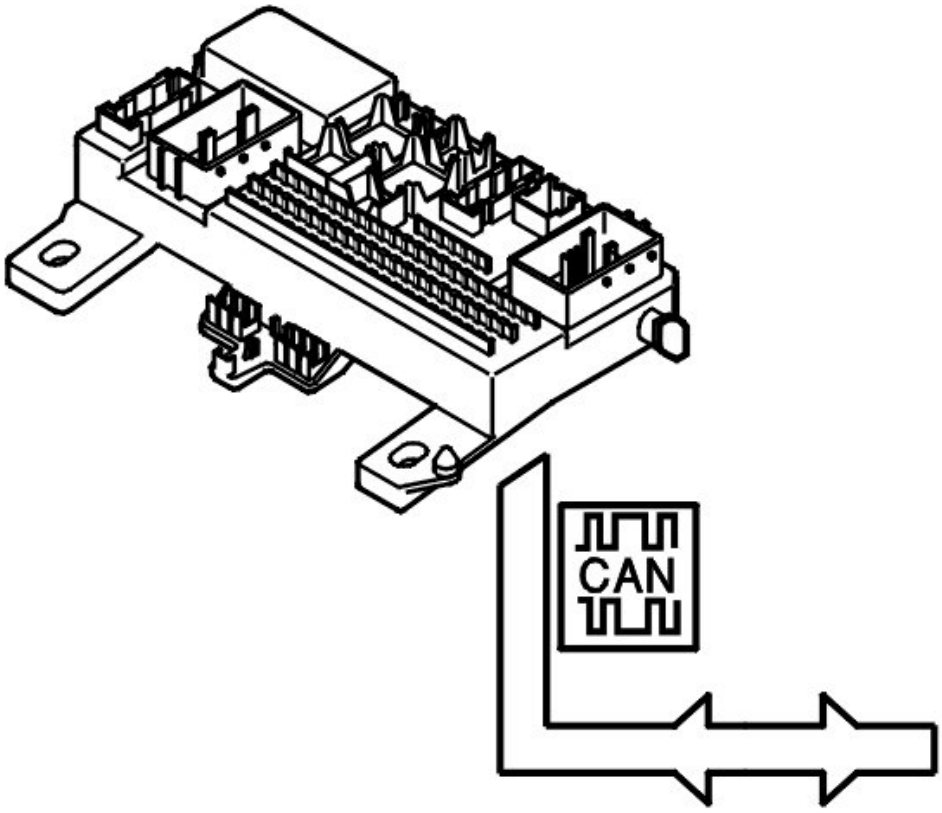


Continue - Verification

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CEM-DF17

Condition



The central electronic module (CEM) checks the voltage in CAN L and CAN H on the high speed network. The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers a short-circuit between CAN L and CAN H in the high speed network.

Note! If DFxx diagnostic trouble codes (DTCs) are stored the central electronic module (CEM) must not be replaced as the diagnostic trouble code (DTC) indicates a short-circuit in one or more conductors in the Control area network. The central electronic module (CEM) is the only control module that monitors the voltage level in the Control area network wiring. The central electronic module (CEM) is therefore the only control module that can store a diagnostic trouble code (DTC) for a short-circuit in one of the cables to ground or supply voltage. Do not replace the central electronic module (CEM) in the event of a CAN fault unless VIDA fault-tracing has indicated that the central electronic module (CEM) has an internal fault.

The diagnostic trouble code (DTC) can be diagnosed when the ignition has been on for more than 10 seconds.

Substitute value
- None.

Possible source
- Short-circuit between CAN L and CAN H in the high speed network.

Fault symptom[s]
- The engine does not start.
- The engine cuts out when driving.
- Malfunction indicator lamp (MIL) lit.
- Message in the display.

Signal Missing

Signal missing

General information

Note! Figures shown are only examples.

Hint: For general information about CAN-troubleshooting, see:
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

General about CAN-related diagnostic trouble codes.
CEM-DF01 - DF17can only be stored in Central electronic module (CEM). These diagnostic trouble codes are stored when an electric fault is detected in CAN-lines. Start with these diagnostic trouble codes first.

CEM-1AXX only stored in Central electronic module (CEM). One diagnostic trouble code for every control module on the CAN-net. These diagnostic trouble codes indicate that Central electronic module (CEM) does not receive any reply from other control modules.
XXX-E000 (HS-CAN)/E001 (LS-CAN) can be stored in all CAN-connected control modules. These diagnostic trouble codes indicate that the control module has detected interference on the CAN-net.
XXX-E003 can be stored in all CAN-connected control modules except in Central electronic module (CEM). The control modules on the CAN-net listen for a message (identity number) that is sent out at regular intervals from Central electronic module (CEM). This diagnostic trouble code indicates that the control module has not received any identity number, or that the expected number is not correct. Interference on the CAN-net can also store this diagnostic trouble code.

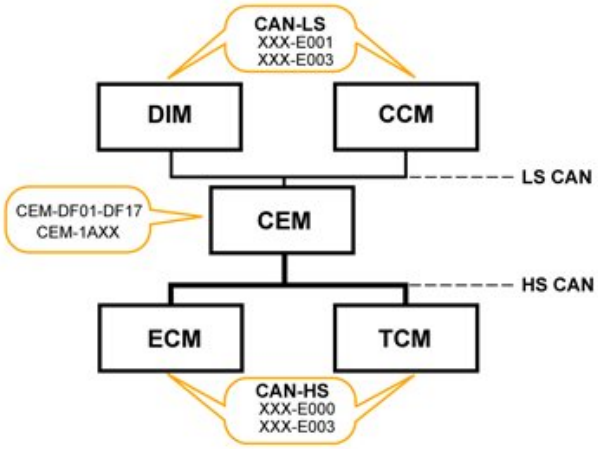
Note! In case of CAN-related faults, it is likely that a combination of above diagnostic trouble codes occur.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

If a communication diagnostic trouble code can be read from the control module, the malfunction is probably intermittent.
Intermittent fault in the voltage supply and ground to a control module on the CAN network results in the Central electronic module (CEM) storing a diagnostic trouble code (DTC) for an open-circuit in communication with the control module where the voltage supply does not work. There will probably not be a diagnostic trouble code (DTC) in the control module where the open-circuit in the voltage supply occurred as the control module cannot store a diagnostic trouble code (DTC) when it is not supplied with power.

Note! Central electronic module (CEM) should not be replaced in case of CAN-fault, unless troubleshooting reveals that Central electronic module (CEM) has an internal fault.

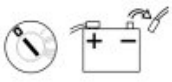
Caution! During this fault-tracing use the wiring diagram to provide support when taking readings.



Select "Continue".

Continue - Checking resistance in CAN-net

Checking resistance in CAN-net



- Ignition off
- Disconnect the battery negative lead
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #6 and #14. The resistance should be approx. 55 - 65 ohms.
- If resistance is approx. 120 ohms, this indicates open circuit in the circuit so that only one terminating resistor (120 ohms) has been

measured.

- If resistance is above 1 kohms this indicates open circuit/high contact resistance somewhere in the circuit.
- If resistance is below 55 ohms this indicates short-circuiting/contact resistance between the CAN-lines somewhere in the circuit.

Hint: For HS-CAN (High Speed) the terminating resistors are located in Brake control module (BCM) and in Engine control module (ECM).

Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

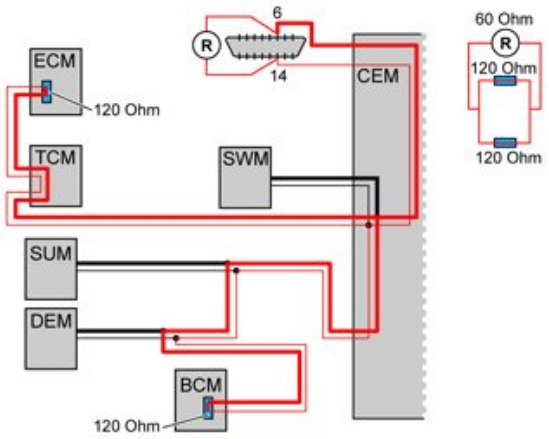
Note! Resistance measurement measures only main lines in the CAN-net (in circuit where both terminating resistors are found), not branches to certain control modules. See wiring diagram for vehicle model in question.Open circuit on branching without a terminating resistor cannot be detected with this measurement. However, short-circuiting on a branch can be detected. To measure resistance in the CAN-net to control modules located in a branching of their own, the measurement shall be done against the CAN-net at that control module. The values shall be as above.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy wiring as necessary.

Other information

- Battery, disconnecting See: Starting and Charging/Battery/Service and Repair/Procedures/Battery, Disconnecting
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

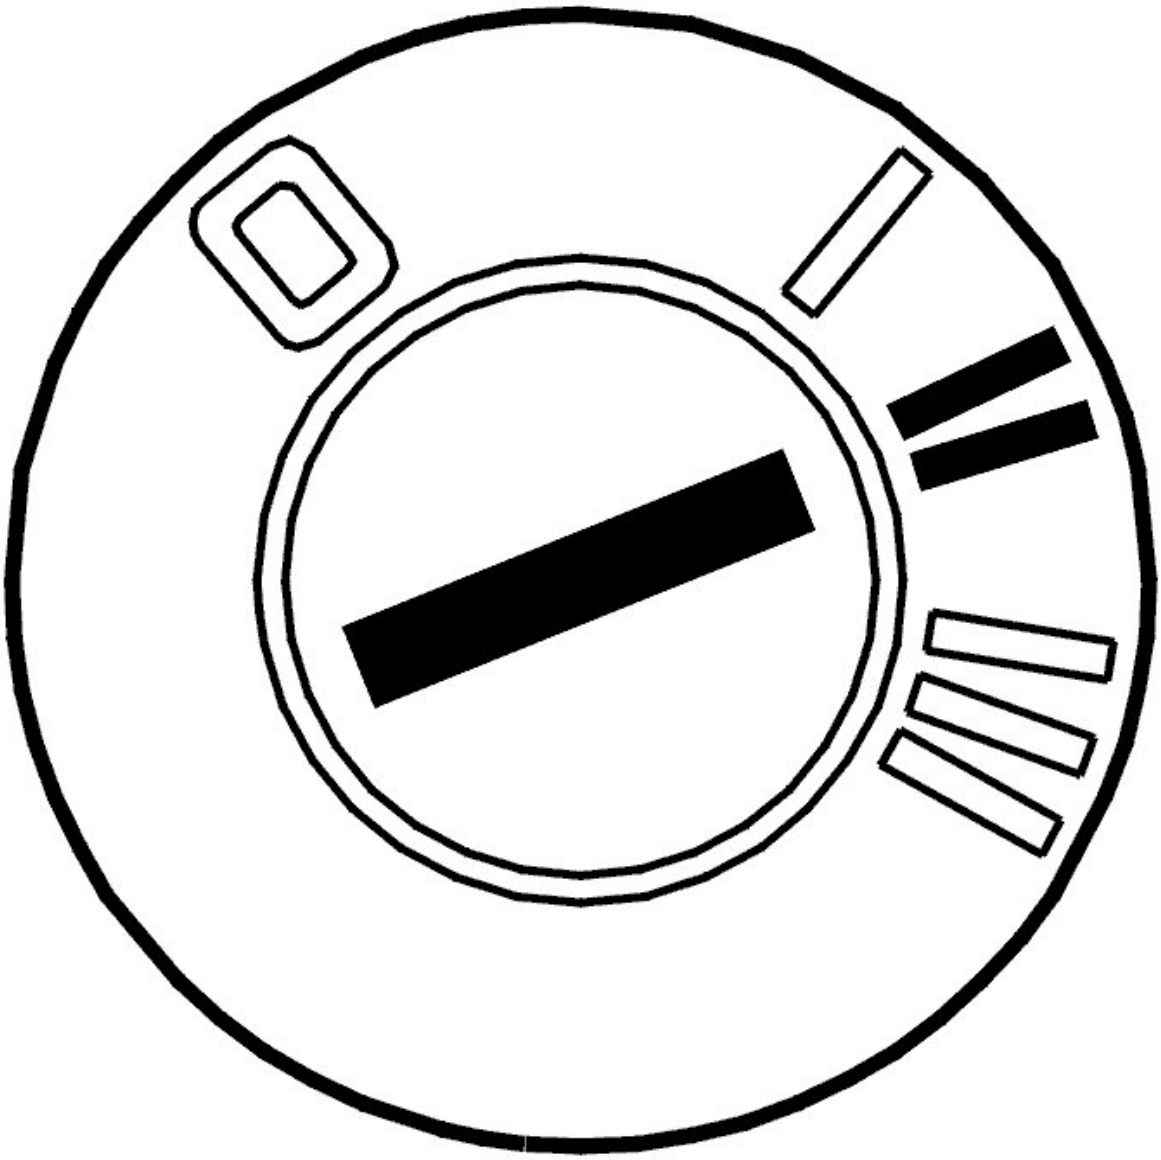


Was a fault detected?

Yes - Verification

No - Checking short-circuiting to ground/voltage in CAN-net

Checking the traffic load on the CAN cables



- Connect the battery
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Faults in the CAN network may be due to a control module sending faulty messages that disrupt normal communication. When messages are sent incorrectly, this results in a considerable increase in the amount of traffic on the CAN network. Check the load by measuring the average voltage value on the CAN cables in relation to ground.
For further information, see the wiring diagram.
Measure voltage between the following connections on the OBDII-box/diagnostics socket.
- #6 and #4 (ground). The voltage should be approx: 2,8 - 3,2 V.
- #14 and #4 (ground). The voltage should be approx: 1,8 - 2,2 V.
- #6 and #14. The voltage shall be between approx. 0.55-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Hint: DiCE Error Frame Finder can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools: **951 3010** (memory card) as well as associated TJ 20402.

- Ignition on.
- Connect DiCE Error Frame Finder to the diagnostics socket.
- Note the blue LED-indicator. The indicator flashes to show detection of fault messages.

Note! Certain interference may occur without any real fault!

Cable fault

- Shake the cables lightly and pull lightly on the connections during the check to locate any fault. Note the blue LED-indicator.

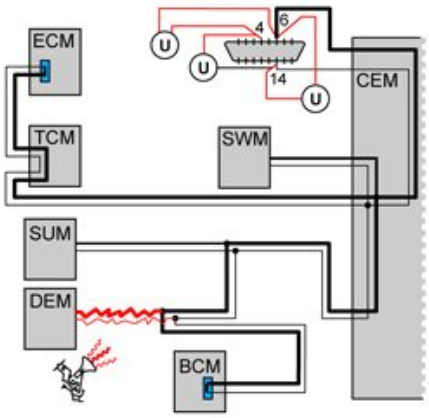
"Chatting" control modules

- "Chatting" control modules may be difficult to find and troubleshooting may take time. Let the vehicle stand with DiCE connected for an extended time period. Afterwards, activate functions to provoke a malfunction. It may take up to several hours before the fault messages are sent. When the indicator starts to flash, remove the fuse for one control module at a time until the indicator stops flashing. When the indicator stops flashing, restore the fuse for the relevant control module and check that the indicator starts to flash again. Then it is likely that the problem is identified.

Remedy wiring as necessary.

Other information

- Battery, disconnecting See: Starting and Charging/Battery/Service and Repair/Procedures/Battery, Disconnecting
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

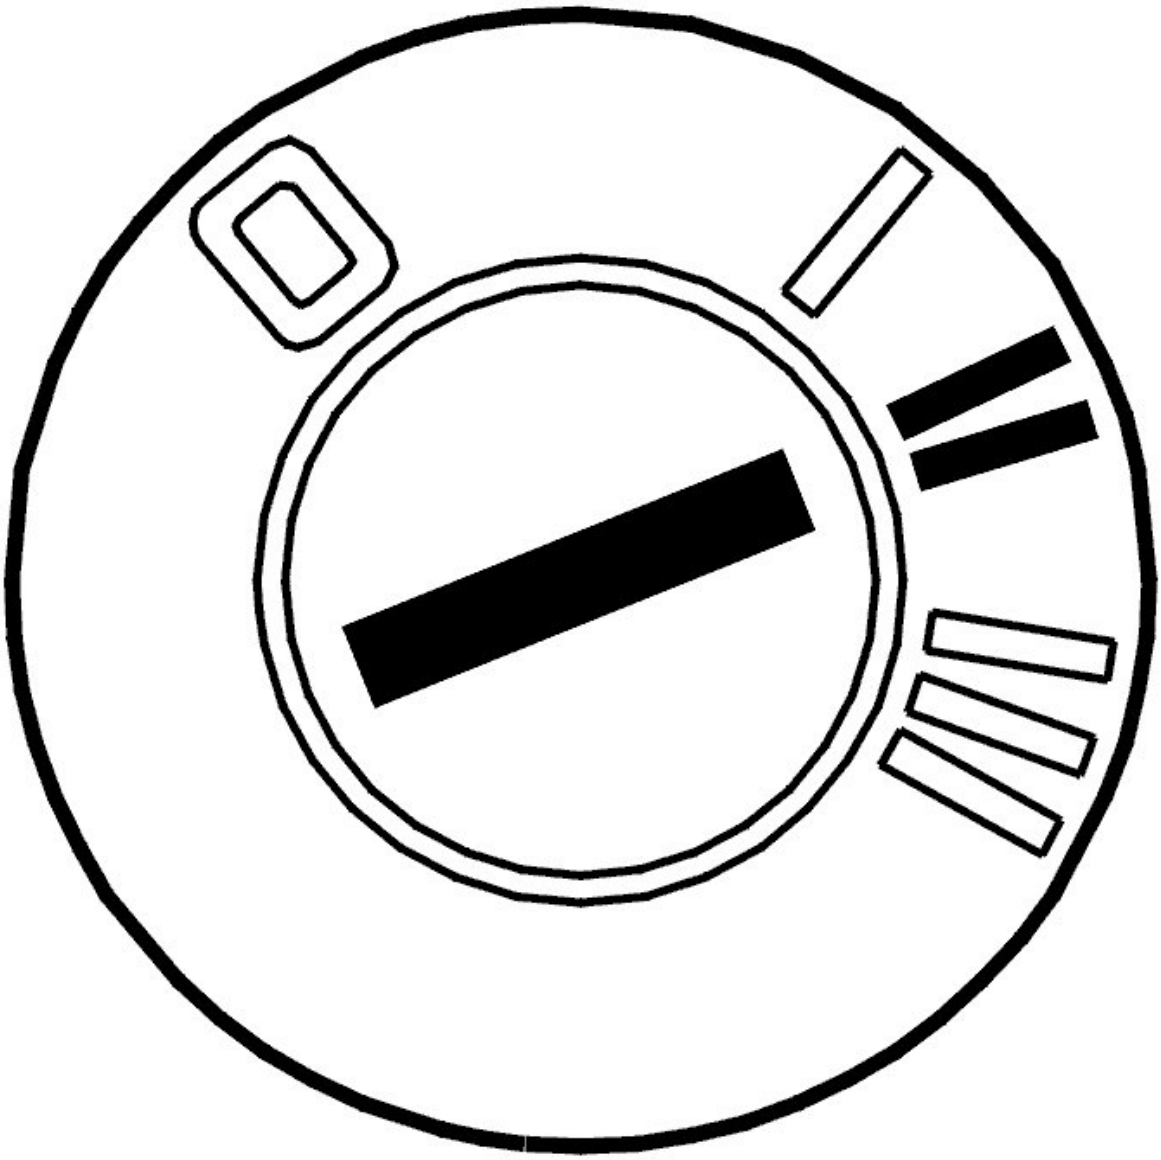


Was a fault detected?

Yes - Identifying a control module in the CAN network

No - respectively

Identifying a control module in the CAN network



Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:

- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Hint: DiCE Error Frame Finder can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools: **951 3010** (memory card) as well as associated TJ 20402.

If the load on the CAN network is too high, this may be due to a control module sending faulty messages on the CAN network (known as a disruptive control module). The fault may also be due to an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The faults can occur without a diagnostic trouble code (DTC) being stored by the control modules. The voltage can be measured between the CAN cables in order to check the load on the CAN network.

Note! It is not necessarily the control module(s) that stored the diagnostic trouble code (DTC) that is communicating faultily. Faulty messages can come from any control module in the same section of the CAN network. However, faulty communication in one network cannot affect the communication on the other network. In other words, faulty communication on the LS-CAN cannot disrupt communication on the HS-CAN and vice versa.

- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Check communication/load on CAN-net by measuring voltage between CAN-L and CAN-H. Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #6 and #14. The average value of the voltage must be approximately 0.6-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

In order to identify which control module has faulty communication, cut the power supply to one control module at a time. Check the voltage in the

CAN cables again. The easiest way to cut the power supply is to remove the fuse(s) for the relevant control module. Repeat until the voltage between the CAN wiring drops to the normal level.

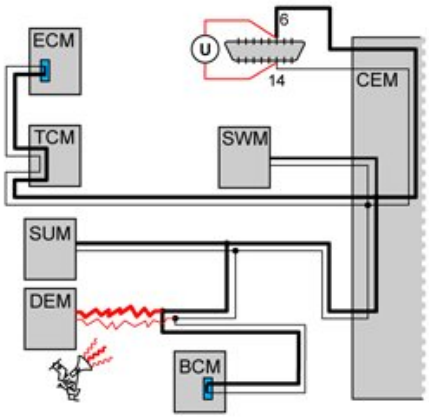
Note! When connecting and disconnecting individual control modules, other diagnostic trouble codes (DTCs) may be stored in certain control modules.

Hint: When the suspected defective control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the malfunction appears and disappears. Switch off the ignition between each check.

Note! Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.

A control module that is communicating incorrectly must be replaced. See Repairing and installing/Removing, replacing and installing.

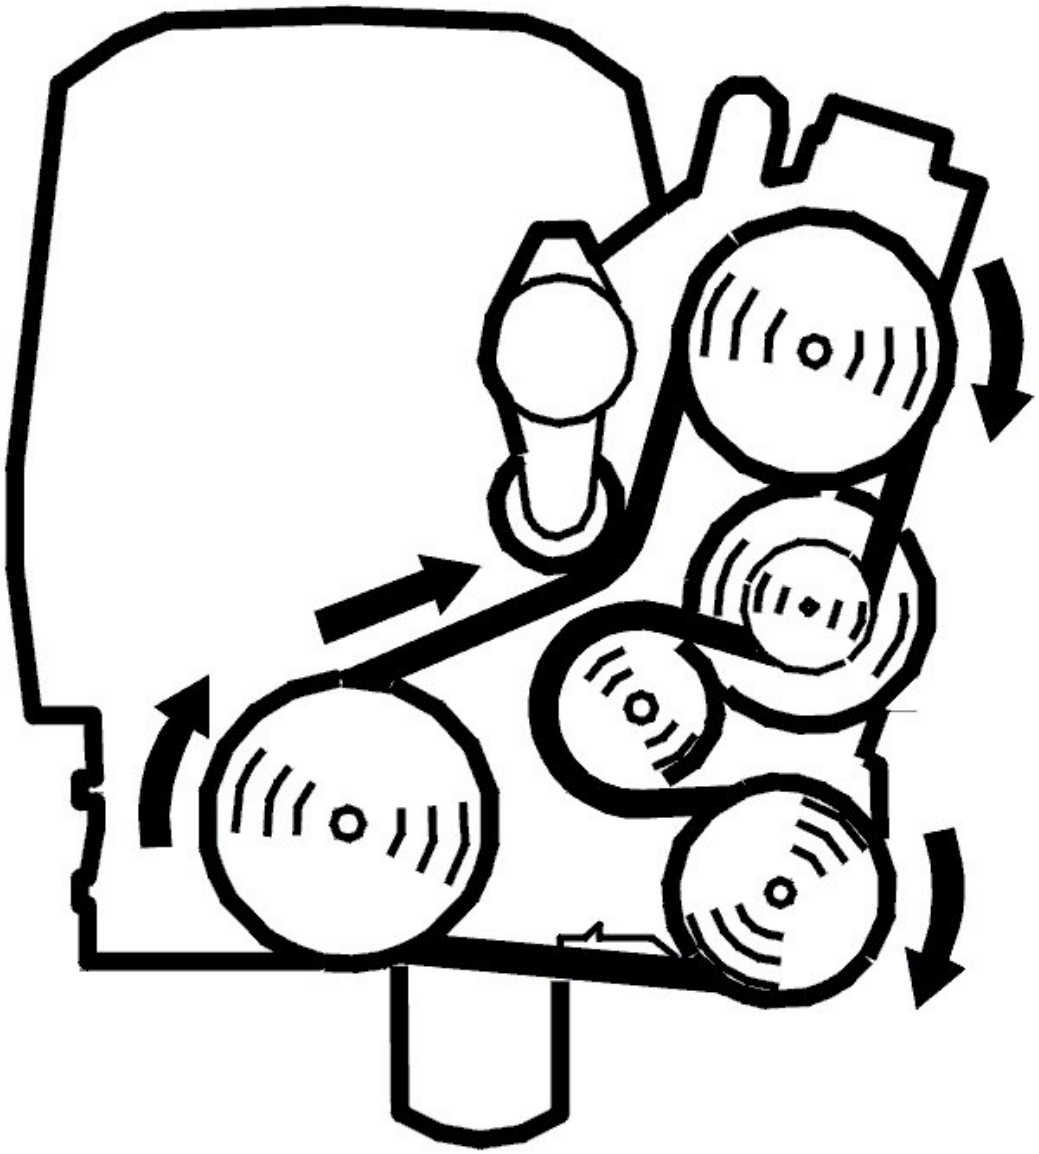
Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

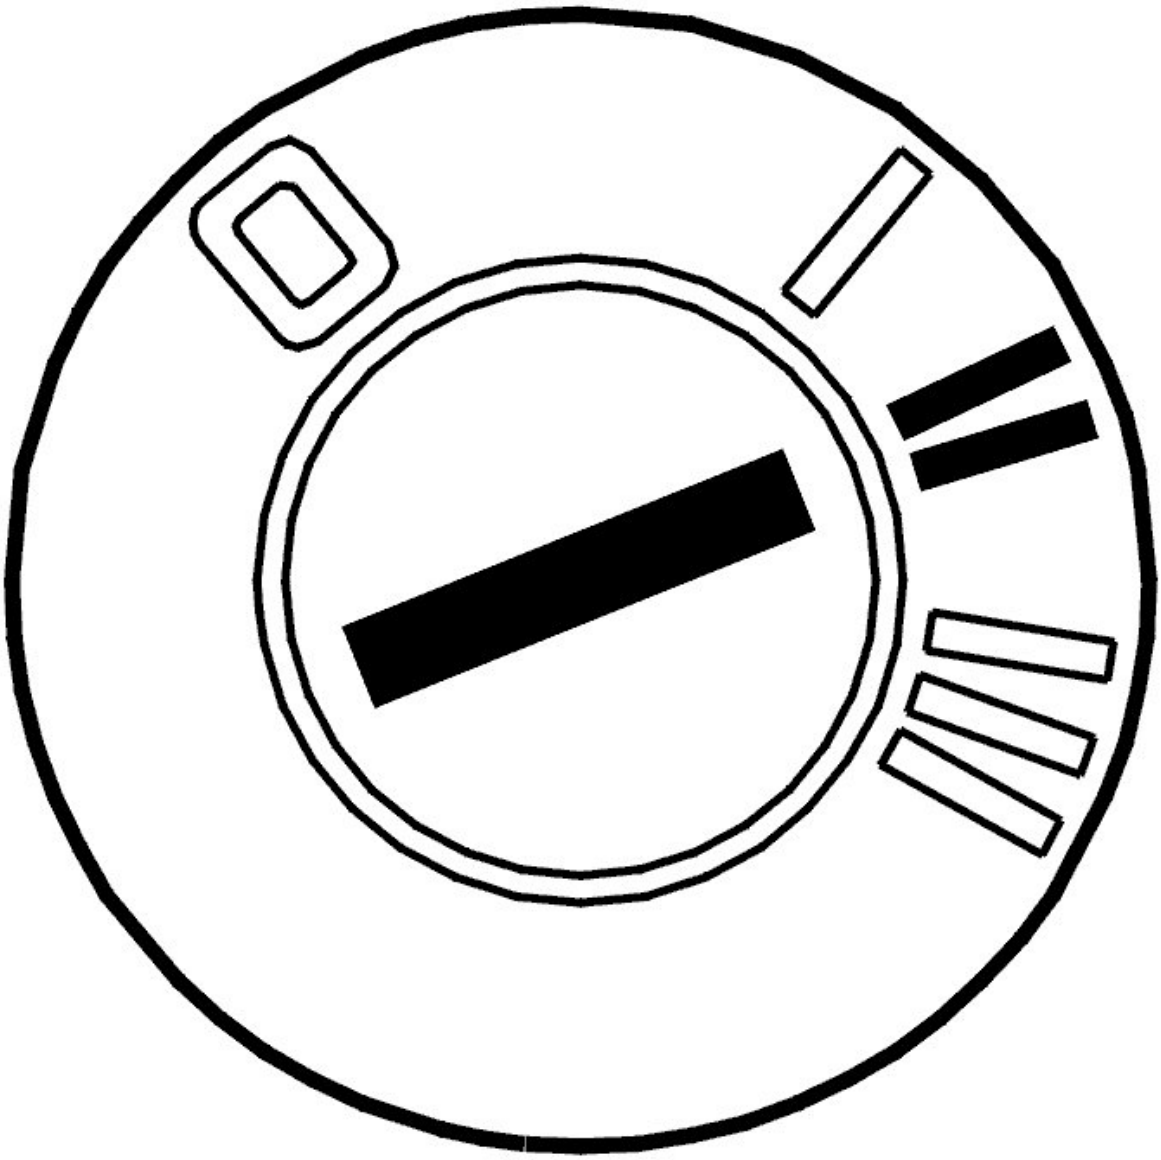


Continue - Verification

Verification

Hint: After rectifying a fault, a verification should be carried out.





- Reinstall the connectors, components etc.
- Ignition on.

Note! For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

- Erase diagnostic trouble codes (DTCs) in all control modules.
- Ignition off.
- Ignition on.
- Start the vehicle. Allow the vehicle to run for 10 minutes.
- Read out the diagnostic trouble codes in the vehicle via the DIAGNOSTICS tab.

Does the diagnostic trouble code (DTC) for faulty communication return?

Yes - Fault-tracing information

No - Fault Found

Fault-tracing information

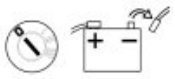
FAULT-TRACING FAILED - FAULT-TRACING FAILED

Attempt New Test - General information

Checking short-circuiting to ground/voltage in CAN-net



- Ignition off.
- Disconnect the battery negative lead.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Checking for a short-circuit to ground

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #6 and #4 (ground). Measurement is shown in the figure. The resistance should be above 1 kohms.
- #14 and #4 (ground). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and ground.

Checking for a short-circuit to voltage

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #6 and #16 (voltage). Measurement is shown in the figure. The resistance should be above 1 kohms.
- #14 and #16 (voltage). The resistance should be above 1 kohms.

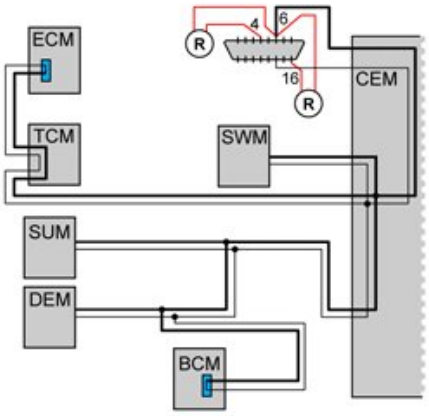
If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and voltage cable.
Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

Hint: Part the CAN-net at suitable points to decide where a short-circuit may be found.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy wiring as necessary.

Other information
- Battery, disconnecting See: Starting and Charging/Battery/Service and Repair/Procedures/Battery, Disconnecting
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

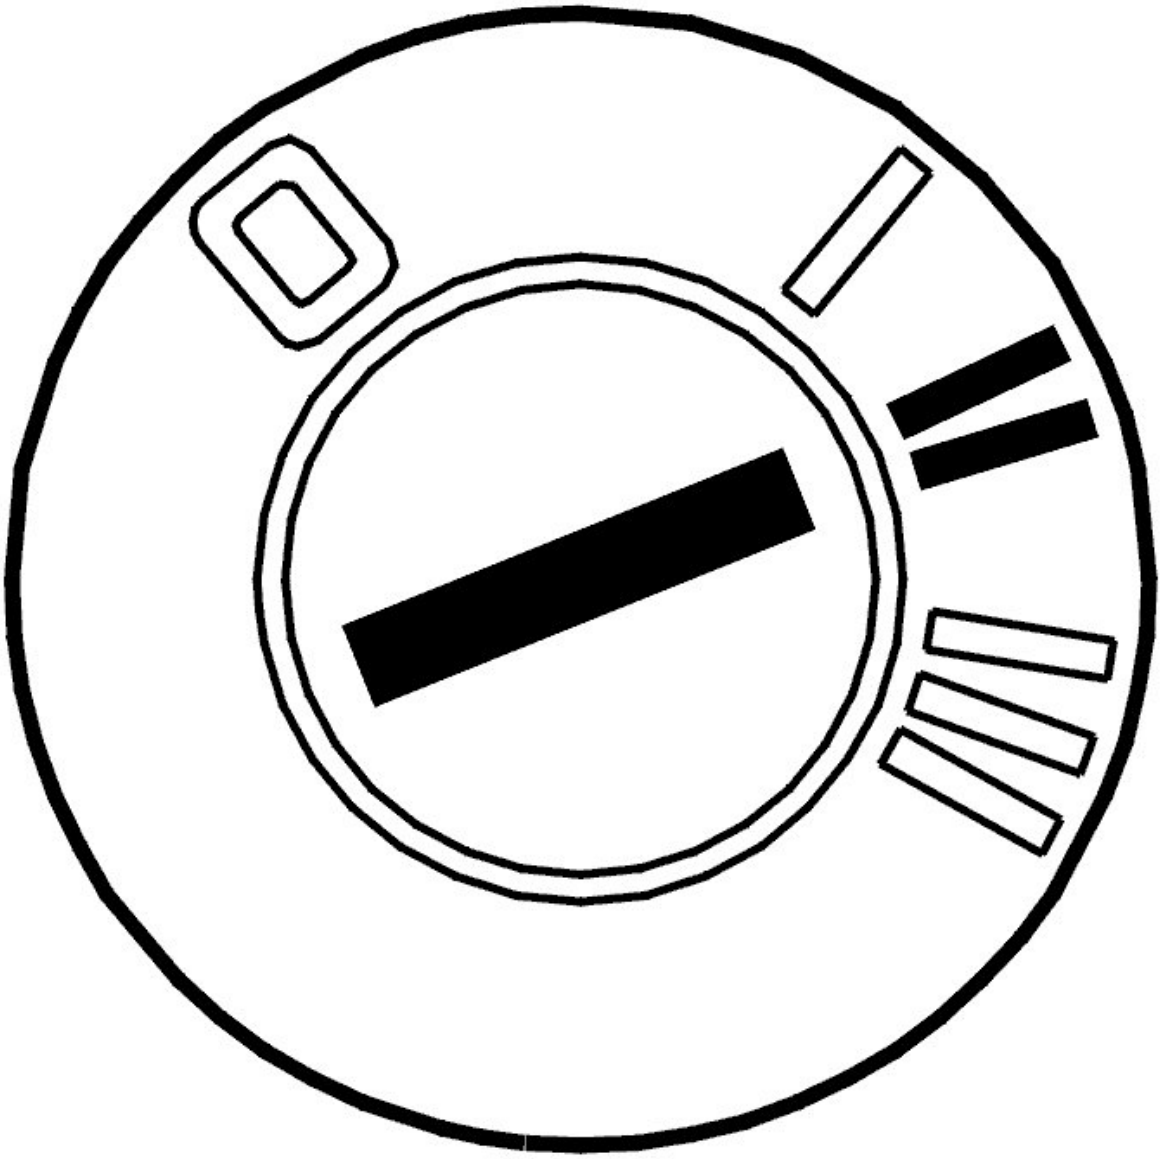


Was a fault detected?

Yes - Verification

No - Checking the traffic load on the CAN cables

Checking voltage-drop in cable for CAN-H and CAN-L, respectively



- Connect the battery.
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

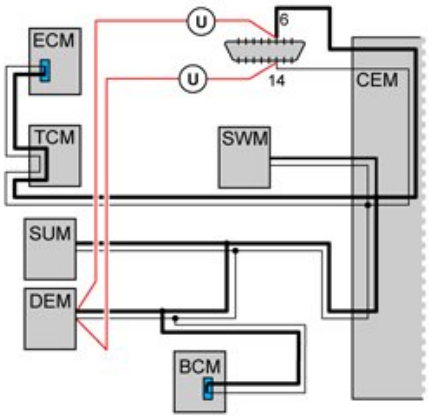
In principle, the voltage measured in each cable in the CAN-net shall be the same at each control module in the network. This means that the voltage-drop in the cable for CAN-H and CAN-L, respectively, between the control modules should be very low. If there is a voltage-difference in the CAN-lines between the diagnostics socket/Central electronic module (CEM) and a control module due to, e.g., contact resistance in a connector or branching, communication may be lost/interfered with.
Check if there is voltage-drop in the cable for CAN-H and CAN-L between the diagnostics socket/Central electronic module (CEM) and the control module where there is problem with communication.
Carry out the following:
Measure voltage between the following connections on the OBDII-box/diagnostics socket.
- #6 and corresponding connection on relevant control module for CAN-H. The voltage shall be lower than 50 mV.
- #14 and corresponding connection on relevant control module for CAN-L. The voltage shall be lower than 50 mV.

If voltage is too high, this indicates too high contact resistance in cable, connector, or branching. Check the circuit between the diagnostics socket and control module in question for contact resistance and oxidation.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy wiring as necessary.

Other information
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

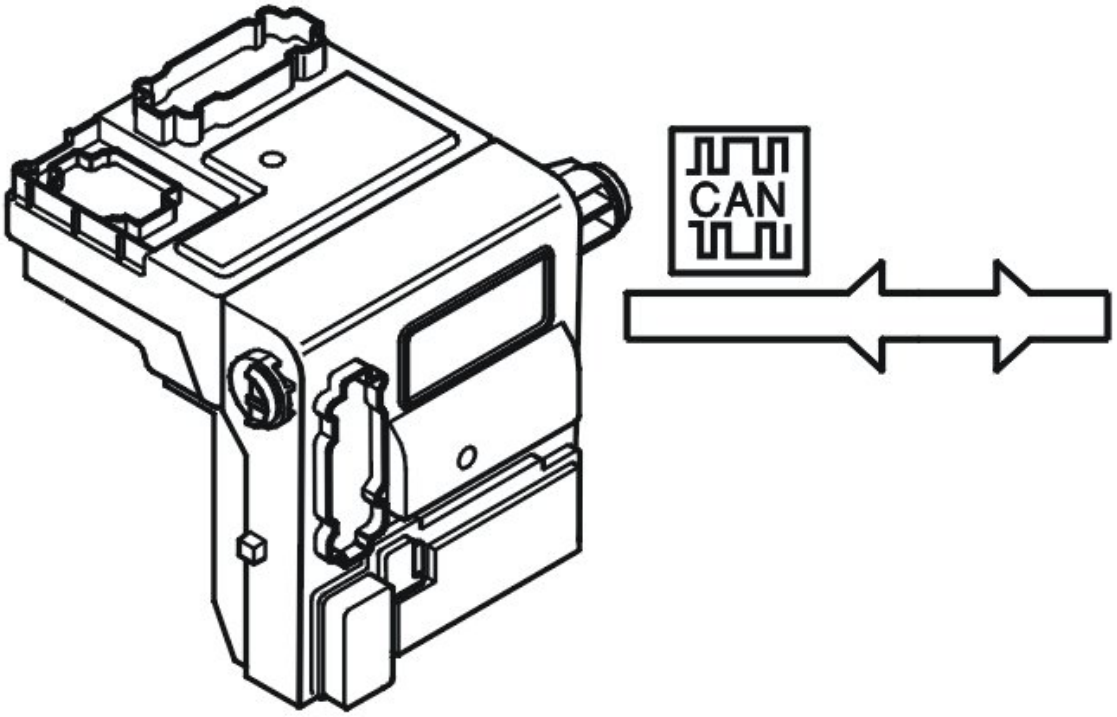


Continue - Verification

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CEM-E000

Condition



The control modules transmit and receive information via a standardized serial communication method - CAN (Control Area Network). The diagnostic trouble code (DTC) is stored if the control module registers serious interference on the high speed network (CAN communication blocked).

Note! In the event of system communication problems, it is not possible to communicate with the control module. Therefore it will only be possible to read off the diagnostic trouble code (DTC) if this type of fault is intermittent.

The diagnostic trouble code (DTC) can be diagnosed when the HS CAN is active.

Substitute value
- The control module shuts itself off ("bus-off").

Hint: The control module will remain shut off until the power supply is broken (15, 30, X). When the power supply is connected the control module will make a new attempt to communicate.

Possible source
- Short-circuit between the control area network (CAN) wiring
- Open-circuit in one of the control area network (CAN) cables
- Internal fault in another control module in the same part of the control area network (CAN)
- Internal fault in the control module.

Fault symptom[s]
- The starter motor turns but the engine does not start.
- The speedometer does not operate.
- Tachometer not working.
- Engine coolant temperature (ECT) gauge does not function.
- Cruise control does not function at all.
- Jerky operation.

Signal Missing

Signal missing

General information

Note! Figures shown are only examples.

Hint: For general information about CAN-troubleshooting, see:

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

Fault-tracing In the CAN Network

General about CAN-related diagnostic trouble codes.
CEM-DF01 - DF17can only be stored in Central electronic module (CEM). These diagnostic trouble codes are stored when an electric fault is detected in CAN-lines. Start with these diagnostic trouble codes first.
CEM-1AXX only stored in Central electronic module (CEM). One diagnostic trouble code for every control module on the CAN-net. These diagnostic trouble codes indicate that Central electronic module (CEM) does not receive any reply from other control modules.
XXX-E000 (HS-CAN)/E001 (LS-CAN) can be stored in all CAN-connected control modules. These diagnostic trouble codes indicate that the control module has detected interference on the CAN-net.
XXX-E003 can be stored in all CAN-connected control modules except in Central electronic module (CEM). The control modules on the CAN-net listen for a message (identity number) that is sent out at regular intervals from Central electronic module (CEM). This diagnostic trouble code indicates that the control module has not received any identity number, or that the expected number is not correct. Interference on the CAN-net can also store this diagnostic trouble code.

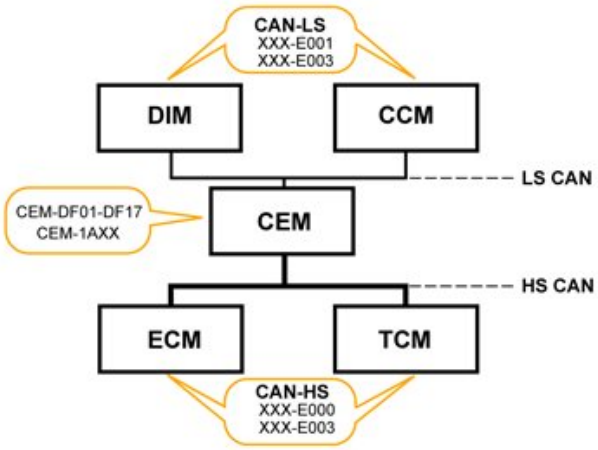
Note! In case of CAN-related faults, it is likely that a combination of above diagnostic trouble codes occur.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

If a communication diagnostic trouble code can be read from the control module, the malfunction is probably intermittent.
Intermittent fault in the voltage supply and ground to a control module on the CAN network results in the Central electronic module (CEM) storing a diagnostic trouble code (DTC) for an open-circuit in communication with the control module where the voltage supply does not work. There will probably not be a diagnostic trouble code (DTC) in the control module where the open-circuit in the voltage supply occurred as the control module cannot store a diagnostic trouble code (DTC) when it is not supplied with power.

Note! Central electronic module (CEM) should not be replaced in case of CAN-fault, unless troubleshooting reveals that Central electronic module (CEM) has an internal fault.

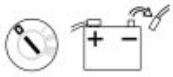
Caution! During this fault-tracing use the wiring diagram to provide support when taking readings.



Select "Continue".

Continue - Checking resistance in CAN-net

Checking resistance in CAN-net



- Ignition off
- Disconnect the battery negative lead
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.

- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Measure resistance between the following connections on the OBDII-box/diagnostics socket.

- #6 and #14. The resistance should be approx. 55 - 65 ohms.
- If resistance is approx. 120 ohms, this indicates open circuit in the circuit so that only one terminating resistor (120 ohms) has been measured.
- If resistance is above 1 kohms this indicates open circuit/high contact resistance somewhere in the circuit.
- If resistance is below 55 ohms this indicates short-circuiting/contact resistance between the CAN-lines somewhere in the circuit.

Hint: For HS-CAN (High Speed) the terminating resistors are located in Brake control module (BCM) and in Engine control module (ECM).

Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

Note! Resistance measurement measures only main lines in the CAN-net (in circuit where both terminating resistors are found), not branches to certain control modules. See wiring diagram for vehicle model in question.Open circuit on branching without a terminating resistor cannot be detected with this measurement. However, short-circuiting on a branch can be detected. To measure resistance in the CAN-net to control modules located in a branching of their own, the measurement shall be done against the CAN-net at that control module. The values shall be as above.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy wiring as necessary.

Other information

- Battery, disconnecting See: Starting and Charging/Battery/Service and Repair/Procedures/Battery, Disconnecting

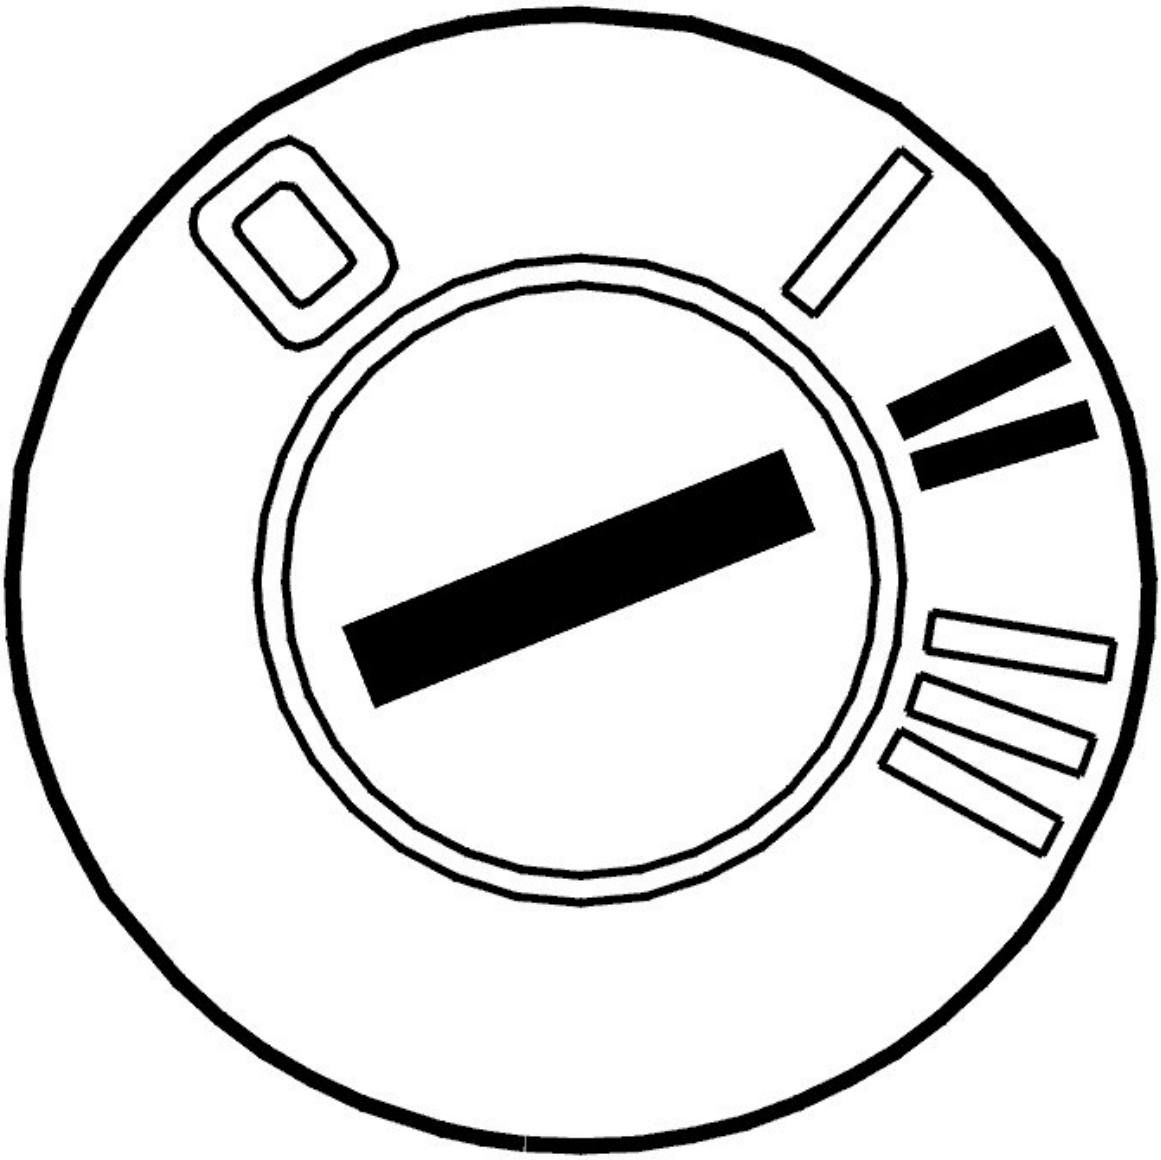
Was a fault detected?

Yes - Verification

No - Checking short-circuiting to ground/voltage in CAN-net

Checking the traffic load on the CAN cables



- Connect the battery
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Faults in the CAN network may be due to a control module sending faulty messages that disrupt normal communication. When messages are sent incorrectly, this results in a considerable increase in the amount of traffic on the CAN network. Check the load by measuring the average voltage value on the CAN cables in relation to ground.
For further information, see the wiring diagram.
Measure voltage between the following connections on the OBDII-box/diagnostics socket.
- #6 and #4 (ground). The voltage should be approx: 2,8 - 3,2 V.
- #14 and #4 (ground). The voltage should be approx: 1,8 - 2,2 V.
- #6 and #14. The voltage shall be between approx. 0.55-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Hint: DiCE Error Frame Finder can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools: **951 3010** (memory card) as well as associated TJ 20402.

- Ignition on.
- Connect DiCE Error Frame Finder to the diagnostics socket.
- Note the blue LED-indicator. The indicator flashes to show detection of fault messages.

Note! Certain interference may occur without any real fault!

Cable fault

- Shake the cables lightly and pull lightly on the connections during the check to locate any fault. Note the blue LED-indicator.

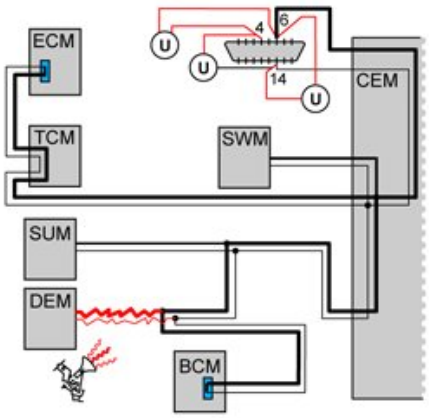
"Chatting" control modules

- "Chatting" control modules may be difficult to find and troubleshooting may take time. Let the vehicle stand with DiCE connected for an extended time period. Afterwards, activate functions to provoke a malfunction. It may take up to several hours before the fault messages are sent. When the indicator starts to flash, remove the fuse for one control module at a time until the indicator stops flashing. When the indicator stops flashing, restore the fuse for the relevant control module and check that the indicator starts to flash again. Then it is likely that the problem is identified.

Remedy wiring as necessary.

Other information

- Battery, disconnecting See: Starting and Charging/Battery/Service and Repair/Procedures/Battery, Disconnecting
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

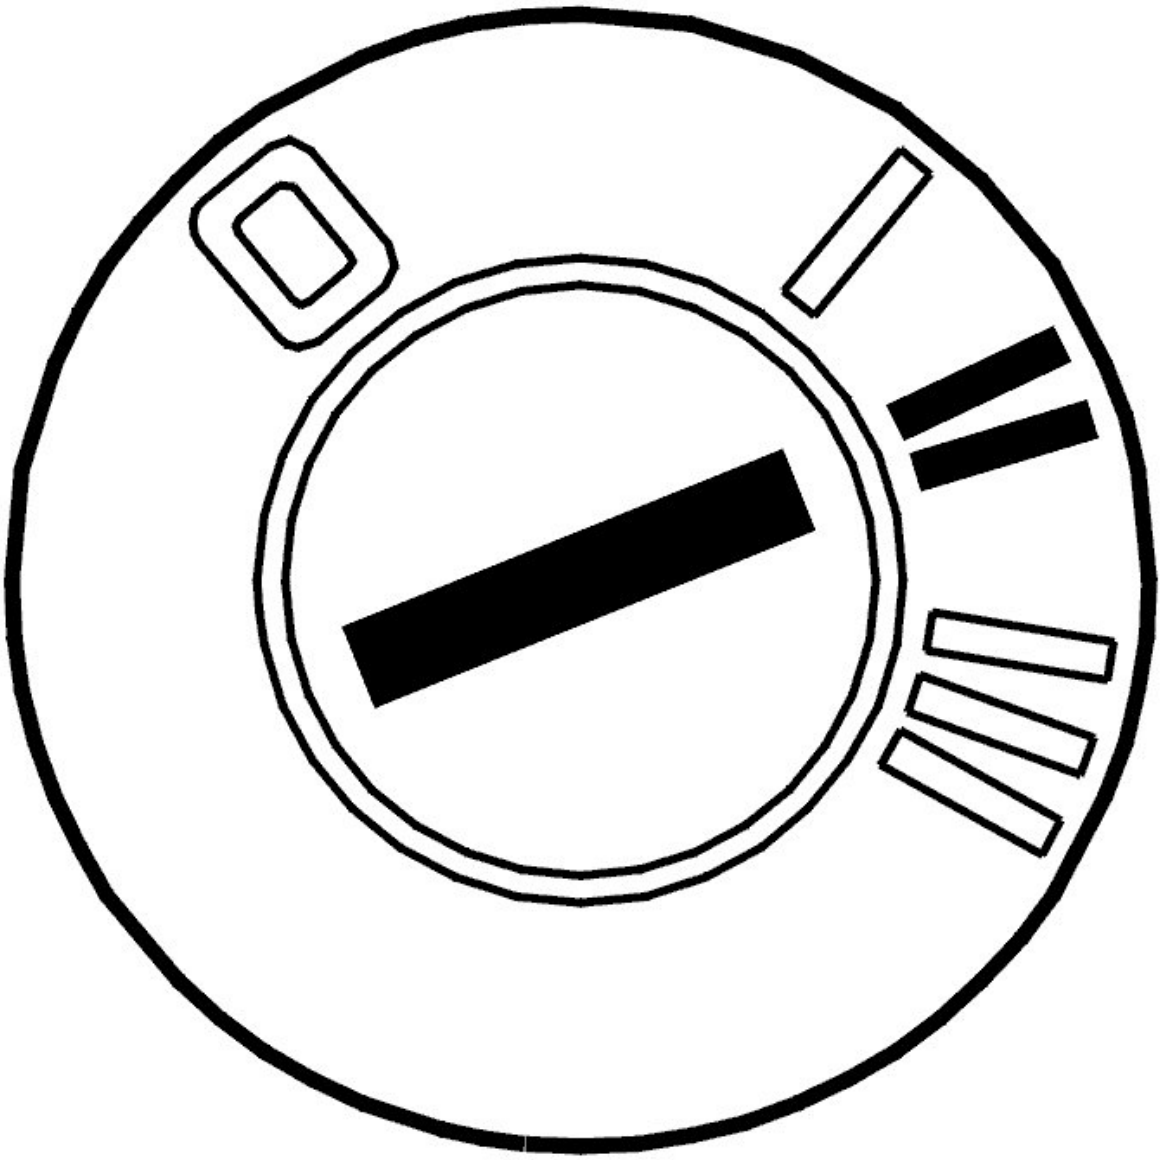


Was a fault detected?

Yes - Identifying a control module in the CAN network

No - respectively

Identifying a control module in the CAN network



Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:

- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Hint: DiCE Error Frame Finder can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools: **951 3010** (memory card) as well as associated TJ 20402.

If the load on the CAN network is too high, this may be due to a control module sending faulty messages on the CAN network (known as a disruptive control module). The fault may also be due to an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The faults can occur without a diagnostic trouble code (DTC) being stored by the control modules. The voltage can be measured between the CAN cables in order to check the load on the CAN network.

Note! It is not necessarily the control module(s) that stored the diagnostic trouble code (DTC) that is communicating faultily. Faulty messages can come from any control module in the same section of the CAN network. However, faulty communication in one network cannot affect the communication on the other network. In other words, faulty communication on the LS-CAN cannot disrupt communication on the HS-CAN and vice versa.

- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Check communication/load on CAN-net by measuring voltage between CAN-L and CAN-H. Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #6 and #14. The average value of the voltage must be approximately 0.6-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

In order to identify which control module has faulty communication, cut the power supply to one control module at a time. Check the voltage in the

CAN cables again. The easiest way to cut the power supply is to remove the fuse(s) for the relevant control module. Repeat until the voltage between the CAN wiring drops to the normal level.

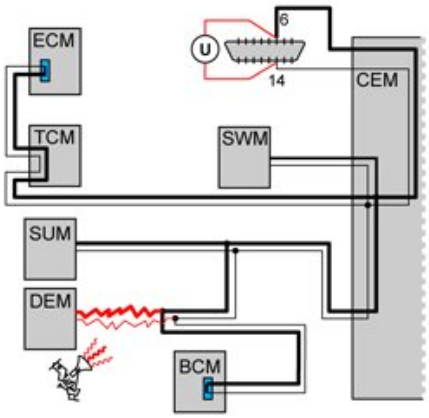
Note! When connecting and disconnecting individual control modules, other diagnostic trouble codes (DTCs) may be stored in certain control modules.

Hint: When the suspected defective control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the malfunction appears and disappears. Switch off the ignition between each check.

Note! Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.

A control module that is communicating incorrectly must be replaced. See Repairing and installing/Removing, replacing and installing.

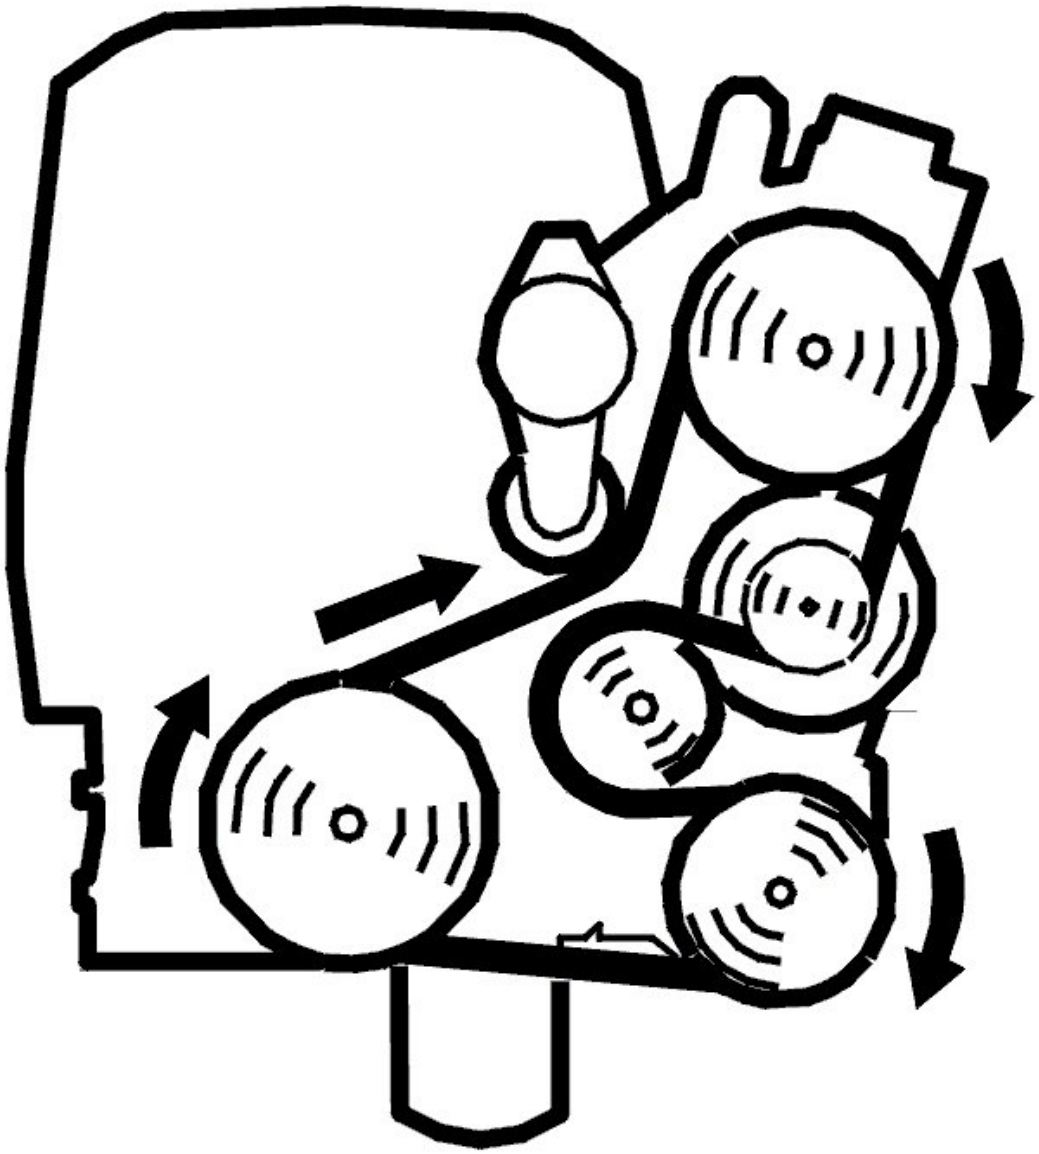
Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

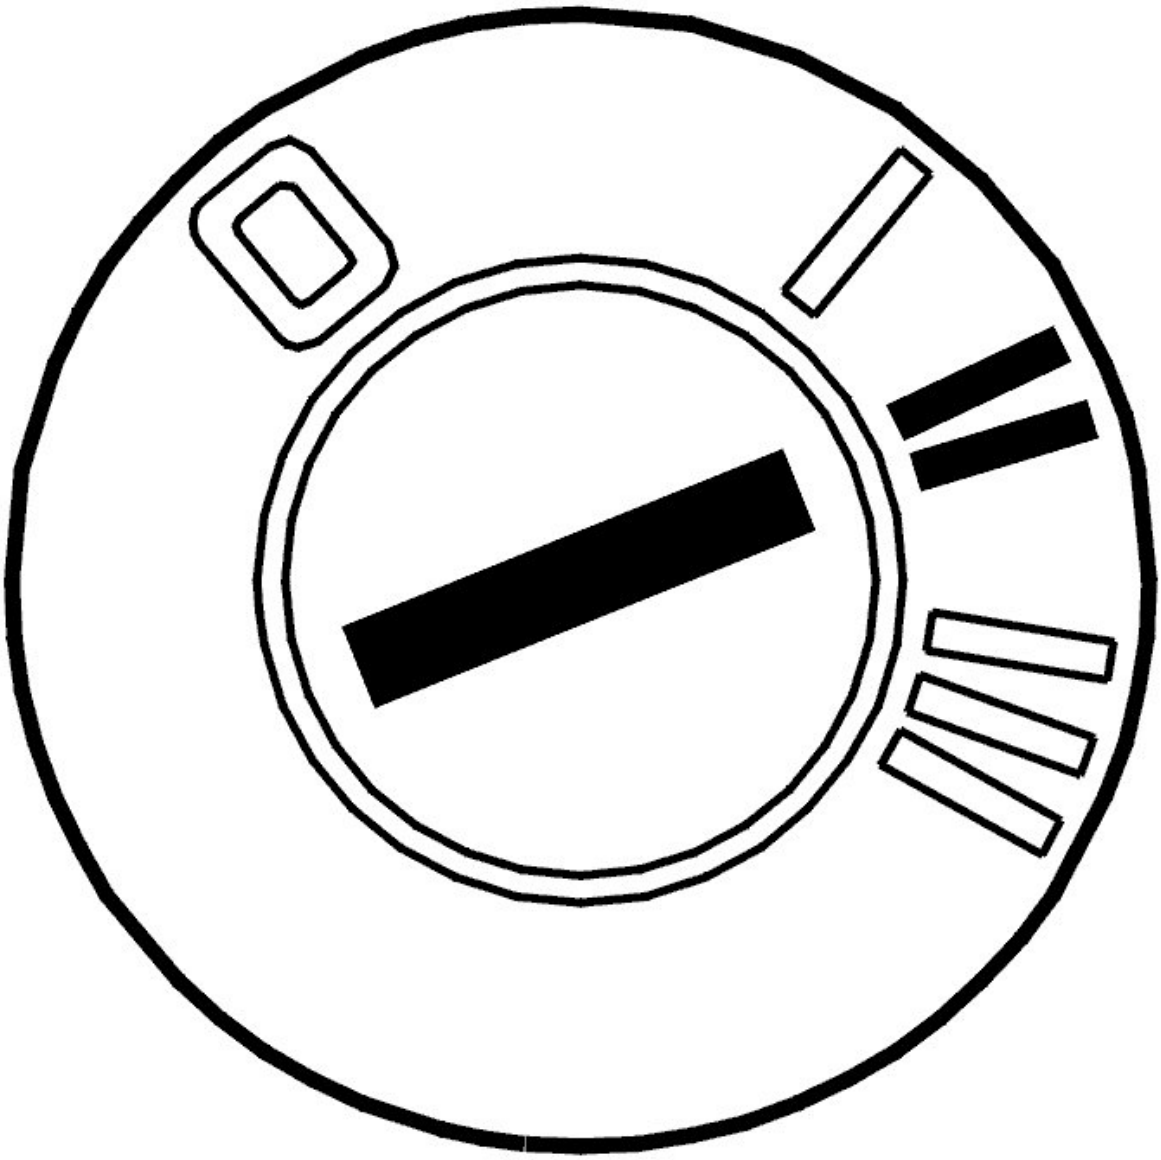


Continue - Verification

Verification

Hint: After rectifying a fault, a verification should be carried out.





- Reinstall the connectors, components etc.
- Ignition on.

Note! For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

- Erase diagnostic trouble codes (DTCs) in all control modules.
- Ignition off.
- Ignition on.
- Start the vehicle. Allow the vehicle to run for 10 minutes.
- Read out the diagnostic trouble codes in the vehicle via the DIAGNOSTICS tab.

Does the diagnostic trouble code (DTC) for faulty communication return?

Yes - Fault-tracing information

No - Fault Found

Fault-tracing information

Information

Fault-tracing information

The fault should have been detected and remedied. As this is not the case fault-tracing has failed.
Exit fault-tracing for this diagnostic trouble code (DTC) or make another attempt.

Do you want to exit fault-tracing?

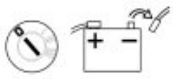
No - Attempt New Test

FAULT-TRACING FAILED - FAULT-TRACING FAILED

Attempt New Test - General information

Checking short-circuiting to ground/voltage in CAN-net



- Ignition off.
- Disconnect the battery negative lead.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Checking for a short-circuit to ground

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #6 and #4 (ground). Measurement is shown in the figure. The resistance should be above 1 kohms.
- #14 and #4 (ground). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and ground.

Checking for a short-circuit to voltage

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #6 and #16 (voltage). Measurement is shown in the figure. The resistance should be above 1 kohms.
- #14 and #16 (voltage). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and voltage cable.
Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

Hint: Part the CAN-net at suitable points to decide where a short-circuit may be found.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy wiring as necessary.

Other information
- Battery, disconnecting See: Starting and Charging/Battery/Service and Repair/Procedures/Battery, Disconnecting

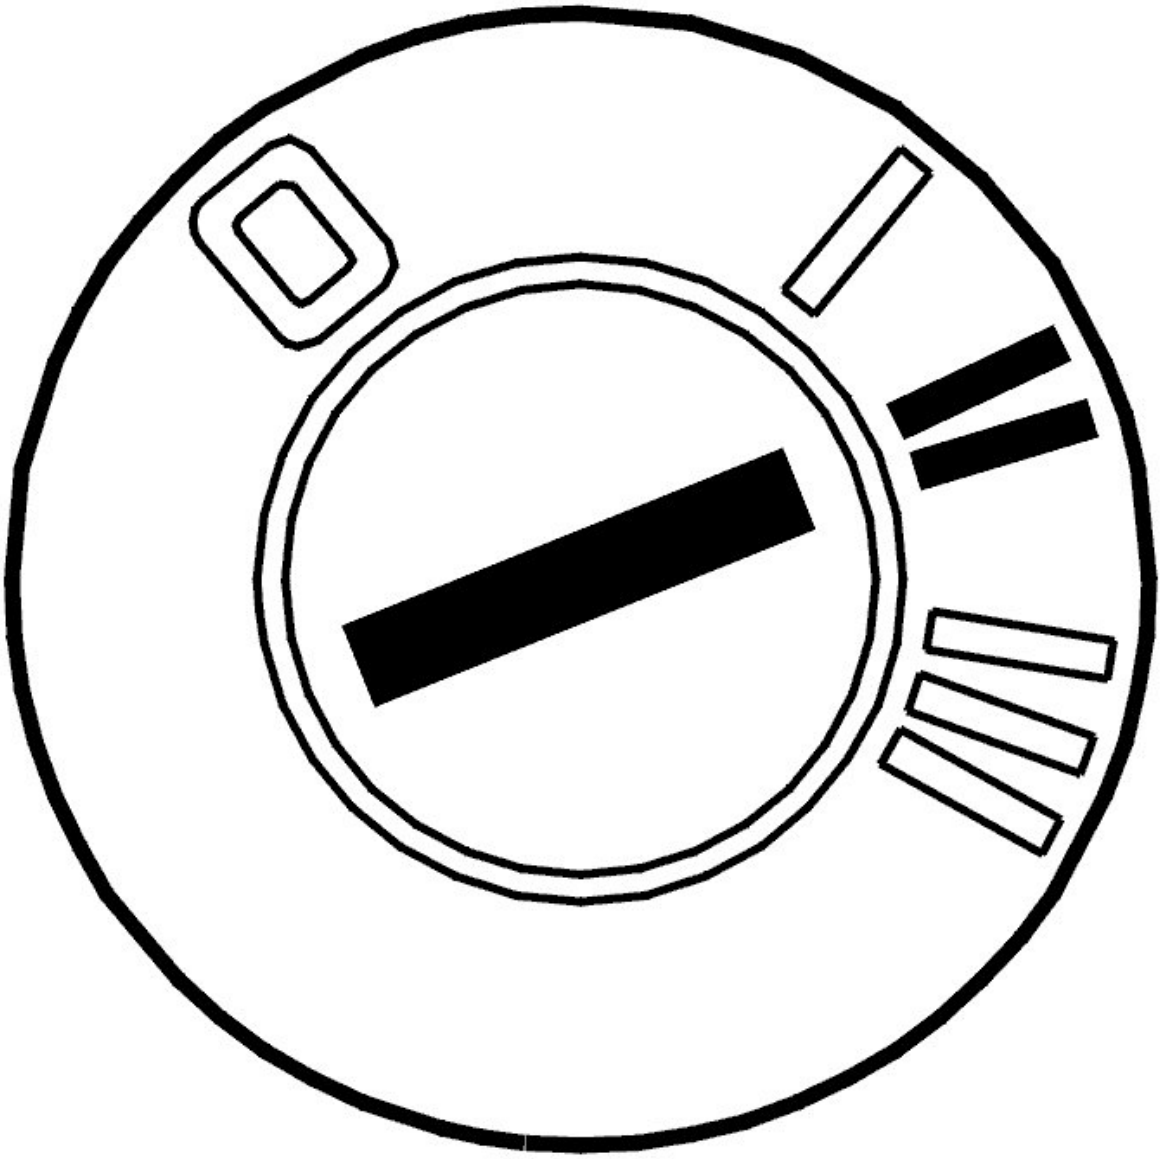
Was a fault detected?

Yes - Verification

No - Checking the traffic load on the CAN cables

Checking voltage-drop in cable for CAN-H and CAN-L, respectively



- Connect the battery.
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

In principle, the voltage measured in each cable in the CAN-net shall be the same at each control module in the network. This means that the voltage-drop in the cable for CAN-H and CAN-L, respectively, between the control modules should be very low. If there is a voltage-difference in the CAN-lines between the diagnostics socket/Central electronic module (CEM) and a control module due to, e.g., contact resistance in a connector or branching, communication may be lost/interfered with.
Check if there is voltage-drop in the cable for CAN-H and CAN-L between the diagnostics socket/Central electronic module (CEM) and the control module where there is problem with communication.
Carry out the following:
Measure voltage between the following connections on the OBDII-box/diagnostics socket.
- #6 and corresponding connection on relevant control module for CAN-H. The voltage shall be lower than 50 mV.
- #14 and corresponding connection on relevant control module for CAN-L. The voltage shall be lower than 50 mV.

If voltage is too high, this indicates too high contact resistance in cable, connector, or branching. Check the circuit between the diagnostics socket and control module in question for contact resistance and oxidation.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy wiring as necessary.

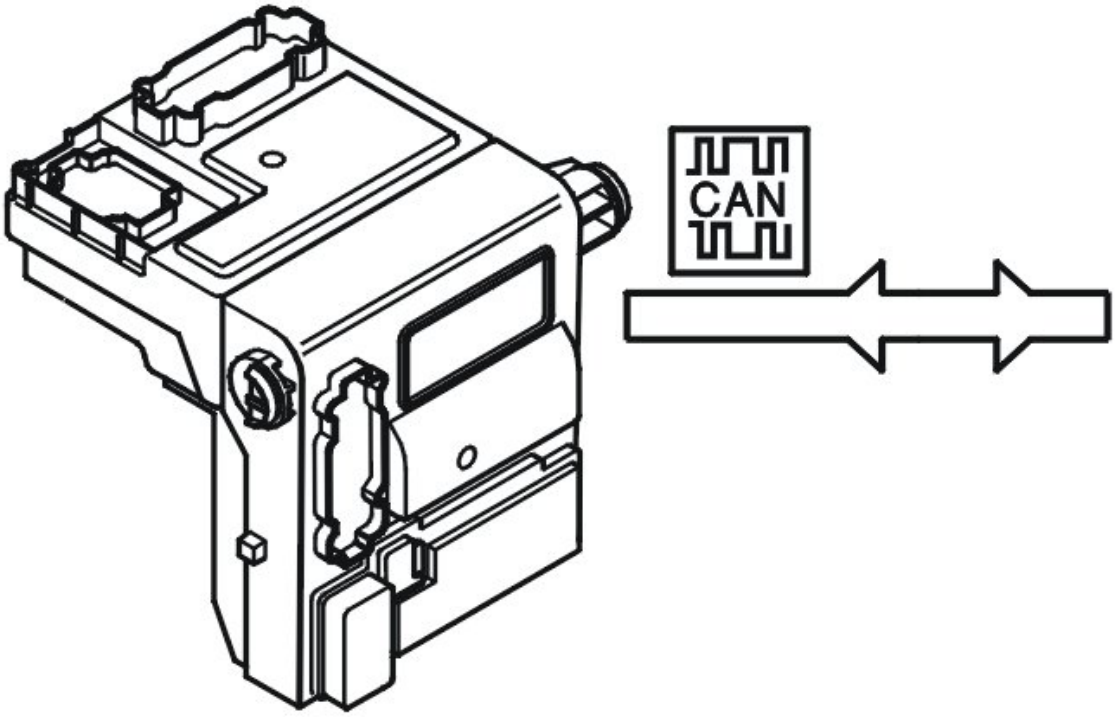
CEM-E001

Diagnostic trouble code (DTC) information CEM-E001

Condition



The control modules transmit and receive information via a standardized serial communication method - CAN (Control Area Network). The diagnostic trouble code (DTC) is stored if the control module registers serious interference on the low speed network (CAN communication blocked).

Substitute value

- The control module shuts itself off ("bus-off").

  Hint: The control module will remain shut off until the power supply is broken (15, 30, X). When the power supply is connected the control module will make a new attempt to communicate.

Possible source

- Short-circuit between the control area network (CAN) wiring
- Open-circuit in one of the control area network (CAN) cables
- Internal fault in the control module
- Internal fault in another control module in the same part of the control area network (CAN).

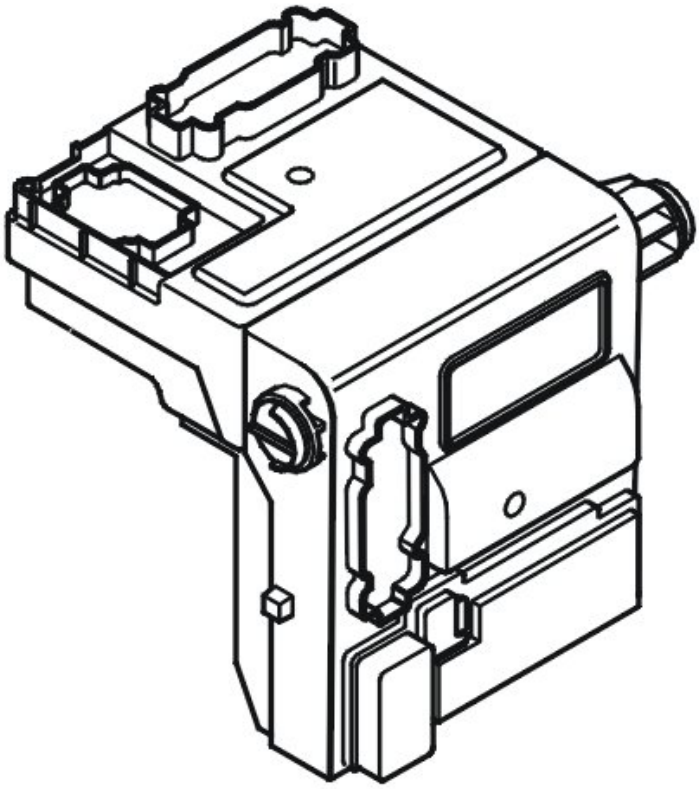
Fault symptom[s]

- No gauges are working
- The instrument lighting does not operate
- Cannot be controlled with the remote control.

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CEM-1A03

Condition



The central electronic module (CEM) monitors the cable for S-supply from the ignition switch.
The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers an open-circuit or a short-circuit to ground in the S-supply.
The diagnostic trouble code (DTC) can be diagnosed in ignition positions I and II.

Substitute value
- None.

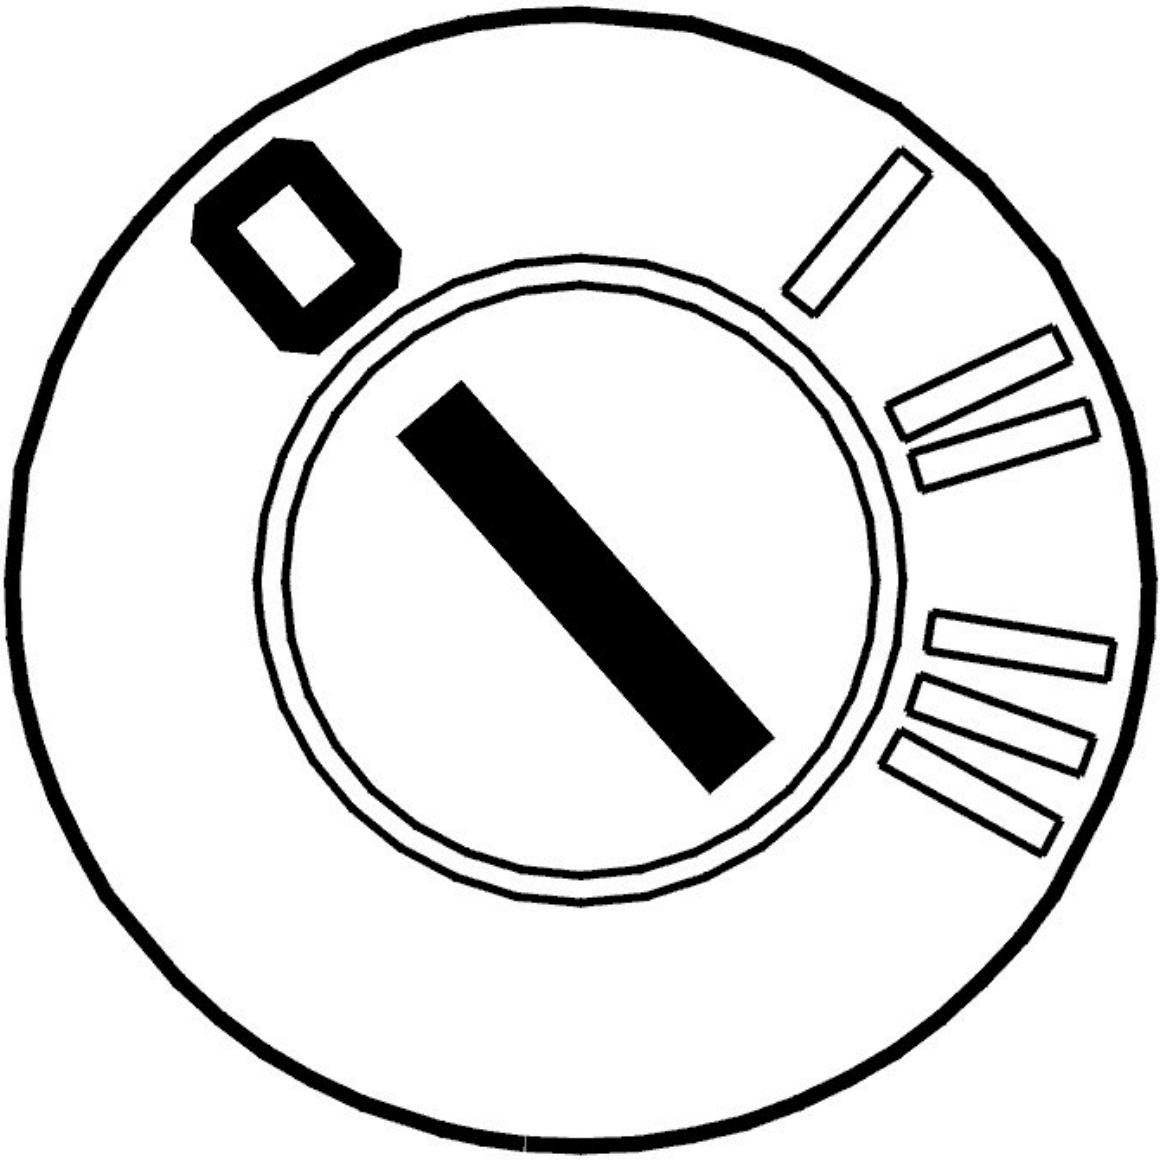
Possible source
- Contact resistance in the terminals
- Open-circuit or short-circuit to ground in the S-supply
- No communication with the key
- Damaged ignition switch.

Fault symptom[s]
- The starter motor does not turn.

Signal Too Low

Signal too low

Checking the connectors



- Ignition off.

Check central electronic module (CEM) connector D. Check for contact resistance and oxidation. Check for loose connections. Remedy as necessary.
Check for any damage.

Hint: If the fault cause is found, reinstall the components, connectors etc.
If the fault cause was not found, do not reconnect the connector before carrying out further fault-tracing.

Other information:

- To replace the connectors for the central electronic module (CEM), see: Central electronic module (CEM), replacing See: Body Control Module/Service and Repair/Central Electronic Module (CEM), Replacing

Diagnostic Trouble Code (DTC) Information

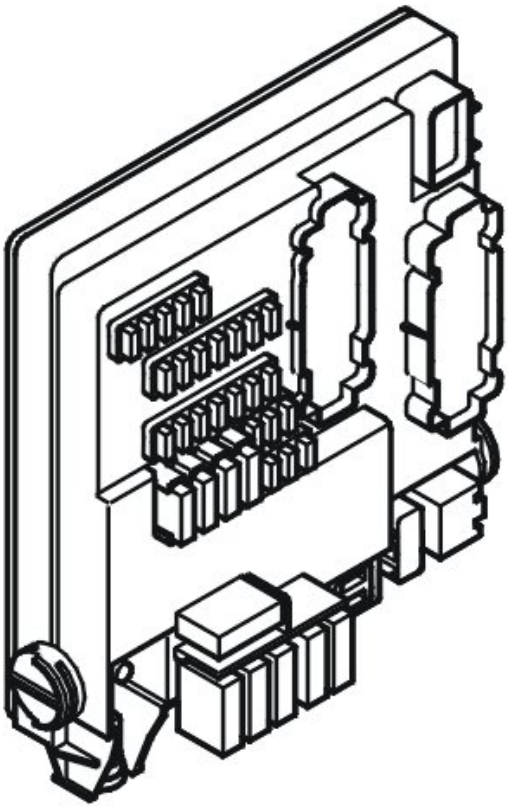
Diagnostic trouble code (DTC) information CEM-1A5A

Condition



The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers that communication with the rear electronic module (REM) is not operating.
The diagnostic trouble code (DTC) can be diagnosed when the ignition has been on for more than 10 seconds.

Note! In the event of CEM-1A5X diagnostic trouble codes (DTCs), the central electronic module (CEM) must not be replaced as the diagnostic trouble code (DTC) indicates a communication fault in the controller area network (CAN).

Substitute value
- None.

Possible source
- No power supply to rear electronic module (REM)
- Open-circuit in the ground lead for the rear electronic module (REM)

- Contact resistance in the terminals
- Open-circuit in the wiring for the CAN low speed network to the rear electronic module (REM)
- The rear electronic module (REM) is not intended for this vehicle (for example a used control module with different software/hardware).

Hint: If several diagnostic trouble codes (DTCs) are stored in the central electronic module (CEM) for communication faults with other control modules in the low speed network, this indicates a common fault in the controller area network (CAN). See the relevant wiring diagram.

Fault symptom[s]
- The fuel gauge indicates zero even though there is fuel in the tank.
- Rear demist does not operate.
- Retractable headrest not operating.
- The central locking system does not function at all.
- No unlocking of the trunk lid.

Signal Missing

Signal missing

Checking the power supply and ground for the rear electronic module (REM)

Check that the fuse for the Rear electronic module (REM) is intact.
Check the power supply and ground for the rear electronic module (REM) as follows.

Other information:
- Checking the supply voltage/ground terminal See: Body and Frame/Body Control Systems/Testing and Inspection/Component Tests and General Diagnostics/Checking the Supply Voltage/Ground Terminal, Rear Electronic Module (REM)
- For information about fuse and terminal numbers, see the relevant Wiring Diagram.

Was a fault detected?

Yes - Checking the function of the rear electronic module (REM)

No - Checking communication with the rear electronic module (REM)

Checking communication with the rear electronic module (REM)

Hint: The CAN communication with the control module is probably OK if the control module ID can be read off. The fault is probably intermittent and may therefore be difficult to locate.

- Try to communicate with the rear electronic module (REM) by reading off the control module ID
- Click on the symbol for VCT2000 to begin reading off

Continue - Signal missing

Signal missing

General information

Note! Figures shown are only examples.

Hint: For general information about CAN-troubleshooting, see:
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

General about CAN-related diagnostic trouble codes.
CEM-DF01 - DF17can only be stored in Central electronic module (CEM). These diagnostic trouble codes are stored when an electric fault is detected in CAN-lines. Start with these diagnostic trouble codes first.

CEM-1AXX only stored in Central electronic module (CEM). One diagnostic trouble code for every control module on the CAN-net. These diagnostic trouble codes indicate that Central electronic module (CEM) does not receive any reply from other control modules.
XXX-E000 (HS-CAN)/E001 (LS-CAN) can be stored in all CAN-connected control modules. These diagnostic trouble codes indicate that the control module has detected interference on the CAN-net.
XXX-E003 can be stored in all CAN-connected control modules except in Central electronic module (CEM). The control modules on the CAN-net listen for a message (identity number) that is sent out at regular intervals from Central electronic module (CEM). This diagnostic trouble code indicates that the control module has not received any identity number, or that the expected number is not correct. Interference on the CAN-net can also store this diagnostic trouble code.

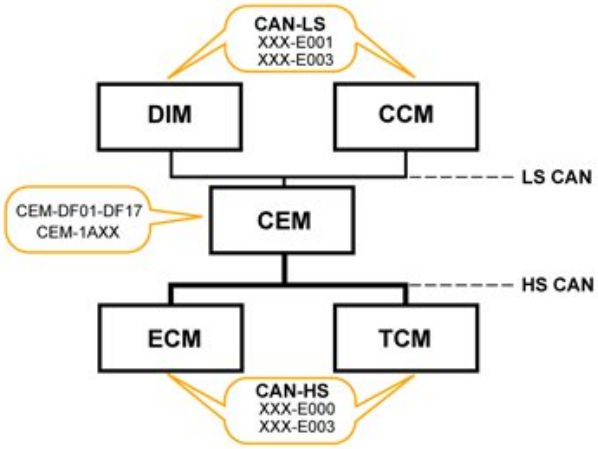
Note! In case of CAN-related faults, it is likely that a combination of above diagnostic trouble codes occur.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

If diagnostic trouble codes (DTCs) for communication faults can be read off from a control module, the fault is probably intermittent.
Intermittent fault in the voltage supply and ground to a control module on the CAN network results in the Central electronic module (CEM) storing a diagnostic trouble code (DTC) for an open-circuit in communication with the control module where the voltage supply does not work. There will probably not be a diagnostic trouble code (DTC) in the control module where the open-circuit in the voltage supply occurred as the control module cannot store a diagnostic trouble code (DTC) when it is not supplied with power.

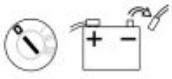
Note! Central electronic module (CEM) should not be replaced in case of CAN-fault, unless troubleshooting reveals that Central electronic module (CEM) has an internal fault.

Caution! During this fault-tracing use the wiring diagram to provide support when taking readings.



Continue - Checking resistance in CAN-net

Checking resistance in CAN-net



- Ignition off
- Disconnect the battery negative lead
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #3 and #11. The resistance should be approx. 55 - 65 ohms.
- If resistance is approx. 120 ohms, this indicates open circuit in the circuit so that only one terminating resistor (120 ohms) has been measured.
- If resistance is above 1 kohms this indicates open circuit/high contact resistance somewhere in the circuit.

- If resistance is below 55 ohms this indicates short-circuiting/contact resistance between the CAN-lines somewhere in the circuit.

Hint: For LS-CAN (Low Speed), terminating resistors are located in Upper electronic module (UEM) and Rear electronic module (REM).

Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

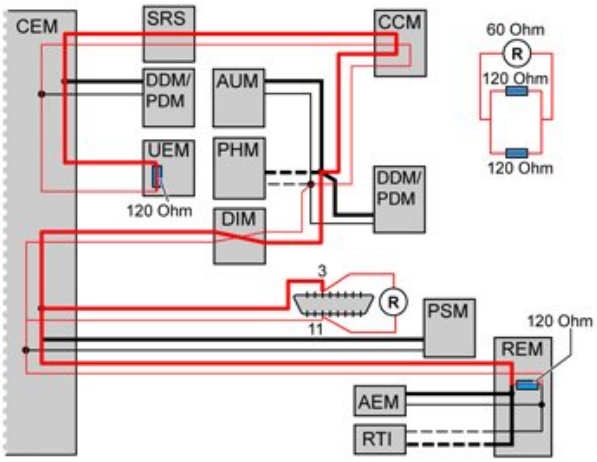
Note! Resistance measurement measures only main lines in the CAN-net (in circuit where both terminating resistors are found), not branches to certain control modules. See wiring diagram for vehicle model in question. Open circuit on branching without a terminating resistor cannot be detected with this measurement. However, short-circuiting on a branch can be detected. To measure resistance in the CAN-net to control modules located in a branching of their own, the measurement shall be done against the CAN-net at that control module. The values shall be as above.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy as necessary.

Other information

- Battery, disconnecting See: Starting and Charging/Battery/Service and Repair/Procedures/Battery, Disconnecting
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

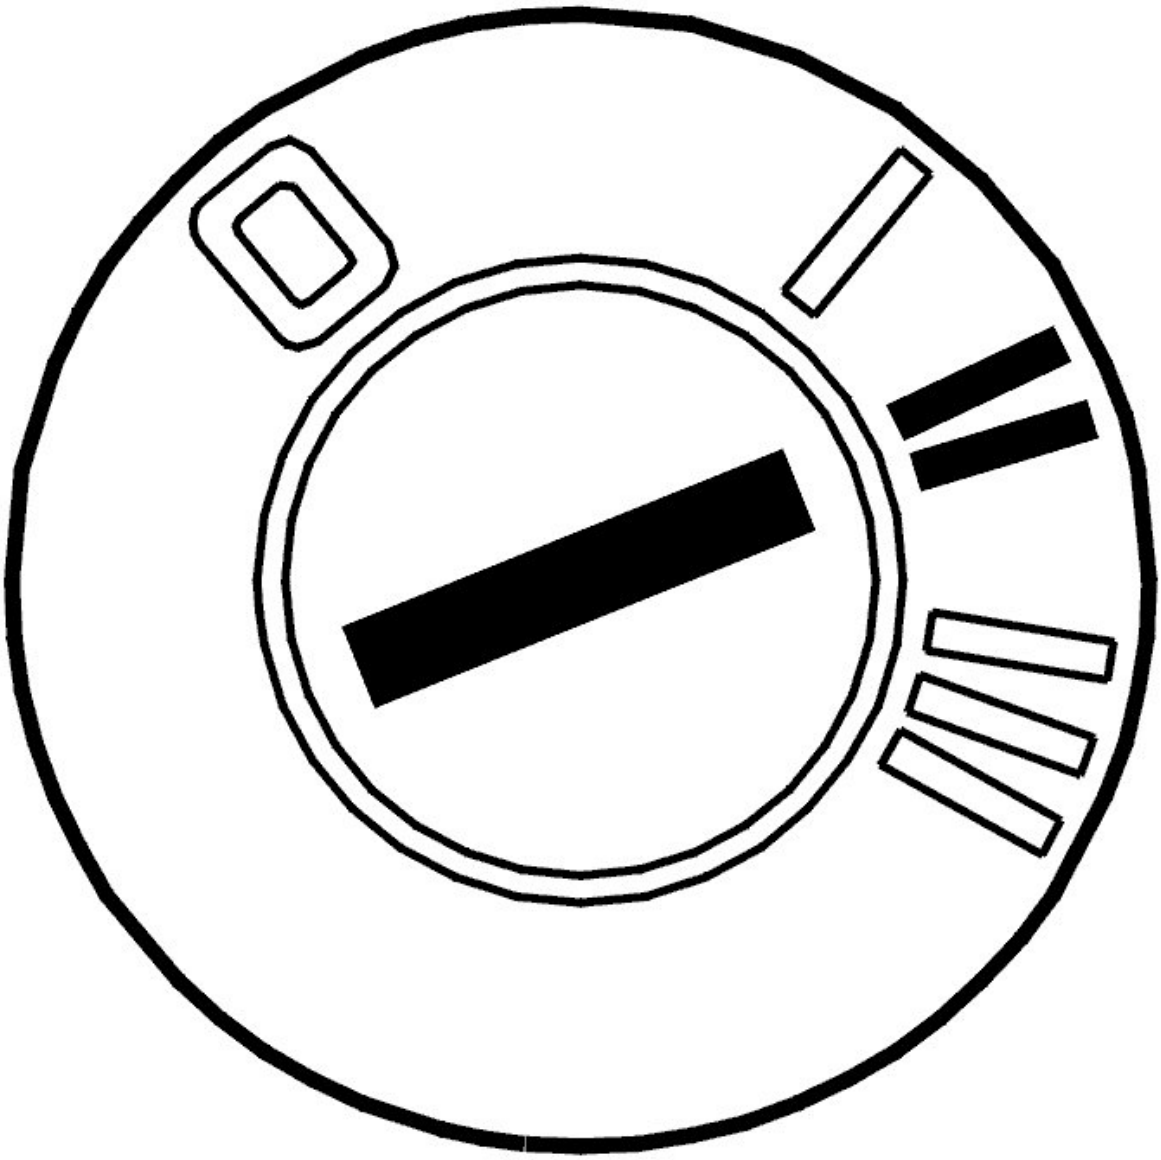


Was a fault detected?

Yes - Verification

No - Checking short-circuiting to ground/voltage in CAN-net

Checking the amount of traffic on the LS-CAN



- Connect the battery
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
Faults in the CAN network may be due to a control module sending faulty messages that disrupt normal communication. When messages are sent incorrectly, this results in a considerable increase in the amount of traffic on the CAN network. The load can be checked by reading the average value of the voltage on the CAN cables in relation to ground.
For further information, see the wiring diagram.
Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #3 and #4 (ground). The voltage should be approx: 2,8 - 3,2 V.
- #11 and #4 (ground). The voltage should be approx: 1,8 - 2,2 V.
- #3 and #11. The voltage shall be between approx. 0.55-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Hint: DiCE Error Frame Finder can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools: **951 3010** (memory card) as well as associated TJ 20402.

- Ignition on.
- Connect DiCE Error Frame Finder to the diagnostics socket.
- Note the blue LED-indicator. The indicator flashes to show detection of fault messages.

Note! Certain interference may occur without any real fault!

Cable fault

- Shake the cables lightly and pull lightly on the connections during the check to locate any fault. Note the blue LED-indicator.

"Chatting" control modules

- "Chatting" control modules may be difficult to find and troubleshooting may take time. Let the vehicle stand with DiCE connected for an extended time period. Afterwards, activate functions to provoke a malfunction. It may take up to several hours before the fault messages are sent. When the indicator starts to flash, remove the fuse for one control module at a time until the indicator stops flashing. When the indicator stops flashing, restore the fuse for the relevant control module and check that the indicator starts to flash again. Then it is likely that the problem is identified.

Remedy wiring as necessary.

Other information

- Battery, disconnecting See: Starting and Charging/Battery/Service and Repair/Procedures/Battery, Disconnecting

- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Hint: DiCE Error Frame Finder can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools: **951 3010** (memory card) as well as associated TJ 20402. If the load on the CAN network is too high, this may be due to a control module transmitting faulty messages on the CAN network. This is called a disruptive control module. The fault may also be due to an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The fault may occur without any of the control modules storing a diagnostic trouble code (DTC). The voltage can be measured between the CAN cables in order to check the load on the CAN network.

Note! It is not necessarily the control module that has set the diagnostic trouble code that communicates incorrectly. Faulty messages can come from any control module in the same section of the CAN network. However, faulty communication in one network cannot affect the communication on the other network. In other words, faulty communication on the LS-CAN cannot disrupt communication on the HS-CAN and vice versa.

- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Check communication/load on CAN-net by measuring voltage between CAN-L and CAN-H. Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #3 and #11. The average value of the voltage must be approximately 0.6-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

In order to identify which control module has faulty communication, cut the power supply to one control module at a time. Check the voltage in the CAN cables again. The easiest way to cut the power supply is to remove the fuse(s) for the relevant control module. Repeat until the voltage between the CAN wiring drops to the normal level.

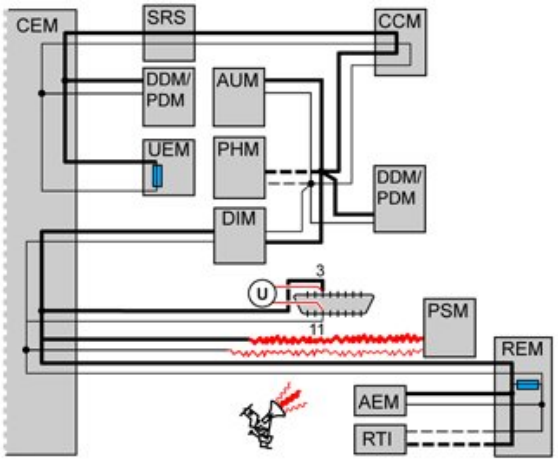
Note! When connecting and disconnecting certain control modules, diagnostic trouble codes (DTCs) may be stored in other control modules.

Hint: When the suspected defective control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the malfunction appears and disappears. Switch off the ignition between each check.

Note! Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.

A control module that is communicating incorrectly must be replaced. See Repairing and installing/Removing, replacing and installing.

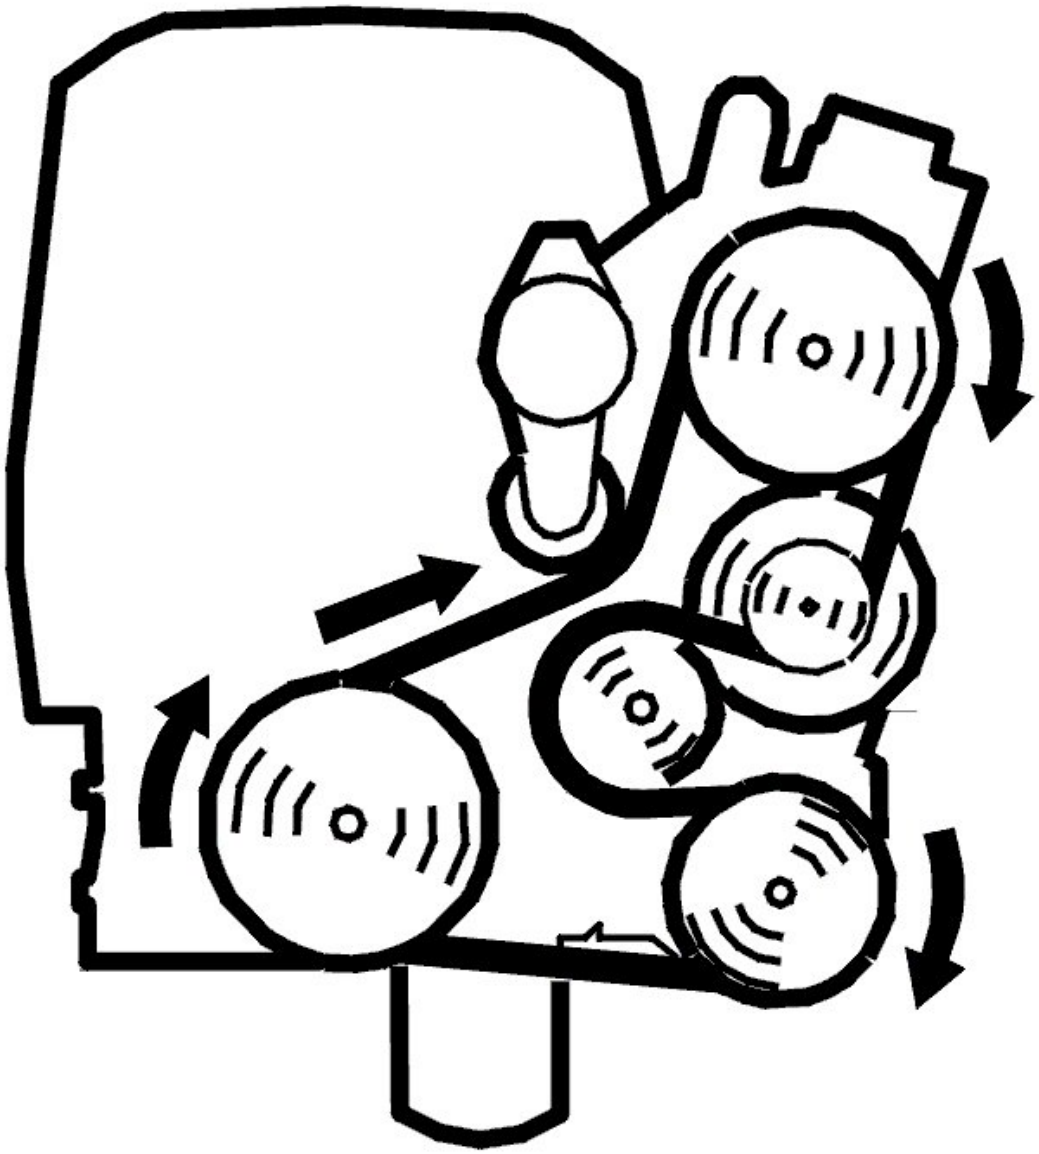
Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

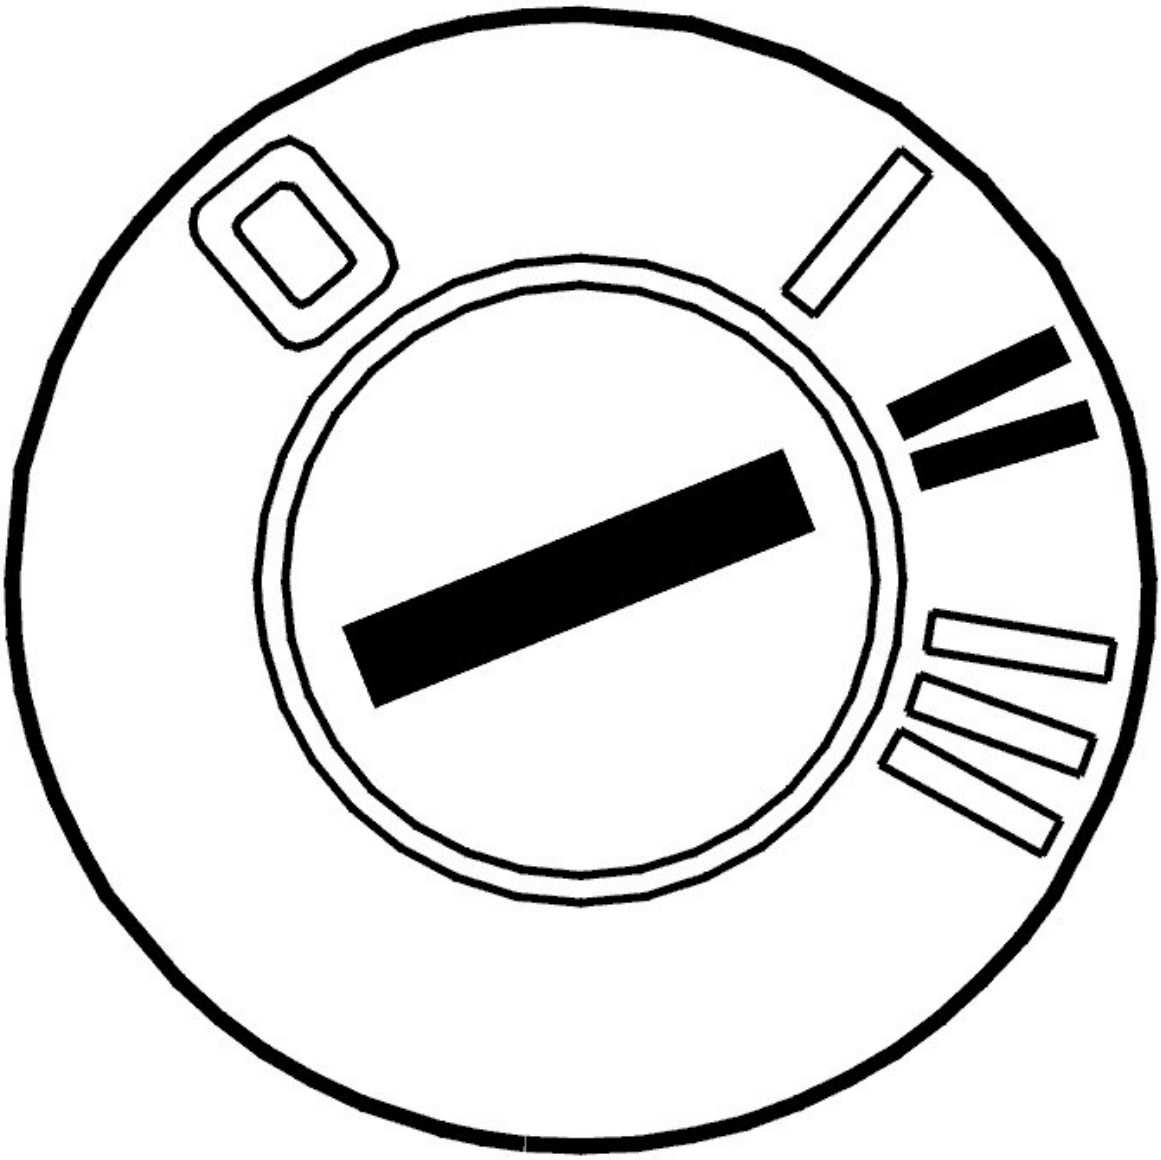


Continue - Verification

Verification

Hint: After rectifying a fault, a verification should be carried out.





- Reinstall the connectors, components etc.
- Ignition on.

Note! For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

- Erase diagnostic trouble codes (DTCs) in all control modules.
- Ignition off.
- Ignition on.
- Start the vehicle. Allow the vehicle to run for 10 minutes. Start the engine. Allow the engine to run at idle speed for 10 minutes
- Read out the diagnostic trouble codes in the vehicle via the DIAGNOSTICS tab.

Does the diagnostic trouble code (DTC) for faulty communication return?

Yes - Fault-tracing information

No - Fault Found

Fault-tracing information

Information

Fault-tracing information

The fault should have been detected and remedied. As this is not the case fault-tracing has failed.
Exit fault-tracing for this diagnostic trouble code (DTC) or make another attempt.

Do you want to exit fault-tracing?

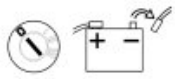
Yes - **FAULT-TRACING FAILED**

No - **Attempt New Test**

FAULT-TRACING FAILED - **FAULT-TRACING FAILED**

Attempt New Test - Signal Missing

Checking short-circuiting to ground/voltage in CAN-net



- Ignition off.
- Disconnect the battery negative lead.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Checking for a short-circuit to ground

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #3 and #4 (ground). Measurement is shown in the figure. The resistance should be above 1 kohms.
- #11 and #4 (ground). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and ground.

Checking for a short-circuit to voltage

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #3 and #16 (voltage). Measurement is shown in the figure. The resistance should be above 1 kohms.
- #11 and #16 (voltage). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and voltage cable.
Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

Hint: Part the CAN-net at suitable points to decide where a short-circuit may be found.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy as necessary.

Other information
- Battery, disconnecting See: Starting and Charging/Battery/Service and Repair/Procedures/Battery, Disconnecting

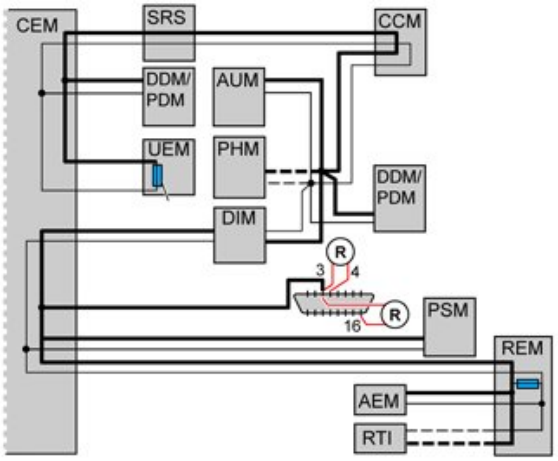
Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

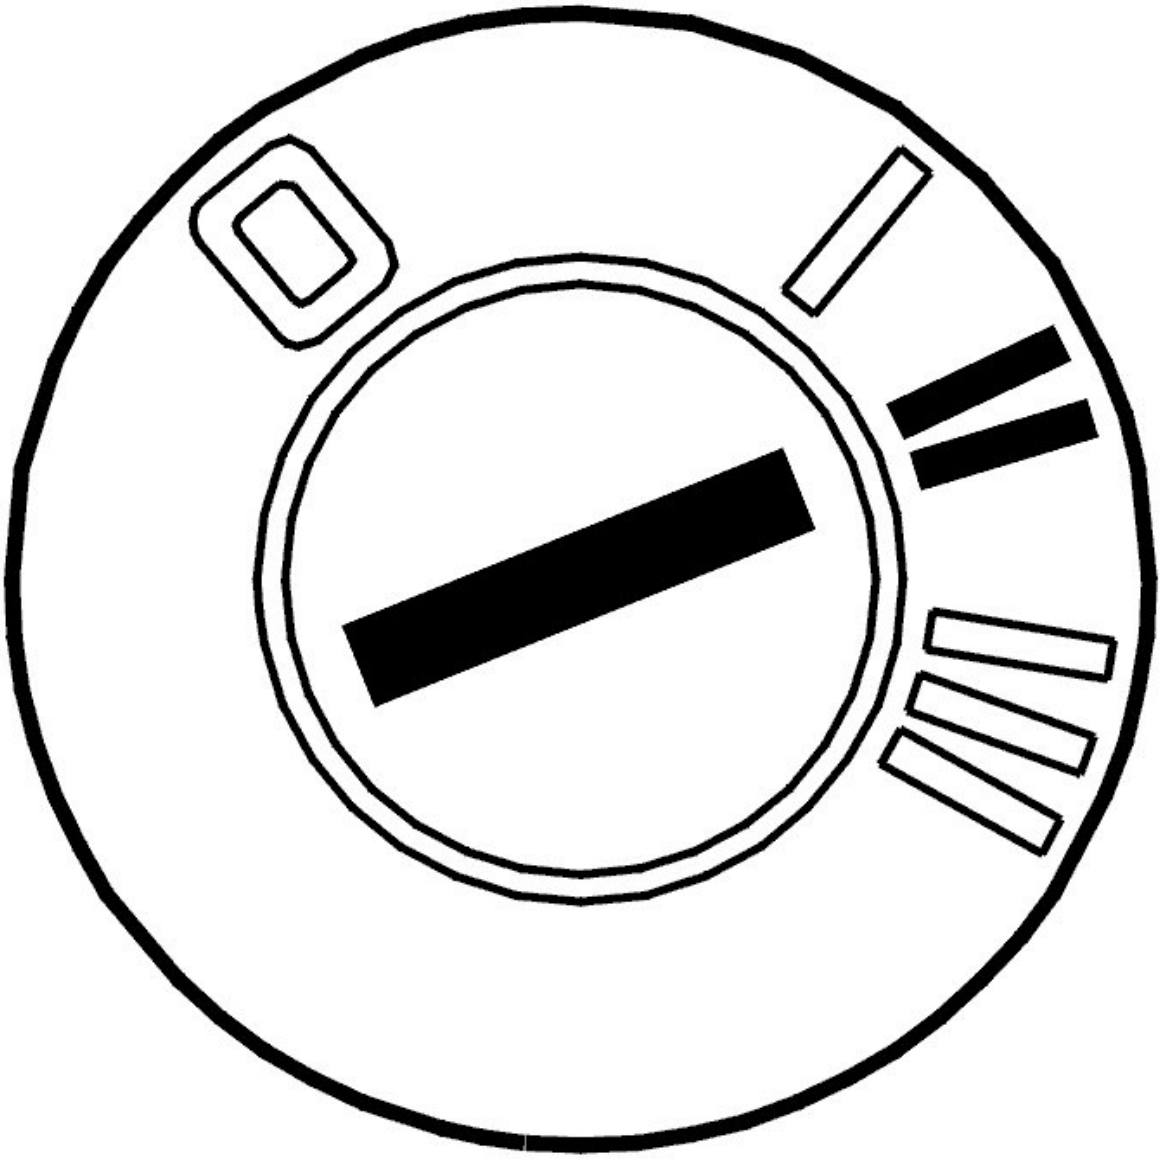


Was a fault detected?

Yes - Verification

No - Checking the amount of traffic on the LS-CAN

Checking voltage-drop in cable for CAN-H and CAN-L, respectively



- Connect the battery.
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

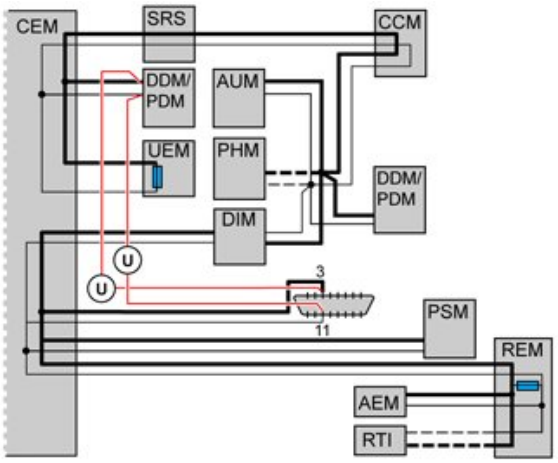
In principle, the voltage measured in each cable in the CAN-net shall be the same at each control module in the network. This means that the voltage-drop in the cable for CAN-H and CAN-L, respectively, between the control modules should be very low. If there is a voltage-difference in the CAN-lines between the diagnostics socket/Central electronic module (CEM) and a control module due to, e.g., contact resistance in a connector or branching, communication may be lost/interfered with. Check if there is voltage-drop in the cable for CAN-H and CAN-L between the diagnostics socket/Central electronic module (CEM) and the control module where there is problem with communication.
Carry out the following:
Measure voltage between the following connections on the OBDII-box/diagnostics socket.
- #3 and corresponding connection on relevant control module for CAN-H. The voltage shall be lower than 50 mV.
- #11 and corresponding connection on relevant control module for CAN-L. The voltage shall be lower than 50 mV.

If voltage is too high, this indicates too high contact resistance in cable, connector, or branching. Check the circuit between the diagnostics socket and control module in question for contact resistance and oxidation.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy wiring as necessary.

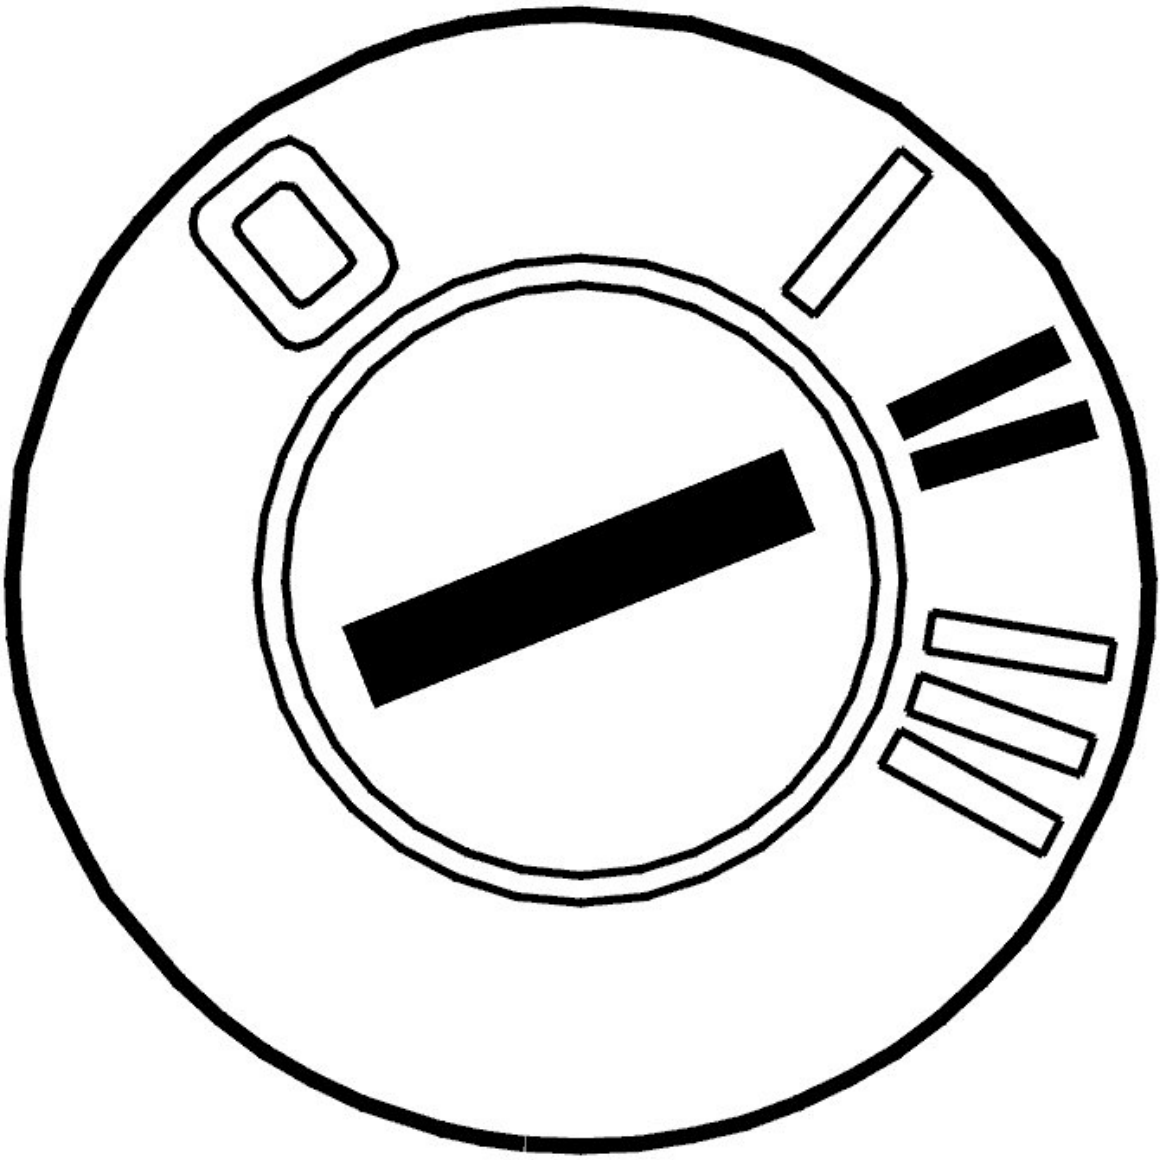
Other information
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

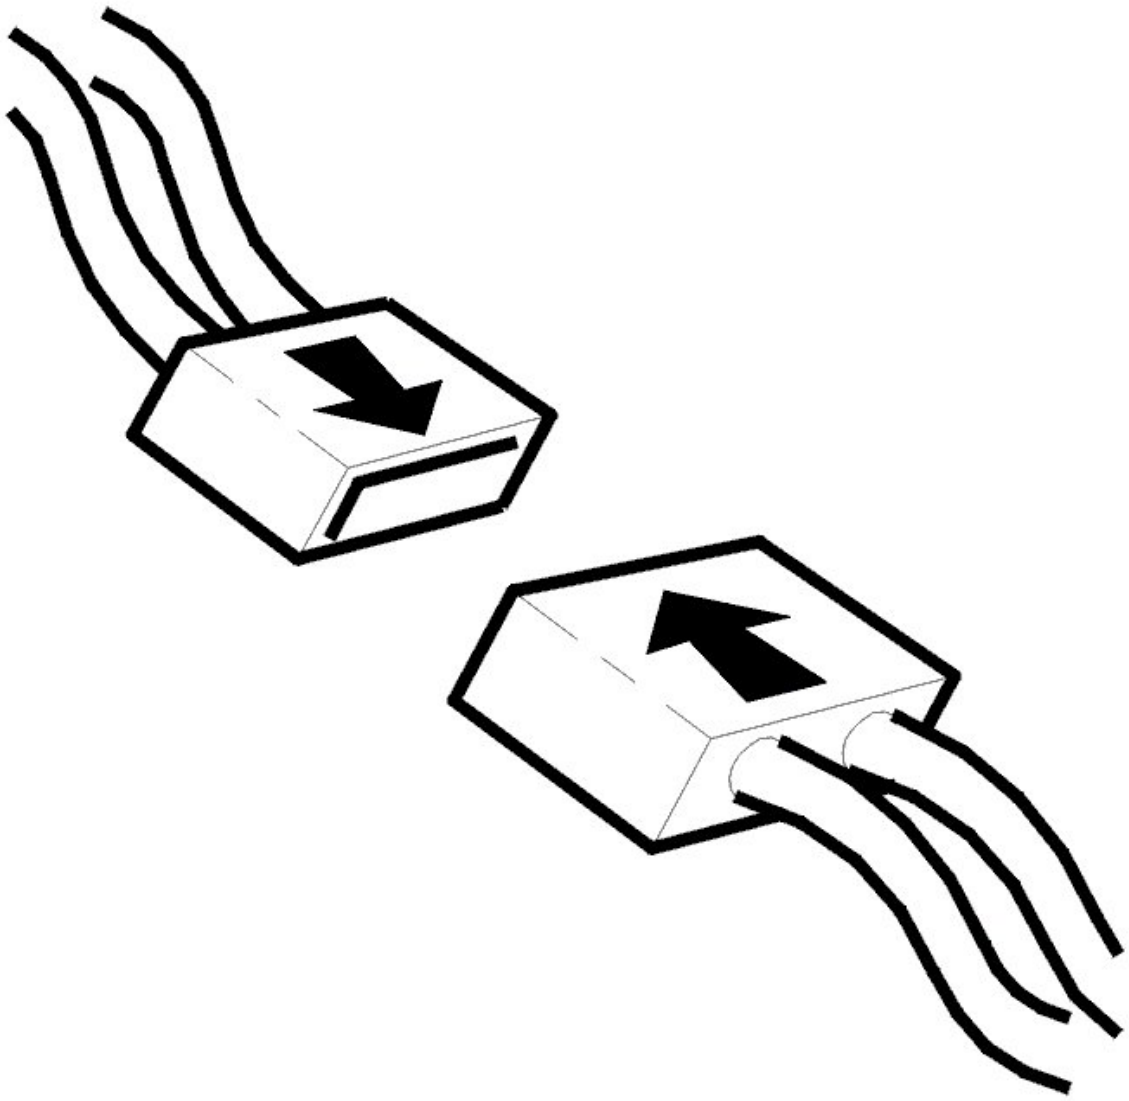


Continue - Verification

Checking the function of the rear electronic module (REM)

Hint: After carrying out the repair, check that the fault has been remedied.





- Ignition off
- Reconnect the connectors. Reinstall the components
- Ignition on.

Check the power supply and the ground for the rear electronic module (REM) by switching on the rear fog lamp using the button on the dashboard. If the central electronic module (CEM) is definitely powered, the power supply for the rear electronic module (REM) can also be checked by pressing the brake pedal. The stop lamp must then light.

- Try to communicate with the rear electronic module (REM) by reading off the control module ID
- Click on the symbol for VCT2000 to begin reading off

Can the control module ID be read out?

Yes - Fault Found

No - Fault-tracing information

Fault-tracing information

Information

Fault-tracing information

The fault should have been detected and remedied. As this is not the case fault-tracing has failed.
Exit fault-tracing for this diagnostic trouble code (DTC) or make another attempt.

Do you want to exit fault-tracing?

Yes - FAULT-TRACING FAILED

No - Attempt New Test

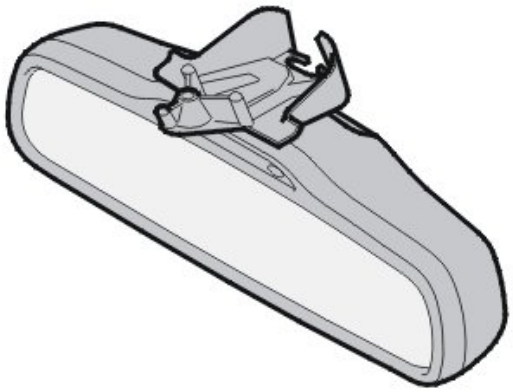
FAULT-TRACING FAILED - FAULT-TRACING FAILED

Attempt New Test - Checking the power supply and ground for the rear electronic module (REM)

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CEM-1A5C

Condition



The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers that communication with the upper electronic module (UEM) is not operating.
The diagnostic trouble code (DTC) can be diagnosed when the ignition has been on for more than 10 seconds.

Note! In the event of CEM-1A5X diagnostic trouble codes (DTCs), the central electronic module (CEM) must not be replaced as the diagnostic trouble code (DTC) indicates a communication fault in the controller area network (CAN).

Substitute value
- None.

Possible source
- No power supply to the upper electronic module (UEM)
- Open-circuit in the ground lead for the upper electronic module (UEM)
- Contact resistance in the terminals
- Open-circuit in the wiring for the CAN low speed network to the upper electronic module (UEM)
- The upper electronic module (UEM) is not intended for this vehicle (for example a used control module with different software/hardware).

Hint: If several diagnostic trouble codes (DTCs) are stored in the central electronic module (CEM) for communication faults with other control modules in the low speed network, this indicates a common fault in the controller area network (CAN). See the wiring diagram.

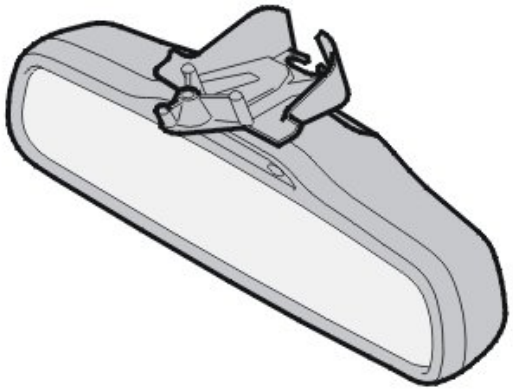
Fault symptom[s]
- SRS warning light on
- Cannot be controlled with the remote control.
- The power sun roof does not operate.
- The interior lighting does not work.

Signal Missing

Signal missing

Checking the function of the upper electronic module (UEM)

Check that the upper electronic module (UEM) is powered by switching on one of the rear reading lamps.



Does one of the rear reading lamps light?

Yes - Checking communication with the upper electronic module (UEM)

No - Checking the power supply and ground for the upper electronic module (UEM)

Checking the power supply and ground for the upper electronic module (UEM)

Check that the fuse for the control module is intact.
For further information about the fuse and terminal pin numbers, see the applicable wiring diagram.
Check the power supply and ground for the upper electronic module (UEM) as follows.
Remedy as necessary.

Other information:

- Checking the ground terminal See: Body and Frame/Body Control Systems/Testing and Inspection/Component Tests and General Diagnostics/Checking the Ground Terminal for the Upper Electronic Module (UEM)
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

Was a fault detected?

Yes - Checking the function of the upper electronic module (UEM)

No - Signal missing

Checking communication with the upper electronic module (UEM)

Hint: The CAN communication with the control module is probably OK if the control module ID can be read off. In that case the fault is probably intermittent and will then be more difficult to trace.

- Try to communicate with the upper electronic module (UEM) by reading off the control module ID
- Click on the symbol for VCT2000 to begin reading off

Continue - Signal missing

Signal missing

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

General information

Note! Figures shown are only examples.

Hint: For general information about CAN-troubleshooting, see:

- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

General about CAN-related diagnostic trouble codes.
CEM-DF01 - DF17can only be stored in Central electronic module (CEM). These diagnostic trouble codes are stored when an electric fault is detected in CAN-lines. Start with these diagnostic trouble codes first.
CEM-1AXX only stored in Central electronic module (CEM). One diagnostic trouble code for every control module on the CAN-net. These diagnostic trouble codes indicate that Central electronic module (CEM) does not receive any reply from other control modules.
XXX-E000 (HS-CAN)/E001 (LS-CAN) can be stored in all CAN-connected control modules. These diagnostic trouble codes indicate that the control module has detected interference on the CAN-net.
XXX-E003 can be stored in all CAN-connected control modules except in Central electronic module (CEM). The control modules on the CAN-net listen for a message (identity number) that is sent out at regular intervals from Central electronic module (CEM). This diagnostic trouble code indicates that the control module has not received any identity number, or that the expected number is not correct. Interference on the CAN-net can also store this diagnostic trouble code.

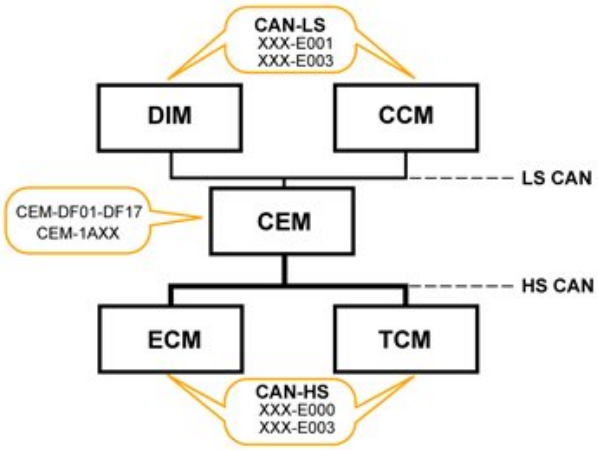
Note! In case of CAN-related faults, it is likely that a combination of above diagnostic trouble codes occur.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

If diagnostic trouble codes (DTCs) for communication faults can be read off from a control module, the fault is probably intermittent.
Intermittent fault in the voltage supply and ground to a control module on the CAN network results in the Central electronic module (CEM) storing a diagnostic trouble code (DTC) for an open-circuit in communication with the control module where the voltage supply does not work. There will probably not be a diagnostic trouble code (DTC) in the control module where the open-circuit in the voltage supply occurred as the control module cannot store a diagnostic trouble code (DTC) when it is not supplied with power.

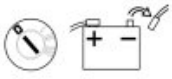
Note! Central electronic module (CEM) should not be replaced in case of CAN-fault, unless troubleshooting reveals that Central electronic module (CEM) has an internal fault.

Caution! During this fault-tracing use the wiring diagram to provide support when taking readings.



Continue - Checking resistance in CAN-net

Checking resistance in CAN-net



- Ignition off
- Disconnect the battery negative lead
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #3 and #11. The resistance should be approx. 55 - 65 ohms.
- If resistance is approx. 120 ohms, this indicates open circuit in the circuit so that only one terminating resistor (120 ohms) has been measured.
- If resistance is above 1 kohms this indicates open circuit/high contact resistance somewhere in the circuit.
- If resistance is below 55 ohms this indicates short-circuiting/contact resistance between the CAN-lines somewhere in the circuit.

Hint: For LS-CAN (Low Speed), terminating resistors are located in Upper electronic module (UEM) and Rear electronic module (REM).

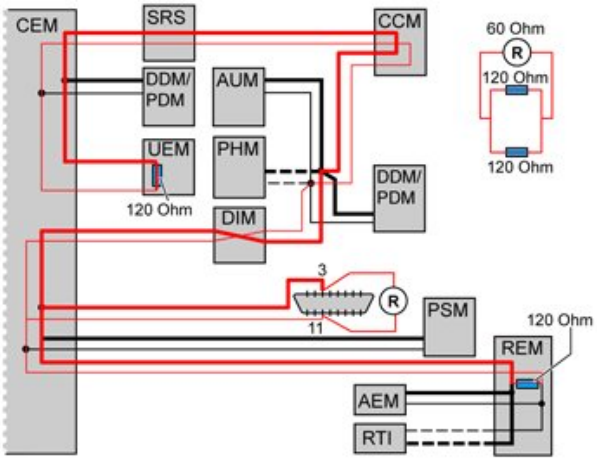
Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

Note! Resistance measurement measures only main lines in the CAN-net (in circuit where both terminating resistors are found), not branches to certain control modules. See wiring diagram for vehicle model in question. Open circuit on branching without a terminating resistor cannot be detected with this measurement. However, short-circuiting on a branch can be detected. To measure resistance in the CAN-net to control modules located in a branching of their own, the measurement shall be done against the CAN-net at that control module. The values shall be as above.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy as necessary.

Other information
- Battery, disconnecting See: Starting and Charging/Battery/Service and Repair/Procedures/Battery, Disconnecting
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

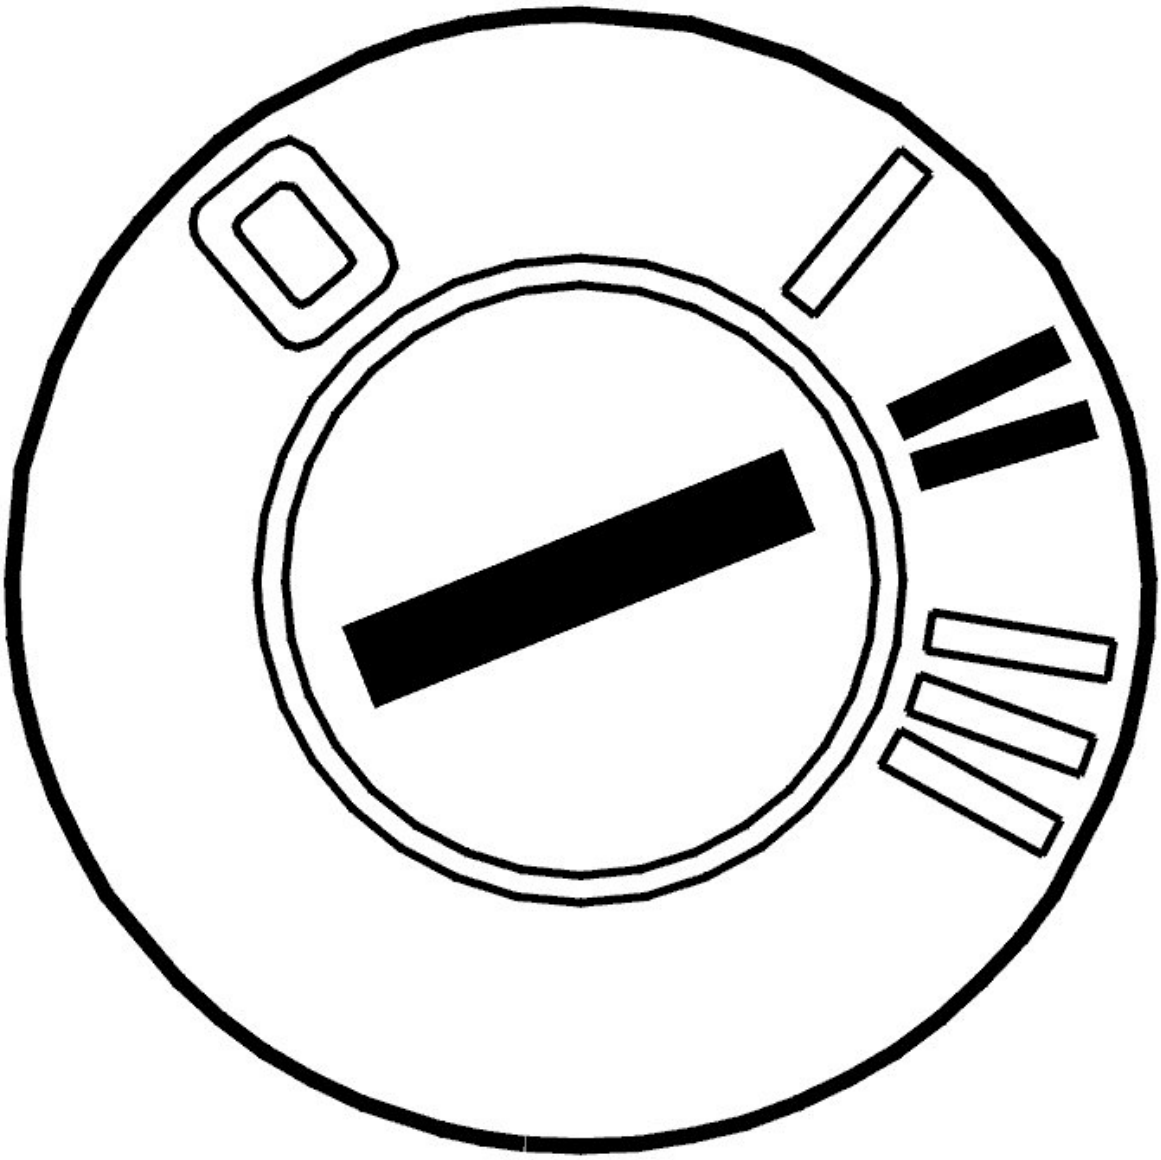


Was a fault detected?

Yes - Verification

No - Checking short-circuiting to ground/voltage in CAN-net

Checking the amount of traffic on the LS-CAN



- Connect the battery
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
Faults in the CAN network may be due to a control module sending faulty messages that disrupt normal communication. When messages are sent incorrectly, this results in a considerable increase in the amount of traffic on the CAN network. The load can be checked by reading the average value of the voltage on the CAN cables in relation to ground.
For further information, see the wiring diagram.
Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #3 and #4 (ground). The voltage should be approx: 2,8 - 3,2 V.
- #11 and #4 (ground). The voltage should be approx: 1,8 - 2,2 V.
- #3 and #11. The voltage shall be between approx. 0.55-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Hint: DiCE Error Frame Finder can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools: **951 3010** (memory card) as well as associated TJ 20402.

- Ignition on.
- Connect DiCE Error Frame Finder to the diagnostics socket.
- Note the blue LED-indicator. The indicator flashes to show detection of fault messages.

Note! Certain interference may occur without any real fault!

Cable fault

- Shake the cables lightly and pull lightly on the connections during the check to locate any fault. Note the blue LED-indicator.

"Chatting" control modules

- "Chatting" control modules may be difficult to find and troubleshooting may take time. Let the vehicle stand with DiCE connected for an extended time period. Afterwards, activate functions to provoke a malfunction. It may take up to several hours before the fault messages are sent. When the indicator starts to flash, remove the fuse for one control module at a time until the indicator stops flashing. When the indicator stops flashing, restore the fuse for the relevant control module and check that the indicator starts to flash again. Then it is likely that the problem is identified.

Remedy wiring as necessary.

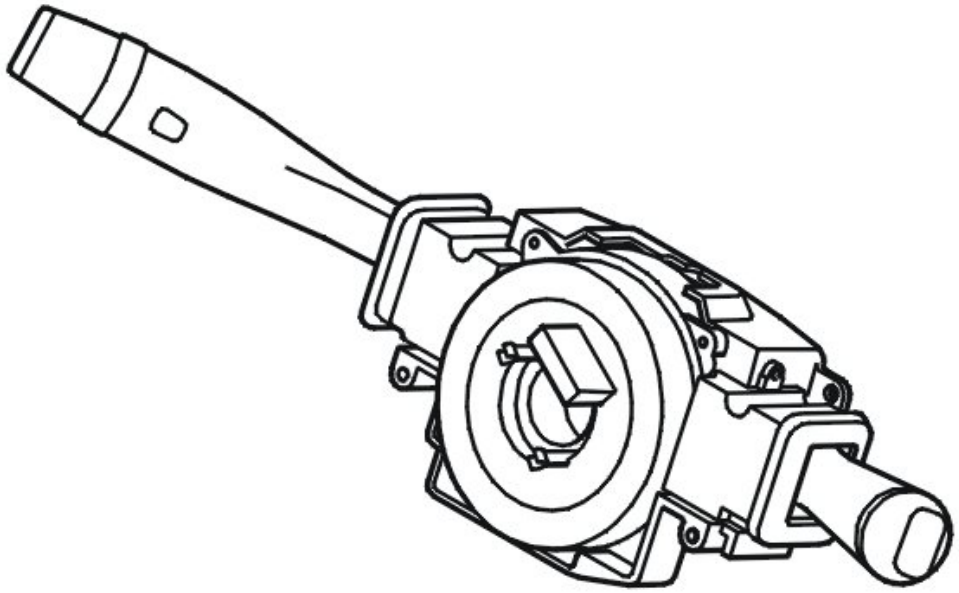
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CEM-1A5E

Condition



The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers that communication with the steering wheel angle sensor module (SAS) is not operating.
The steering wheel angle sensor module (SAS) is located inside, and is supplied with power by, the steering wheel module (SWM). Only the steering wheel angle sensor module (SAS) communicates on the controller area network (CAN).
The diagnostic trouble code (DTC) can be diagnosed when the ignition has been on for more than 10 seconds.

Note! In the event of CEM-1A5X diagnostic trouble codes (DTCs), the central electronic module (CEM) must not be replaced as the diagnostic trouble code (DTC) indicates a communication fault in the controller area network (CAN)!

Substitute value
- None.

Possible source
- No power supply to the steering wheel module (SWM)
- Open-circuit in the ground lead for the steering wheel module (SWM)
- Contact resistance in the terminals
- Open-circuit in the wiring for the CAN high speed network to the steering wheel angle sensor module (SAS)
- The steering wheel module (SWM) is not intended for this vehicle (for example a used control module with different software/hardware).

Hint: If several diagnostic trouble codes (DTCs) are stored in the central electronic module (CEM) for communication faults with other control modules in the high speed network, this indicates a common fault in the controller area network (CAN). See the wiring diagram.

Fault symptom[s]
- No stability function.

- Message in the display.

Signal Missing

Signal missing

Checking the power supply and ground for the steering wheel module (SWM)

Note! Steering wheel angle sensor module (SAS) is located inside, and is supplied with power by, the steering wheel module (SWM). Only the steering wheel angle sensor module (SAS) communicates on the controller area network (CAN). The brake control module (BCM) will store a diagnostic trouble code (DTC) if the communication between the brake control module (BCM) and the steering wheel angle sensor module (SAS) has been interrupted. DSTC will not be activated after a fault in the system has been repaired until the vehicle reaches a speed of approximately 50 km/h.

Check that the fuse for the control module is intact.
Check the power supply and ground for the steering wheel module (SWM) as follows.
Remedy as necessary.

Other information

- Checking the voltage / ground terminal See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Testing and Inspection/Component Tests and General Diagnostics/Checking the Voltage/Ground, Steering Wheel Angle Sensor Module (SAS)
- For information about fuse and terminal numbers, see the relevant Wiring Diagram.
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

Was a fault detected?

Yes - Checking the steering wheel angle sensor module (SAS)

No - Checking communication with the steering wheel angle sensor module (SAS)

Checking communication with the steering wheel angle sensor module (SAS)

Hint: The CAN communication with the control module is probably OK if the control module ID can be read off. In that case the fault is probably intermittent and will then be more difficult to trace.

- Try to communicate with the steering wheel angle sensor module (SAS) by reading off the control module ID
- Click on the symbol for VCT2000 to begin reading off

Continue - Signal missing

Signal missing

General information

Note! Figures shown are only examples.

Hint: For general information about CAN-troubleshooting, see:

- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

General about CAN-related diagnostic trouble codes.
CEM-DF01 - DF17can only be stored in Central electronic module (CEM). These diagnostic trouble codes are stored when an electric fault is detected in CAN-lines. Start with these diagnostic trouble codes first.
CEM-1AXX only stored in Central electronic module (CEM). One diagnostic trouble code for every control module on the CAN-net. These diagnostic trouble codes indicate that Central electronic module (CEM) does not receive any reply from other control modules.
XXX-E000 (HS-CAN)/E001 (LS-CAN) can be stored in all CAN-connected control modules. These diagnostic trouble codes indicate that the control module has detected interference on the CAN-net.
XXX-E003 can be stored in all CAN-connected control modules except in Central electronic module (CEM). The control modules on the CAN-net

listen for a message (identity number) that is sent out at regular intervals from Central electronic module (CEM). This diagnostic trouble code indicates that the control module has not received any identity number, or that the expected number is not correct. Interference on the CAN-net can also store this diagnostic trouble code.

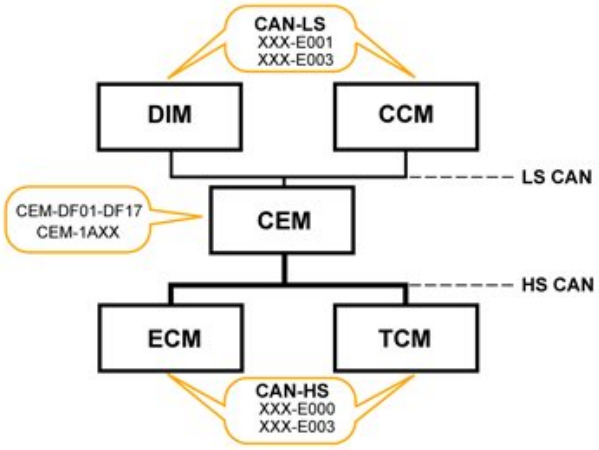
Note! In case of CAN-related faults, it is likely that a combination of above diagnostic trouble codes occur.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

If diagnostic trouble codes (DTCs) for communication faults can be read off from a control module, the fault is probably intermittent. Intermittent fault in the voltage supply and ground to a control module on the CAN network results in the Central electronic module (CEM) storing a diagnostic trouble code (DTC) for an open-circuit in communication with the control module where the voltage supply does not work. There will probably not be a diagnostic trouble code (DTC) in the control module where the open-circuit in the voltage supply occurred as the control module cannot store a diagnostic trouble code (DTC) when it is not supplied with power.

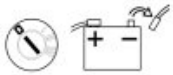
Note! Central electronic module (CEM) should not be replaced in case of CAN-fault, unless troubleshooting reveals that Central electronic module (CEM) has an internal fault.

Caution! During this fault-tracing use the wiring diagram to provide support when taking readings.



Continue - Checking resistance in CAN-net

Checking resistance in CAN-net



- Ignition off
- Disconnect the battery negative lead
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #3 and #11. The resistance should be approx. 55 - 65 ohms.
- If resistance is approx. 120 ohms, this indicates open circuit in the circuit so that only one terminating resistor (120 ohms) has been measured.
- If resistance is above 1 kohms this indicates open circuit/high contact resistance somewhere in the circuit.
- If resistance is below 55 ohms this indicates short-circuiting/contact resistance between the CAN-lines somewhere in the circuit.

Hint: For LS-CAN (Low Speed), terminating resistors are located in Upper electronic module (UEM) and Rear electronic module (REM).

Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the

resistance changes to detect intermittent short-circuits or open circuit.

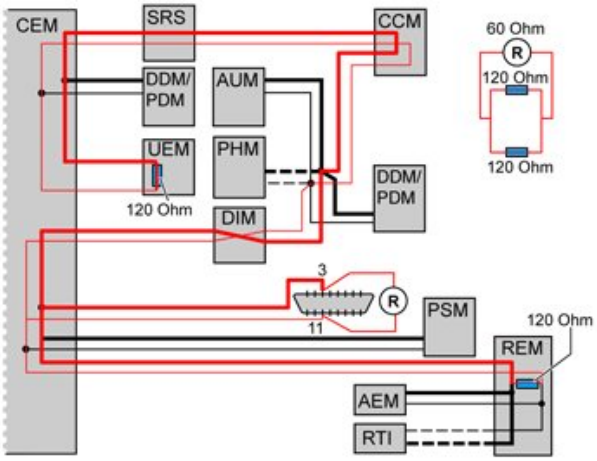
Note! Resistance measurement measures only main lines in the CAN-net (in circuit where both terminating resistors are found), not branches to certain control modules. See wiring diagram for vehicle model in question. Open circuit on branching without a terminating resistor cannot be detected with this measurement. However, short-circuiting on a branch can be detected. To measure resistance in the CAN-net to control modules located in a branching of their own, the measurement shall be done against the CAN-net at that control module. The values shall be as above.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy as necessary.

Other information

- Battery, disconnecting See: Starting and Charging/Battery/Service and Repair/Procedures/Battery, Disconnecting
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

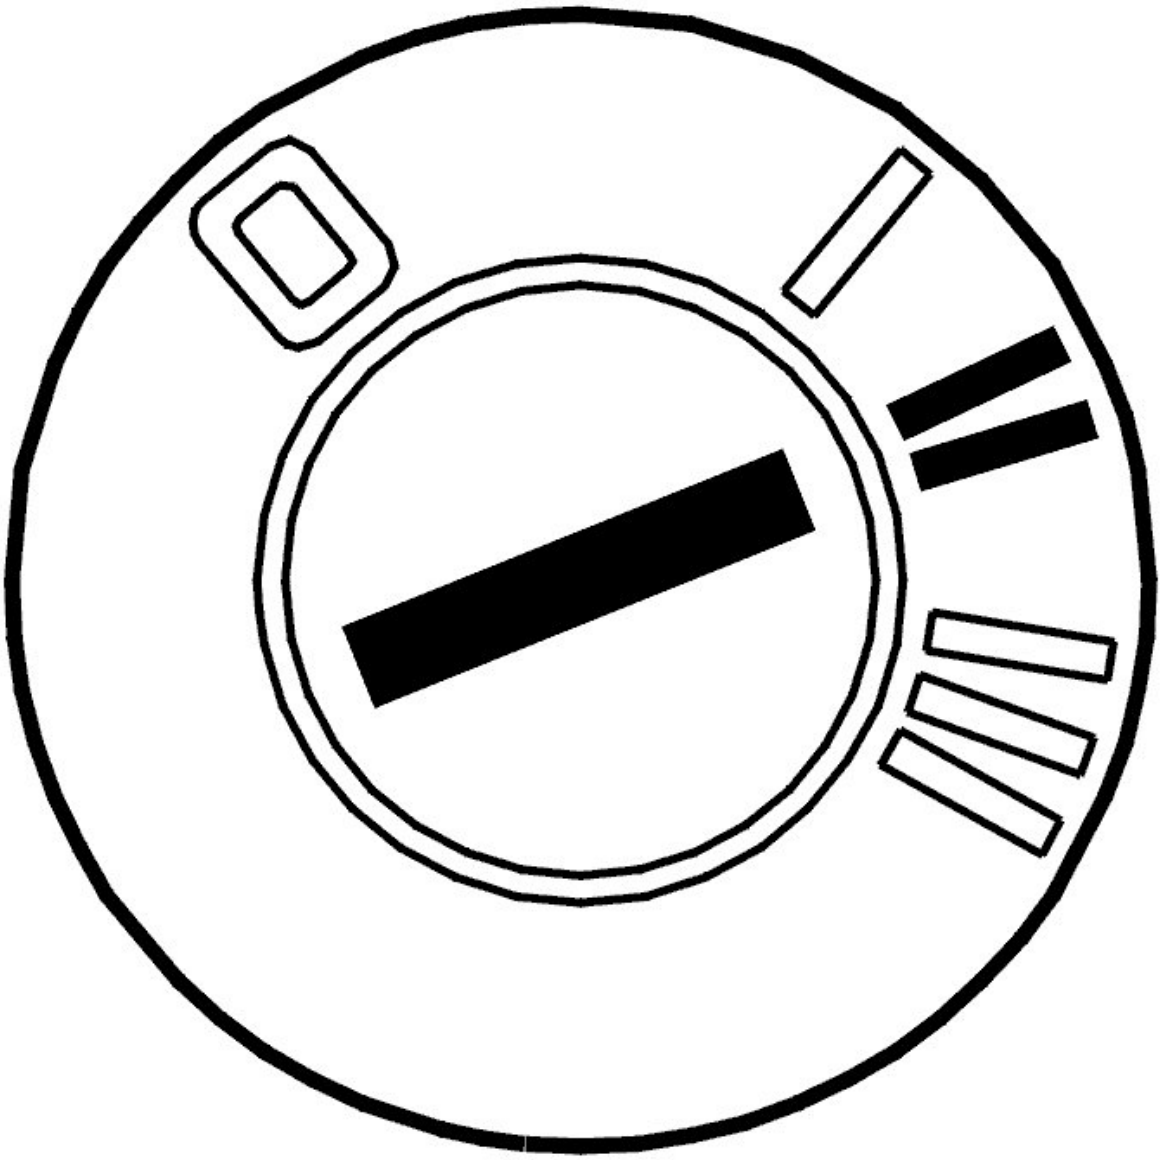


Was a fault detected?

Yes - Verification

No - Checking short-circuiting to ground/voltage in CAN-net

Checking the amount of traffic on the LS-CAN



- Connect the battery
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
Faults in the CAN network may be due to a control module sending faulty messages that disrupt normal communication. When messages are sent incorrectly, this results in a considerable increase in the amount of traffic on the CAN network. The load can be checked by reading the average value of the voltage on the CAN cables in relation to ground.
For further information, see the wiring diagram.
Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #3 and #4 (ground). The voltage should be approx: 2,8 - 3,2 V.
- #11 and #4 (ground). The voltage should be approx: 1,8 - 2,2 V.
- #3 and #11. The voltage shall be between approx. 0.55-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Hint: DiCE Error Frame Finder can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools: **951 3010** (memory card) as well as associated TJ 20402.

- Ignition on.
- Connect DiCE Error Frame Finder to the diagnostics socket.
- Note the blue LED-indicator. The indicator flashes to show detection of fault messages.

Note! Certain interference may occur without any real fault!

Cable fault

- Shake the cables lightly and pull lightly on the connections during the check to locate any fault. Note the blue LED-indicator.

"Chatting" control modules

- "Chatting" control modules may be difficult to find and troubleshooting may take time. Let the vehicle stand with DiCE connected for an extended time period. Afterwards, activate functions to provoke a malfunction. It may take up to several hours before the fault messages are sent. When the indicator starts to flash, remove the fuse for one control module at a time until the indicator stops flashing. When the indicator stops flashing, restore the fuse for the relevant control module and check that the indicator starts to flash again. Then it is likely that the problem is identified.

Remedy wiring as necessary.

Other information

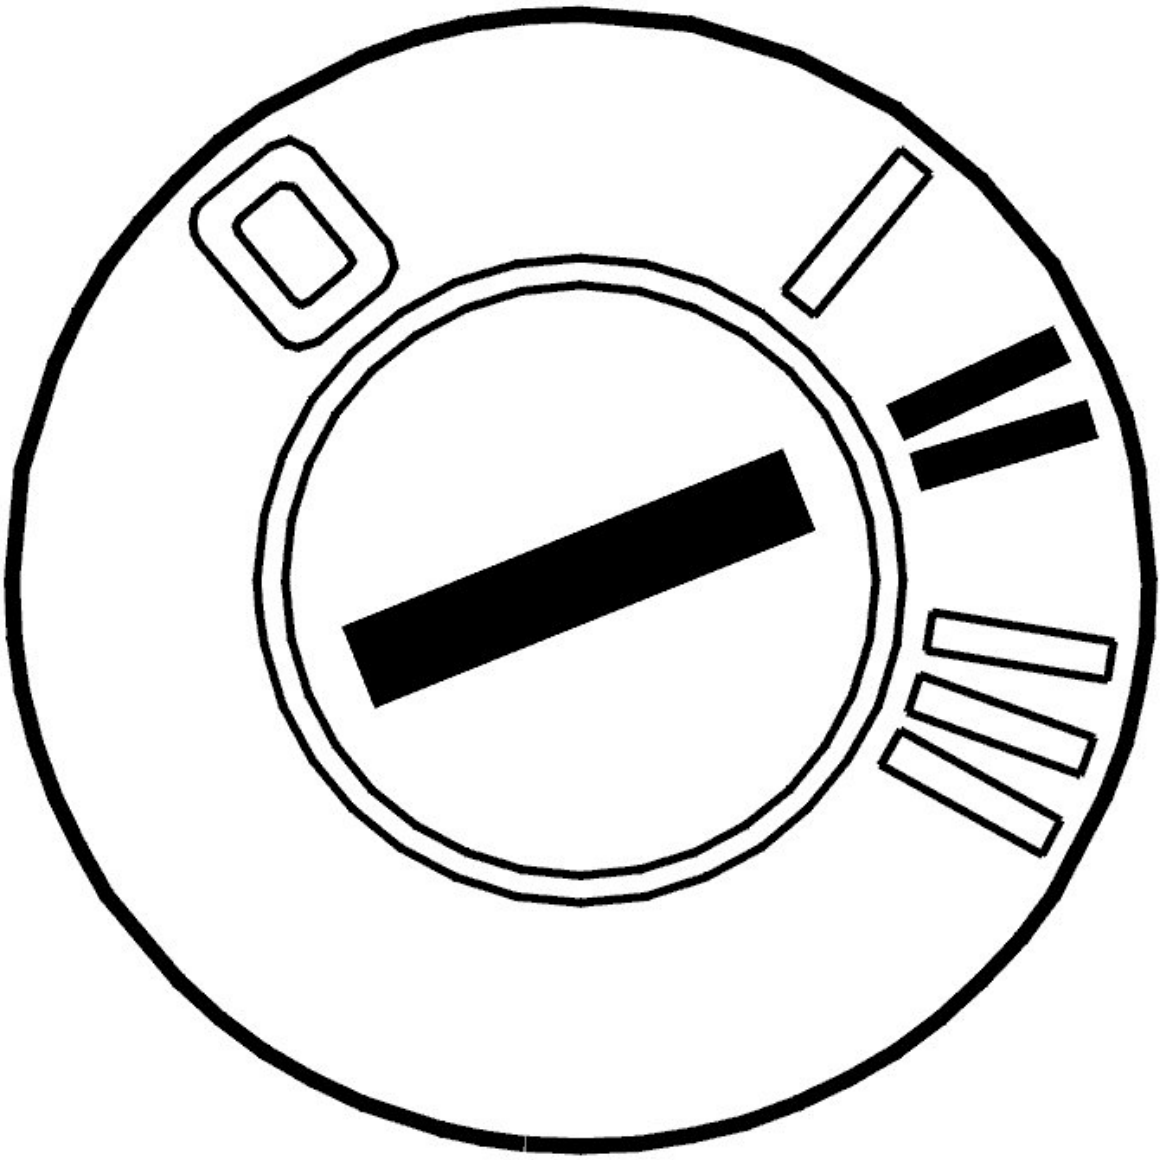
Was a fault detected?

Yes - Identifying a control module in the CAN network

No - Checking voltage-drop in cable for CAN-H and CAN-L, respectively

---

Identifying a control module in the CAN network



Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:

- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Hint: DiCE Error Frame Finder can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools: **951 3010** (memory card) as well as associated TJ 20402. If the load on the CAN network is too high, this may be due to a control module transmitting faulty messages on the CAN network. This is called a disruptive control module. The fault may also be due to an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The fault may occur without any of the control modules storing a diagnostic trouble code (DTC). The voltage can be measured between the CAN cables in order to check the load on the CAN network.

Note! It is not necessarily the control module that has set the diagnostic trouble code that communicates incorrectly. Faulty messages can come from any control module in the same section of the CAN network. However, faulty communication in one network cannot affect the communication on the other network. In other words, faulty communication on the LS-CAN cannot disrupt communication on the HS-CAN and vice versa.

- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Check communication/load on CAN-net by measuring voltage between CAN-L and CAN-H. Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #3 and #11. The average value of the voltage must be approximately 0.6-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

In order to identify which control module has faulty communication, cut the power supply to one control module at a time. Check the voltage in the CAN cables again. The easiest way to cut the power supply is to remove the fuse(s) for the relevant control module. Repeat until the voltage between the CAN wiring drops to the normal level.

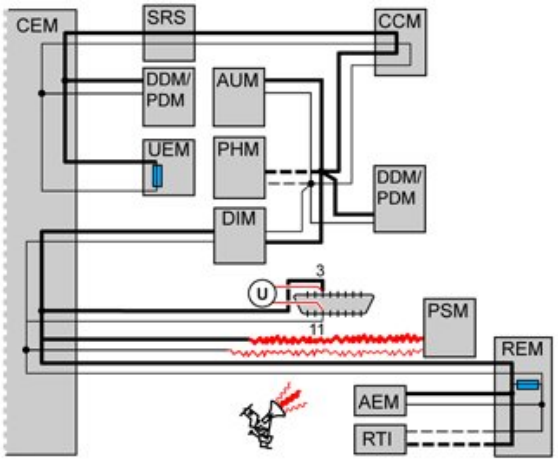
Note! When connecting and disconnecting certain control modules, diagnostic trouble codes (DTCs) may be stored in other control modules.

Hint: When the suspected defective control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the malfunction appears and disappears. Switch off the ignition between each check.

Note! Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.

A control module that is communicating incorrectly must be replaced. See Repairing and installing/Removing, replacing and installing.

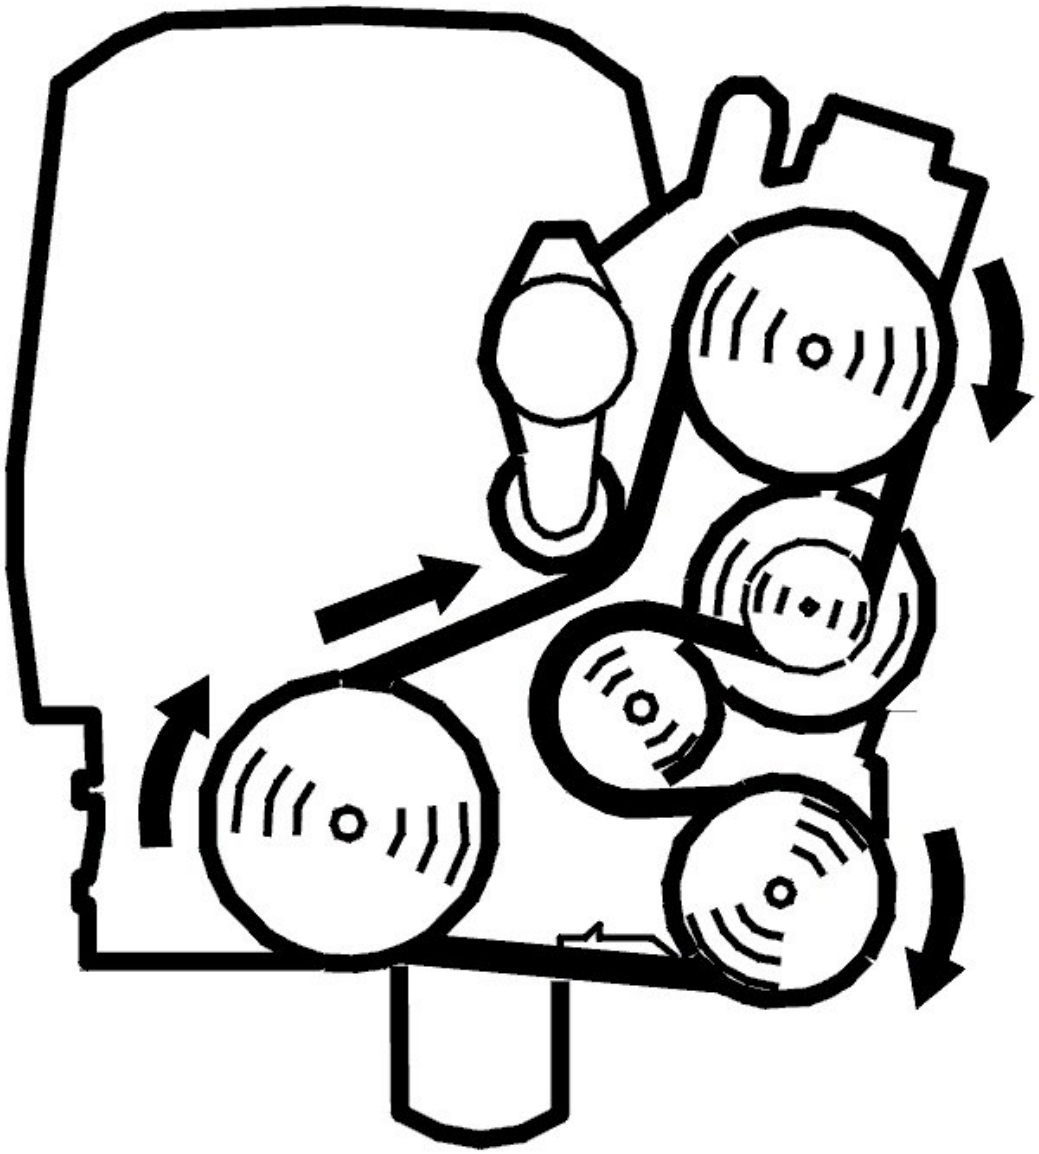
Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

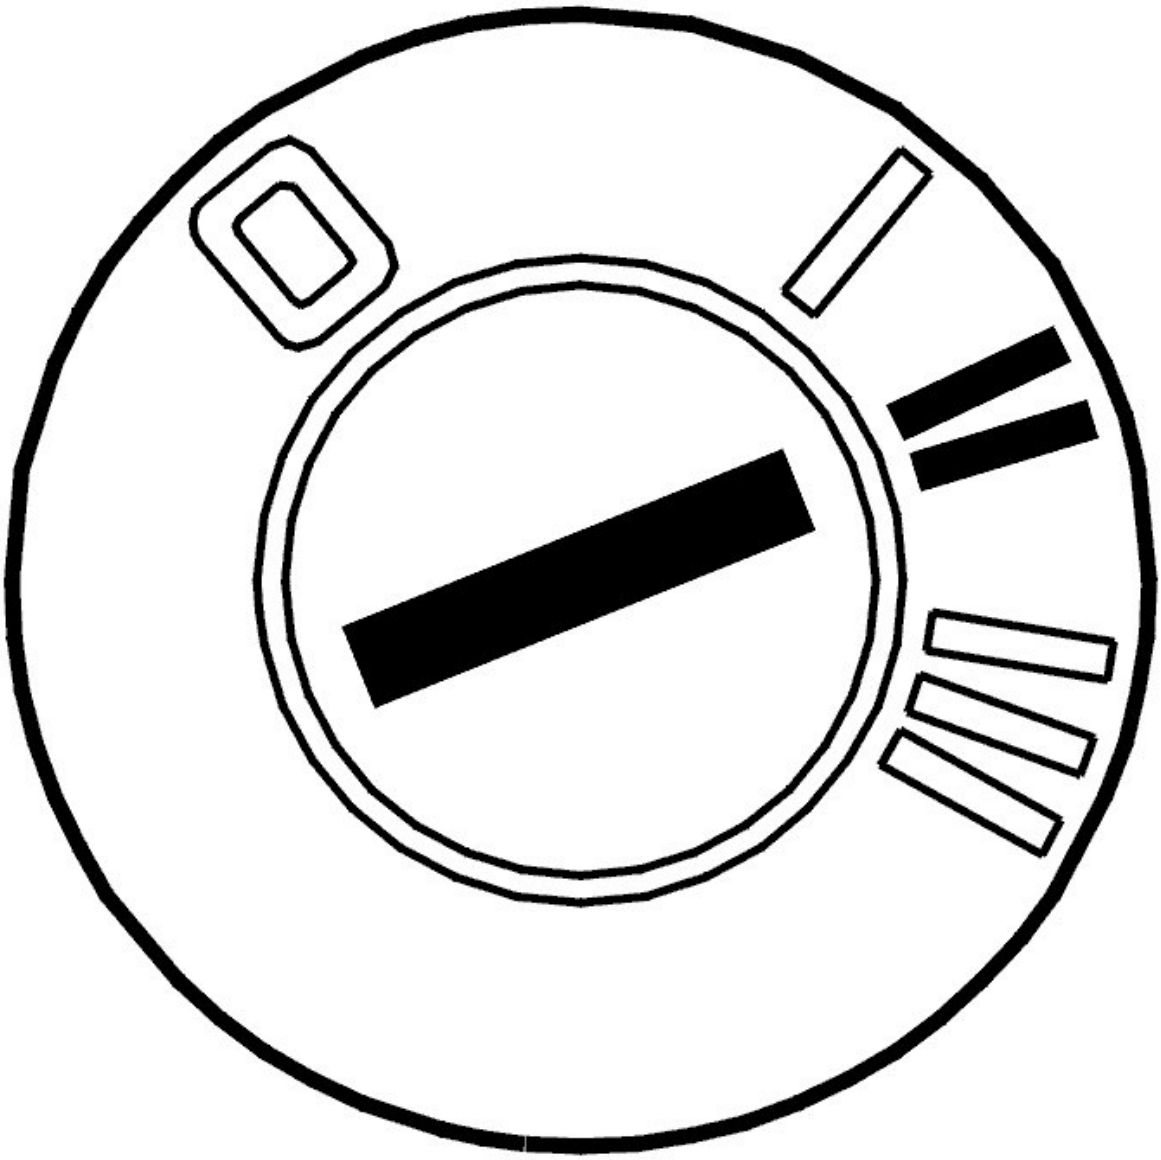


Continue - Verification

Verification

Hint: After rectifying a fault, a verification should be carried out.





- Reinstall the connectors, components etc.
- Ignition on.

Note! For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

- Erase diagnostic trouble codes (DTCs) in all control modules.
- Ignition off.
- Ignition on.
- Start the vehicle. Allow the vehicle to run for 10 minutes. Start the engine. Allow the engine to run at idle speed for 10 minutes
- Read out the diagnostic trouble codes in the vehicle via the DIAGNOSTICS tab.

Does the diagnostic trouble code (DTC) for faulty communication return?

Yes - Fault-tracing information

No - Fault Found

Fault-tracing information

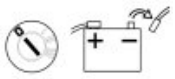
Checking short-circuiting to ground/voltage in CAN-net



- Ignition off.
- Disconnect the battery negative lead.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Checking for a short-circuit to ground

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #3 and #4 (ground). Measurement is shown in the figure. The resistance should be above 1 kohms.
- #11 and #4 (ground). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and ground.

Checking for a short-circuit to voltage

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #3 and #16 (voltage). Measurement is shown in the figure. The resistance should be above 1 kohms.
- #11 and #16 (voltage). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and voltage cable.
Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

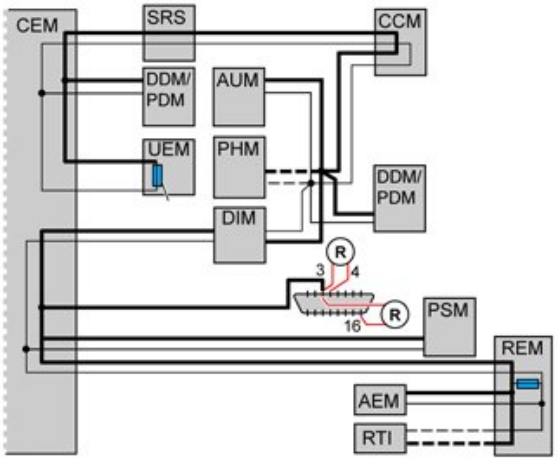
Hint: Part the CAN-net at suitable points to decide where a short-circuit may be found.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy as necessary.

Other information
- Battery, disconnecting See: Starting and Charging/Battery/Service and Repair/Procedures/Battery, Disconnecting
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

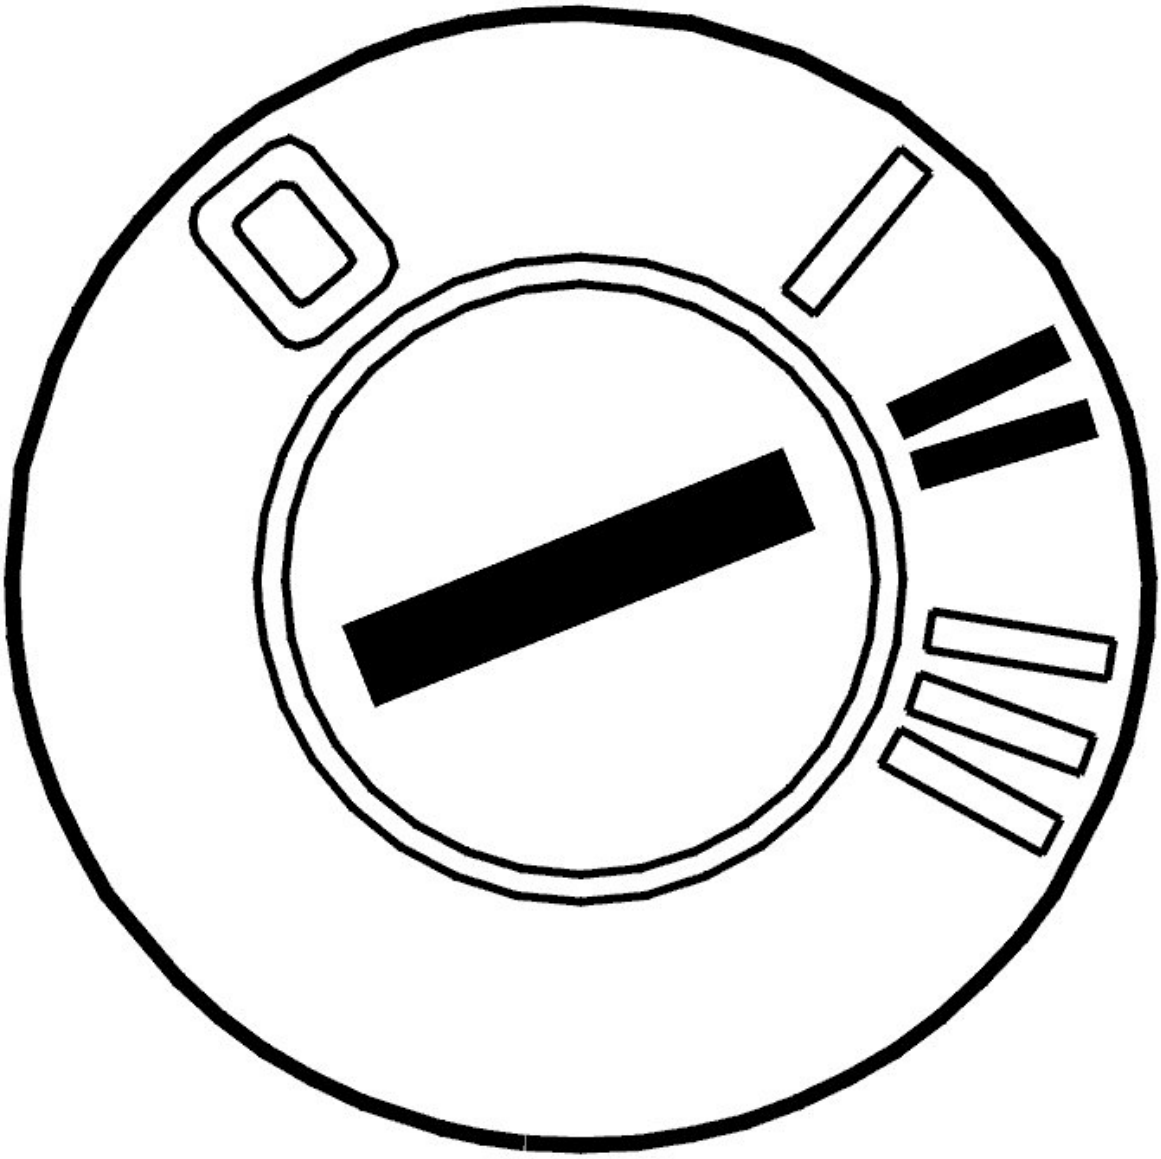


Was a fault detected?

Yes - Verification

No - Checking the amount of traffic on the LS-CAN

Checking voltage-drop in cable for CAN-H and CAN-L, respectively



- Connect the battery.
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

In principle, the voltage measured in each cable in the CAN-net shall be the same at each control module in the network. This means that the voltage-drop in the cable for CAN-H and CAN-L, respectively, between the control modules should be very low. If there is a voltage-difference in the CAN-lines between the diagnostics socket/Central electronic module (CEM) and a control module due to, e.g., contact resistance in a connector or branching, communication may be lost/interfered with. Check if there is voltage-drop in the cable for CAN-H and CAN-L between the diagnostics socket/Central electronic module (CEM) and the control module where there is problem with communication.
Carry out the following:
Measure voltage between the following connections on the OBDII-box/diagnostics socket.
- #3 and corresponding connection on relevant control module for CAN-H. The voltage shall be lower than 50 mV.
- #11 and corresponding connection on relevant control module for CAN-L. The voltage shall be lower than 50 mV.

If voltage is too high, this indicates too high contact resistance in cable, connector, or branching. Check the circuit between the diagnostics socket and control module in question for contact resistance and oxidation.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

General information

Note! Figures shown are only examples.

Hint: For general information about CAN-troubleshooting, see:
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

General about CAN-related diagnostic trouble codes.
CEM-DF01 - DF17can only be stored in Central electronic module (CEM). These diagnostic trouble codes are stored when an electric fault is detected in CAN-lines. Start with these diagnostic trouble codes first.
CEM-1AXX only stored in Central electronic module (CEM). One diagnostic trouble code for every control module on the CAN-net. These diagnostic trouble codes indicate that Central electronic module (CEM) does not receive any reply from other control modules.
XXX-E000 (HS-CAN)/E001 (LS-CAN) can be stored in all CAN-connected control modules. These diagnostic trouble codes indicate that the control module has detected interference on the CAN-net.
XXX-E003 can be stored in all CAN-connected control modules except in Central electronic module (CEM). The control modules on the CAN-net

listen for a message (identity number) that is sent out at regular intervals from Central electronic module (CEM). This diagnostic trouble code indicates that the control module has not received any identity number, or that the expected number is not correct. Interference on the CAN-net can also store this diagnostic trouble code.

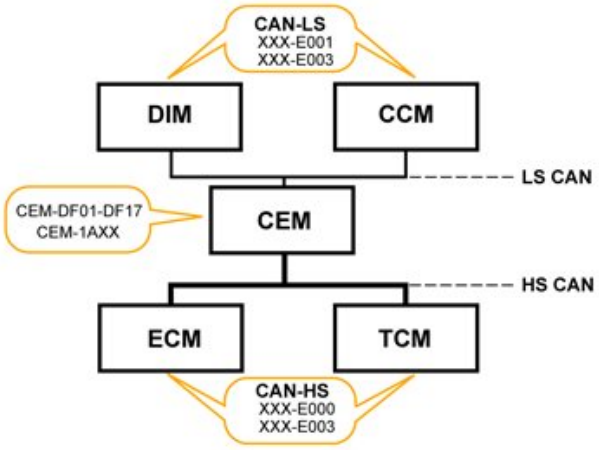
Note! In case of CAN-related faults, it is likely that a combination of above diagnostic trouble codes occur.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

If diagnostic trouble codes (DTCs) for communication faults can be read off from a control module, the fault is probably intermittent. Intermittent fault in the voltage supply and ground to a control module on the CAN network results in the Central electronic module (CEM) storing a diagnostic trouble code (DTC) for an open-circuit in communication with the control module where the voltage supply does not work. There will probably not be a diagnostic trouble code (DTC) in the control module where the open-circuit in the voltage supply occurred as the control module cannot store a diagnostic trouble code (DTC) when it is not supplied with power.

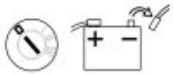
Note! Central electronic module (CEM) should not be replaced in case of CAN-fault, unless troubleshooting reveals that Central electronic module (CEM) has an internal fault.

Caution! During this fault-tracing use the wiring diagram to provide support when taking readings.



Continue - Checking resistance in CAN-net

Checking resistance in CAN-net



- Ignition off

Was a fault detected?

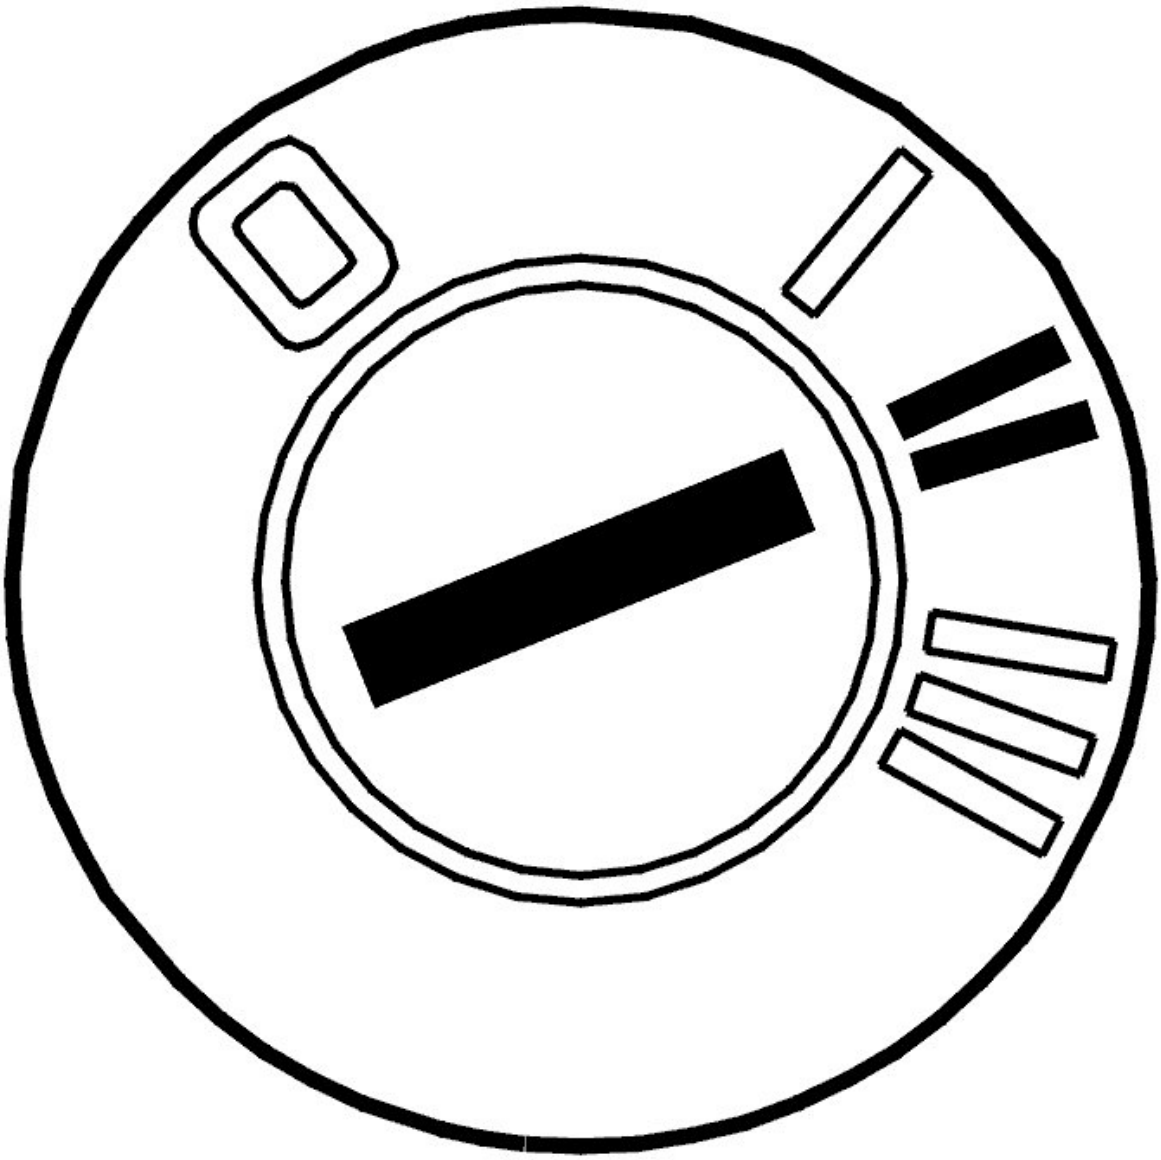
Yes - Identifying a control module in the CAN network

No - Checking voltage-drop in cable for CAN-H and CAN-L, respectively

---

Identifying a control module in the CAN network



Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:

- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Hint: DiCE Error Frame Finder can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools: **951 3010** (memory card) as well as associated TJ 20402. If the load on the CAN network is too high, this may be due to a control module transmitting faulty messages on the CAN network. This is called a disruptive control module. The fault may also be due to an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The fault may occur without any of the control modules storing a diagnostic trouble code (DTC). The voltage can be measured between the CAN cables in order to check the load on the CAN network.

Note! It is not necessarily the control module that has set the diagnostic trouble code that communicates incorrectly. Faulty messages can come from any control module in the same section of the CAN network. However, faulty communication in one network cannot affect the communication on the other network. In other words, faulty communication on the LS-CAN cannot disrupt communication on the HS-CAN and vice versa.

- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Check communication/load on CAN-net by measuring voltage between CAN-L and CAN-H. Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #3 and #11. The average value of the voltage must be approximately 0.6-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

In order to identify which control module has faulty communication, cut the power supply to one control module at a time. Check the voltage in the CAN cables again. The easiest way to cut the power supply is to remove the fuse(s) for the relevant control module. Repeat until the voltage between the CAN wiring drops to the normal level.

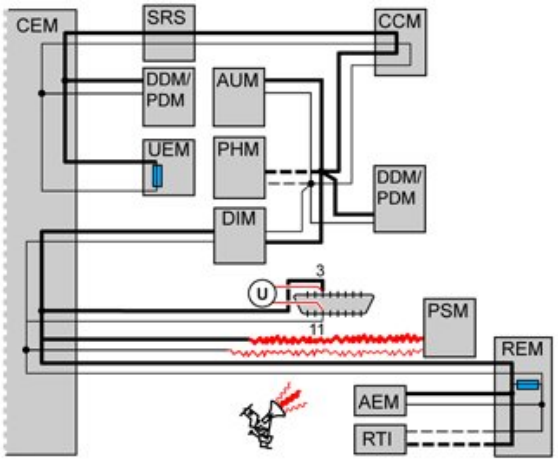
Note! When connecting and disconnecting certain control modules, diagnostic trouble codes (DTCs) may be stored in other control modules.

Hint: When the suspected defective control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the malfunction appears and disappears. Switch off the ignition between each check.

Note! Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.

A control module that is communicating incorrectly must be replaced. See Repairing and installing/Removing, replacing and installing.

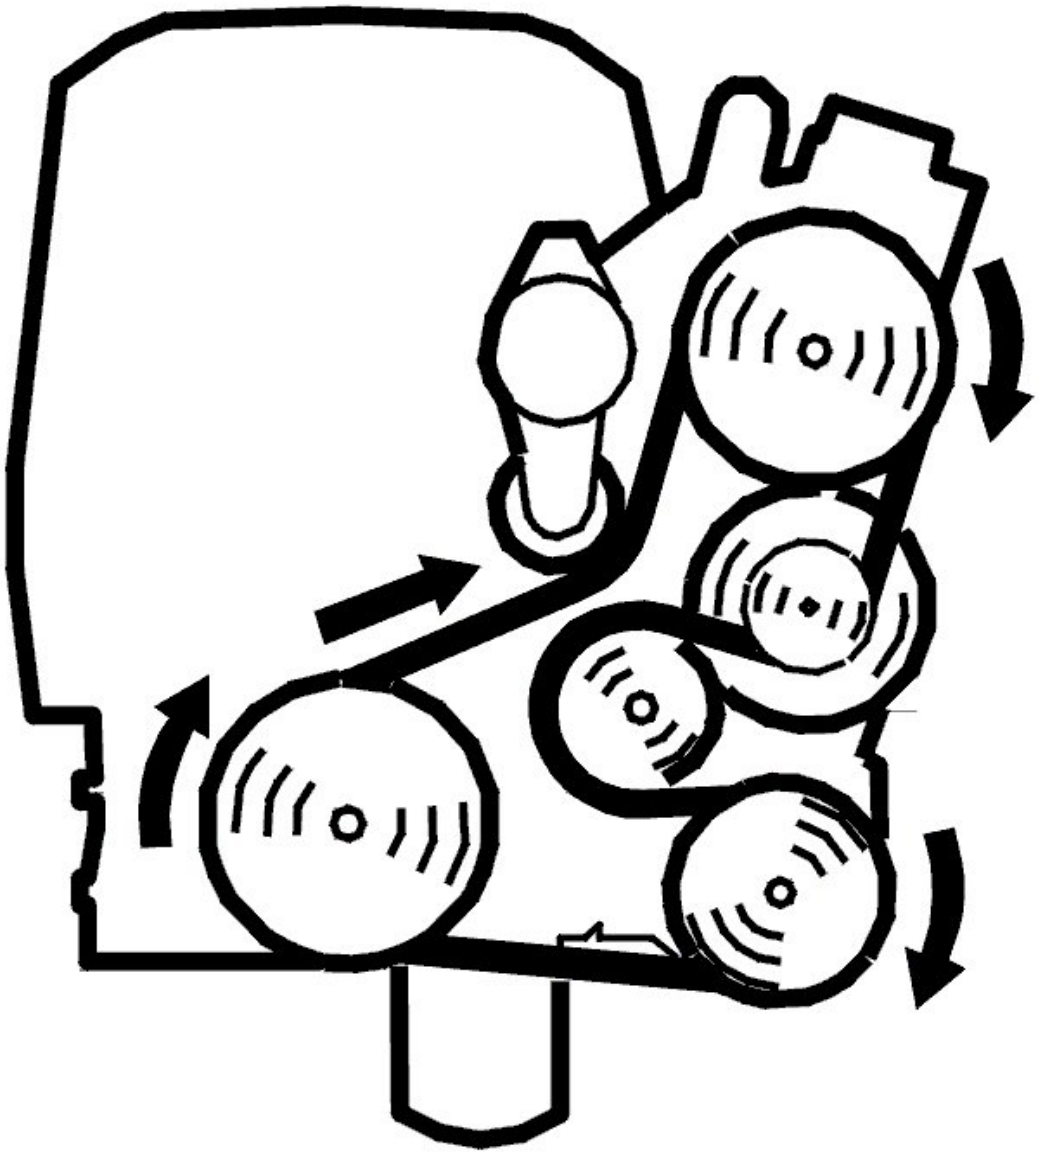
Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

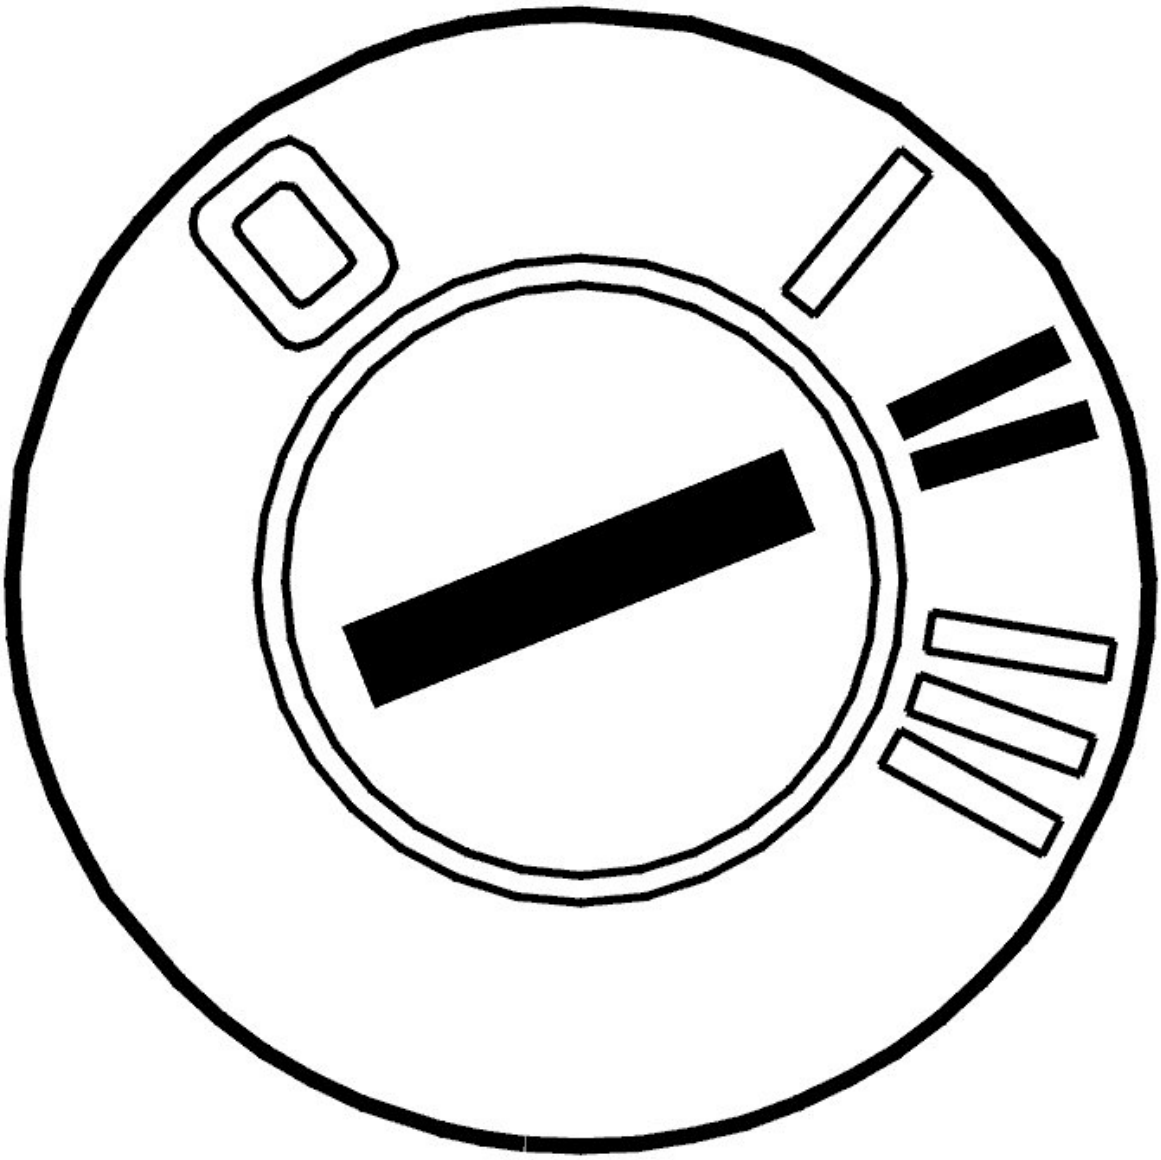


Continue - Verification

Verification

Hint: After rectifying a fault, a verification should be carried out.





- Reinstall the connectors, components etc.
- Ignition on.

Note! For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

- Erase diagnostic trouble codes (DTCs) in all control modules.
- Ignition off.
- Ignition on.
- Start the vehicle. Allow the vehicle to run for 10 minutes. Start the engine. Allow the engine to run at idle speed for 10 minutes
- Read out the diagnostic trouble codes in the vehicle via the DIAGNOSTICS tab.

Does the diagnostic trouble code (DTC) for faulty communication return?

Yes - Fault-tracing information

No - Fault Found

Fault-tracing information

Information

Fault-tracing information

The fault should have been detected and remedied. As this is not the case fault-tracing has failed.
Exit fault-tracing for this diagnostic trouble code (DTC) or make another attempt.

Do you want to exit fault-tracing?

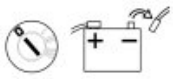
Yes - **FAULT-TRACING FAILED**

No - **Attempt New Test**

FAULT-TRACING FAILED - **FAULT-TRACING FAILED**

Attempt New Test - Signal Missing

Checking short-circuiting to ground/voltage in CAN-net



- Ignition off.
- Disconnect the battery negative lead.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Checking for a short-circuit to ground

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #3 and #4 (ground). Measurement is shown in the figure. The resistance should be above 1 kohms.
- #11 and #4 (ground). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and ground.

Checking for a short-circuit to voltage

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #3 and #16 (voltage). Measurement is shown in the figure. The resistance should be above 1 kohms.
- #11 and #16 (voltage). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and voltage cable.
Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

Hint: Part the CAN-net at suitable points to decide where a short-circuit may be found.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy as necessary.

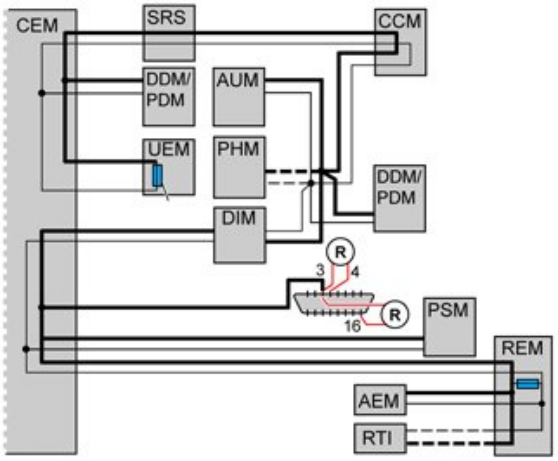
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

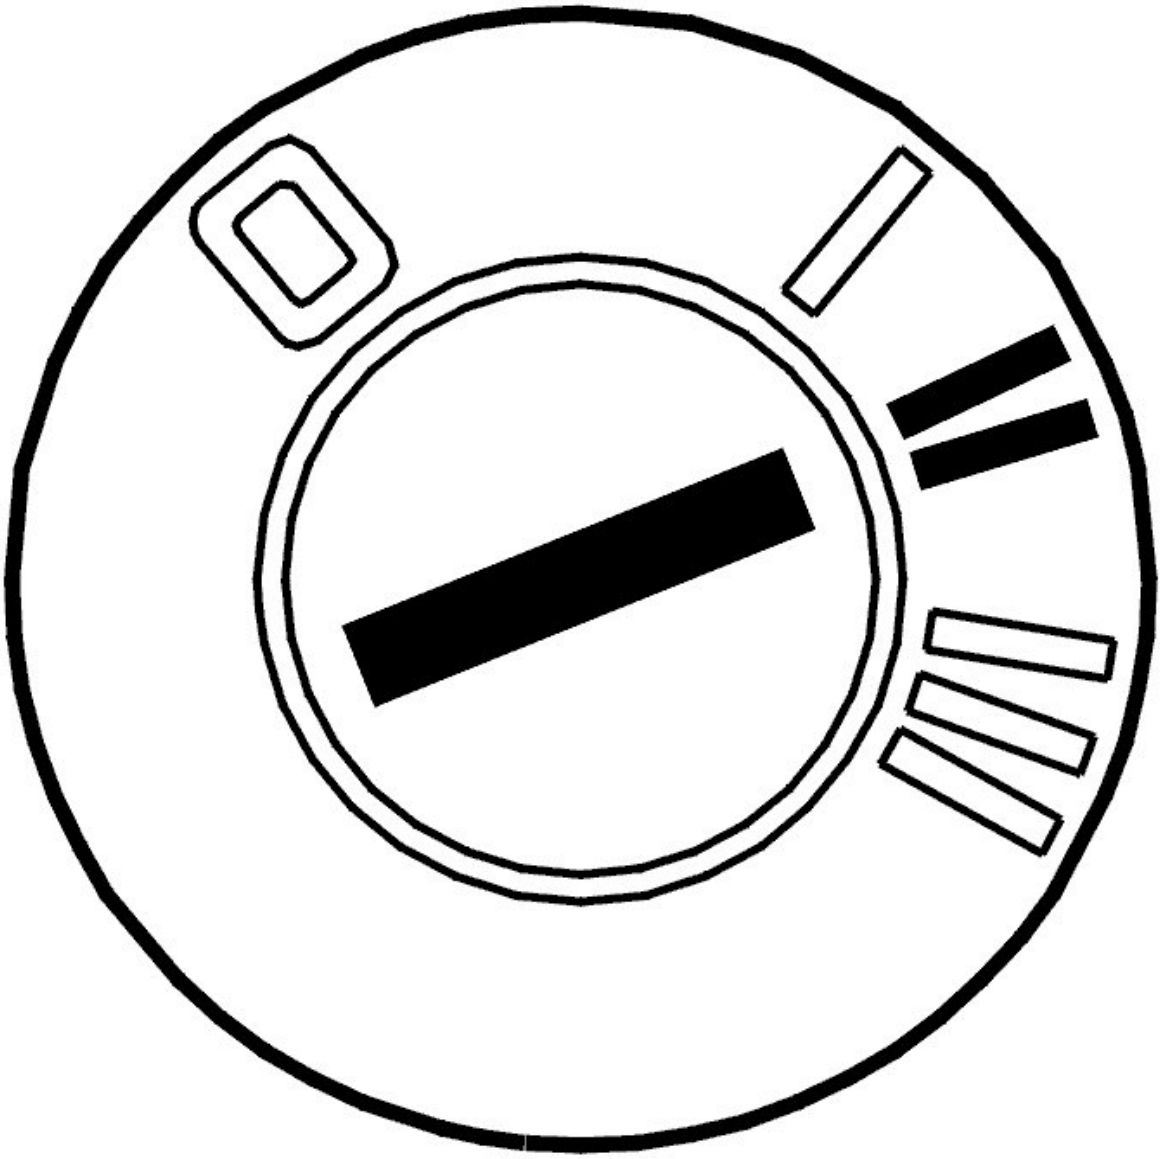


Was a fault detected?

Yes - Verification

No - Checking the amount of traffic on the LS-CAN

Checking voltage-drop in cable for CAN-H and CAN-L, respectively



- Connect the battery.
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

In principle, the voltage measured in each cable in the CAN-net shall be the same at each control module in the network. This means that the voltage-drop in the cable for CAN-H and CAN-L, respectively, between the control modules should be very low. If there is a voltage-difference in the CAN-lines between the diagnostics socket/Central electronic module (CEM) and a control module due to, e.g., contact resistance in a connector or branching, communication may be lost/interfered with. Check if there is voltage-drop in the cable for CAN-H and CAN-L between the diagnostics socket/Central electronic module (CEM) and the control module where there is problem with communication.
Carry out the following:
Measure voltage between the following connections on the OBDII-box/diagnostics socket.
- #3 and corresponding connection on relevant control module for CAN-H. The voltage shall be lower than 50 mV.
- #11 and corresponding connection on relevant control module for CAN-L. The voltage shall be lower than 50 mV.

If voltage is too high, this indicates too high contact resistance in cable, connector, or branching. Check the circuit between the diagnostics socket and control module in question for contact resistance and oxidation.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy wiring as necessary.

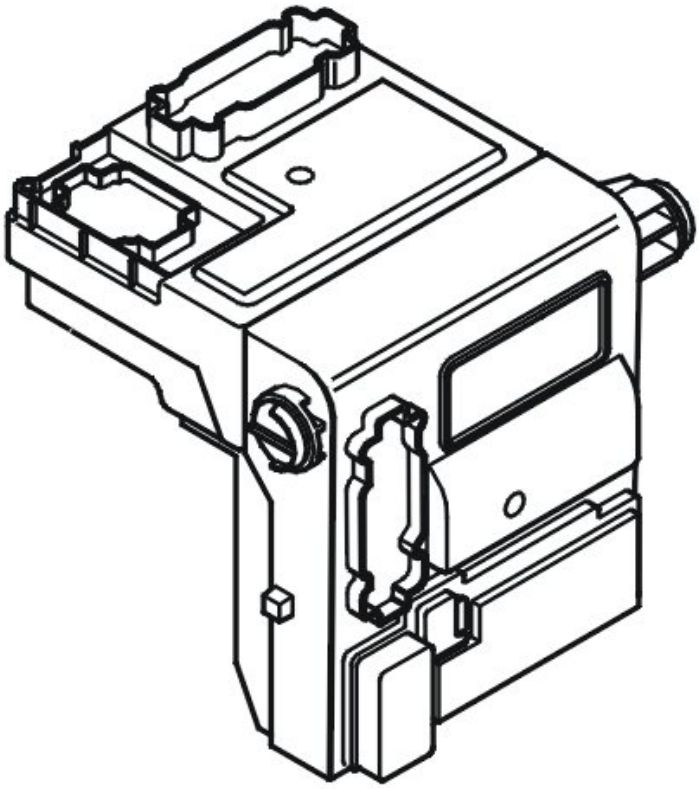
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CEM-1A06

Condition



The central electronic module (CEM) monitors the cable for 15-supply from the ignition switch.
The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers an open-circuit in the cable for 15-supply or a short-circuit to ground in the cable.
The diagnostic trouble code (DTC) can be diagnosed at ignition switch position III (start attempt).

Substitute value
- None.

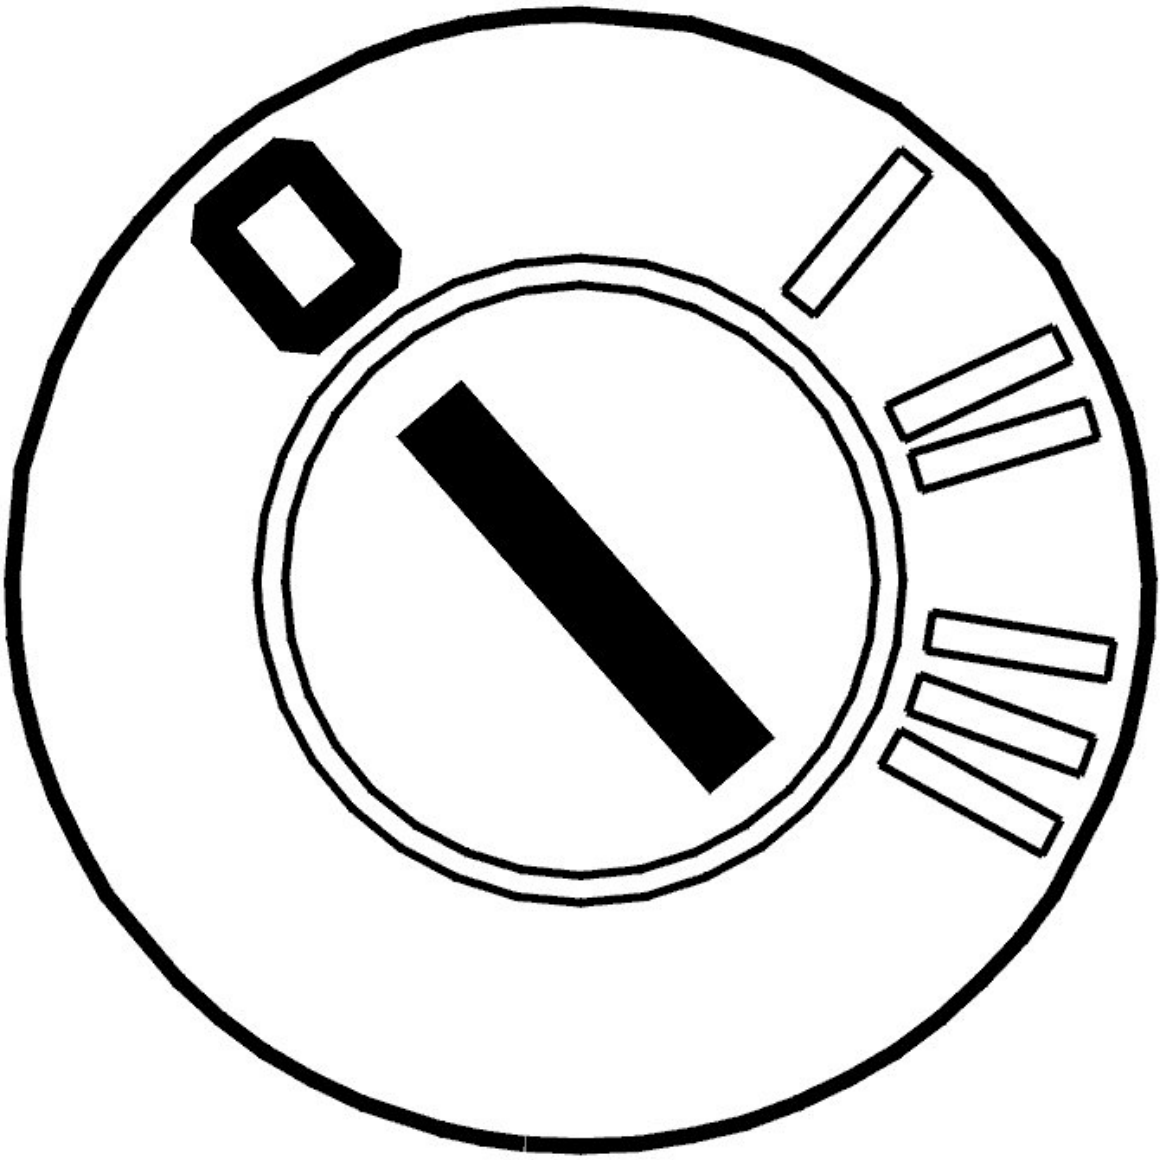
Possible source
- Open-circuit in the 15-supply cable
- Short-circuit to ground in the 15-supply cable
- Damaged ignition switch.

Fault symptom[s]
- The windshield wipers are not working.
- The starter motor does not turn.

Signal Too Low

Signal too low

Checking the connectors



- Ignition off.

Check central electronic module (CEM) connector D. Check for contact resistance and oxidation. Remedy as necessary.
Check for any damage.

Hint: If the fault cause is found, reinstall the components, connectors etc.
If the fault cause was not found, do not reconnect the connector before carrying out further fault-tracing.

Other information:

- To replace the connectors for the central electronic module (CEM), see: Central electronic module (CEM), replacing See: Body Control Module/Service and Repair/Central Electronic Module (CEM), Replacing

Diagnostic Trouble Code (DTC) Information

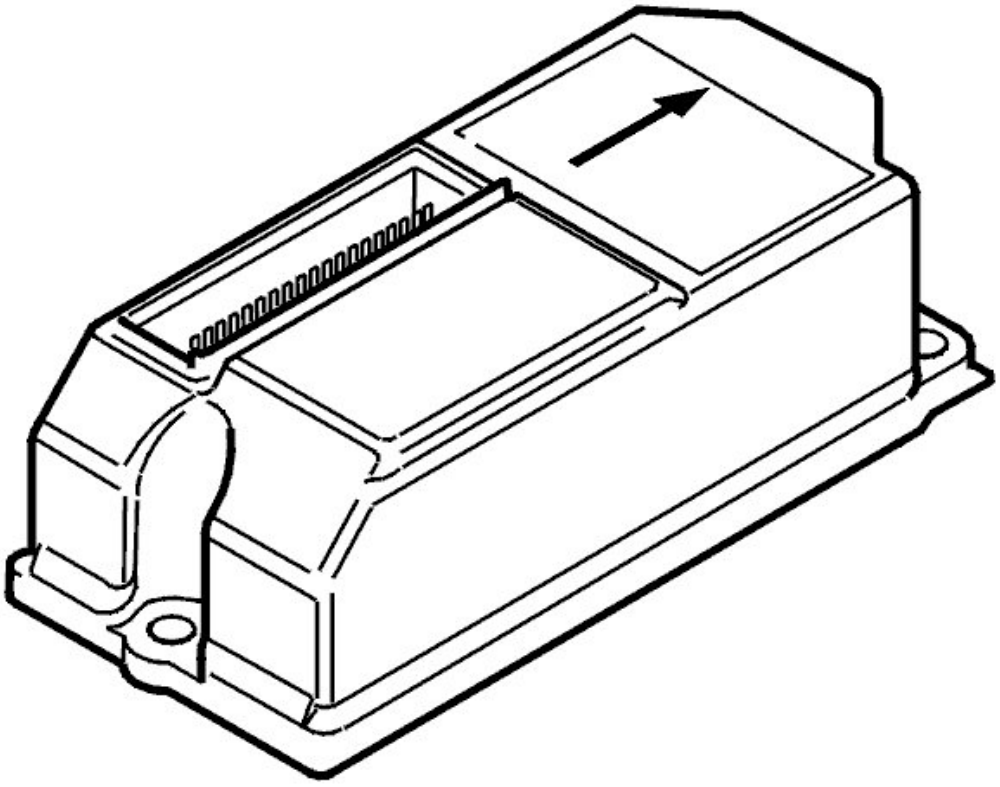
Diagnostic trouble code (DTC) information CEM-1A51

Condition



The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers that communication with the supplementary restraint system (SRS) control module is not operating.
The diagnostic trouble code (DTC) can be diagnosed when the ignition has been on for more than 10 seconds.

Note! In the event of CEM-1A5X diagnostic trouble codes (DTCs), the central electronic module (CEM) must not be replaced as the diagnostic trouble code (DTC) indicates a communication fault in the controller area network (CAN)!

Substitute value
- None.

Possible source
- No power supply to SRS control module
- Open-circuit in the ground lead for the supplemental restraint system module (SRS)
- Contact resistance in the terminals
- Open-circuit in the wiring for the CAN low speed network to the SRS control module
- The supplemental restraint system module (SRS) is not intended for this vehicle (for example a used control module with different software/hardware).

Hint: If several diagnostic trouble codes (DTCs) are stored in the central electronic module (CEM) for communication faults with other control modules in the low speed network, this indicates a common fault in the controller area network (CAN). See the relevant wiring diagram.

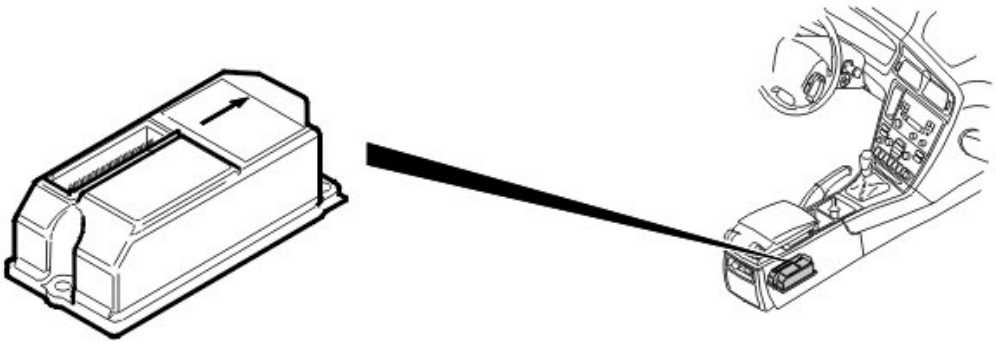
Fault symptom[s]
- The SRS indicator lamp is lit.

Signal Missing

Signal missing

Checking the power supply for the supplemental restraint system module (SRS)

Check the power supply to the control module by turning the ignition key to ignition position II.
The SRS (supplemental restraint system) indicator lamp in the driver information module (DIM) must light. The lamp must go out after a few seconds.



Does the warning lamp go out?

Yes - Checking communication with the supplemental restraint system module (SRS)

No - Checking the power supply and ground for the supplemental restraint system module (SRS)

Checking the power supply and ground for the supplemental restraint system module (SRS)

Check that the fuse for the control module is intact.
Check the power supply and ground terminal for the supplemental restraint system module (SRS).

Note! The supplemental restraint system module (SRS) is powered via two power inputs. Check that the control module is powered in all ignition positions according to the instructions below.

Remedy as necessary

General information

Note! Figures shown are only examples.

Hint: For general information about CAN-troubleshooting, see:
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

General about CAN-related diagnostic trouble codes.
CEM-DF01 - DF17can only be stored in Central electronic module (CEM). These diagnostic trouble codes are stored when an electric fault is detected in CAN-lines. Start with these diagnostic trouble codes first.
CEM-1AXX only stored in Central electronic module (CEM). One diagnostic trouble code for every control module on the CAN-net. These diagnostic trouble codes indicate that Central electronic module (CEM) does not receive any reply from other control modules.
XXX-E000 (HS-CAN)/E001 (LS-CAN) can be stored in all CAN-connected control modules. These diagnostic trouble codes indicate that the control module has detected interference on the CAN-net.
XXX-E003 can be stored in all CAN-connected control modules except in Central electronic module (CEM). The control modules on the CAN-net listen for a message (identity number) that is sent out at regular intervals from Central electronic module (CEM). This diagnostic trouble code indicates that the control module has not received any identity number, or that the expected number is not correct. Interference on the CAN-net can also store this diagnostic trouble code.

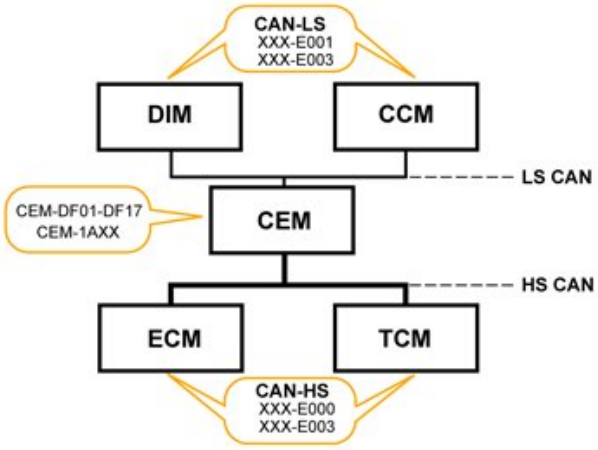
Note! In case of CAN-related faults, it is likely that a combination of above diagnostic trouble codes occur.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

If diagnostic trouble codes (DTCs) for communication faults can be read off from a control module, the fault is probably intermittent.
Intermittent fault in the voltage supply and ground to a control module on the CAN network results in the Central electronic module (CEM) storing a diagnostic trouble code (DTC) for an open-circuit in communication with the control module where the voltage supply does not work. There will probably not be a diagnostic trouble code (DTC) in the control module where the open-circuit in the voltage supply occurred as the control module cannot store a diagnostic trouble code (DTC) when it is not supplied with power.

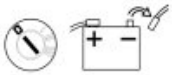
Note! Central electronic module (CEM) should not be replaced in case of CAN-fault, unless troubleshooting reveals that Central electronic module (CEM) has an internal fault.

Caution! During this fault-tracing use the wiring diagram to provide support when taking readings.



Continue - Checking resistance in CAN-net

Checking resistance in CAN-net



- Ignition off
- Disconnect the battery negative lead
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #3 and #11. The resistance should be approx. 55 - 65 ohms.
- If resistance is approx. 120 ohms, this indicates open circuit in the circuit so that only one terminating resistor (120 ohms) has been measured.
- If resistance is above 1 kohms this indicates open circuit/high contact resistance somewhere in the circuit.
- If resistance is below 55 ohms this indicates short-circuiting/contact resistance between the CAN-lines somewhere in the circuit.

Hint: For LS-CAN (Low Speed), terminating resistors are located in Upper electronic module (UEM) and Rear electronic module (REM).

Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

Note! Resistance measurement measures only main lines in the CAN-net (in circuit where both terminating resistors are found), not branches to certain control modules. See wiring diagram for vehicle model in question. Open circuit on branching without a terminating resistor cannot be detected with this measurement. However, short-circuiting on a branch can be detected. To measure resistance in the CAN-net to control modules located in a branching of their own, the measurement shall be done against the CAN-net at that control module. The values shall be as above.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy as necessary.

Other information

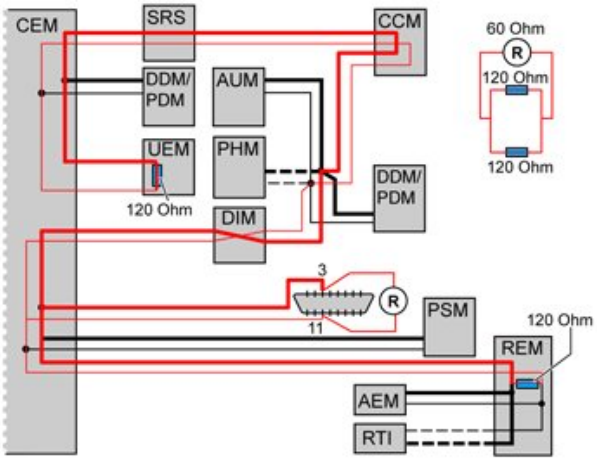
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

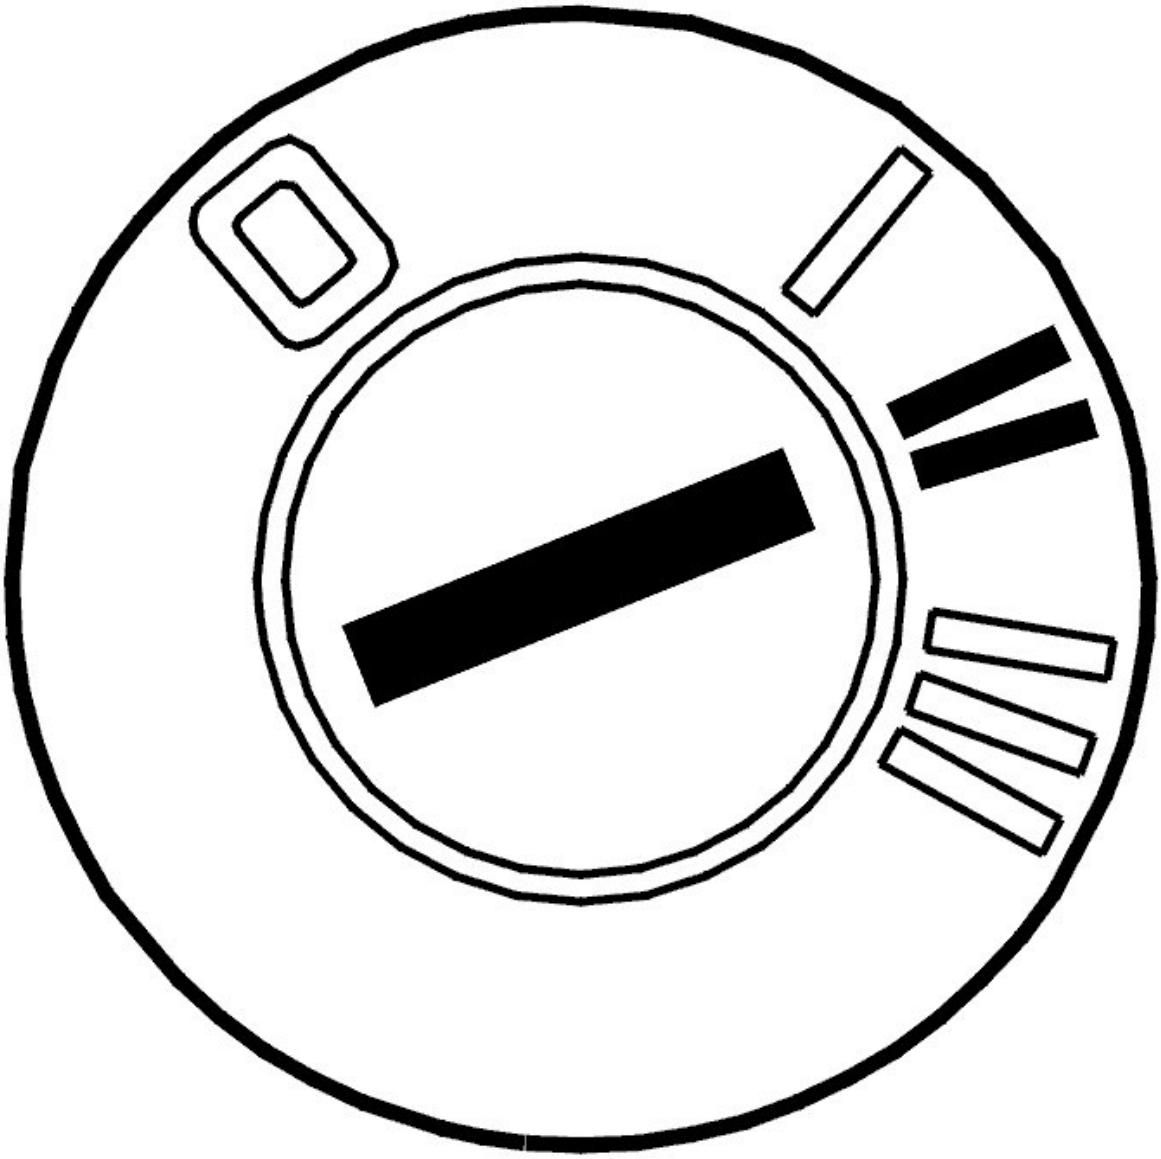


Was a fault detected?

Yes - Verification

No - Checking short-circuiting to ground/voltage in CAN-net

Checking the amount of traffic on the LS-CAN



- Connect the battery
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
Faults in the CAN network may be due to a control module sending faulty messages that disrupt normal communication. When messages are sent incorrectly, this results in a considerable increase in the amount of traffic on the CAN network. The load can be checked by reading the average value of the voltage on the CAN cables in relation to ground.
For further information, see the wiring diagram.
Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #3 and #4 (ground). The voltage should be approx: 2,8 - 3,2 V.
- #11 and #4 (ground). The voltage should be approx: 1,8 - 2,2 V.
- #3 and #11. The voltage shall be between approx. 0.55-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Hint: DiCE Error Frame Finder can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools: **951 3010** (memory card) as well as associated TJ 20402.

- Ignition on.
- Connect DiCE Error Frame Finder to the diagnostics socket.
- Note the blue LED-indicator. The indicator flashes to show detection of fault messages.

Note! Certain interference may occur without any real fault!

Cable fault

- Shake the cables lightly and pull lightly on the connections during the check to locate any fault. Note the blue LED-indicator.

"Chatting" control modules

- "Chatting" control modules may be difficult to find and troubleshooting may take time. Let the vehicle stand with DiCE connected for an extended time period. Afterwards, activate functions to provoke a malfunction. It may take up to several hours before the fault messages are sent. When the indicator starts to flash, remove the fuse for one control module at a time until the indicator stops flashing. When the indicator stops flashing, restore the fuse for the relevant control module and check that the indicator starts to flash again. Then it is likely that the problem is identified.

Remedy wiring as necessary.

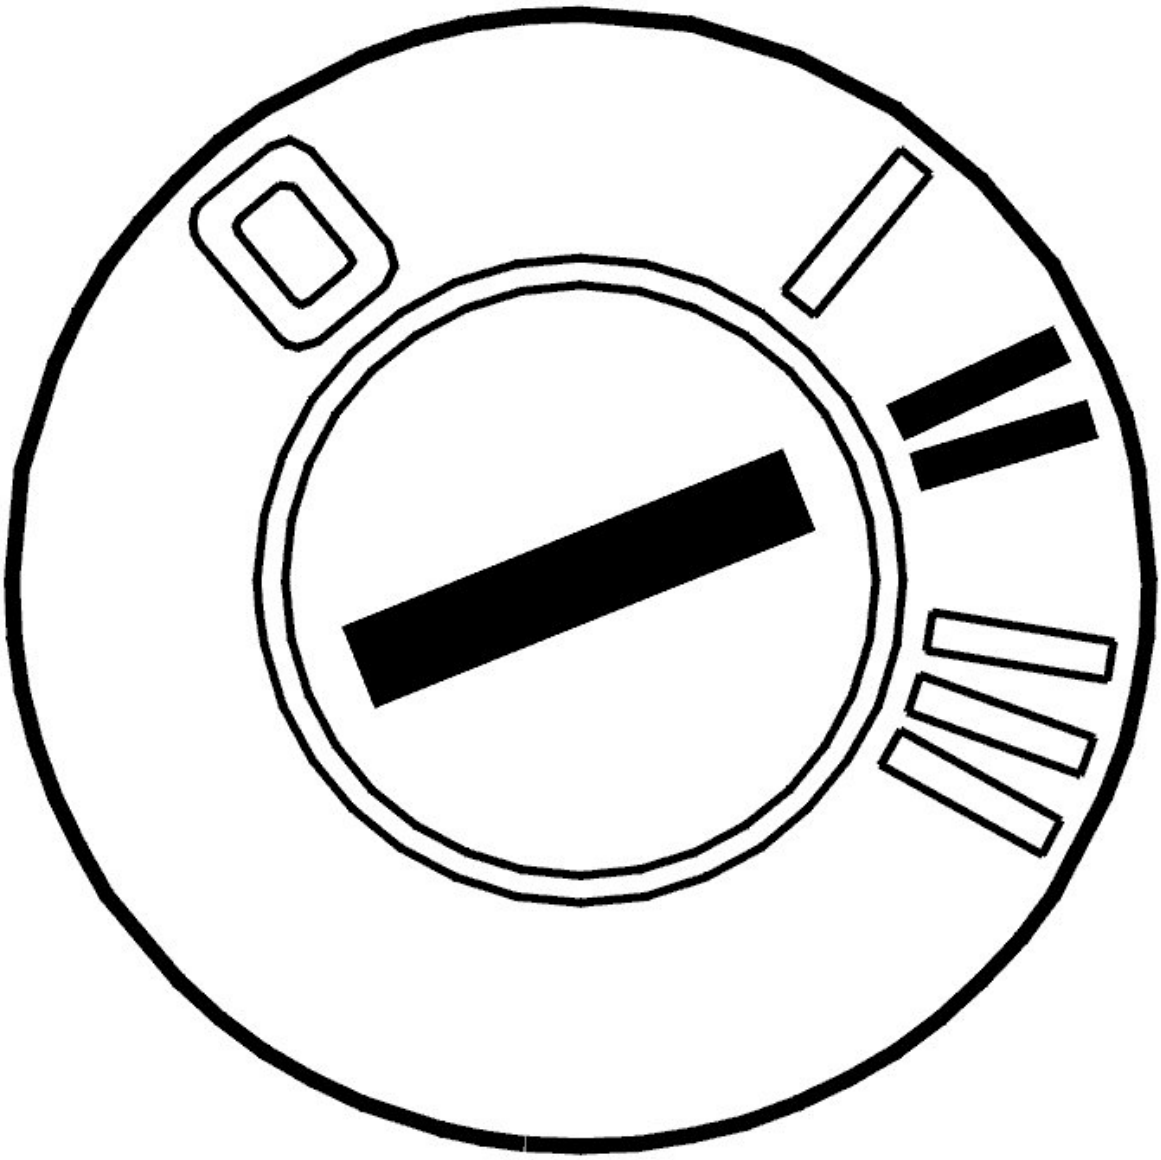
Was a fault detected?

Yes - Identifying a control module in the CAN network

No - Checking voltage-drop in cable for CAN-H and CAN-L, respectively

---

Identifying a control module in the CAN network



Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:

- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Hint: DiCE Error Frame Finder can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools: **951 3010** (memory card) as well as associated TJ 20402. If the load on the CAN network is too high, this may be due to a control module transmitting faulty messages on the CAN network. This is called a disruptive control module. The fault may also be due to an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The fault may occur without any of the control modules storing a diagnostic trouble code (DTC). The voltage can be measured between the CAN cables in order to check the load on the CAN network.

Note! It is not necessarily the control module that has set the diagnostic trouble code that communicates incorrectly. Faulty messages can come from any control module in the same section of the CAN network. However, faulty communication in one network cannot affect the communication on the other network. In other words, faulty communication on the LS-CAN cannot disrupt communication on the HS-CAN and vice versa.

- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Check communication/load on CAN-net by measuring voltage between CAN-L and CAN-H. Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #3 and #11. The average value of the voltage must be approximately 0.6-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

In order to identify which control module has faulty communication, cut the power supply to one control module at a time. Check the voltage in the CAN cables again. The easiest way to cut the power supply is to remove the fuse(s) for the relevant control module. Repeat until the voltage between the CAN wiring drops to the normal level.

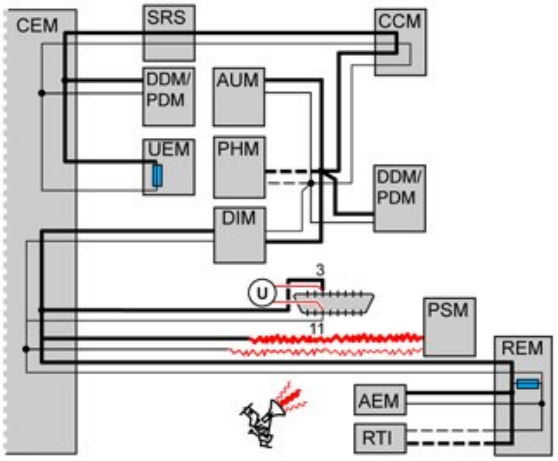
Note! When connecting and disconnecting certain control modules, diagnostic trouble codes (DTCs) may be stored in other control modules.

Hint: When the suspected defective control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the malfunction appears and disappears. Switch off the ignition between each check.

Note! Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.

A control module that is communicating incorrectly must be replaced. See Repairing and installing/Removing, replacing and installing.

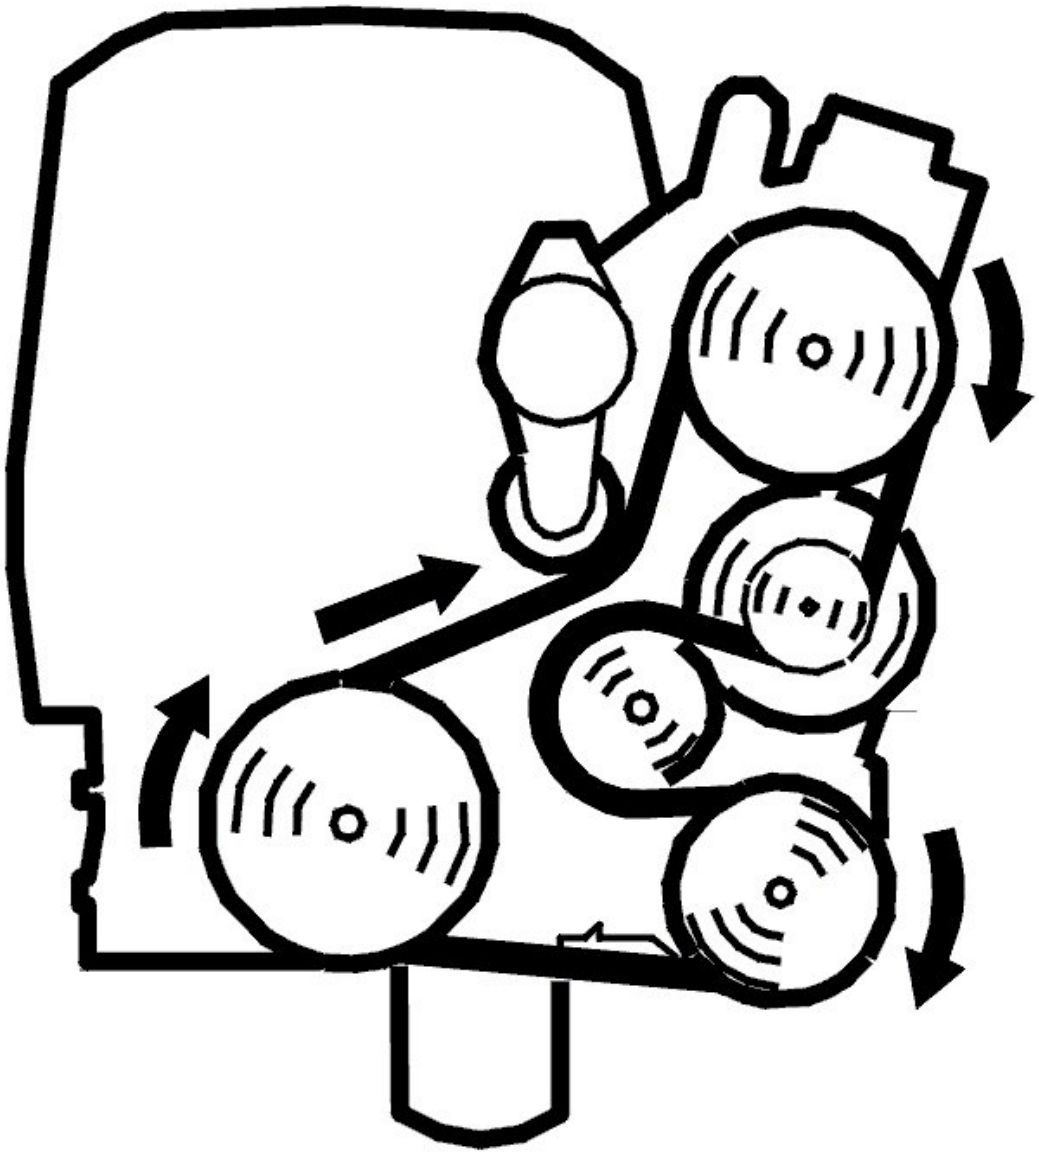
Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

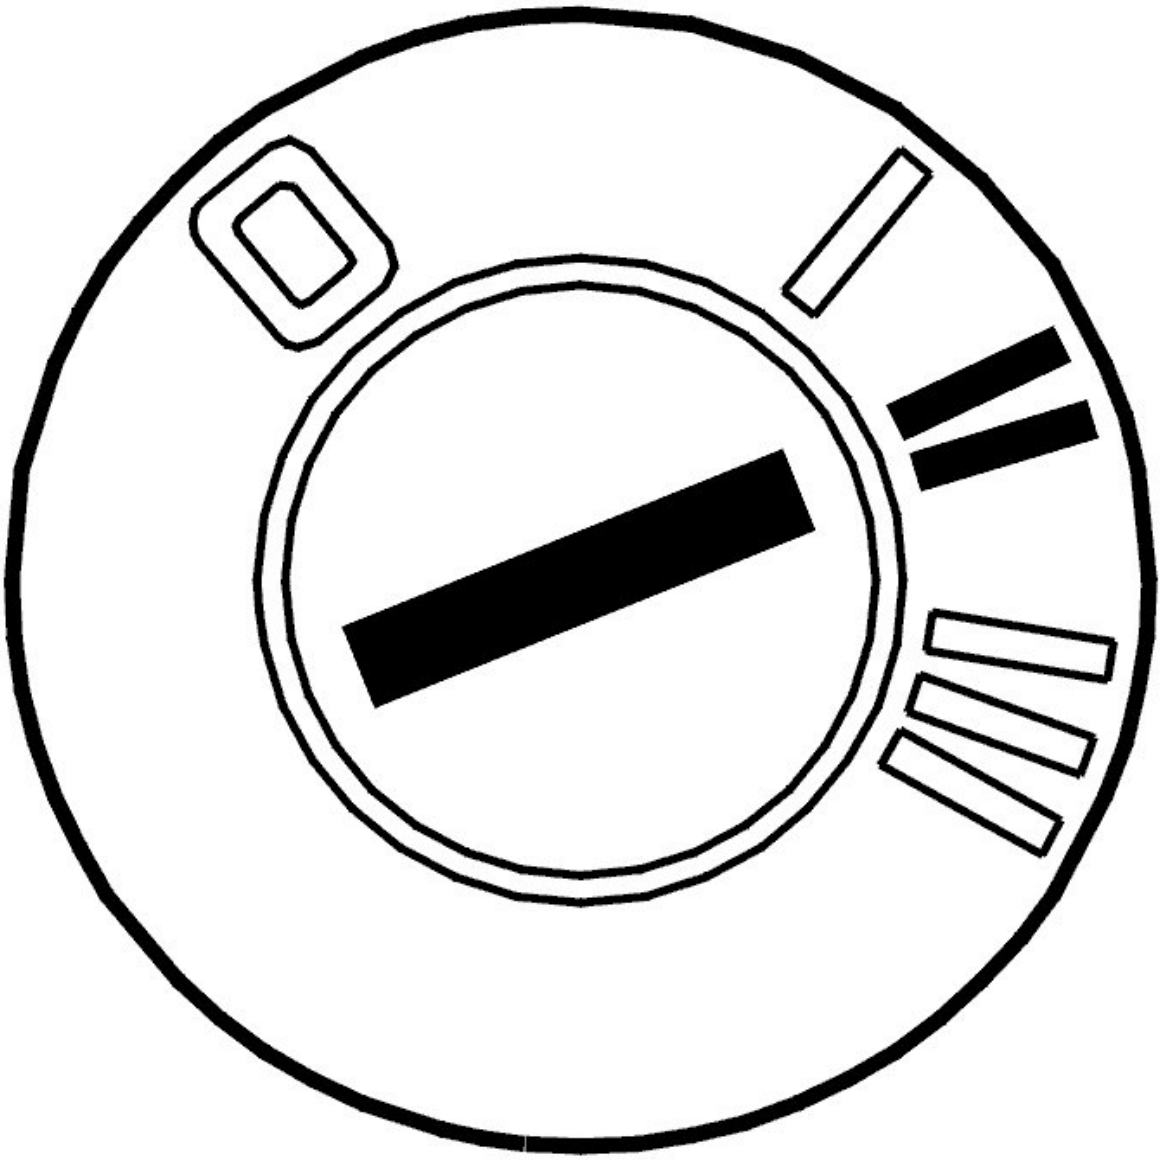


Continue - Verification

Verification

Hint: After rectifying a fault, a verification should be carried out.





- Reinstall the connectors, components etc.
- Ignition on.

Note! For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

- Erase diagnostic trouble codes (DTCs) in all control modules.
- Ignition off.
- Ignition on.
- Start the vehicle. Allow the vehicle to run for 10 minutes. Start the engine. Allow the engine to run at idle speed for 10 minutes
- Read out the diagnostic trouble codes in the vehicle via the DIAGNOSTICS tab.

Does the diagnostic trouble code (DTC) for faulty communication return?

Yes - Fault-tracing information

No - Fault Found

Fault-tracing information

Information

Fault-tracing information

The fault should have been detected and remedied. As this is not the case fault-tracing has failed.
Exit fault-tracing for this diagnostic trouble code (DTC) or make another attempt.

Do you want to exit fault-tracing?

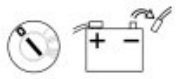
Yes - **FAULT-TRACING FAILED**

No - **Attempt New Test**

FAULT-TRACING FAILED - **FAULT-TRACING FAILED**

Attempt New Test - Signal Missing

Checking short-circuiting to ground/voltage in CAN-net



- Ignition off.
- Disconnect the battery negative lead.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Checking for a short-circuit to ground

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #3 and #4 (ground). Measurement is shown in the figure. The resistance should be above 1 kohms.
- #11 and #4 (ground). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and ground.

Checking for a short-circuit to voltage

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #3 and #16 (voltage). Measurement is shown in the figure. The resistance should be above 1 kohms.
- #11 and #16 (voltage). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and voltage cable.
Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

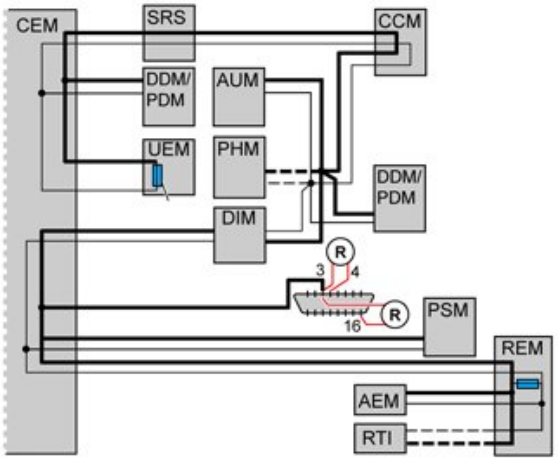
Hint: Part the CAN-net at suitable points to decide where a short-circuit may be found.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy as necessary.

Other information
- Battery, disconnecting See: Starting and Charging/Battery/Service and Repair/Procedures/Battery, Disconnecting
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

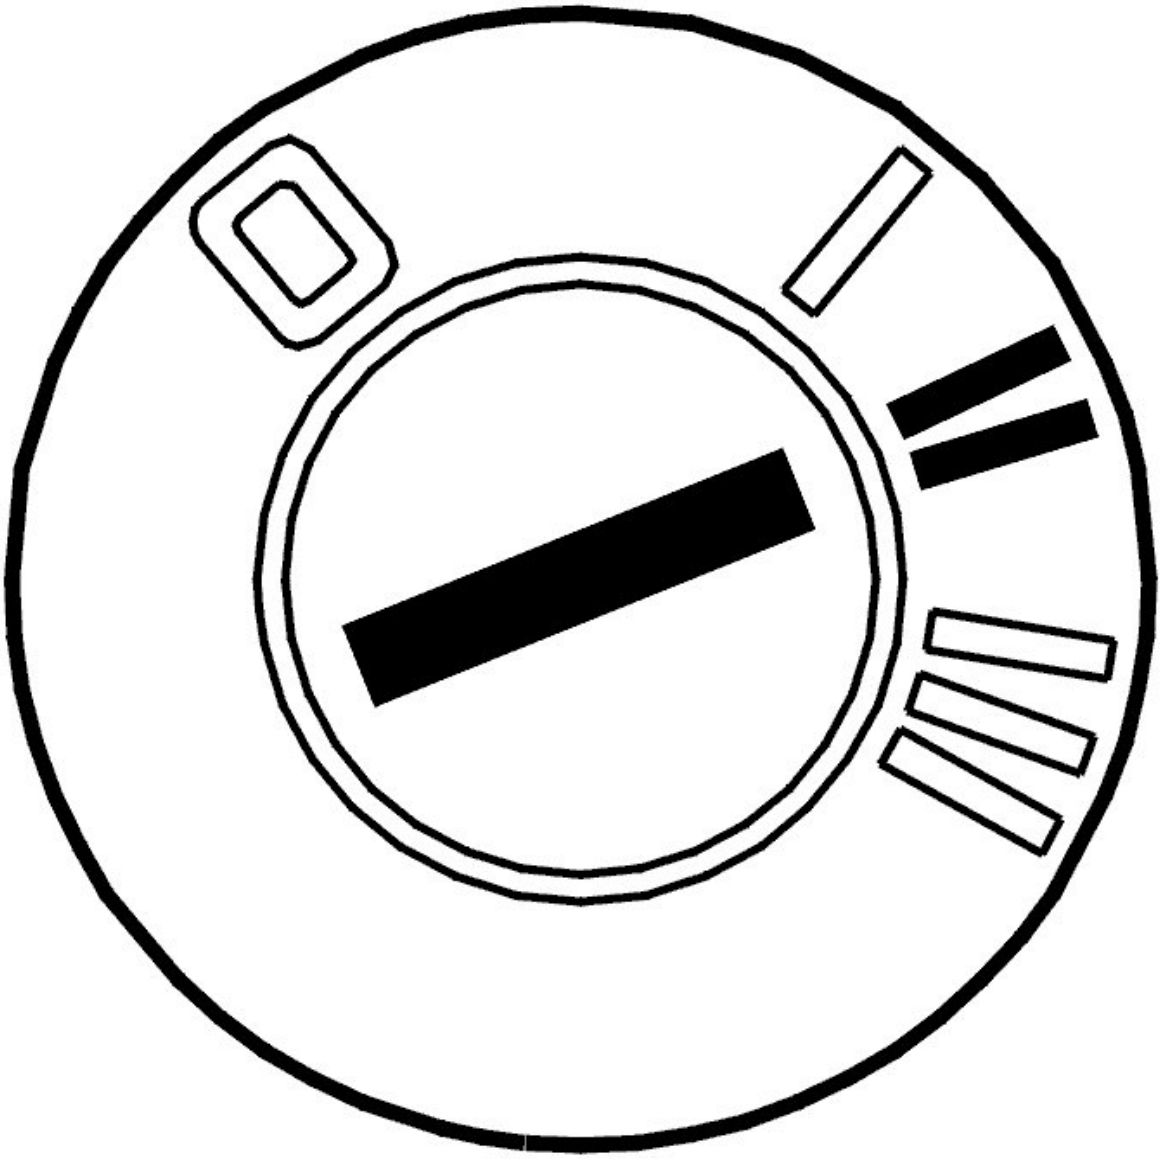


Was a fault detected?

Yes - Verification

No - Checking the amount of traffic on the LS-CAN

Checking voltage-drop in cable for CAN-H and CAN-L, respectively



- Connect the battery.
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

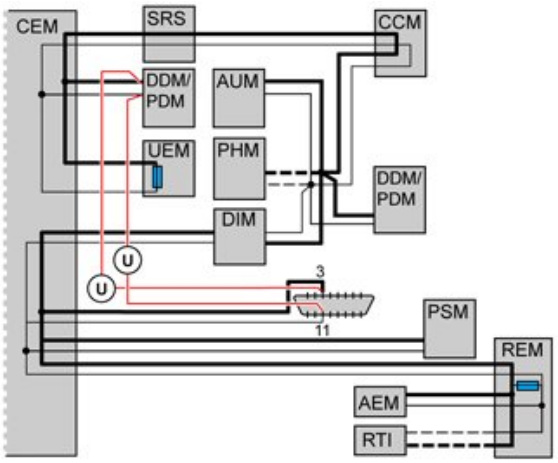
In principle, the voltage measured in each cable in the CAN-net shall be the same at each control module in the network. This means that the voltage-drop in the cable for CAN-H and CAN-L, respectively, between the control modules should be very low. If there is a voltage-difference in the CAN-lines between the diagnostics socket/Central electronic module (CEM) and a control module due to, e.g., contact resistance in a connector or branching, communication may be lost/interfered with. Check if there is voltage-drop in the cable for CAN-H and CAN-L between the diagnostics socket/Central electronic module (CEM) and the control module where there is problem with communication.
Carry out the following:
Measure voltage between the following connections on the OBDII-box/diagnostics socket.
- #3 and corresponding connection on relevant control module for CAN-H. The voltage shall be lower than 50 mV.
- #11 and corresponding connection on relevant control module for CAN-L. The voltage shall be lower than 50 mV.

If voltage is too high, this indicates too high contact resistance in cable, connector, or branching. Check the circuit between the diagnostics socket and control module in question for contact resistance and oxidation.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy wiring as necessary.

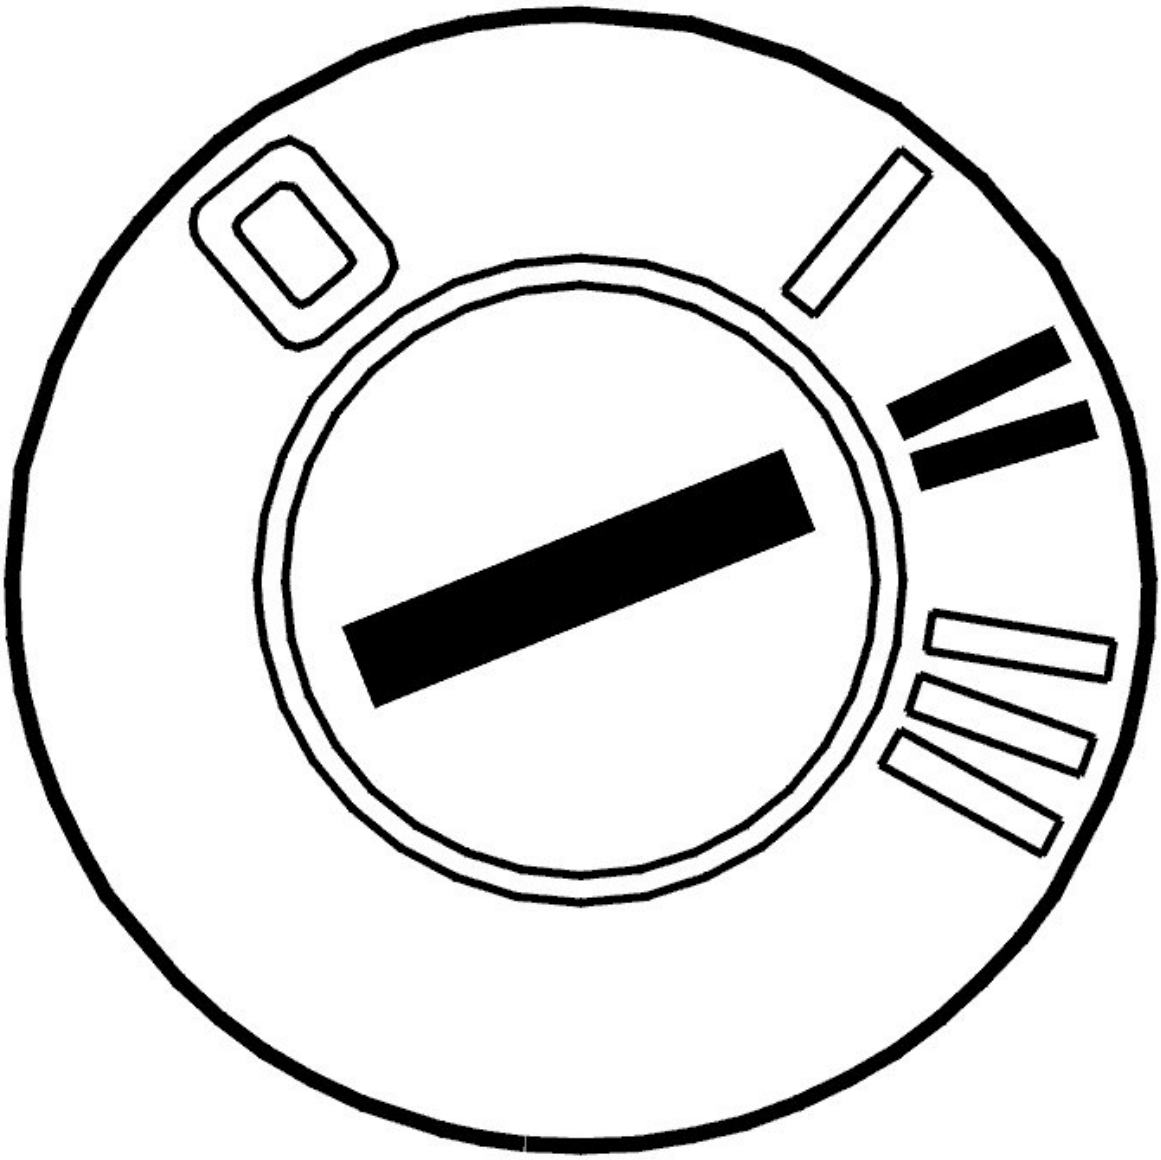
Other information
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

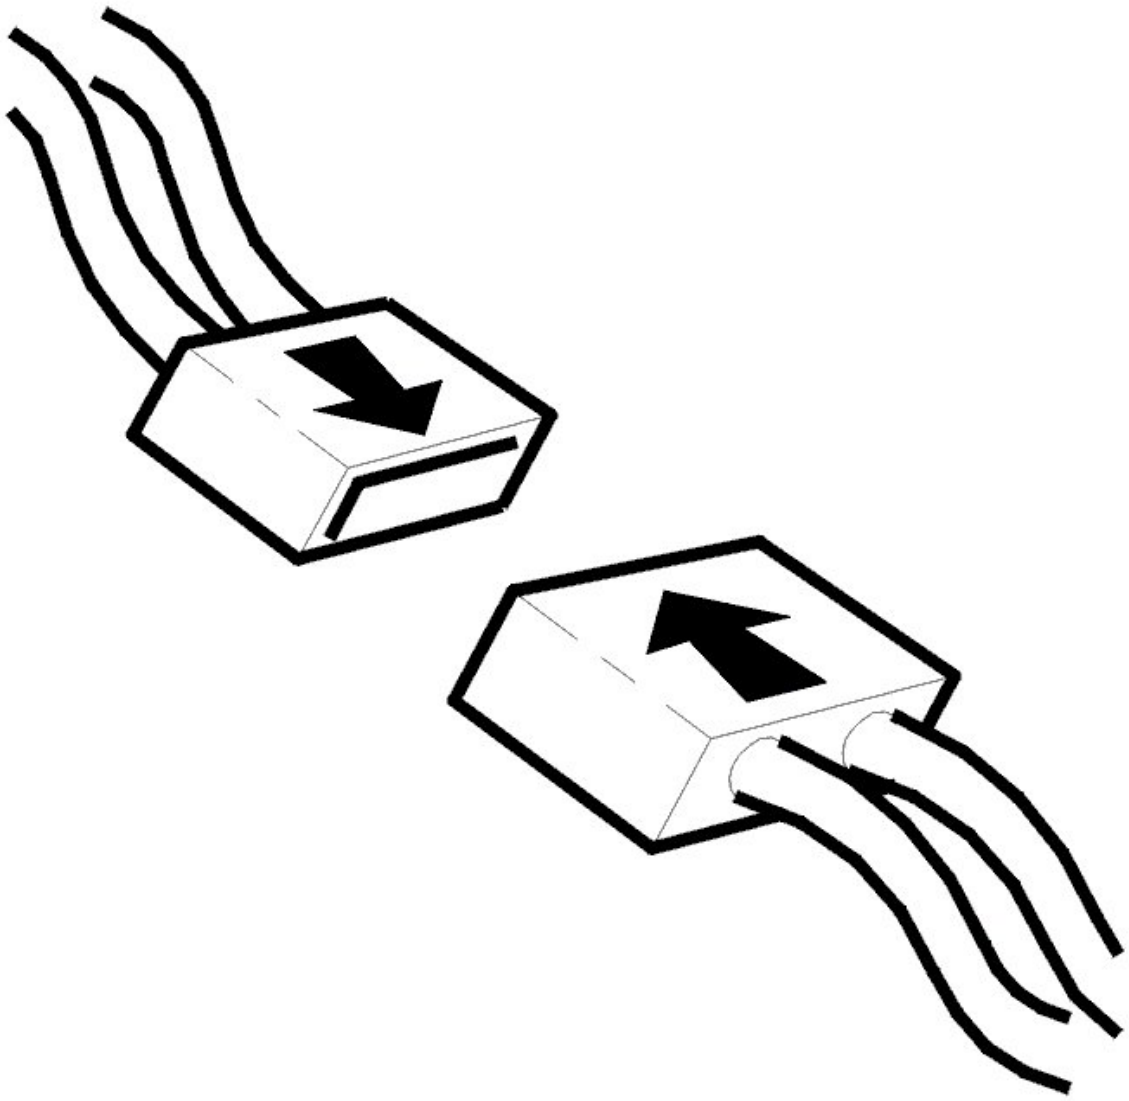


Continue - Verification

Checking the function of the supplemental restraint system module (SRS)

Hint: After carrying out the repair, check that the fault has been remedied.





- Ignition off
- Reconnect the connectors. Reinstall the components
- Ignition on.

Check the power supply to the control module by turning the ignition key to ignition position II.
The indicator lamp in the driver information module (DIM) must light up. The lamp must go out after a few seconds.

Does the indicator lamp go out?

Yes - Fault Found

No - Fault-tracing information

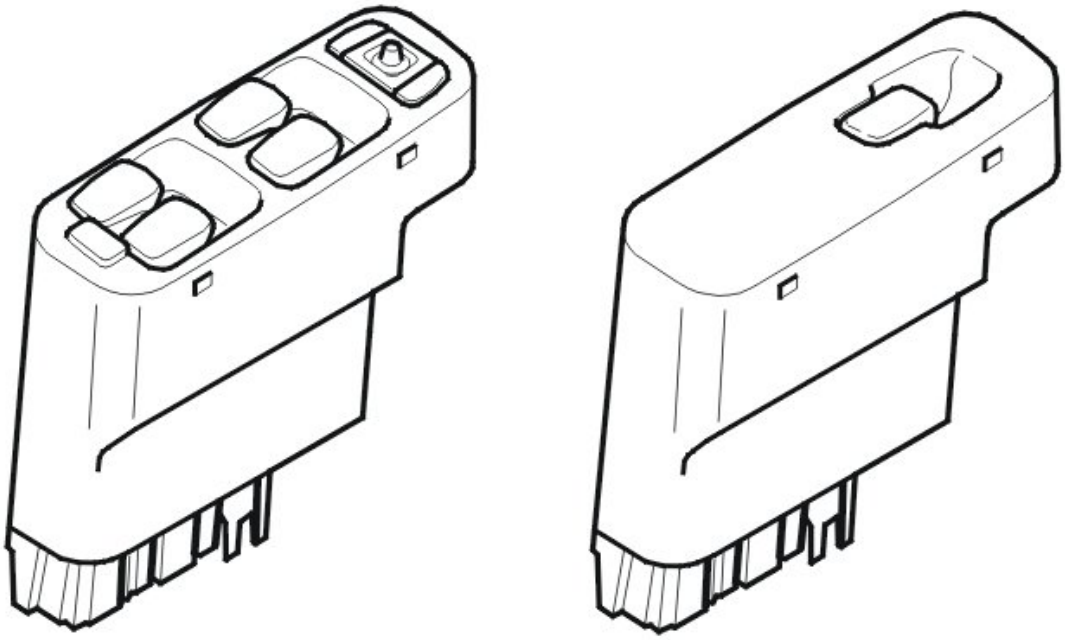
FAULT-TRACING FAILED - FAULT-TRACING FAILED

Attempt New Test - Checking the power supply for the supplemental restraint system module (SRS)

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CEM-1A52

Condition



The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers that communication with the driver's door module (DDM) is not operating.
The diagnostic trouble code (DTC) can be diagnosed when the ignition has been on for more than 10 seconds.

Note! In the event of CEM-1A5X diagnostic trouble codes (DTCs), the central electronic module (CEM) must not be replaced as the diagnostic trouble code (DTC) indicates a communication fault in the controller area network (CAN)!

Substitute value
- None.

Possible source
- No power supply to the driver's door module (DDM)
- Open-circuit in the ground lead for the driver's door module (DDM)
- Contact resistance in the terminals
- Open-circuit in the wiring for the CAN low speed network to the driver's door module (DDM)
- The driver door module (DDM) is not intended for this vehicle (for example a used control module with different software/hardware).

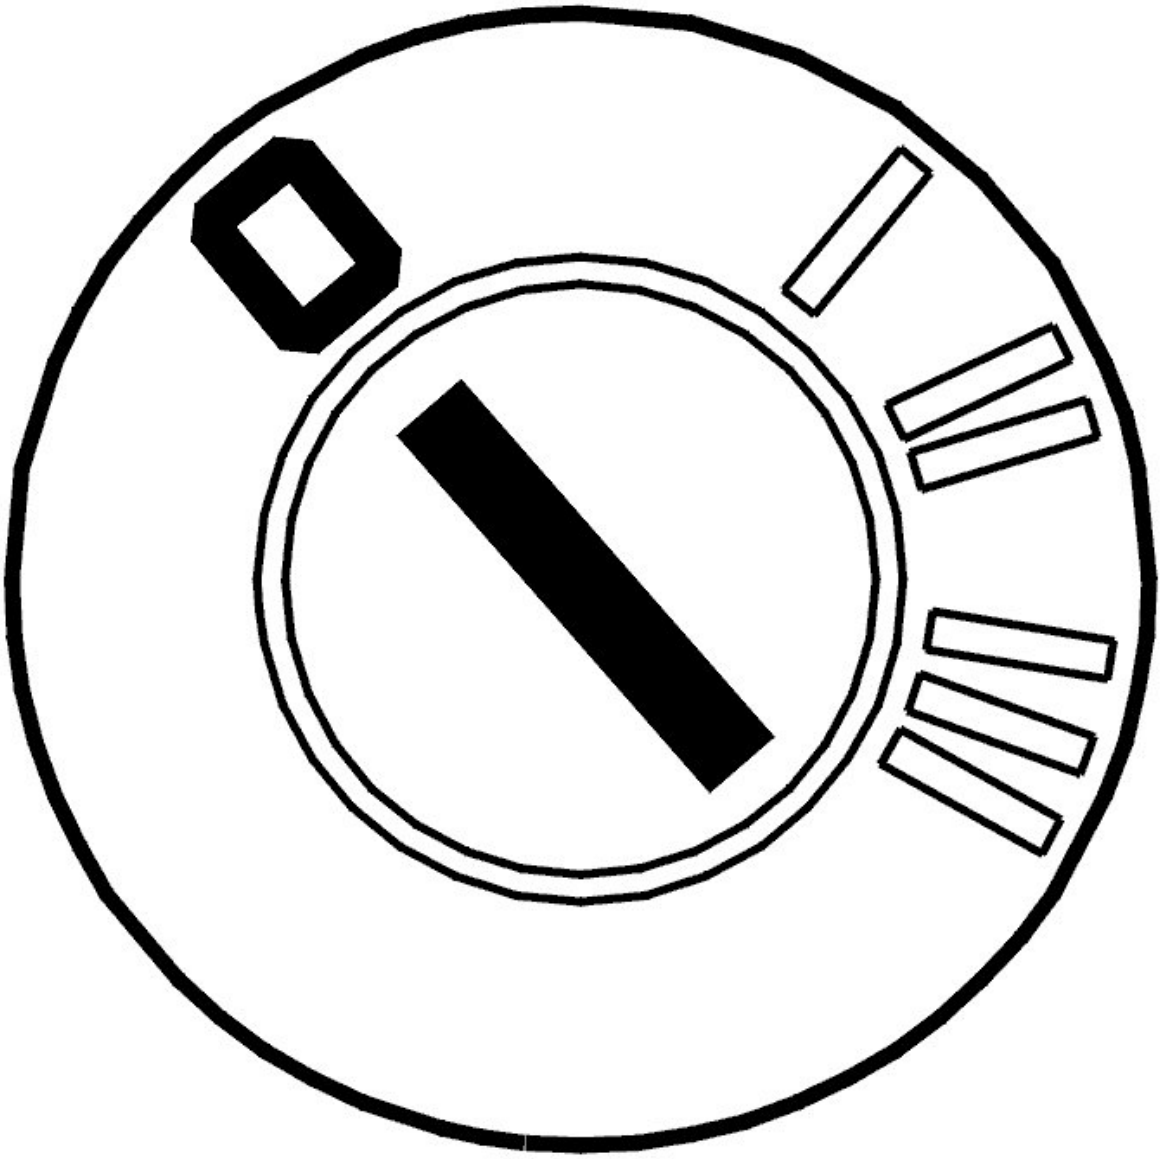
Hint: If several diagnostic trouble codes (DTCs) are stored in the central electronic module (CEM) for communication faults with other control modules in the low speed network, this indicates a common fault in the controller area network (CAN). See the relevant wiring diagram.

Fault symptom[s]
- Does not lock / unlock a door.
- The driver's door switch panel does not work.

Signal Missing

Signal missing

Checking the power supply and ground for the driver door module (DDM)



- Ignition off.

Check that the fuse for the control module is intact.
Check the power supply and ground terminal as instructed.

Other information:

- Checking the power supply and ground terminals See: Body and Frame/Body Control Systems/Testing and Inspection/Component Tests and General Diagnostics/Checking the Voltage/Ground Terminal, Driver Door Module (DDM)/ Passenger Door Module (PDM)
- For information about fuse and terminal numbers, see the relevant Wiring Diagram.
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

Was a fault detected?

Yes - Checking the function of the driver door module (DDM)

No - Signal missing

Checking the communication with the driver door module (DDM)

Hint: The CAN communication with the control module is probably OK if the control module ID can be read off. The fault is probably intermittent and may therefore be difficult to locate.

- Ignition on
- Try to communicate with the driver door module (DDM) by reading off the control module ID
- Click on the symbol for VCT2000 to begin reading off

Select Continue

Continue - Signal missing

Signal missing

General information

Note! Figures shown are only examples.

Hint: For general information about CAN-troubleshooting, see:
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

General about CAN-related diagnostic trouble codes.
CEM-DF01 - DF17can only be stored in Central electronic module (CEM). These diagnostic trouble codes are stored when an electric fault is detected in CAN-lines. Start with these diagnostic trouble codes first.
CEM-1AXX only stored in Central electronic module (CEM). One diagnostic trouble code for every control module on the CAN-net. These diagnostic trouble codes indicate that Central electronic module (CEM) does not receive any reply from other control modules.
XXX-E000 (HS-CAN)/E001 (LS-CAN) can be stored in all CAN-connected control modules. These diagnostic trouble codes indicate that the control module has detected interference on the CAN-net.
XXX-E003 can be stored in all CAN-connected control modules except in Central electronic module (CEM). The control modules on the CAN-net listen for a message (identity number) that is sent out at regular intervals from Central electronic module (CEM). This diagnostic trouble code indicates that the control module has not received any identity number, or that the expected number is not correct. Interference on the CAN-net can also store this diagnostic trouble code.

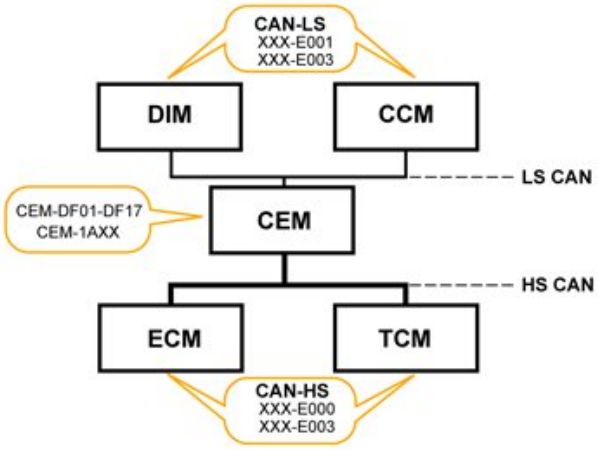
Note! In case of CAN-related faults, it is likely that a combination of above diagnostic trouble codes occur.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

If diagnostic trouble codes (DTCs) for communication faults can be read off from a control module, the fault is probably intermittent.
Intermittent fault in the voltage supply and ground to a control module on the CAN network results in the Central electronic module (CEM) storing a diagnostic trouble code (DTC) for an open-circuit in communication with the control module where the voltage supply does not work. There will probably not be a diagnostic trouble code (DTC) in the control module where the open-circuit in the voltage supply occurred as the control module cannot store a diagnostic trouble code (DTC) when it is not supplied with power.

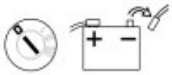
Note! Central electronic module (CEM) should not be replaced in case of CAN-fault, unless troubleshooting reveals that Central electronic module (CEM) has an internal fault.

Caution! During this fault-tracing use the wiring diagram to provide support when taking readings.



Continue - Checking resistance in CAN-net

Checking resistance in CAN-net



- Ignition off
- Disconnect the battery negative lead
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #3 and #11. The resistance should be approx. 55 - 65 ohms.
- If resistance is approx. 120 ohms, this indicates open circuit in the circuit so that only one terminating resistor (120 ohms) has been measured.
- If resistance is above 1 kohms this indicates open circuit/high contact resistance somewhere in the circuit.
- If resistance is below 55 ohms this indicates short-circuiting/contact resistance between the CAN-lines somewhere in the circuit.

Hint: For LS-CAN (Low Speed), terminating resistors are located in Upper electronic module (UEM) and Rear electronic module (REM).

Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

Note! Resistance measurement measures only main lines in the CAN-net (in circuit where both terminating resistors are found), not branches to certain control modules. See wiring diagram for vehicle model in question. Open circuit on branching without a terminating resistor cannot be detected with this measurement. However, short-circuiting on a branch can be detected. To measure resistance in the CAN-net to control modules located in a branching of their own, the measurement shall be done against the CAN-net at that control module. The values shall be as above.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy as necessary.

Checking for a short-circuit to ground

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #3 and #4 (ground). Measurement is shown in the figure. The resistance should be above 1 kohms.
- #11 and #4 (ground). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and ground.

Checking for a short-circuit to voltage

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #3 and #16 (voltage). Measurement is shown in the figure. The resistance should be above 1 kohms.
- #11 and #16 (voltage). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and voltage cable.
Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

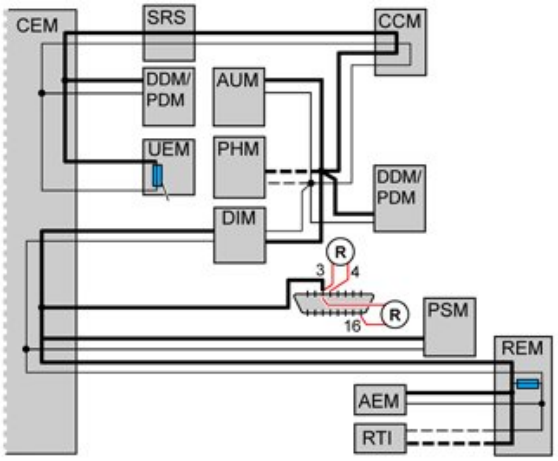
Hint: Part the CAN-net at suitable points to decide where a short-circuit may be found.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy as necessary.

Other information
- Battery, disconnecting See: Starting and Charging/Battery/Service and Repair/Procedures/Battery, Disconnecting
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

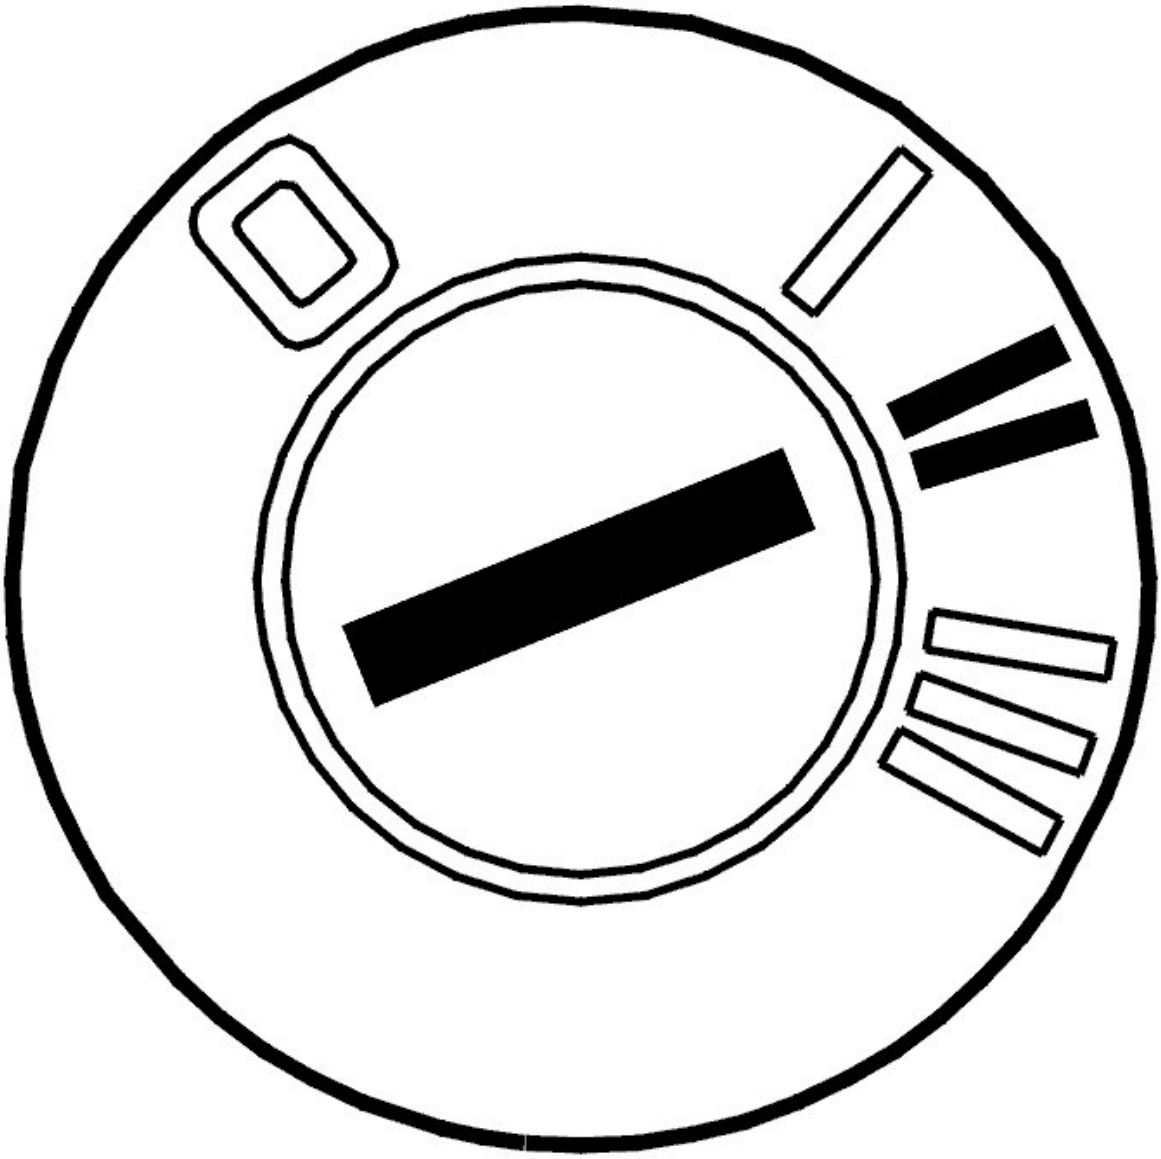


Was a fault detected?

Yes - Verification

No - Checking the amount of traffic on the LS-CAN

Checking voltage-drop in cable for CAN-H and CAN-L, respectively



- Connect the battery.
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

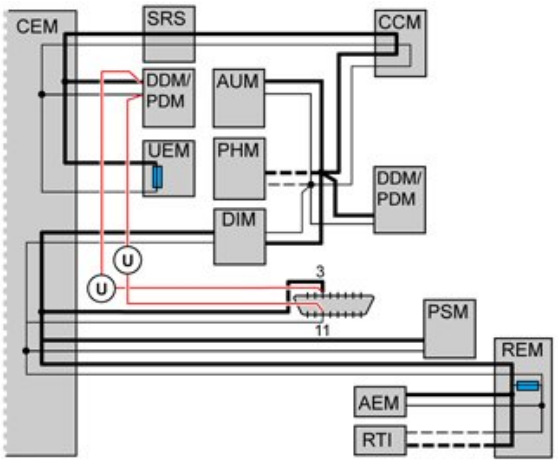
In principle, the voltage measured in each cable in the CAN-net shall be the same at each control module in the network. This means that the voltage-drop in the cable for CAN-H and CAN-L, respectively, between the control modules should be very low. If there is a voltage-difference in the CAN-lines between the diagnostics socket/Central electronic module (CEM) and a control module due to, e.g., contact resistance in a connector or branching, communication may be lost/interfered with. Check if there is voltage-drop in the cable for CAN-H and CAN-L between the diagnostics socket/Central electronic module (CEM) and the control module where there is problem with communication.
Carry out the following:
Measure voltage between the following connections on the OBDII-box/diagnostics socket.
- #3 and corresponding connection on relevant control module for CAN-H. The voltage shall be lower than 50 mV.
- #11 and corresponding connection on relevant control module for CAN-L. The voltage shall be lower than 50 mV.

If voltage is too high, this indicates too high contact resistance in cable, connector, or branching. Check the circuit between the diagnostics socket and control module in question for contact resistance and oxidation.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy wiring as necessary.

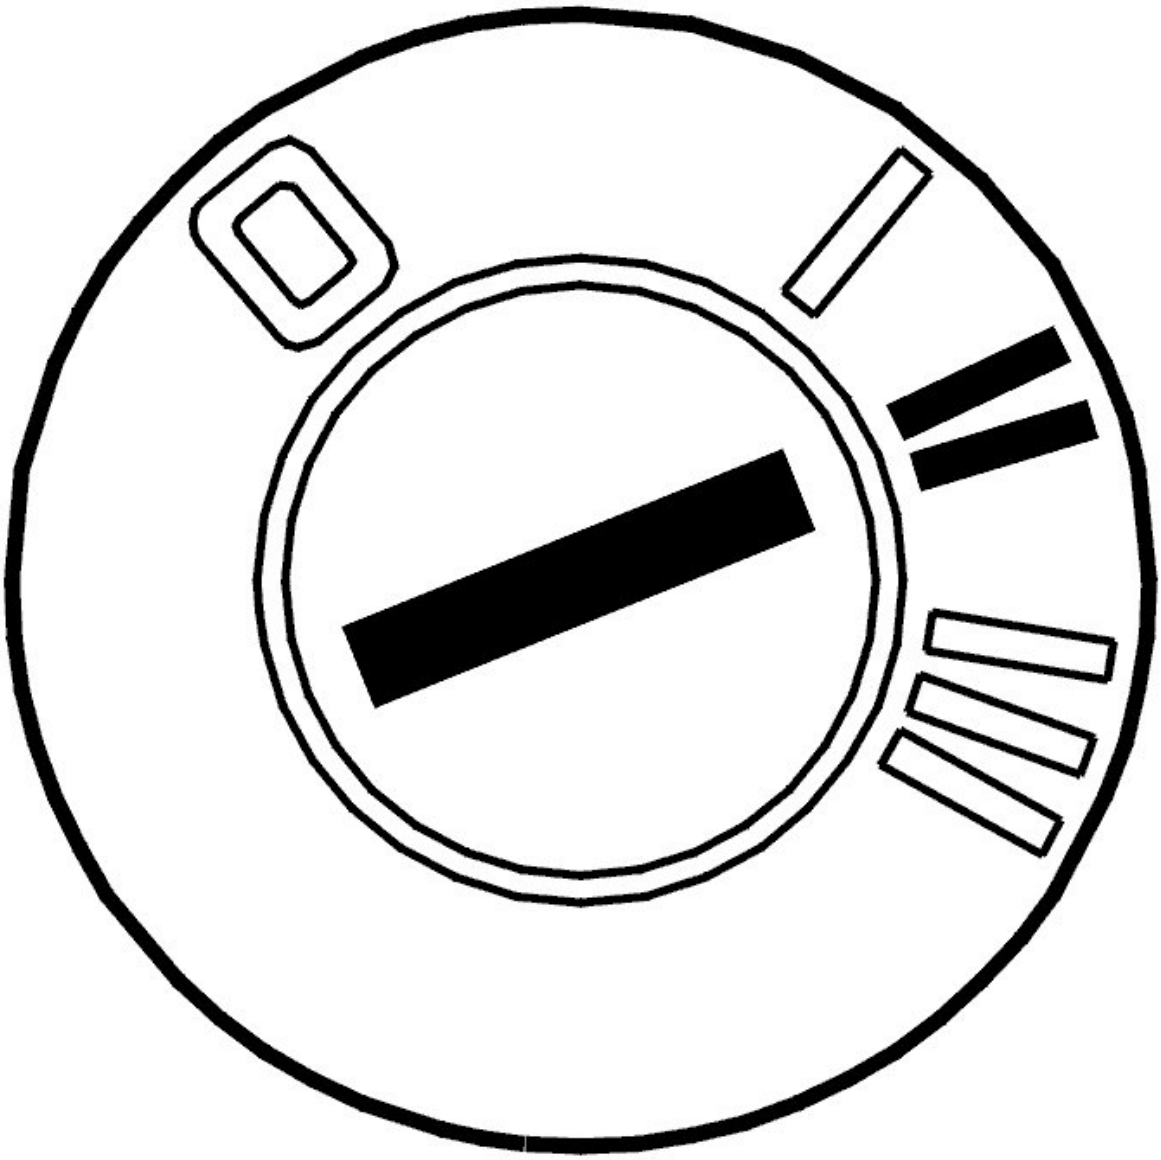
Other information
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

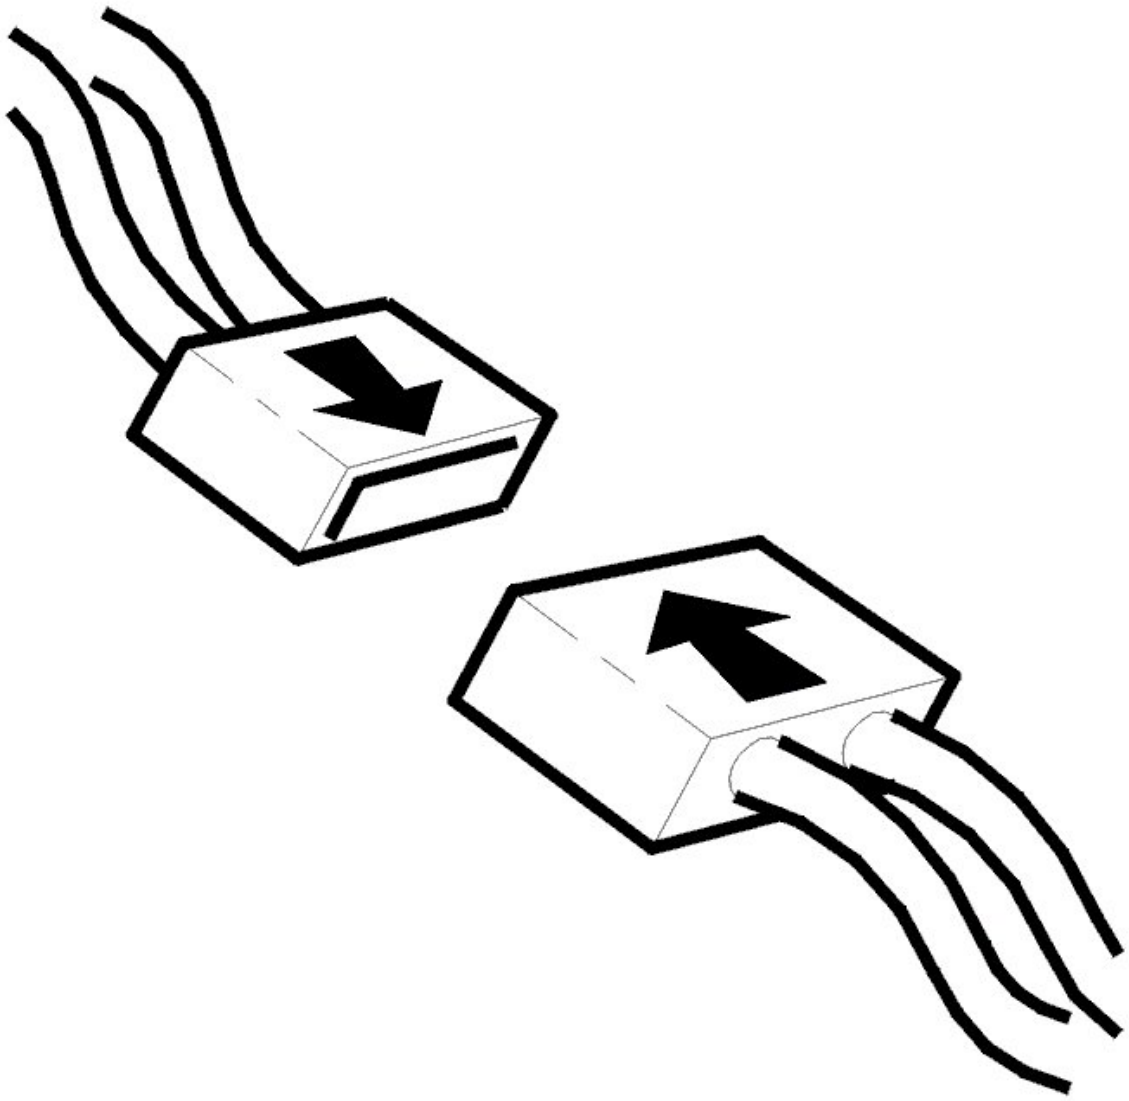


Continue - Verification

Checking the function of the driver door module (DDM)

Hint: After carrying out the repair, check that the fault has been remedied.





- Ignition off
- Reconnect the connectors. Reinstall the components
- Ignition on.

For further information about the fuse and terminal pin numbers, see the relevant Wiring Diagram.
Check the function of the control module by pressing the up and down buttons for the power window mechanism. The window must open or close.
Also activate the central locking buttons. The doors must lock and unlock.

Is the function OK?

Yes - Fault Found

No - Fault-tracing information

Fault-tracing information

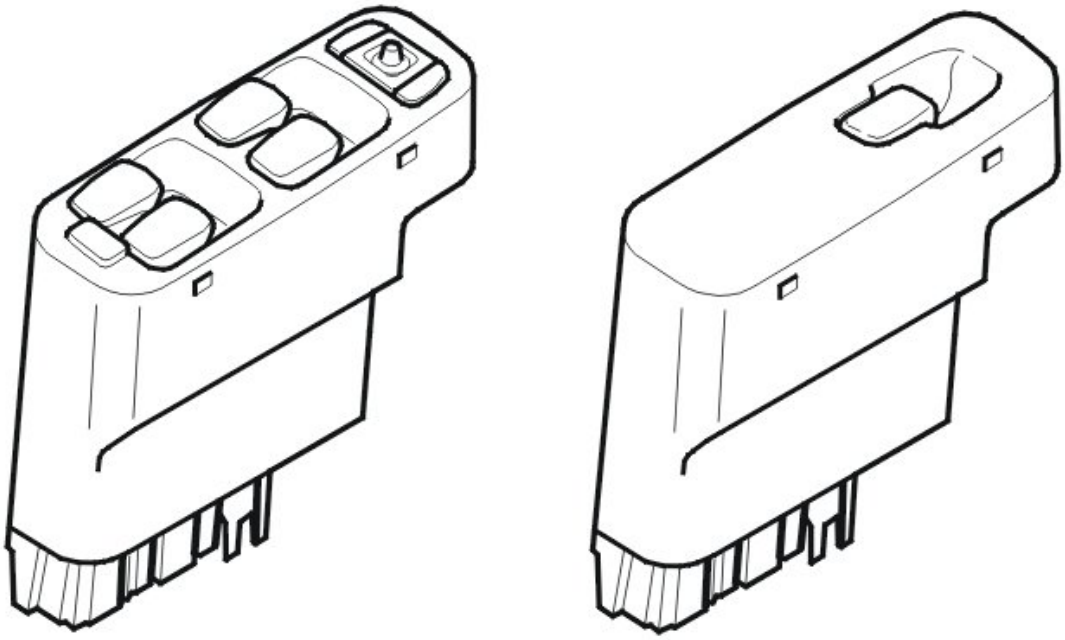
FAULT-TRACING FAILED - FAULT-TRACING FAILED

Attempt New Test - Checking the power supply and ground for the driver door module (DDM)

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CEM-1A53

Condition



The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers that communication with the passenger door module (PDM) is not operating.
The diagnostic trouble code (DTC) can be diagnosed when the ignition has been on for more than 10 seconds.

Note! In the event of CEM-1A5X diagnostic trouble codes (DTCs), the central electronic module (CEM) must not be replaced as the diagnostic trouble code (DTC) indicates a communication fault in the controller area network (CAN)!

Substitute value
- None.

Possible source
- No power supply to passenger door module (PDM)
- Open-circuit in the ground lead for the passenger door module (PDM)
- Contact resistance in the terminals
- Open-circuit in the wiring for the CAN low speed network to the passenger door module (PDM)
- The passenger door module (PDM) is not intended for this vehicle (for example a used control module with different software/hardware).

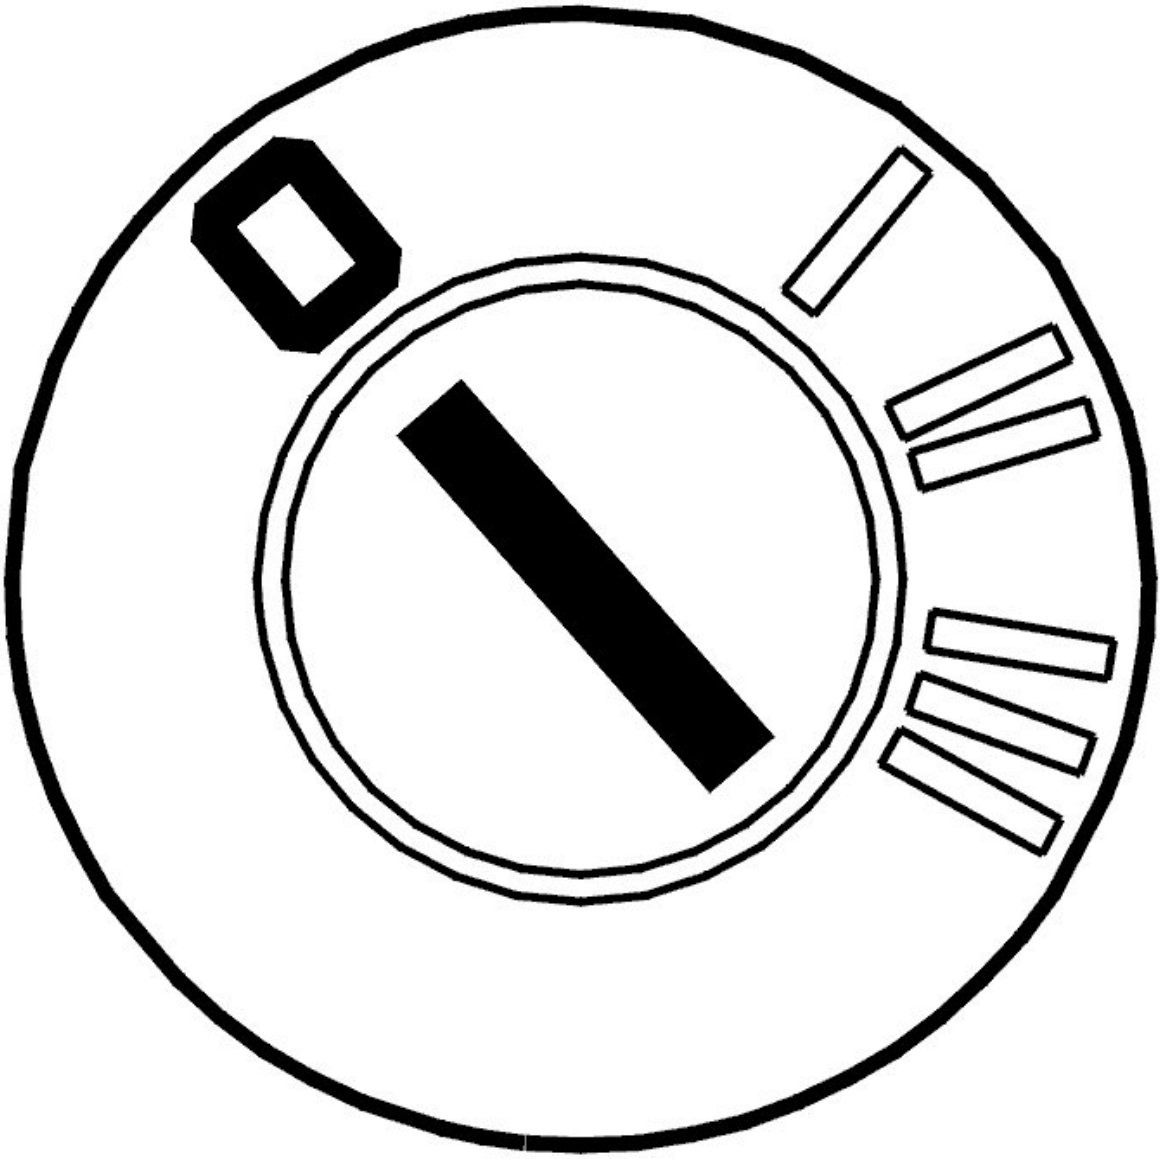
Hint: If several diagnostic trouble codes (DTCs) are stored in the central electronic module (CEM) for communication faults with other control modules in the low speed network, this indicates a common fault in the controller area network (CAN). See the relevant wiring diagram.

Fault symptom[s]
- Does not lock / unlock a door.
- The passenger door switch panel does not work.

Signal Missing

Signal missing

Checking the power supply and ground for the passenger door module (PDM)



- Ignition off.

Check that the fuse for the control module is intact.
Check the power supply and ground terminal as instructed.

Other information:

General information

Note! Figures shown are only examples.

Hint: For general information about CAN-troubleshooting, see:
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

General about CAN-related diagnostic trouble codes.

CEM-DF01 - DF17can only be stored in Central electronic module (CEM). These diagnostic trouble codes are stored when an electric fault is detected in CAN-lines. Start with these diagnostic trouble codes first.
CEM-1AXX only stored in Central electronic module (CEM). One diagnostic trouble code for every control module on the CAN-net. These diagnostic trouble codes indicate that Central electronic module (CEM) does not receive any reply from other control modules.
XXX-E000 (HS-CAN)/E001 (LS-CAN) can be stored in all CAN-connected control modules. These diagnostic trouble codes indicate that the control module has detected interference on the CAN-net.
XXX-E003 can be stored in all CAN-connected control modules except in Central electronic module (CEM). The control modules on the CAN-net listen for a message (identity number) that is sent out at regular intervals from Central electronic module (CEM). This diagnostic trouble code indicates that the control module has not received any identity number, or that the expected number is not correct. Interference on the CAN-net can also store this diagnostic trouble code.

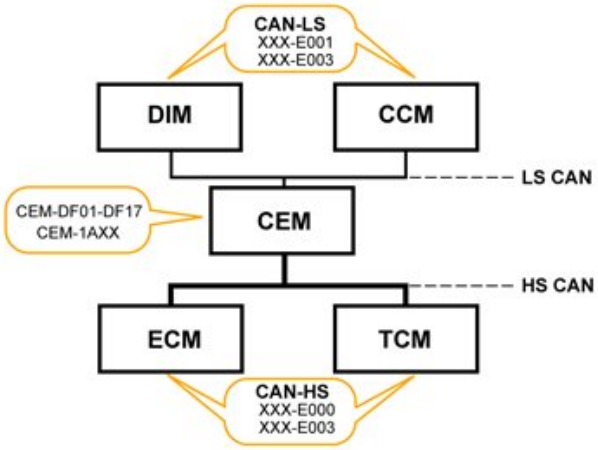
Note! In case of CAN-related faults, it is likely that a combination of above diagnostic trouble codes occur.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

If diagnostic trouble codes (DTCs) for communication faults can be read off from a control module, the fault is probably intermittent.
Intermittent fault in the voltage supply and ground to a control module on the CAN network results in the Central electronic module (CEM) storing a diagnostic trouble code (DTC) for an open-circuit in communication with the control module where the voltage supply does not work. There will probably not be a diagnostic trouble code (DTC) in the control module where the open-circuit in the voltage supply occurred as the control module cannot store a diagnostic trouble code (DTC) when it is not supplied with power.

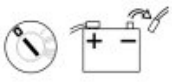
Note! Central electronic module (CEM) should not be replaced in case of CAN-fault, unless troubleshooting reveals that Central electronic module (CEM) has an internal fault.

Caution! During this fault-tracing use the wiring diagram to provide support when taking readings.



Continue - Checking resistance in CAN-net

Checking resistance in CAN-net



- Ignition off
- Disconnect the battery negative lead
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #3 and #11. The resistance should be approx. 55 - 65 ohms.
- If resistance is approx. 120 ohms, this indicates open circuit in the circuit so that only one terminating resistor (120 ohms) has been

measured.

- If resistance is above 1 kohms this indicates open circuit/high contact resistance somewhere in the circuit.
- If resistance is below 55 ohms this indicates short-circuiting/contact resistance between the CAN-lines somewhere in the circuit.

Hint: For LS-CAN (Low Speed), terminating resistors are located in Upper electronic module (UEM) and Rear electronic module (REM).

Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

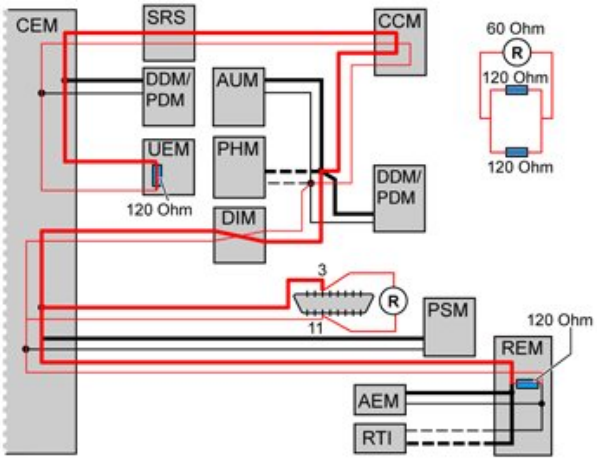
Note! Resistance measurement measures only main lines in the CAN-net (in circuit where both terminating resistors are found), not branches to certain control modules. See wiring diagram for vehicle model in question. Open circuit on branching without a terminating resistor cannot be detected with this measurement. However, short-circuiting on a branch can be detected. To measure resistance in the CAN-net to control modules located in a branching of their own, the measurement shall be done against the CAN-net at that control module. The values shall be as above.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy as necessary.

Other information

- Battery, disconnecting See: Starting and Charging/Battery/Service and Repair/Procedures/Battery, Disconnecting
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

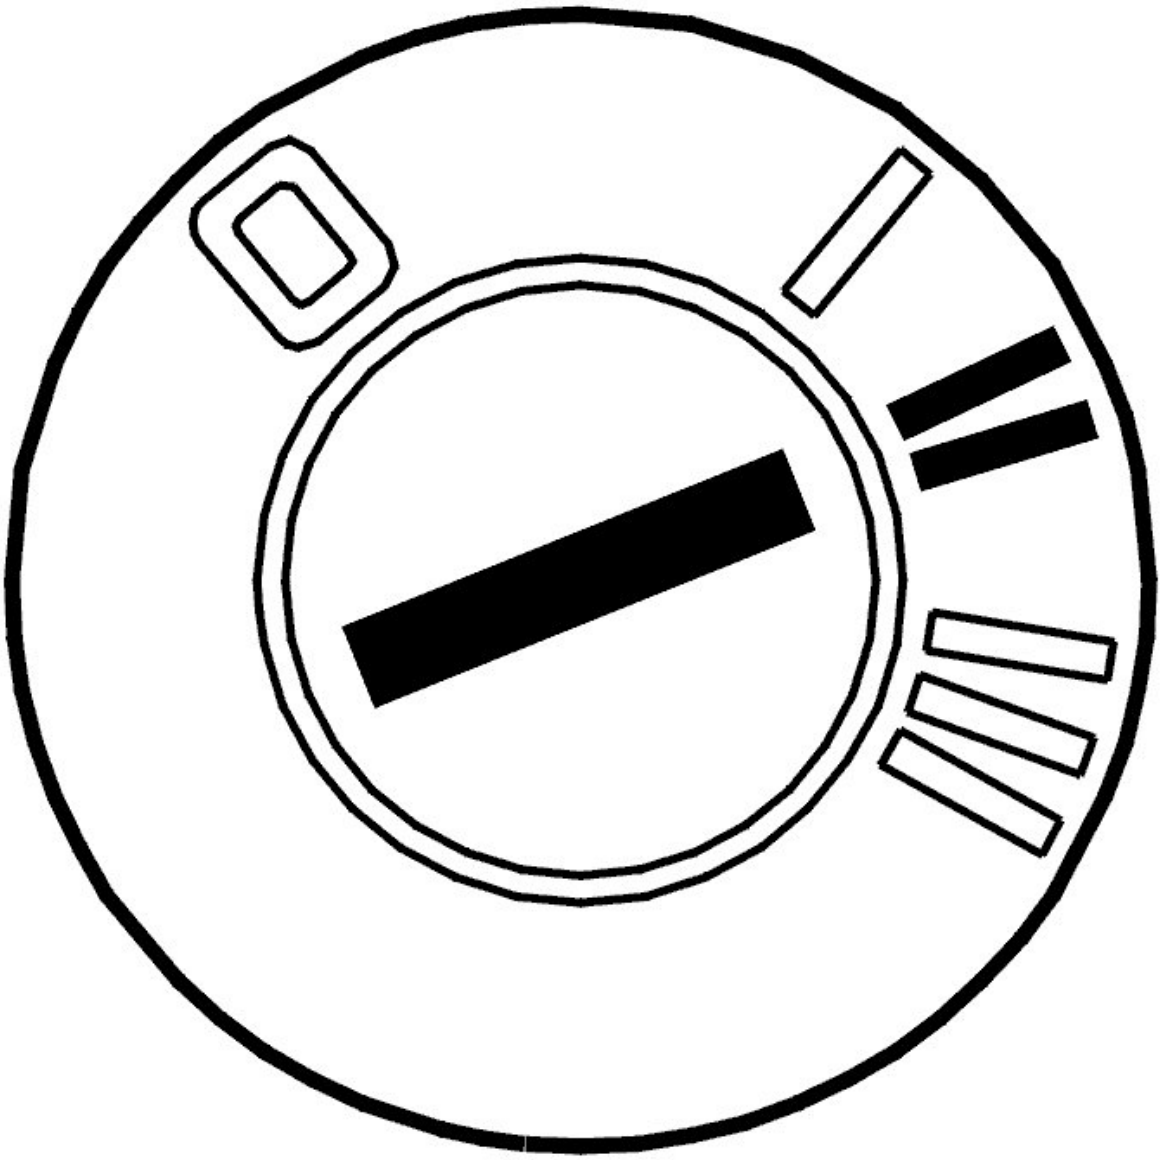


Was a fault detected?

Yes - Verification

No - Checking short-circuiting to ground/voltage in CAN-net

Checking the amount of traffic on the LS-CAN



- Connect the battery
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
Faults in the CAN network may be due to a control module sending faulty messages that disrupt normal communication. When messages are sent incorrectly, this results in a considerable increase in the amount of traffic on the CAN network. The load can be checked by reading the average value of the voltage on the CAN cables in relation to ground.
For further information, see the wiring diagram.
Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #3 and #4 (ground). The voltage should be approx: 2,8 - 3,2 V.
- #11 and #4 (ground). The voltage should be approx: 1,8 - 2,2 V.
- #3 and #11. The voltage shall be between approx. 0.55-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Hint: DiCE Error Frame Finder can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools: **951 3010** (memory card) as well as associated TJ 20402.

- Ignition on.
- Connect DiCE Error Frame Finder to the diagnostics socket.
- Note the blue LED-indicator. The indicator flashes to show detection of fault messages.

Note! Certain interference may occur without any real fault!

Cable fault

- Shake the cables lightly and pull lightly on the connections during the check to locate any fault. Note the blue LED-indicator.

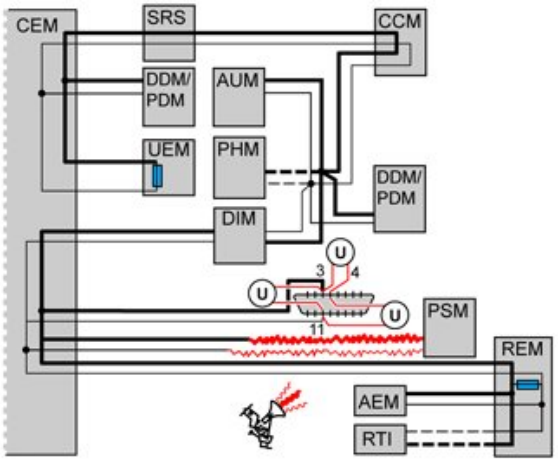
"Chatting" control modules

- "Chatting" control modules may be difficult to find and troubleshooting may take time. Let the vehicle stand with DiCE connected for an extended time period. Afterwards, activate functions to provoke a malfunction. It may take up to several hours before the fault messages are sent. When the indicator starts to flash, remove the fuse for one control module at a time until the indicator stops flashing. When the indicator stops flashing, restore the fuse for the relevant control module and check that the indicator starts to flash again. Then it is likely that the problem is identified.

Remedy wiring as necessary.

Other information

- Battery, disconnecting See: Starting and Charging/Battery/Service and Repair/Procedures/Battery, Disconnecting
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals



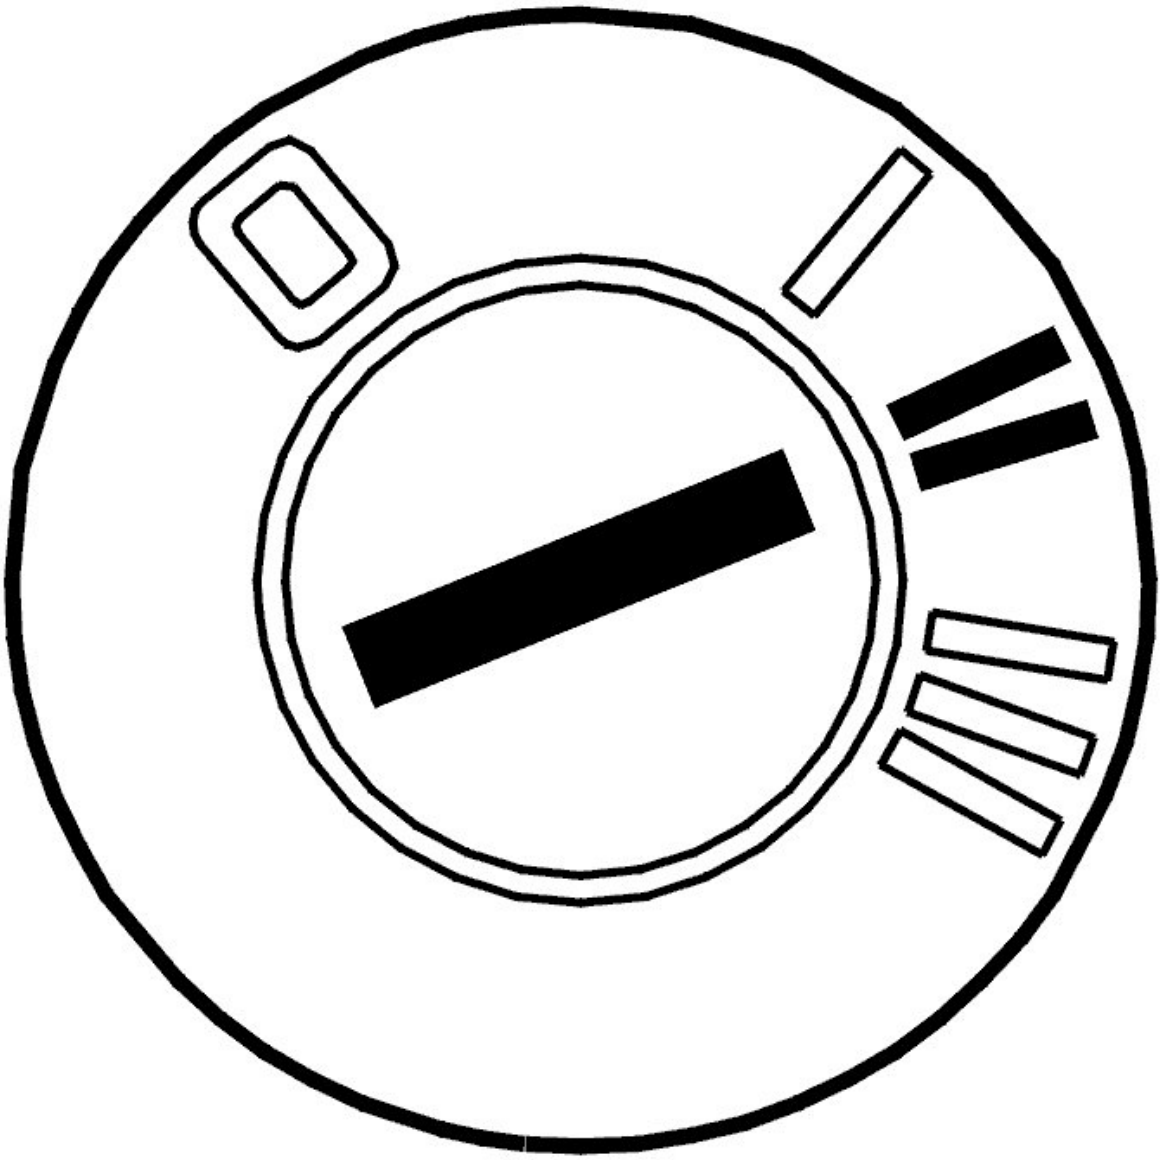
Was a fault detected?

Yes - Identifying a control module in the CAN network

No - Checking voltage-drop in cable for CAN-H and CAN-L, respectively

---

Identifying a control module in the CAN network



Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:

- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Hint: DiCE Error Frame Finder can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools: **951 3010** (memory card) as well as associated TJ 20402. If the load on the CAN network is too high, this may be due to a control module transmitting faulty messages on the CAN network. This is called a disruptive control module. The fault may also be due to an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The fault may occur without any of the control modules storing a diagnostic trouble code (DTC). The voltage can be measured between the CAN cables in order to check the load on the CAN network.

Note! It is not necessarily the control module that has set the diagnostic trouble code that communicates incorrectly. Faulty messages can come from any control module in the same section of the CAN network. However, faulty communication in one network cannot affect the communication on the other network. In other words, faulty communication on the LS-CAN cannot disrupt communication on the HS-CAN and vice versa.

- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Check communication/load on CAN-net by measuring voltage between CAN-L and CAN-H. Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #3 and #11. The average value of the voltage must be approximately 0.6-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

In order to identify which control module has faulty communication, cut the power supply to one control module at a time. Check the voltage in the CAN cables again. The easiest way to cut the power supply is to remove the fuse(s) for the relevant control module. Repeat until the voltage between the CAN wiring drops to the normal level.

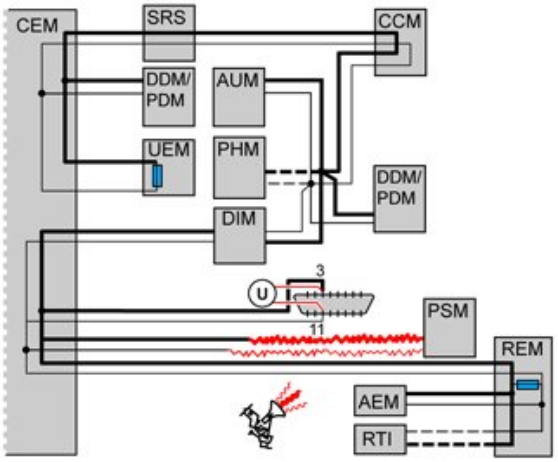
Note! When connecting and disconnecting certain control modules, diagnostic trouble codes (DTCs) may be stored in other control modules.

Hint: When the suspected defective control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the malfunction appears and disappears. Switch off the ignition between each check.

Note! Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.

A control module that is communicating incorrectly must be replaced. See Repairing and installing/Removing, replacing and installing.

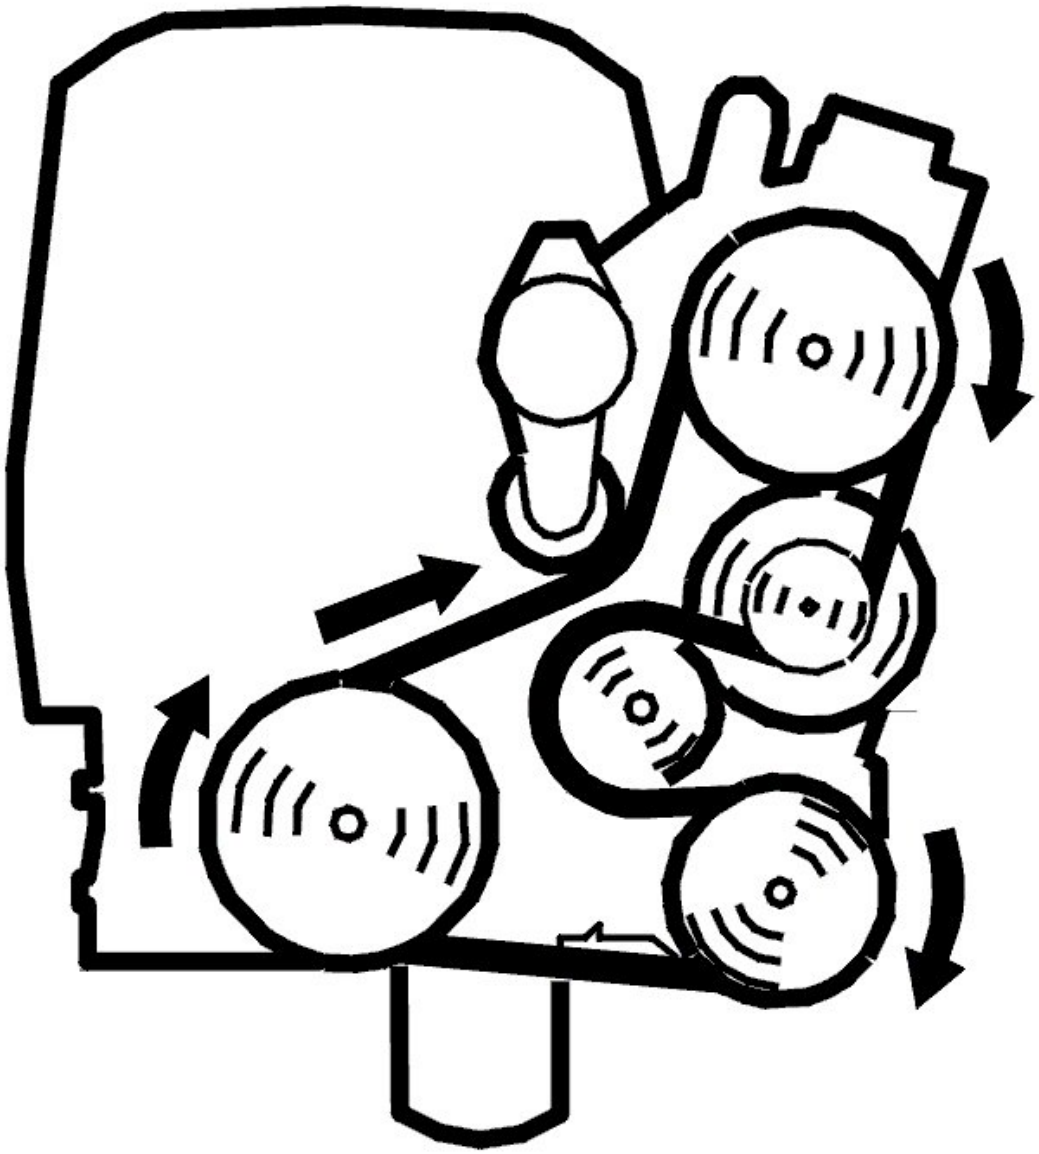
Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

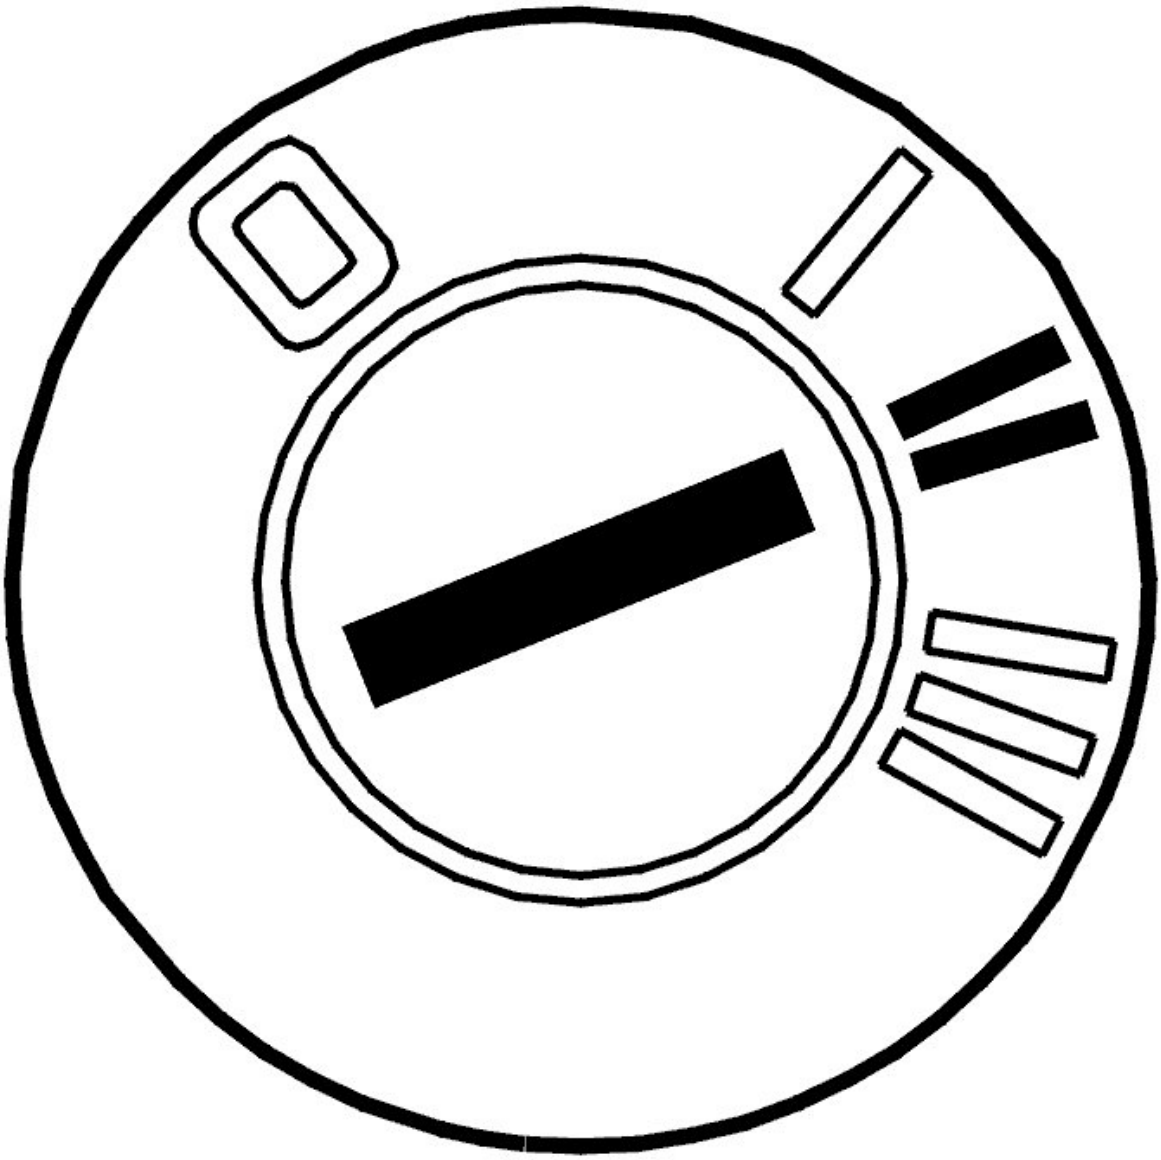


Continue - Verification

Verification

Hint: After rectifying a fault, a verification should be carried out.





- Reinstall the connectors, components etc.
- Ignition on.

Note! For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

- Erase diagnostic trouble codes (DTCs) in all control modules.
- Ignition off.
- Ignition on.
- Start the vehicle. Allow the vehicle to run for 10 minutes. Start the engine. Allow the engine to run at idle speed for 10 minutes
- Read out the diagnostic trouble codes in the vehicle via the DIAGNOSTICS tab.

Does the diagnostic trouble code (DTC) for faulty communication return?

Yes - Fault-tracing information

No - Fault Found

General information

Note! Figures shown are only examples.

Hint: For general information about CAN-troubleshooting, see:

- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

General about CAN-related diagnostic trouble codes.
CEM-DF01 - DF17can only be stored in Central electronic module (CEM). These diagnostic trouble codes are stored when an electric fault is detected in CAN-lines. Start with these diagnostic trouble codes first.
CEM-1AXX only stored in Central electronic module (CEM). One diagnostic trouble code for every control module on the CAN-net. These diagnostic trouble codes indicate that Central electronic module (CEM) does not receive any reply from other control modules.
XXX-E000 (HS-CAN)/E001 (LS-CAN) can be stored in all CAN-connected control modules. These diagnostic trouble codes indicate that the control module has detected interference on the CAN-net.
XXX-E003 can be stored in all CAN-connected control modules except in Central electronic module (CEM). The control modules on the CAN-net listen for a message (identity number) that is sent out at regular intervals from Central electronic module (CEM). This diagnostic trouble code indicates that the control module has not received any identity number, or that the expected number is not correct. Interference on the CAN-net can also store this diagnostic trouble code.

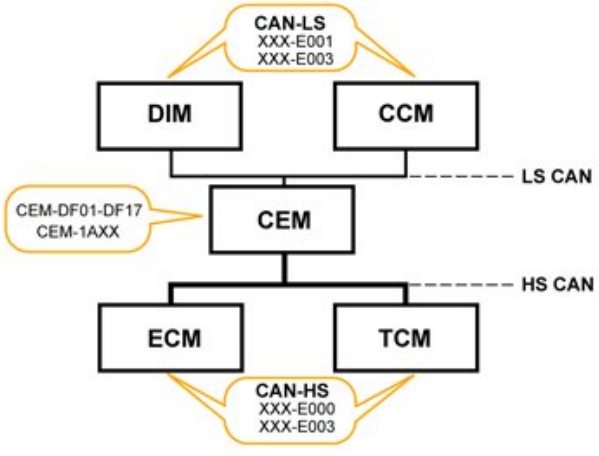
Note! In case of CAN-related faults, it is likely that a combination of above diagnostic trouble codes occur.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

If diagnostic trouble codes (DTCs) for communication faults can be read off from a control module, the fault is probably intermittent.
Intermittent fault in the voltage supply and ground to a control module on the CAN network results in the Central electronic module (CEM) storing a diagnostic trouble code (DTC) for an open-circuit in communication with the control module where the voltage supply does not work. There will probably not be a diagnostic trouble code (DTC) in the control module where the open-circuit in the voltage supply occurred as the control module cannot store a diagnostic trouble code (DTC) when it is not supplied with power.

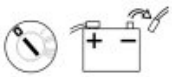
Note! Central electronic module (CEM) should not be replaced in case of CAN-fault, unless troubleshooting reveals that Central electronic module (CEM) has an internal fault.

Caution! During this fault-tracing use the wiring diagram to provide support when taking readings.



Continue - Checking resistance in CAN-net

Checking resistance in CAN-net



- Ignition off
- Disconnect the battery negative lead
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #3 and #11. The resistance should be approx. 55 - 65 ohms.
- If resistance is approx. 120 ohms, this indicates open circuit in the circuit so that only one terminating resistor (120 ohms) has been measured.
- If resistance is above 1 kohms this indicates open circuit/high contact resistance somewhere in the circuit.
- If resistance is below 55 ohms this indicates short-circuiting/contact resistance between the CAN-lines somewhere in the circuit.

Hint: For LS-CAN (Low Speed), terminating resistors are located in Upper electronic module (UEM) and Rear electronic module (REM).

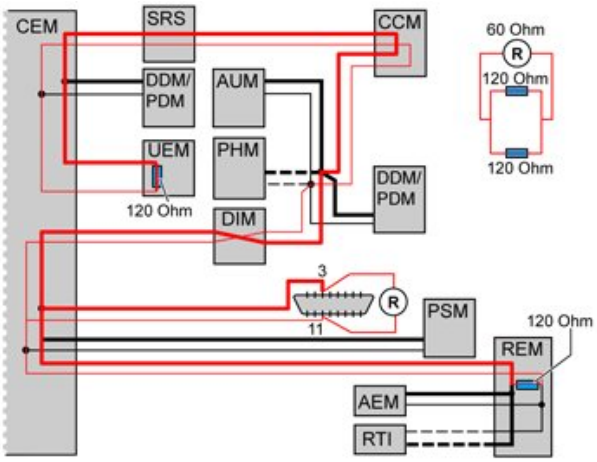
Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

Note! Resistance measurement measures only main lines in the CAN-net (in circuit where both terminating resistors are found), not branches to certain control modules. See wiring diagram for vehicle model in question. Open circuit on branching without a terminating resistor cannot be detected with this measurement. However, short-circuiting on a branch can be detected. To measure resistance in the CAN-net to control modules located in a branching of their own, the measurement shall be done against the CAN-net at that control module. The values shall be as above.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy as necessary.

Other information
- Battery, disconnecting See: Starting and Charging/Battery/Service and Repair/Procedures/Battery, Disconnecting
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

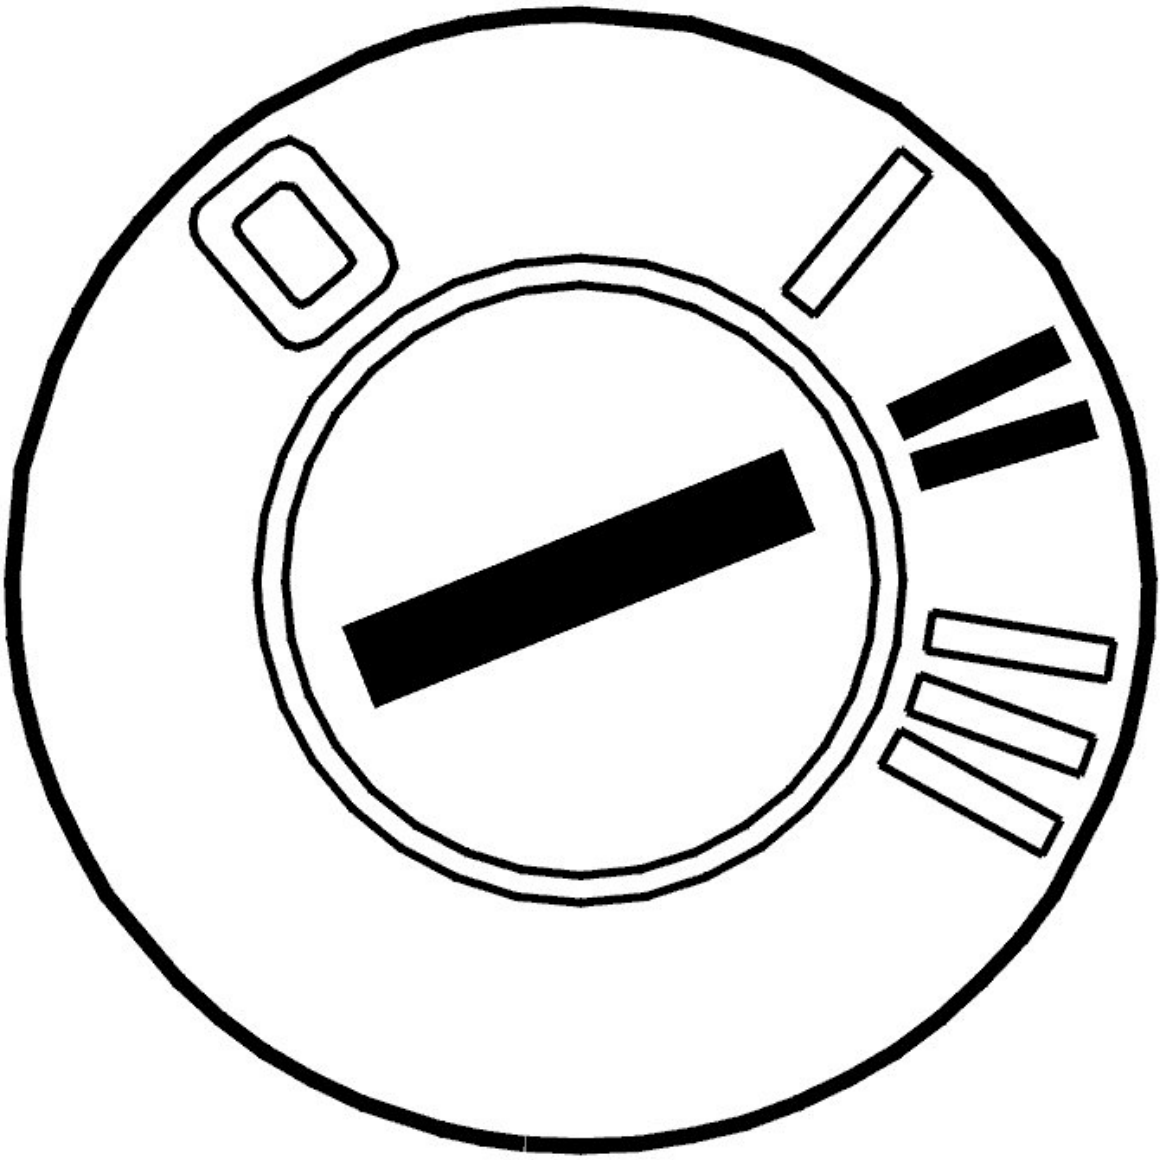


Was a fault detected?

Yes - Verification

No - Checking short-circuiting to ground/voltage in CAN-net

Checking the amount of traffic on the LS-CAN



- Connect the battery
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
Faults in the CAN network may be due to a control module sending faulty messages that disrupt normal communication. When messages are sent incorrectly, this results in a considerable increase in the amount of traffic on the CAN network. The load can be checked by reading the average value of the voltage on the CAN cables in relation to ground.
For further information, see the wiring diagram.
Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #3 and #4 (ground). The voltage should be approx: 2,8 - 3,2 V.
- #11 and #4 (ground). The voltage should be approx: 1,8 - 2,2 V.
- #3 and #11. The voltage shall be between approx. 0.55-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Hint: DiCE Error Frame Finder can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools: **951 3010** (memory card) as well as associated TJ 20402.

- Ignition on.
- Connect DiCE Error Frame Finder to the diagnostics socket.
- Note the blue LED-indicator. The indicator flashes to show detection of fault messages.

Note! Certain interference may occur without any real fault!

Cable fault

- Shake the cables lightly and pull lightly on the connections during the check to locate any fault. Note the blue LED-indicator.

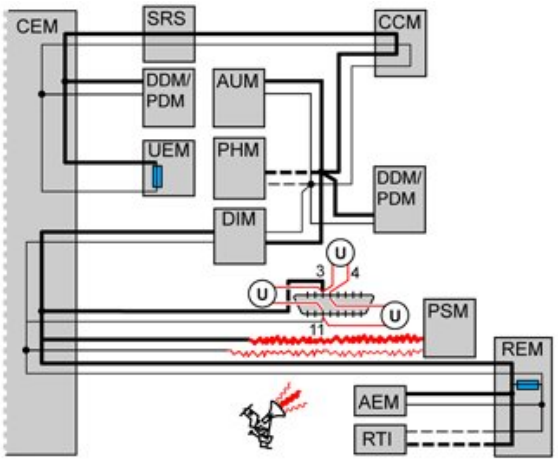
"Chatting" control modules

- "Chatting" control modules may be difficult to find and troubleshooting may take time. Let the vehicle stand with DiCE connected for an extended time period. Afterwards, activate functions to provoke a malfunction. It may take up to several hours before the fault messages are sent. When the indicator starts to flash, remove the fuse for one control module at a time until the indicator stops flashing. When the indicator stops flashing, restore the fuse for the relevant control module and check that the indicator starts to flash again. Then it is likely that the problem is identified.

Remedy wiring as necessary.

Other information

- Battery, disconnecting See: Starting and Charging/Battery/Service and Repair/Procedures/Battery, Disconnecting
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals



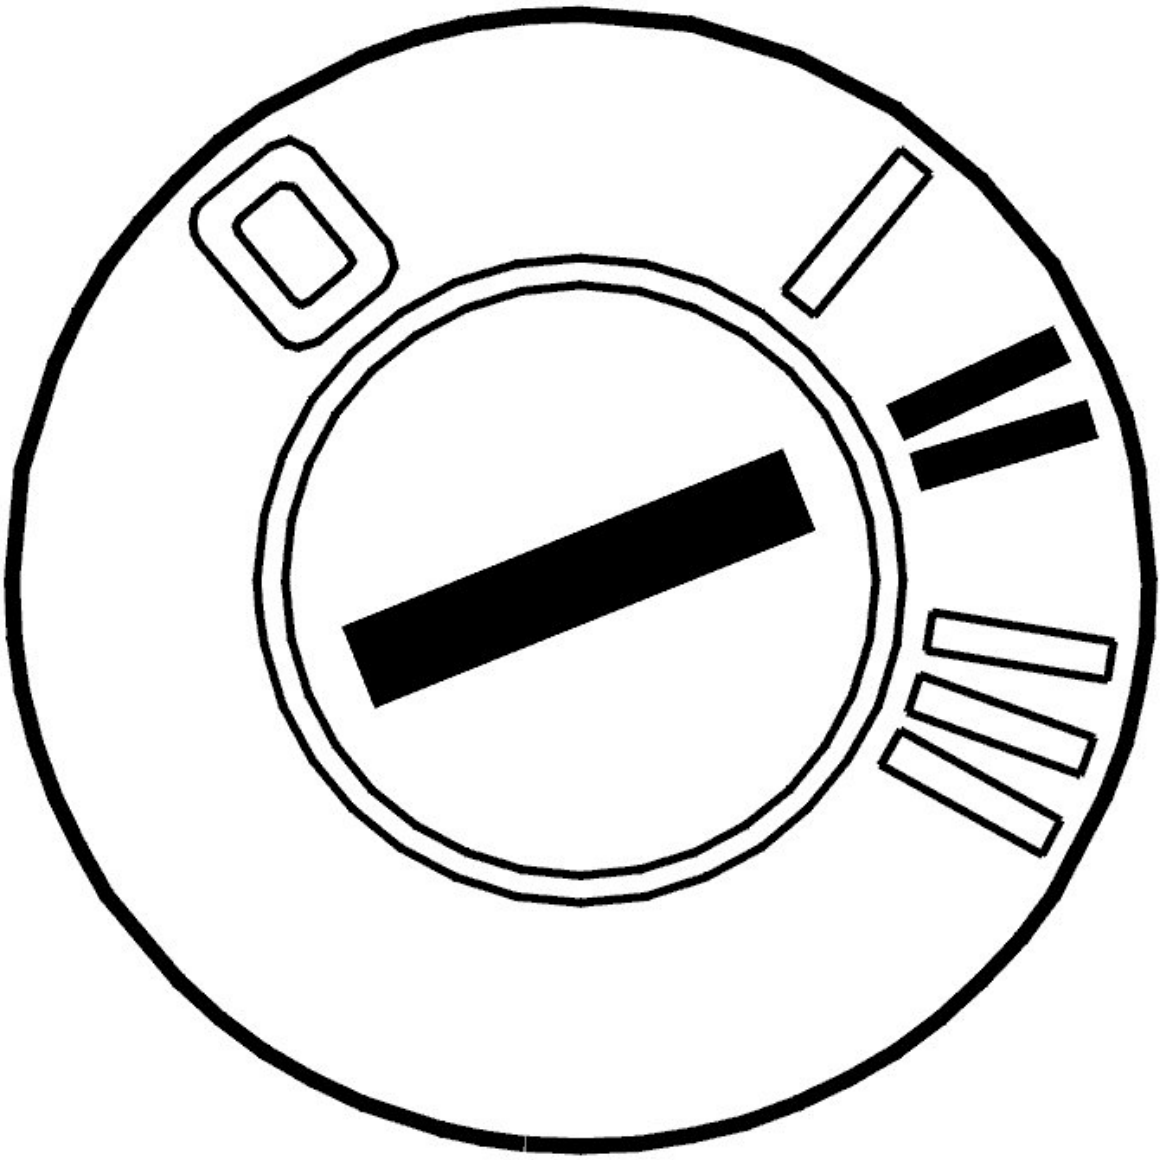
Was a fault detected?

Yes - Identifying a control module in the CAN network

No - Checking voltage-drop in cable for CAN-H and CAN-L, respectively

---

Identifying a control module in the CAN network



Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:

- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Hint: DiCE Error Frame Finder can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools: **951 3010** (memory card) as well as associated TJ 20402. If the load on the CAN network is too high, this may be due to a control module transmitting faulty messages on the CAN network. This is called a disruptive control module. The fault may also be due to an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The fault may occur without any of the control modules storing a diagnostic trouble code (DTC). The voltage can be measured between the CAN cables in order to check the load on the CAN network.

Note! It is not necessarily the control module that has set the diagnostic trouble code that communicates incorrectly. Faulty messages can come from any control module in the same section of the CAN network. However, faulty communication in one network cannot affect the communication on the other network. In other words, faulty communication on the LS-CAN cannot disrupt communication on the HS-CAN and vice versa.

- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Check communication/load on CAN-net by measuring voltage between CAN-L and CAN-H. Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #3 and #11. The average value of the voltage must be approximately 0.6-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

In order to identify which control module has faulty communication, cut the power supply to one control module at a time. Check the voltage in the CAN cables again. The easiest way to cut the power supply is to remove the fuse(s) for the relevant control module. Repeat until the voltage

between the CAN wiring drops to the normal level.

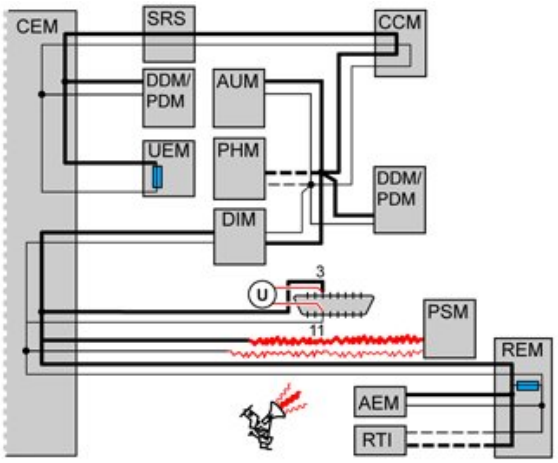
Note! When connecting and disconnecting certain control modules, diagnostic trouble codes (DTCs) may be stored in other control modules.

Hint: When the suspected defective control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the malfunction appears and disappears. Switch off the ignition between each check.

Note! Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.

A control module that is communicating incorrectly must be replaced. See Repairing and installing/Removing, replacing and installing.

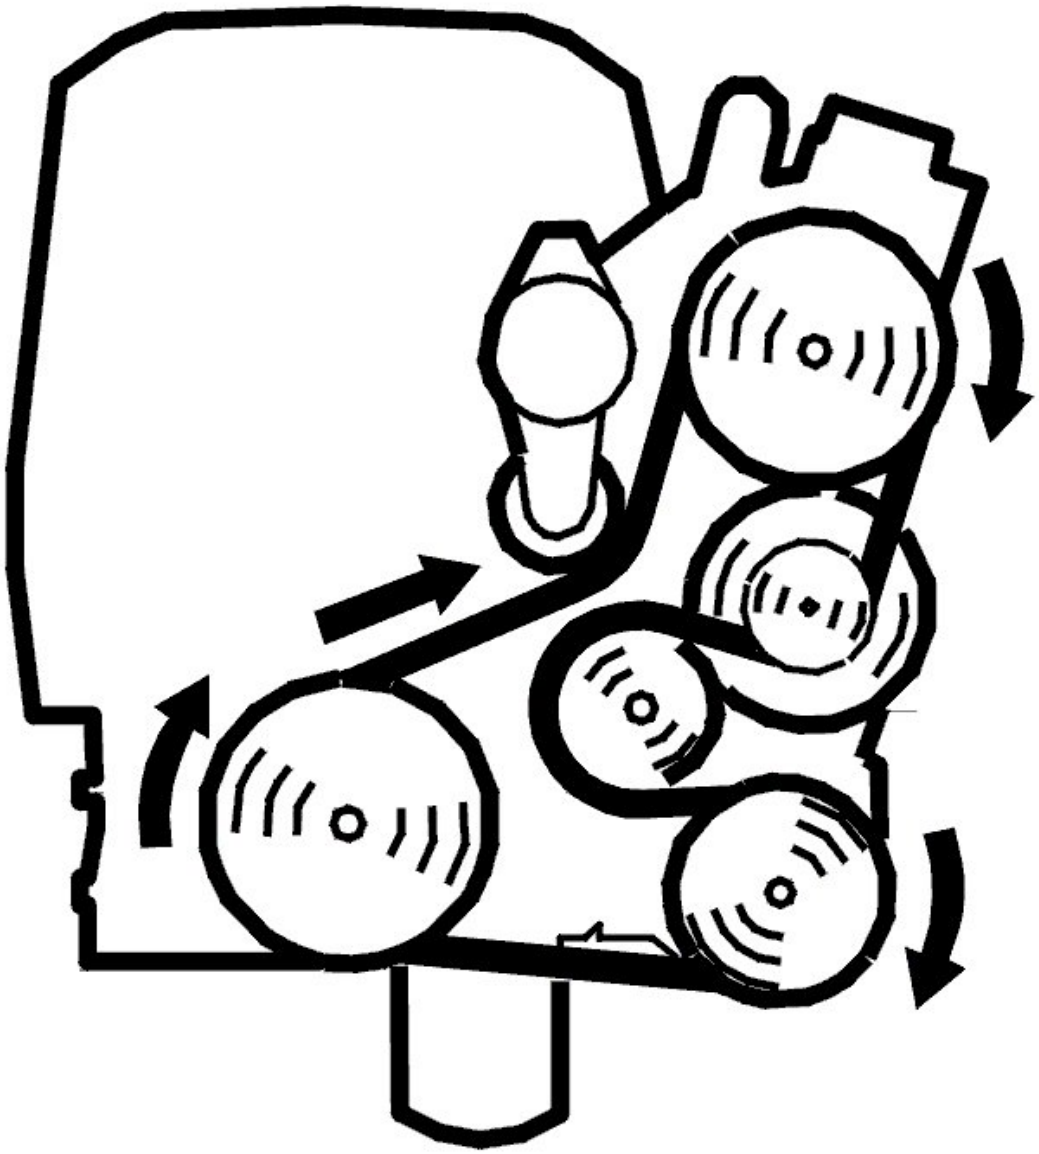
Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

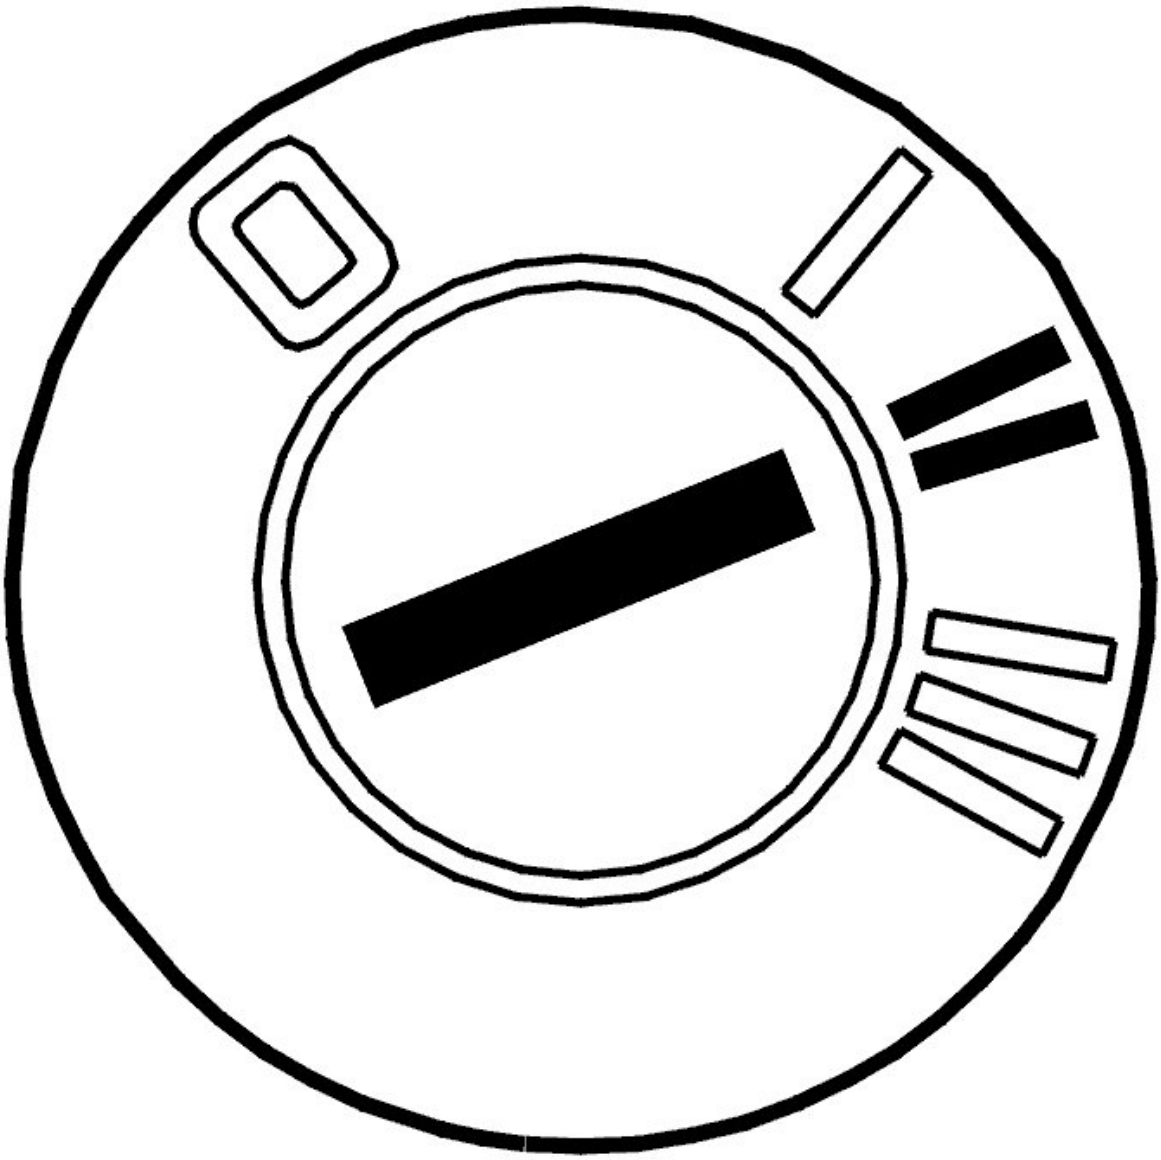


Continue - Verification

Verification

Hint: After rectifying a fault, a verification should be carried out.





- Reinstall the connectors, components etc.
- Ignition on.

Note! For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

- Erase diagnostic trouble codes (DTCs) in all control modules.
- Ignition off.
- Ignition on.
- Start the vehicle. Allow the vehicle to run for 10 minutes. Start the engine. Allow the engine to run at idle speed for 10 minutes
- Read out the diagnostic trouble codes in the vehicle via the DIAGNOSTICS tab.

Does the diagnostic trouble code (DTC) for faulty communication return?

Yes - Fault-tracing information

No - Fault Found

Fault-tracing information

Information

Fault-tracing information

The fault should have been detected and remedied. As this is not the case fault-tracing has failed.
Exit fault-tracing for this diagnostic trouble code (DTC) or make another attempt.

Do you want to exit fault-tracing?

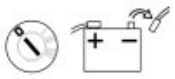
Yes - **FAULT-TRACING FAILED**

No - **Attempt New Test**

FAULT-TRACING FAILED - **FAULT-TRACING FAILED**

Attempt New Test - Signal missing

Checking short-circuiting to ground/voltage in CAN-net



- Ignition off.
- Disconnect the battery negative lead.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Checking for a short-circuit to ground

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #3 and #4 (ground). Measurement is shown in the figure. The resistance should be above 1 kohms.
- #11 and #4 (ground). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and ground.

Checking for a short-circuit to voltage

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #3 and #16 (voltage). Measurement is shown in the figure. The resistance should be above 1 kohms.
- #11 and #16 (voltage). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and voltage cable.
Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

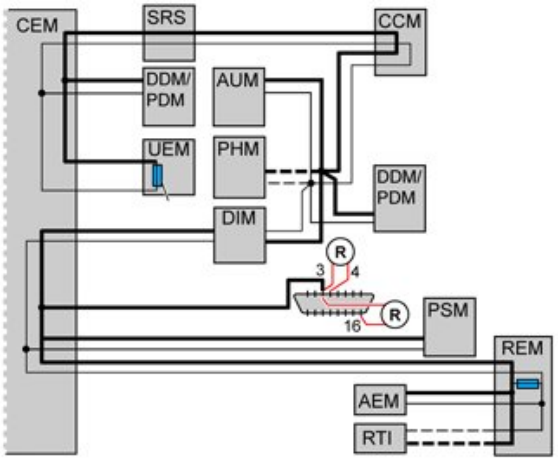
Hint: Part the CAN-net at suitable points to decide where a short-circuit may be found.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy as necessary.

Other information
- Battery, disconnecting See: Starting and Charging/Battery/Service and Repair/Procedures/Battery, Disconnecting
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

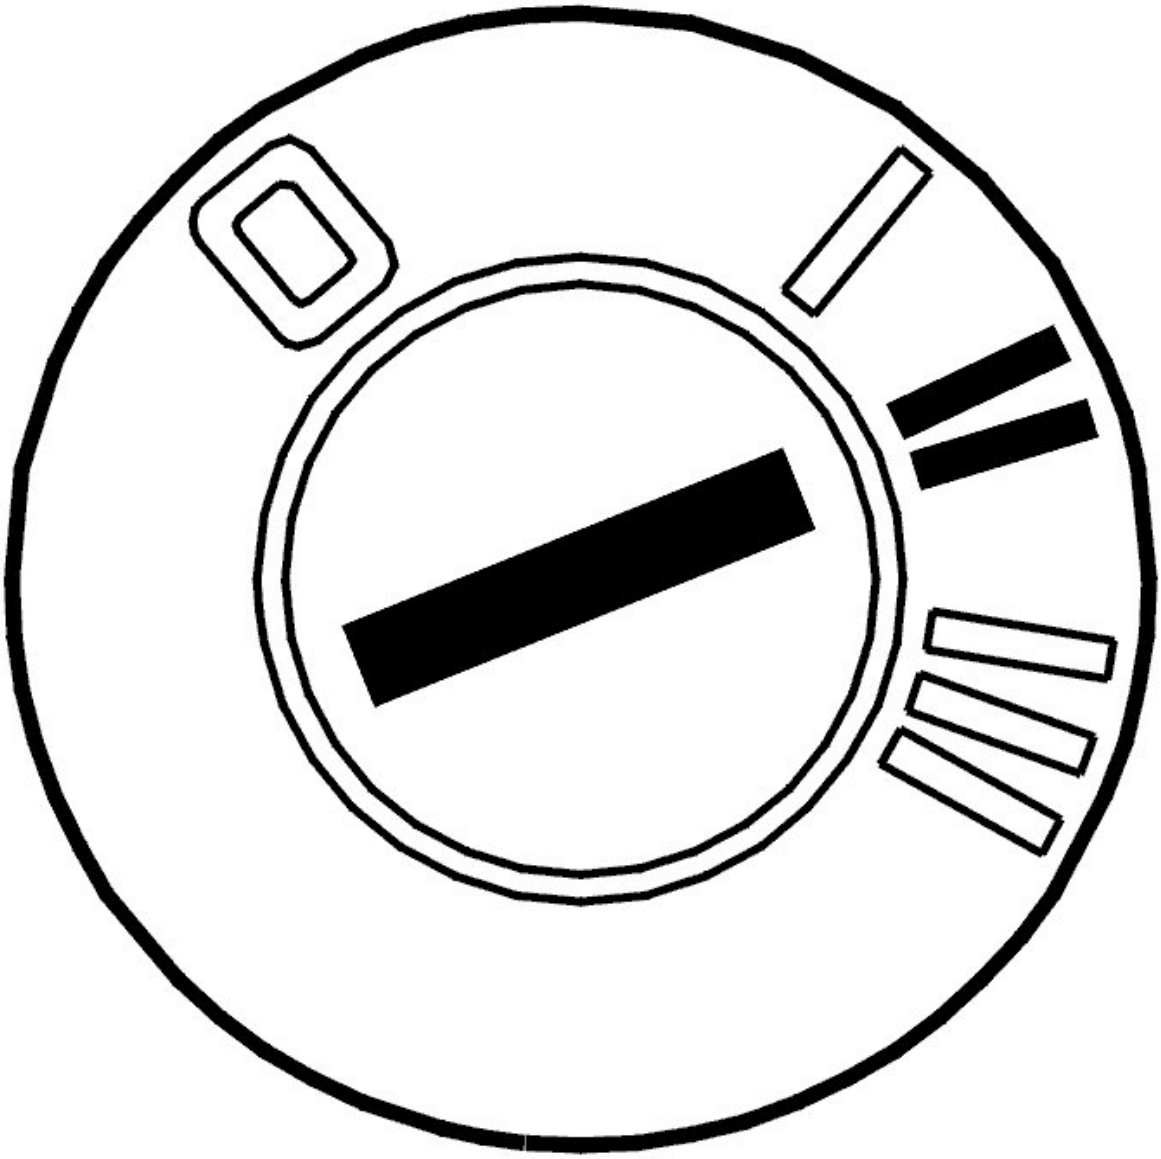


Was a fault detected?

Yes - Verification

No - Checking the amount of traffic on the LS-CAN

Checking voltage-drop in cable for CAN-H and CAN-L, respectively



- Connect the battery.
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

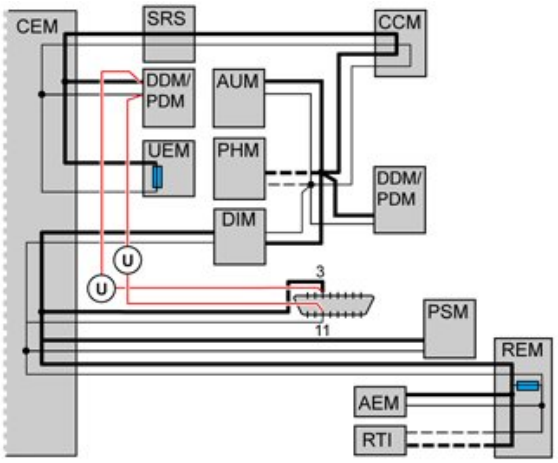
In principle, the voltage measured in each cable in the CAN-net shall be the same at each control module in the network. This means that the voltage-drop in the cable for CAN-H and CAN-L, respectively, between the control modules should be very low. If there is a voltage-difference in the CAN-lines between the diagnostics socket/Central electronic module (CEM) and a control module due to, e.g., contact resistance in a connector or branching, communication may be lost/interfered with. Check if there is voltage-drop in the cable for CAN-H and CAN-L between the diagnostics socket/Central electronic module (CEM) and the control module where there is problem with communication.
Carry out the following:
Measure voltage between the following connections on the OBDII-box/diagnostics socket.
- #3 and corresponding connection on relevant control module for CAN-H. The voltage shall be lower than 50 mV.
- #11 and corresponding connection on relevant control module for CAN-L. The voltage shall be lower than 50 mV.

If voltage is too high, this indicates too high contact resistance in cable, connector, or branching. Check the circuit between the diagnostics socket and control module in question for contact resistance and oxidation.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy wiring as necessary.

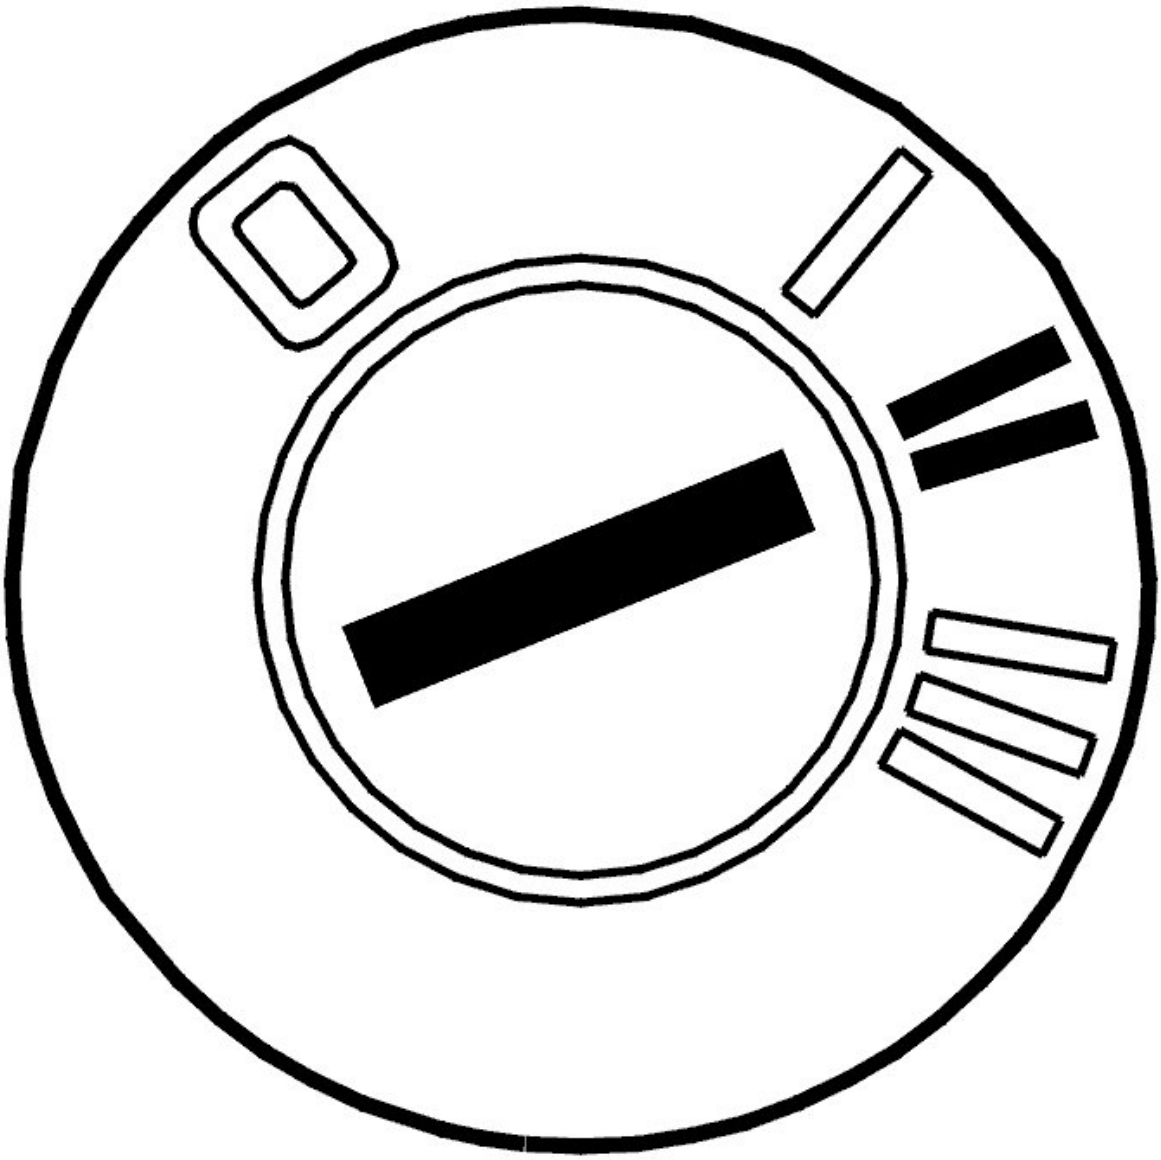
Other information
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

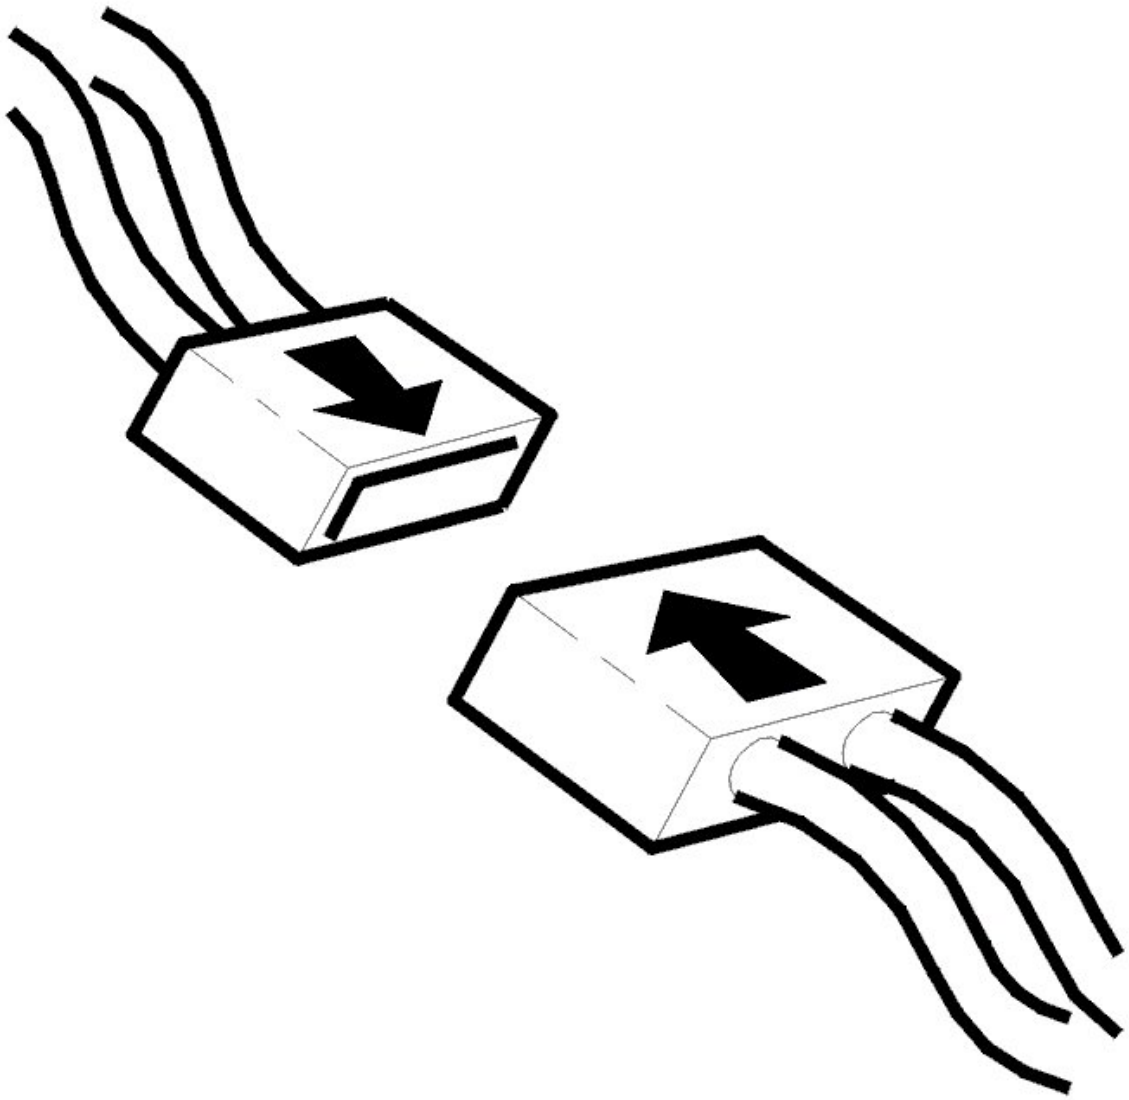


Continue - Verification

Checking the function of the power seat module (PSM)

Hint: After carrying out the repair, check that the fault has been remedied.





- Ignition off
- Reconnect the connectors. Reinstall the components
- Ignition on.

Check the function of the control module by operating the seat using the controls.
Also check the memory function of the seat, that the seat position can be programmed, recalled and that automatic setting of the seat and door mirrors occurs when the car is unlocked using the remote control.

Can the seat be operated?

Yes - Fault Found

No - Fault-tracing information

Fault-tracing information

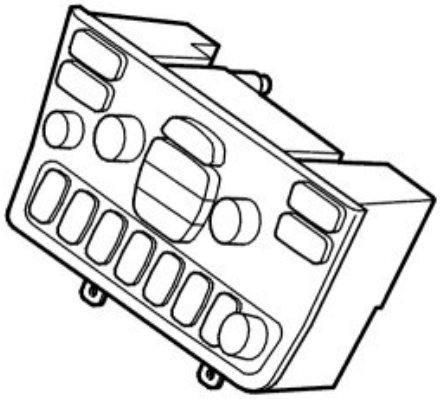
FAULT-TRACING FAILED - FAULT-TRACING FAILED

Attempt New Test - Checking the function of the power seat module (PSM)

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CEM-1A55

Condition



The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers that communication with the climate control module (CCM) is not operating.
The diagnostic trouble code (DTC) can be diagnosed when the ignition has been on for more than 10 seconds.

Note! In the event of CEM-1A5X diagnostic trouble codes (DTCs), the central electronic module (CEM) must not be replaced as the diagnostic trouble code (DTC) indicates a communication fault in the controller area network (CAN).

Substitute value
- None.

Possible source
- No power supply to climate control module (CCM)
- Open-circuit in the ground lead for the climate control module (CCM)
- Contact resistance in the terminals
- Open-circuit in the wiring for the CAN low speed network to the climate control module (CCM)
- The climate control module (CCM) is not intended for this vehicle (for example a used control module with different software/hardware).

Note! In the event of missing CAN communication, but with the power supply still on, the climate control module (CCM) will function for a few minutes after the key has been removed (Limp-home function).

Hint: If several diagnostic trouble codes (DTCs) are stored in the central electronic module (CEM) for communication faults with other control modules in the low speed network, this indicates a common fault in the controller area network (CAN). See the relevant wiring diagram.

Fault symptom[s]
- The climate control system does not function at all.
- The lower row of buttons on the climate control system does not function.
- The climate control system functions after the key has been removed.

Signal Missing

Signal missing

Checking the function of the climate control module (CCM)
- Ignition on.

Check the power supply to the control module by switching on the climate control module (CCM).
The blower fan must blow and it must be possible to regulate the fan speed.

Does the blower fan start?

Yes - Checking communication with the climate control module (CCM)

No - Checking the power supply and ground for the climate control module (CCM)

Checking the power supply and ground for the climate control module (CCM)

Check that the fuse for the control module is intact.
Check the power supply and ground terminal for the climate control module (CCM) as follows.
Remedy as necessary.

Other information:

- Climate control module (CCM): Checking the supply voltage/ground terminal See: Heating and Air Conditioning/Testing and Inspection/Component Tests and General Diagnostics/Checking the Supply Voltage/Ground Terminal
- For information about fuse and terminal numbers, see the relevant Wiring Diagram.
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

Was a fault detected?

Yes - Checking the function of the climate control module (CCM)

No - Signal missing

Checking communication with the climate control module (CCM)

Hint: The CAN communication with the control module is probably OK if the control module ID can be read off. The fault is probably intermittent and may therefore be difficult to locate.

- Try to communicate with the climate control module (CCM) by reading off the control module ID
- Click on the symbol for VCT2000 to begin reading off

Continue - Signal missing

Signal missing

General information

Note! Figures shown are only examples.

Hint: For general information about CAN-troubleshooting, see:

- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

General about CAN-related diagnostic trouble codes.
CEM-DF01 - DF17can only be stored in Central electronic module (CEM). These diagnostic trouble codes are stored when an electric fault is detected in CAN-lines. Start with these diagnostic trouble codes first.
CEM-1AXX only stored in Central electronic module (CEM). One diagnostic trouble code for every control module on the CAN-net. These diagnostic trouble codes indicate that Central electronic module (CEM) does not receive any reply from other control modules.
XXX-E000 (HS-CAN)/E001 (LS-CAN) can be stored in all CAN-connected control modules. These diagnostic trouble codes indicate that the control module has detected interference on the CAN-net.
XXX-E003 can be stored in all CAN-connected control modules except in Central electronic module (CEM). The control modules on the CAN-net listen for a message (identity number) that is sent out at regular intervals from Central electronic module (CEM). This diagnostic trouble code indicates that the control module has not received any identity number, or that the expected number is not correct. Interference on the CAN-net can also store this diagnostic trouble code.

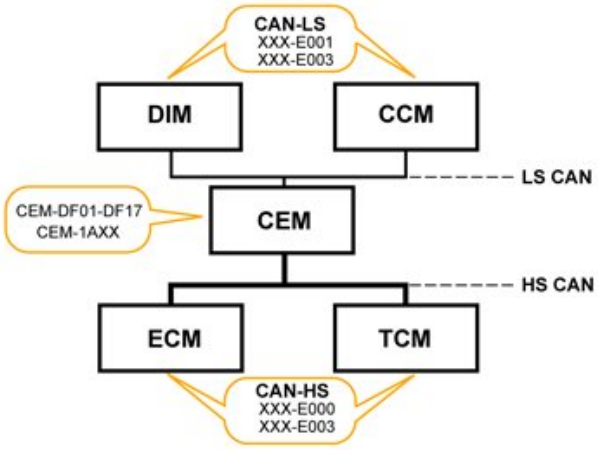
Note! In case of CAN-related faults, it is likely that a combination of above diagnostic trouble codes occur.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

If diagnostic trouble codes (DTCs) for communication faults can be read off from a control module, the fault is probably intermittent. Intermittent fault in the voltage supply and ground to a control module on the CAN network results in the Central electronic module (CEM) storing a diagnostic trouble code (DTC) for an open-circuit in communication with the control module where the voltage supply does not work. There will probably not be a diagnostic trouble code (DTC) in the control module where the open-circuit in the voltage supply occurred as the control module cannot store a diagnostic trouble code (DTC) when it is not supplied with power.

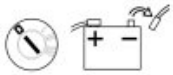
Note! Central electronic module (CEM) should not be replaced in case of CAN-fault, unless troubleshooting reveals that Central electronic module (CEM) has an internal fault.

Caution! During this fault-tracing use the wiring diagram to provide support when taking readings.



Continue - Checking resistance in CAN-net

Checking resistance in CAN-net



- Ignition off
- Disconnect the battery negative lead
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #3 and #11. The resistance should be approx. 55 - 65 ohms.
- If resistance is approx. 120 ohms, this indicates open circuit in the circuit so that only one terminating resistor (120 ohms) has been measured.
- If resistance is above 1 kohms this indicates open circuit/high contact resistance somewhere in the circuit.
- If resistance is below 55 ohms this indicates short-circuiting/contact resistance between the CAN-lines somewhere in the circuit.

Hint: For LS-CAN (Low Speed), terminating resistors are located in Upper electronic module (UEM) and Rear electronic module (REM).

Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

Note! Resistance measurement measures only main lines in the CAN-net (in circuit where both terminating resistors are found), not

branches to certain control modules. See wiring diagram for vehicle model in question. Open circuit on branching without a terminating resistor cannot be detected with this measurement. However, short-circuiting on a branch can be detected. To measure resistance in the CAN-net to control modules located in a branching of their own, the measurement shall be done against the CAN-net at that control module. The values shall be as above.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy as necessary.

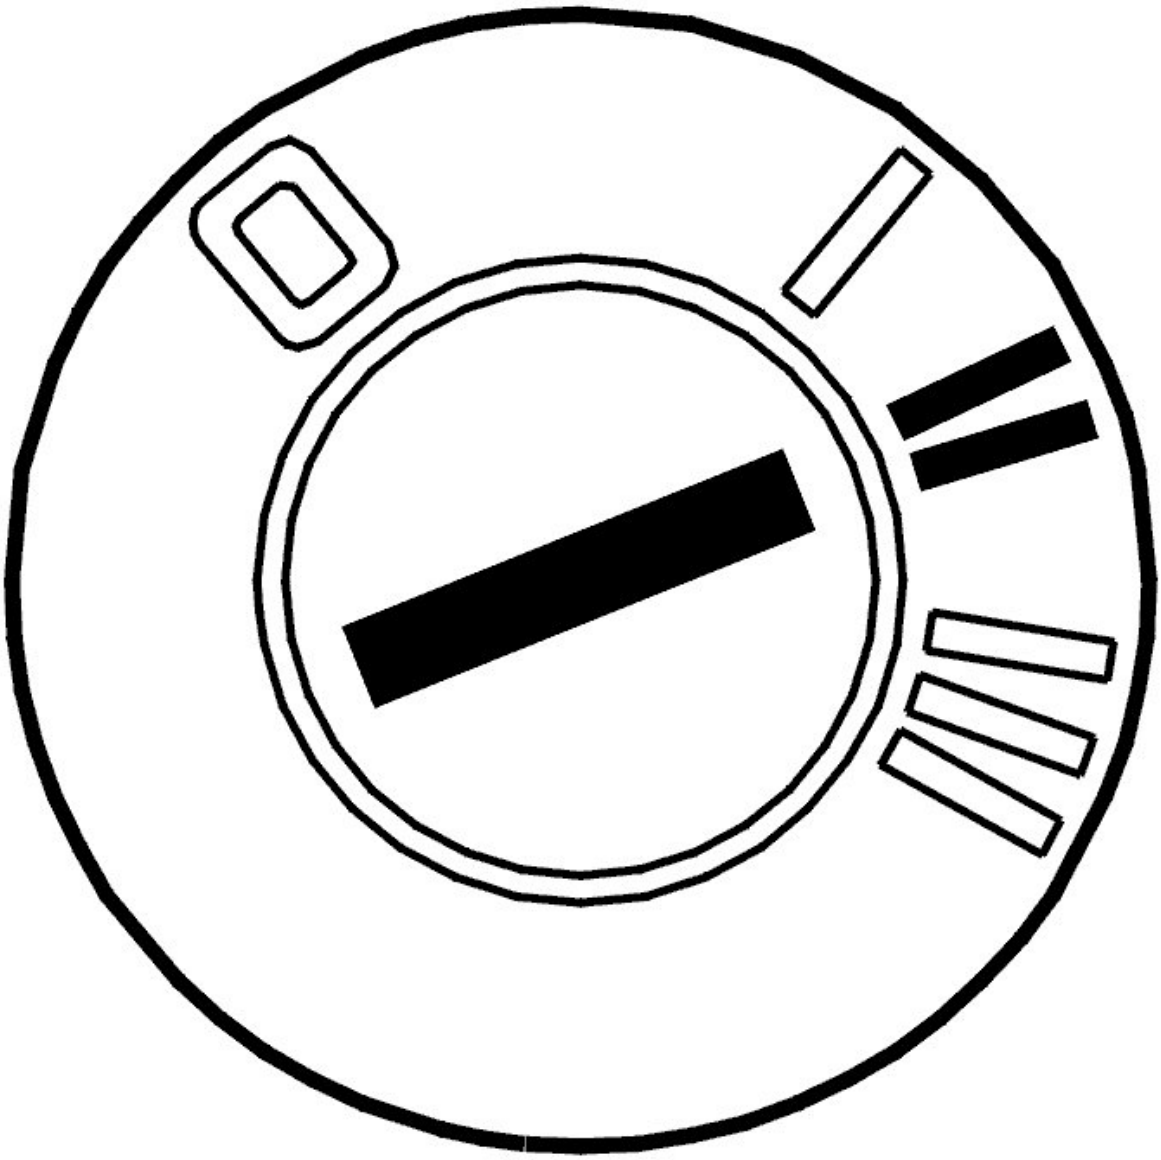
Was a fault detected?

Yes - Verification

No - Checking short-circuiting to ground/voltage in CAN-net

Checking the amount of traffic on the LS-CAN



- Connect the battery
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
Faults in the CAN network may be due to a control module sending faulty messages that disrupt normal communication. When messages are sent incorrectly, this results in a considerable increase in the amount of traffic on the CAN network. The load can be checked by reading the average value of the voltage on the CAN cables in relation to ground.
For further information, see the wiring diagram.
Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #3 and #4 (ground). The voltage should be approx: 2,8 - 3,2 V.
- #11 and #4 (ground). The voltage should be approx: 1,8 - 2,2 V.
- #3 and #11. The voltage shall be between approx. 0.55-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Hint: DiCE Error Frame Finder can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools: **951 3010** (memory card) as well as associated TJ 20402.

- Ignition on.
- Connect DiCE Error Frame Finder to the diagnostics socket.
- Note the blue LED-indicator. The indicator flashes to show detection of fault messages.

Note! Certain interference may occur without any real fault!

Cable fault

- Shake the cables lightly and pull lightly on the connections during the check to locate any fault. Note the blue LED-indicator.

"Chatting" control modules

- "Chatting" control modules may be difficult to find and troubleshooting may take time. Let the vehicle stand with DiCE connected for an extended time period. Afterwards, activate functions to provoke a malfunction. It may take up to several hours before the fault messages are sent. When the indicator starts to flash, remove the fuse for one control module at a time until the indicator stops flashing. When the indicator stops flashing, restore the fuse for the relevant control module and check that the indicator starts to flash again. Then it is likely that the problem is identified.

Remedy wiring as necessary.

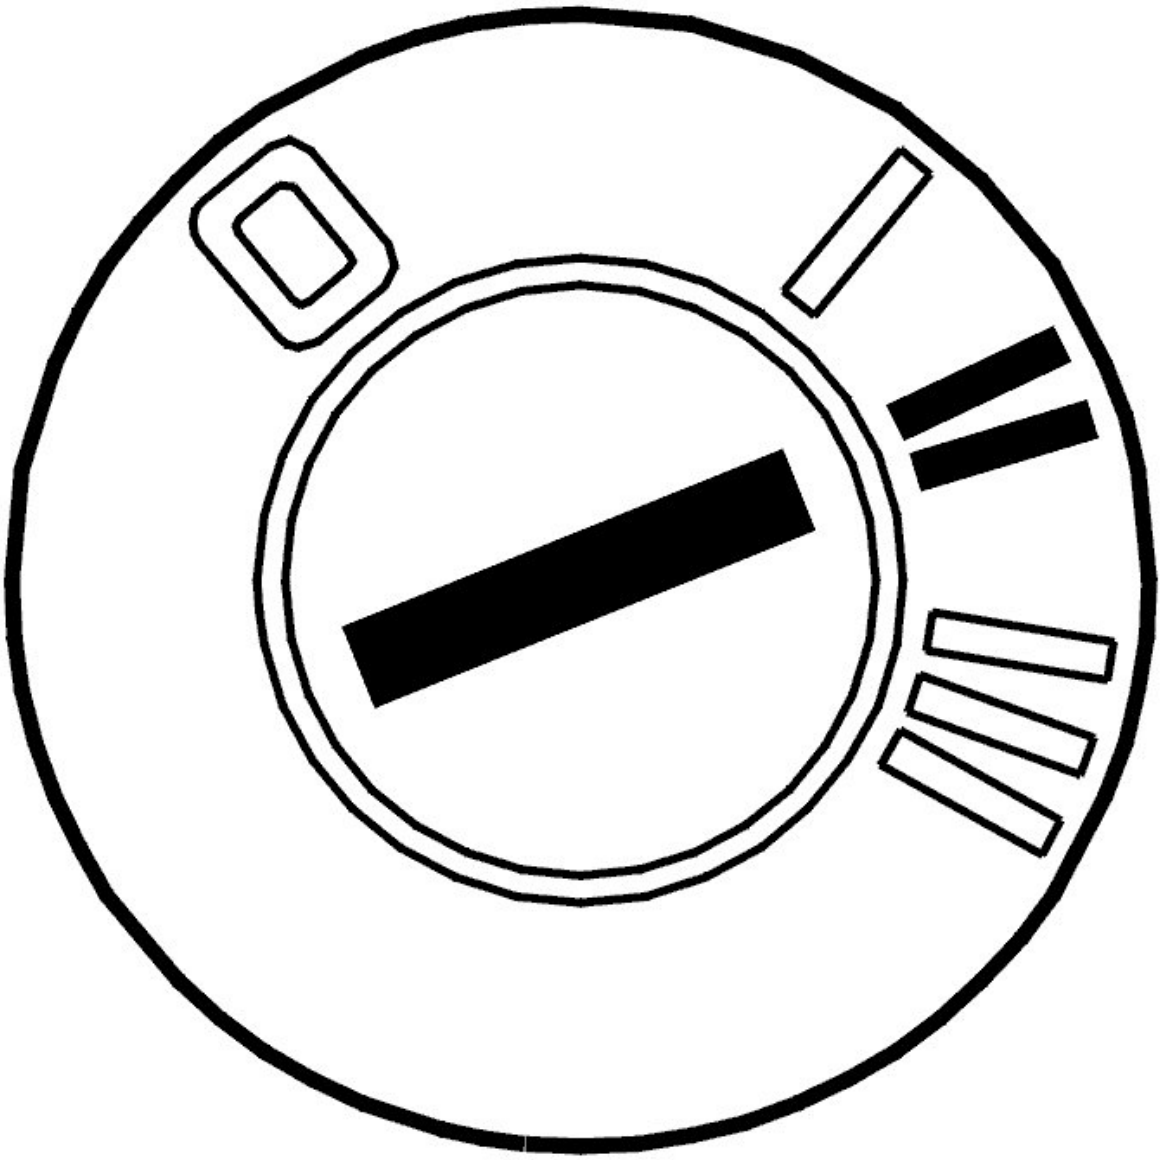
---

Identifying a control module in the CAN network



Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:

- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Hint: DiCE Error Frame Finder can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools: **951 3010** (memory card) as well as associated TJ 20402. If the load on the CAN network is too high, this may be due to a control module transmitting faulty messages on the CAN network. This is called a disruptive control module. The fault may also be due to an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The fault may occur without any of the control modules storing a diagnostic trouble code (DTC). The voltage can be measured between the CAN cables in order to check the load on the CAN network.

Note! It is not necessarily the control module that has set the diagnostic trouble code that communicates incorrectly. Faulty messages can come from any control module in the same section of the CAN network. However, faulty communication in one network cannot affect the communication on the other network. In other words, faulty communication on the LS-CAN cannot disrupt communication on the HS-CAN and vice versa.

- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Check communication/load on CAN-net by measuring voltage between CAN-L and CAN-H. Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #3 and #11. The average value of the voltage must be approximately 0.6-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

In order to identify which control module has faulty communication, cut the power supply to one control module at a time. Check the voltage in the CAN cables again. The easiest way to cut the power supply is to remove the fuse(s) for the relevant control module. Repeat until the voltage

between the CAN wiring drops to the normal level.

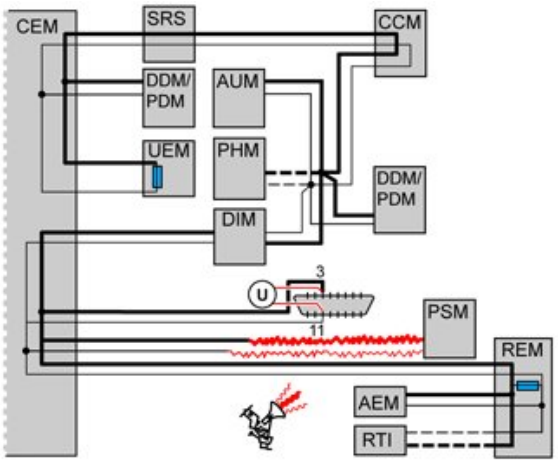
Note! When connecting and disconnecting certain control modules, diagnostic trouble codes (DTCs) may be stored in other control modules.

Hint: When the suspected defective control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the malfunction appears and disappears. Switch off the ignition between each check.

Note! Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.

A control module that is communicating incorrectly must be replaced. See Repairing and installing/Removing, replacing and installing.

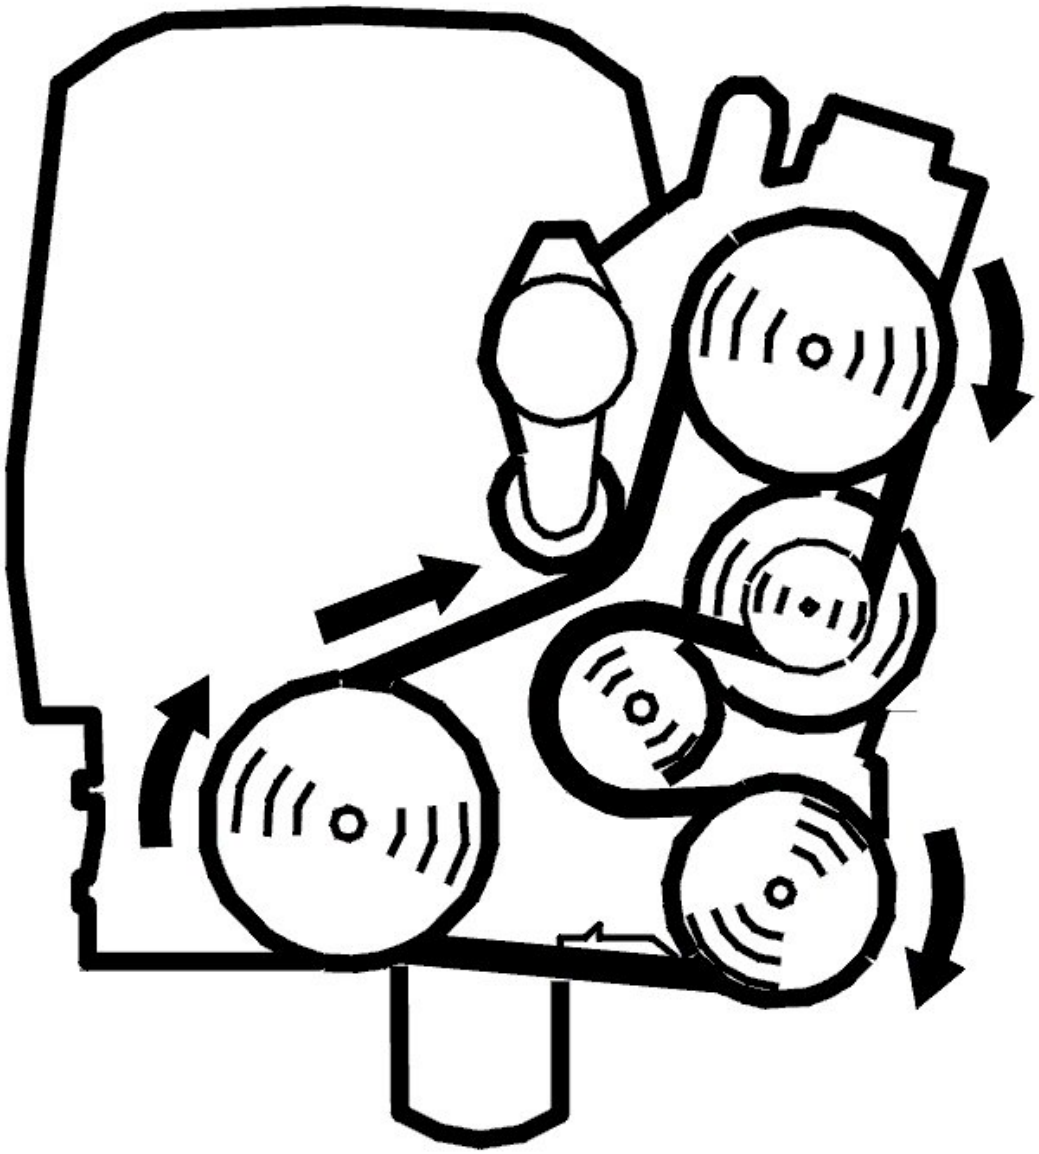
Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

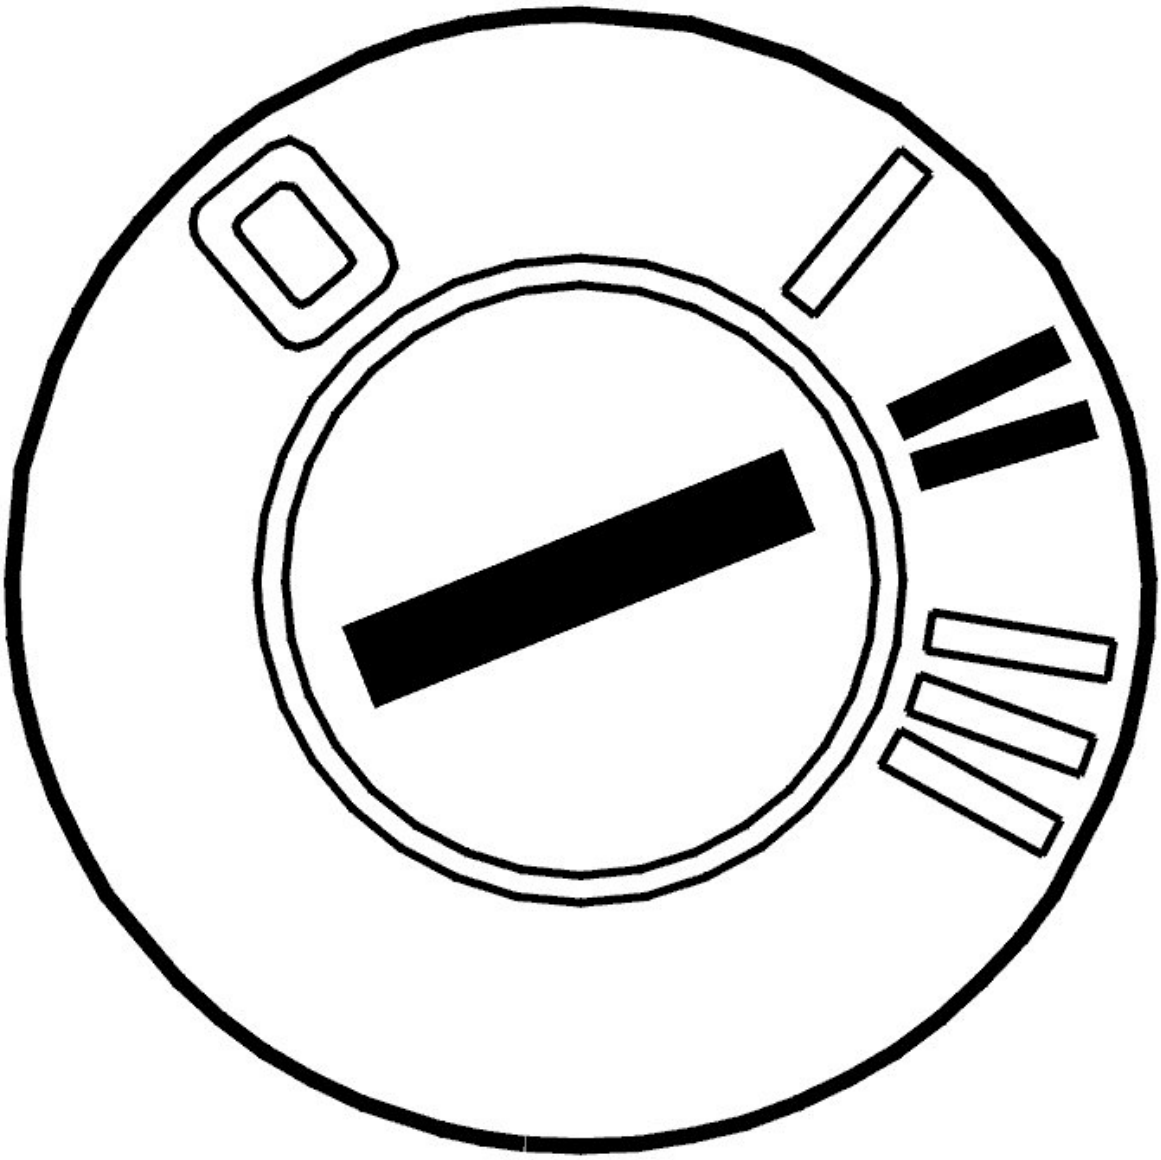


Continue - Verification

Verification

Hint: After rectifying a fault, a verification should be carried out.





- Reinstall the connectors, components etc.
- Ignition on.

Note! For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

- Erase diagnostic trouble codes (DTCs) in all control modules.
- Ignition off.
- Ignition on.
- Start the vehicle. Allow the vehicle to run for 10 minutes. Start the engine. Allow the engine to run at idle speed for 10 minutes

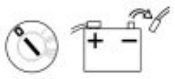
Checking short-circuiting to ground/voltage in CAN-net



- Ignition off.
- Disconnect the battery negative lead.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Checking for a short-circuit to ground

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #3 and #4 (ground). Measurement is shown in the figure. The resistance should be above 1 kohms.
- #11 and #4 (ground). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and ground.

Checking for a short-circuit to voltage

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #3 and #16 (voltage). Measurement is shown in the figure. The resistance should be above 1 kohms.
- #11 and #16 (voltage). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and voltage cable.
Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

Hint: Part the CAN-net at suitable points to decide where a short-circuit may be found.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy as necessary.

Other information
- Battery, disconnecting See: Starting and Charging/Battery/Service and Repair/Procedures/Battery, Disconnecting

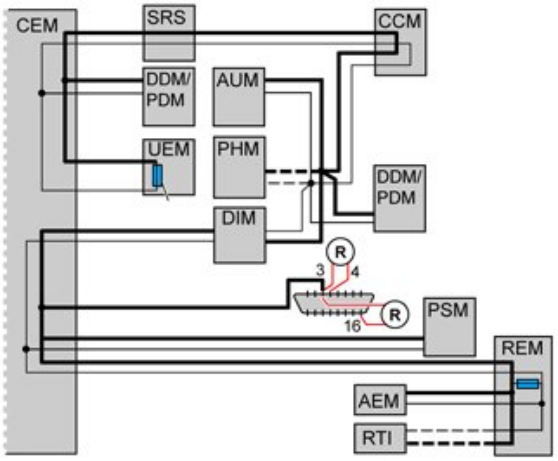
Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

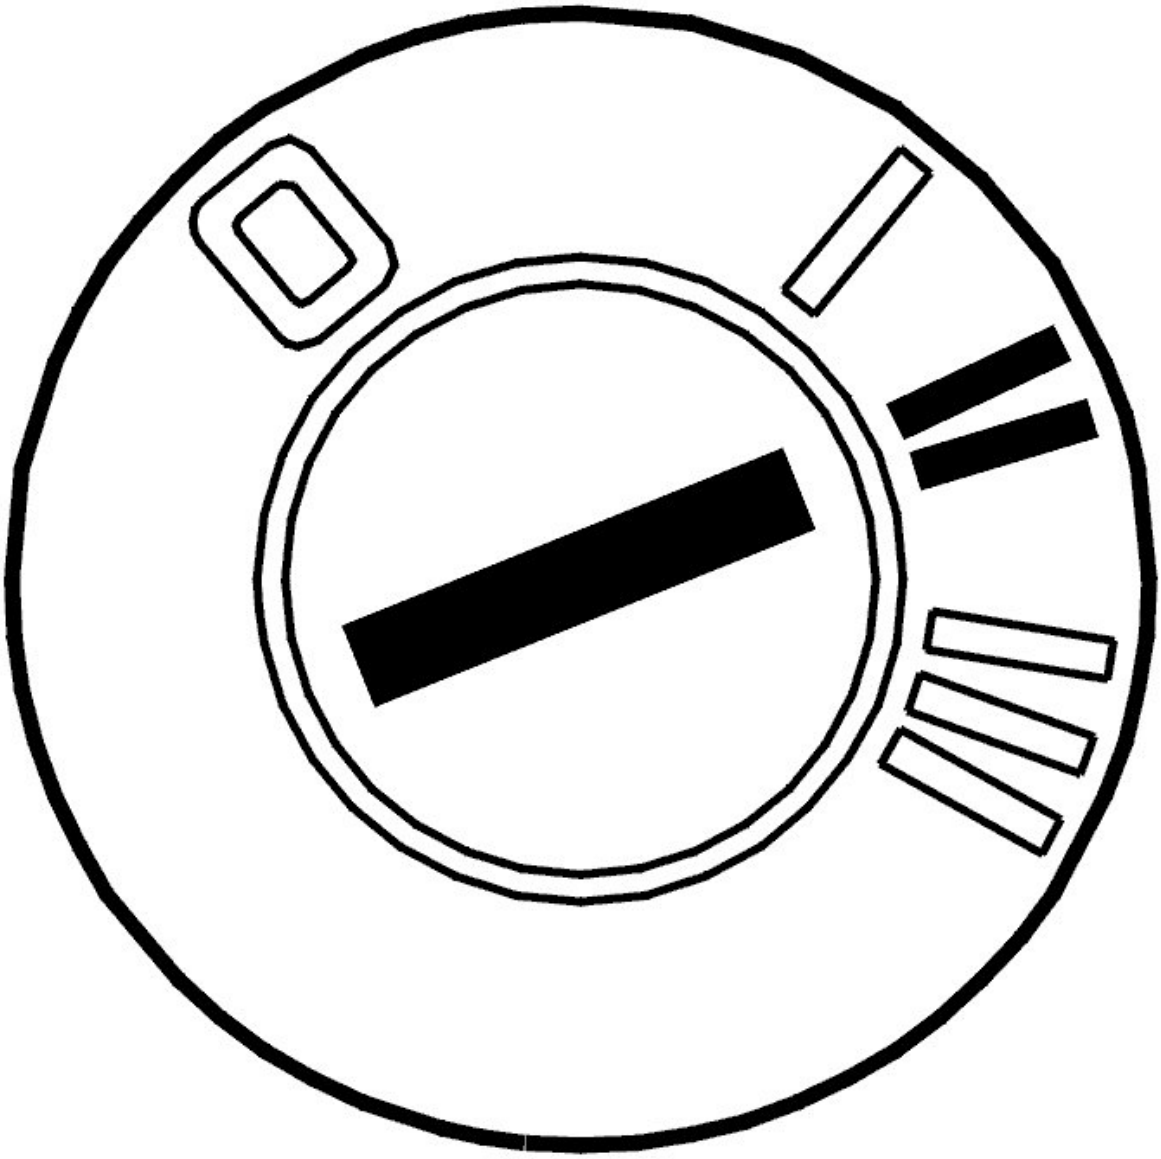


Was a fault detected?

Yes - Verification

No - Checking the amount of traffic on the LS-CAN

Checking voltage-drop in cable for CAN-H and CAN-L, respectively



- Connect the battery.
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

In principle, the voltage measured in each cable in the CAN-net shall be the same at each control module in the network. This means that the voltage-drop in the cable for CAN-H and CAN-L, respectively, between the control modules should be very low. If there is a voltage-difference in the CAN-lines between the diagnostics socket/Central electronic module (CEM) and a control module due to, e.g., contact resistance in a connector or branching, communication may be lost/interfered with. Check if there is voltage-drop in the cable for CAN-H and CAN-L between the diagnostics socket/Central electronic module (CEM) and the control module where there is problem with communication.
Carry out the following:
Measure voltage between the following connections on the OBDII-box/diagnostics socket.
- #3 and corresponding connection on relevant control module for CAN-H. The voltage shall be lower than 50 mV.
- #11 and corresponding connection on relevant control module for CAN-L. The voltage shall be lower than 50 mV.

If voltage is too high, this indicates too high contact resistance in cable, connector, or branching. Check the circuit between the diagnostics socket and control module in question for contact resistance and oxidation.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy wiring as necessary.

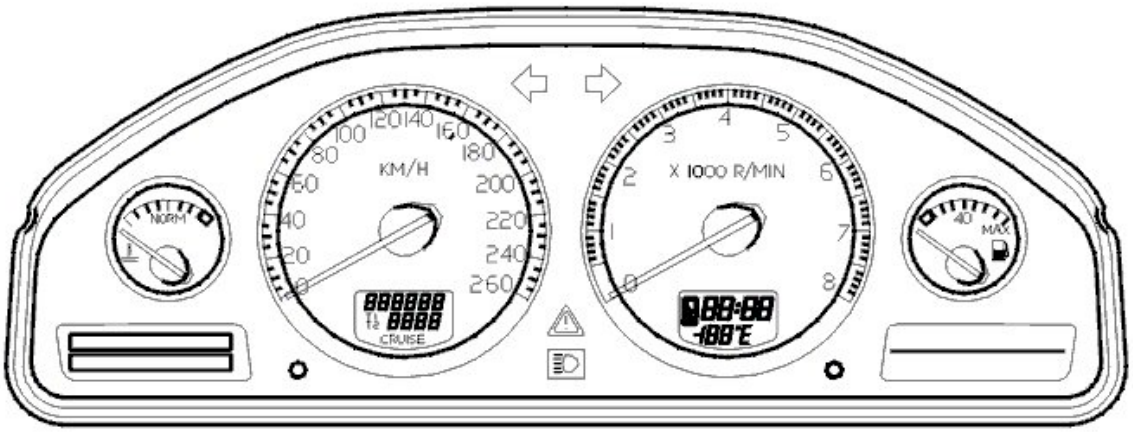
Attempt New Test - Checking the function of the climate control module (CCM)

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CEM-1A56

Condition



The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers that communication with the driver information module (DIM) is not operating.
The diagnostic trouble code (DTC) can be diagnosed when the ignition has been on for more than 10 seconds.

Note! In the event of CEM-1A5X diagnostic trouble codes (DTCs), the central electronic module (CEM) must not be replaced as the diagnostic trouble code (DTC) indicates a communication fault in the controller area network (CAN).

Substitute value
- None.

Possible source
- No power supply to the driver information module (DIM)
- Open-circuit in the ground lead for the driver information module (DIM)
- Contact resistance in the terminals
- Open-circuit in the wiring for the CAN low speed network to the drive information module (DIM)
- The driver information module (DIM) is not intended for this vehicle (for example a used control module with different software/hardware).

Hint: If several diagnostic trouble codes (DTCs) are stored in the central electronic module (CEM) for communication faults with other control modules in the low speed network, this indicates a common fault in the controller area network (CAN). See the relevant wiring diagram.

Fault symptom[s]
- No gauges working.
- The instrument lighting does not operate.

Signal Missing

Signal missing

Checking the function of the driver information module (DIM)

Check the power supply for the driver information module (DIM) by switching on the ignition.

The lighting in the instrument panel must light up.

Does the lighting in the driver information module (DIM) light up?

Yes - Checking communication with the driver information module (DIM)

No - Checking the power supply and ground for the driver information module (DIM)

Checking the power supply and ground for the driver information module (DIM)

Check that the fuse for the control module is intact.
Check the power supply and ground terminal for the driver information module (DIM) as follows.
Remedy as necessary.

Other information:

- Driver information module (DIM): Checking the voltage / ground terminal See: Instrument Panel, Gauges and Warning Indicators/Instrument Cluster / Carrier/Testing and Inspection/Component Tests and General Diagnostics/Checking the Supply Voltage/Ground Terminal, Driver Information Module (DIM)
- For information about fuse and terminal numbers, see the relevant Wiring Diagram.

Was a fault detected?

Yes - Checking the function of the driver information module (DIM)

No - Signal missing

Checking communication with the driver information module (DIM)

Hint: The CAN communication with the control module is probably OK if the control module ID can be read off. The fault is probably intermittent and may therefore be difficult to locate.

- Try to communicate with the driver information module (DIM) by reading off the control module ID
- Click on the symbol for VCT2000 to begin reading off

Continue - Signal missing

Signal missing

General information

Note! Figures shown are only examples.

Hint: For general information about CAN-troubleshooting, see:

- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

General about CAN-related diagnostic trouble codes.
CEM-DF01 - DF17can only be stored in Central electronic module (CEM). These diagnostic trouble codes are stored when an electric fault is detected in CAN-lines. Start with these diagnostic trouble codes first.
CEM-1AXX only stored in Central electronic module (CEM). One diagnostic trouble code for every control module on the CAN-net. These diagnostic trouble codes indicate that Central electronic module (CEM) does not receive any reply from other control modules.
XXX-E000 (HS-CAN)/E001 (LS-CAN) can be stored in all CAN-connected control modules. These diagnostic trouble codes indicate that the control module has detected interference on the CAN-net.

XXX-E003 can be stored in all CAN-connected control modules except in Central electronic module (CEM). The control modules on the CAN-net listen for a message (identity number) that is sent out at regular intervals from Central electronic module (CEM). This diagnostic trouble code indicates that the control module has not received any identity number, or that the expected number is not correct. Interference on the CAN-net can also store this diagnostic trouble code.

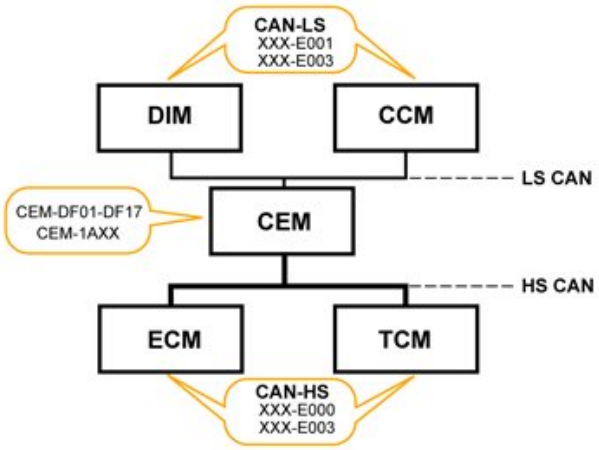
Note! In case of CAN-related faults, it is likely that a combination of above diagnostic trouble codes occur.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

If diagnostic trouble codes (DTCs) for communication faults can be read off from a control module, the fault is probably intermittent.
Intermittent fault in the voltage supply and ground to a control module on the CAN network results in the Central electronic module (CEM) storing a diagnostic trouble code (DTC) for an open-circuit in communication with the control module where the voltage supply does not work. There will probably not be a diagnostic trouble code (DTC) in the control module where the open-circuit in the voltage supply occurred as the control module cannot store a diagnostic trouble code (DTC) when it is not supplied with power.

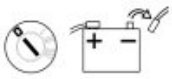
Note! Central electronic module (CEM) should not be replaced in case of CAN-fault, unless troubleshooting reveals that Central electronic module (CEM) has an internal fault.

Caution! During this fault-tracing use the wiring diagram to provide support when taking readings.



Continue - Checking resistance in CAN-net

Checking resistance in CAN-net



- Ignition off
- Disconnect the battery negative lead
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #3 and #11. The resistance should be approx. 55 - 65 ohms.
- If resistance is approx. 120 ohms, this indicates open circuit in the circuit so that only one terminating resistor (120 ohms) has been measured.
- If resistance is above 1 kohms this indicates open circuit/high contact resistance somewhere in the circuit.
- If resistance is below 55 ohms this indicates short-circuiting/contact resistance between the CAN-lines somewhere in the circuit.

Hint: For LS-CAN (Low Speed), terminating resistors are located in Upper electronic module (UEM) and Rear electronic module (REM).

Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

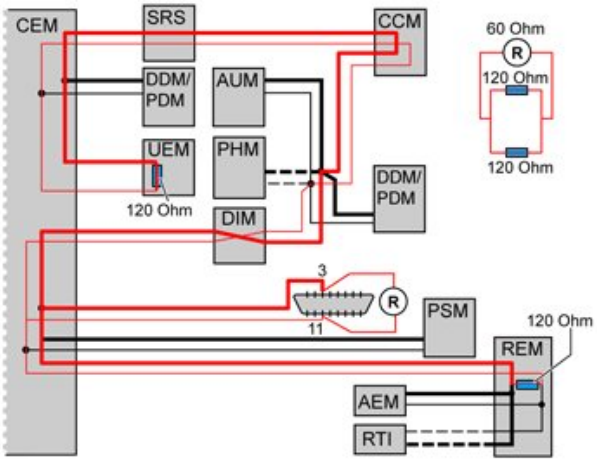
Note! Resistance measurement measures only main lines in the CAN-net (in circuit where both terminating resistors are found), not branches to certain control modules. See wiring diagram for vehicle model in question. Open circuit on branching without a terminating resistor cannot be detected with this measurement. However, short-circuiting on a branch can be detected. To measure resistance in the CAN-net to control modules located in a branching of their own, the measurement shall be done against the CAN-net at that control module. The values shall be as above.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy as necessary.

Other information

- Battery, disconnecting See: Starting and Charging/Battery/Service and Repair/Procedures/Battery, Disconnecting
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

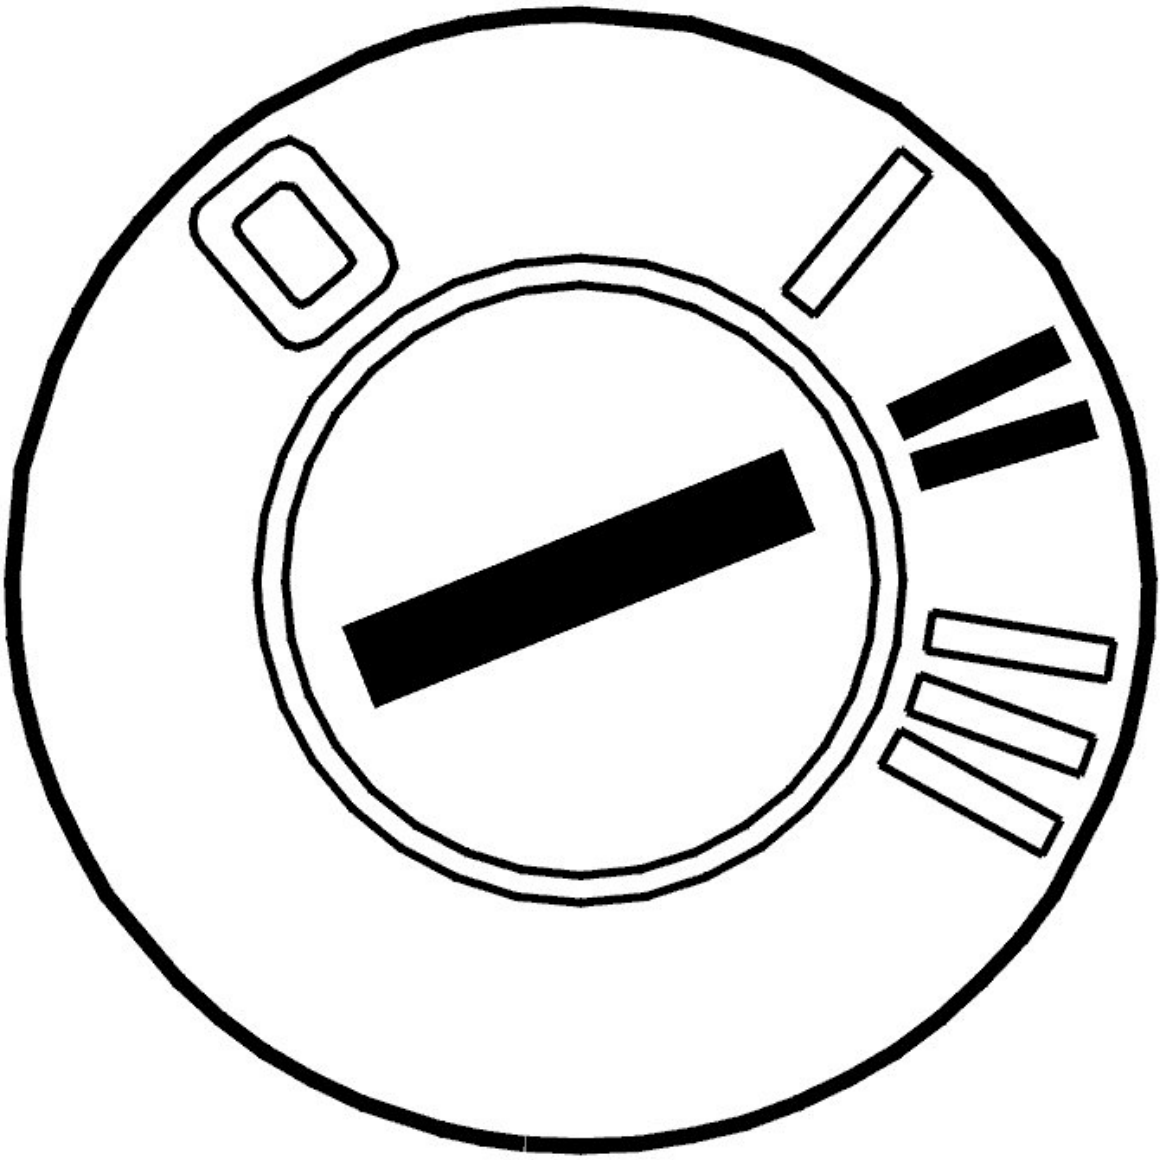


Was a fault detected?

Yes - Verification

No - Checking short-circuiting to ground/voltage in CAN-net

Checking the amount of traffic on the LS-CAN



- Connect the battery
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
Faults in the CAN network may be due to a control module sending faulty messages that disrupt normal communication. When messages are sent incorrectly, this results in a considerable increase in the amount of traffic on the CAN network. The load can be checked by reading the average value of the voltage on the CAN cables in relation to ground.
For further information, see the wiring diagram.
Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #3 and #4 (ground). The voltage should be approx: 2,8 - 3,2 V.
- #11 and #4 (ground). The voltage should be approx: 1,8 - 2,2 V.
- #3 and #11. The voltage shall be between approx. 0.55-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Hint: DiCE Error Frame Finder can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools: **951 3010** (memory card) as well as associated TJ 20402.

- Ignition on.
- Connect DiCE Error Frame Finder to the diagnostics socket.
- Note the blue LED-indicator. The indicator flashes to show detection of fault messages.

Note! Certain interference may occur without any real fault!

Cable fault

- Shake the cables lightly and pull lightly on the connections during the check to locate any fault. Note the blue LED-indicator.

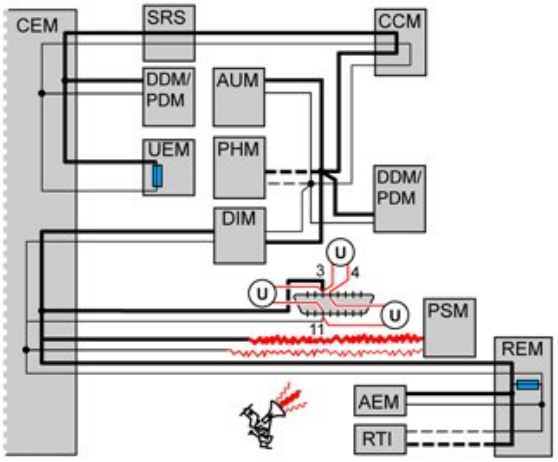
"Chatting" control modules

- "Chatting" control modules may be difficult to find and troubleshooting may take time. Let the vehicle stand with DiCE connected for an extended time period. Afterwards, activate functions to provoke a malfunction. It may take up to several hours before the fault messages are sent. When the indicator starts to flash, remove the fuse for one control module at a time until the indicator stops flashing. When the indicator stops flashing, restore the fuse for the relevant control module and check that the indicator starts to flash again. Then it is likely that the problem is identified.

Remedy wiring as necessary.

Other information

- Battery, disconnecting See: Starting and Charging/Battery/Service and Repair/Procedures/Battery, Disconnecting
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals



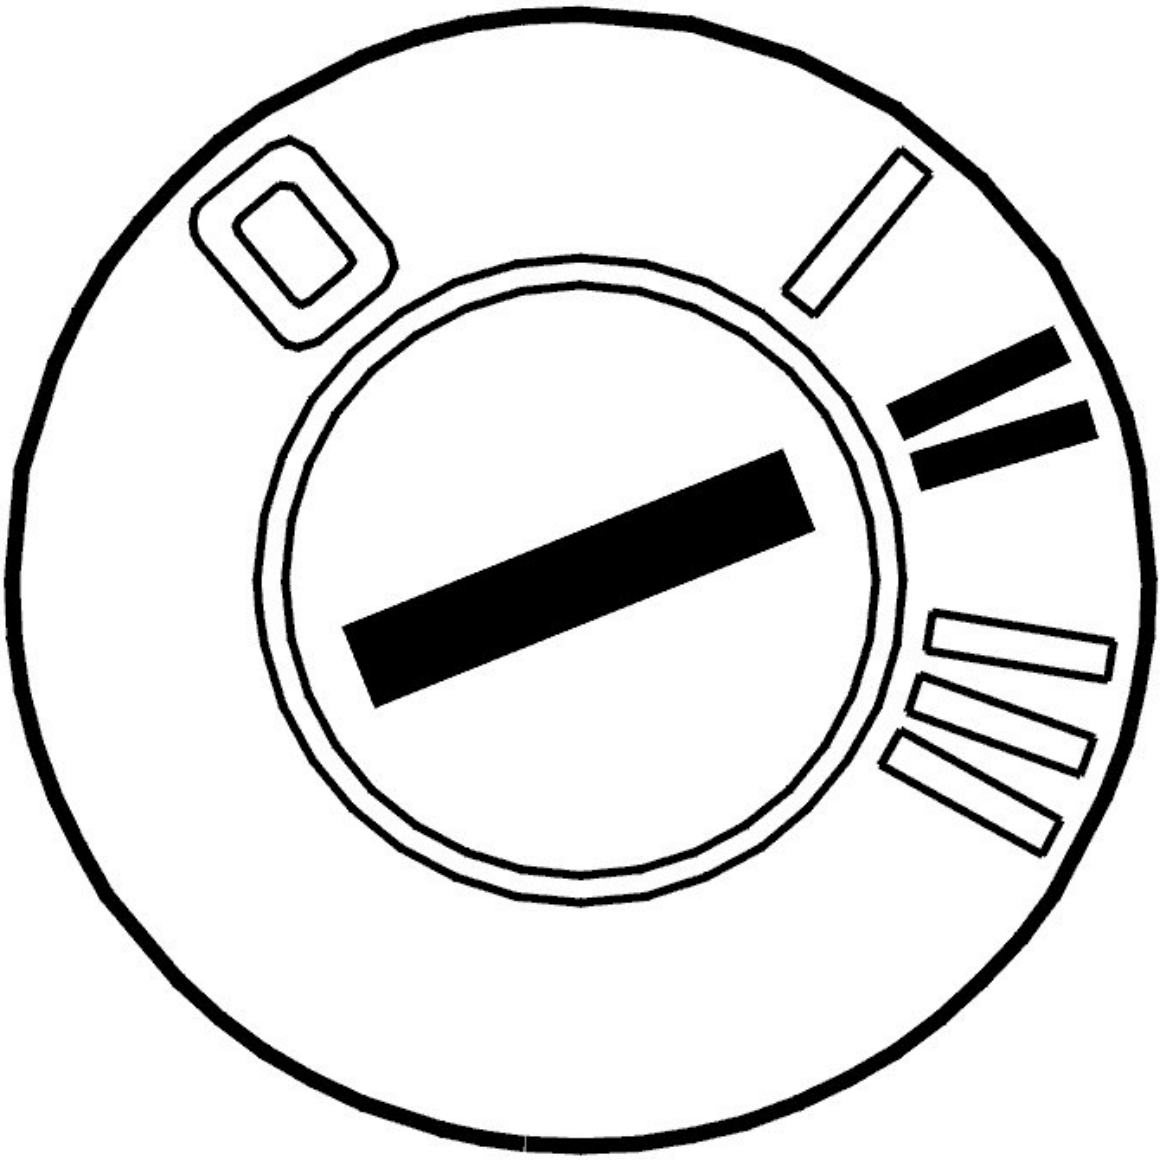
Was a fault detected?

Yes - Identifying a control module in the CAN network

No - Checking voltage-drop in cable for CAN-H and CAN-L, respectively

---

Identifying a control module in the CAN network



Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:

- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Hint: DiCE Error Frame Finder can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools: **951 3010** (memory card) as well as associated TJ 20402. If the load on the CAN network is too high, this may be due to a control module transmitting faulty messages on the CAN network. This is called a disruptive control module. The fault may also be due to an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The fault may occur without any of the control modules storing a diagnostic trouble code (DTC). The voltage can be measured between the CAN cables in order to check the load on the CAN network.

Note! It is not necessarily the control module that has set the diagnostic trouble code that communicates incorrectly. Faulty messages can come from any control module in the same section of the CAN network. However, faulty communication in one network cannot affect the communication on the other network. In other words, faulty communication on the LS-CAN cannot disrupt communication on the HS-CAN and vice versa.

- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Check communication/load on CAN-net by measuring voltage between CAN-L and CAN-H. Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #3 and #11. The average value of the voltage must be approximately 0.6-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

In order to identify which control module has faulty communication, cut the power supply to one control module at a time. Check the voltage in the CAN cables again. The easiest way to cut the power supply is to remove the fuse(s) for the relevant control module. Repeat until the voltage

between the CAN wiring drops to the normal level.

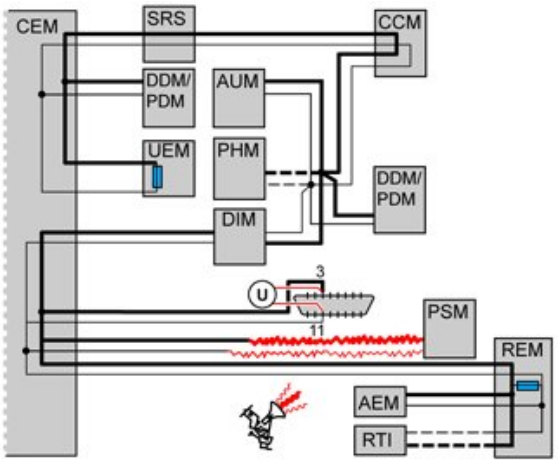
Note! When connecting and disconnecting certain control modules, diagnostic trouble codes (DTCs) may be stored in other control modules.

Hint: When the suspected defective control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the malfunction appears and disappears. Switch off the ignition between each check.

Note! Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.

A control module that is communicating incorrectly must be replaced. See Repairing and installing/Removing, replacing and installing.

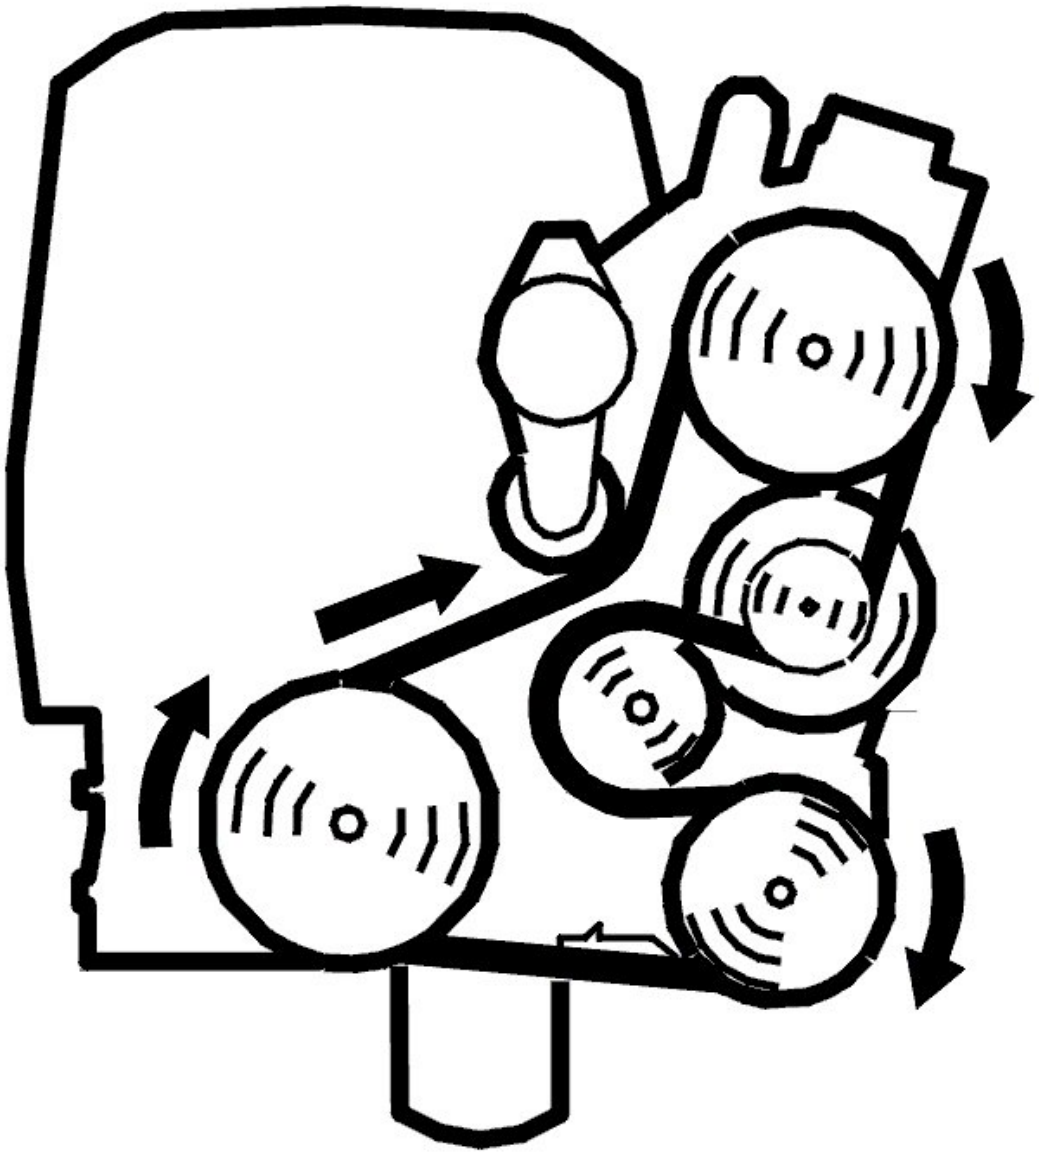
Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

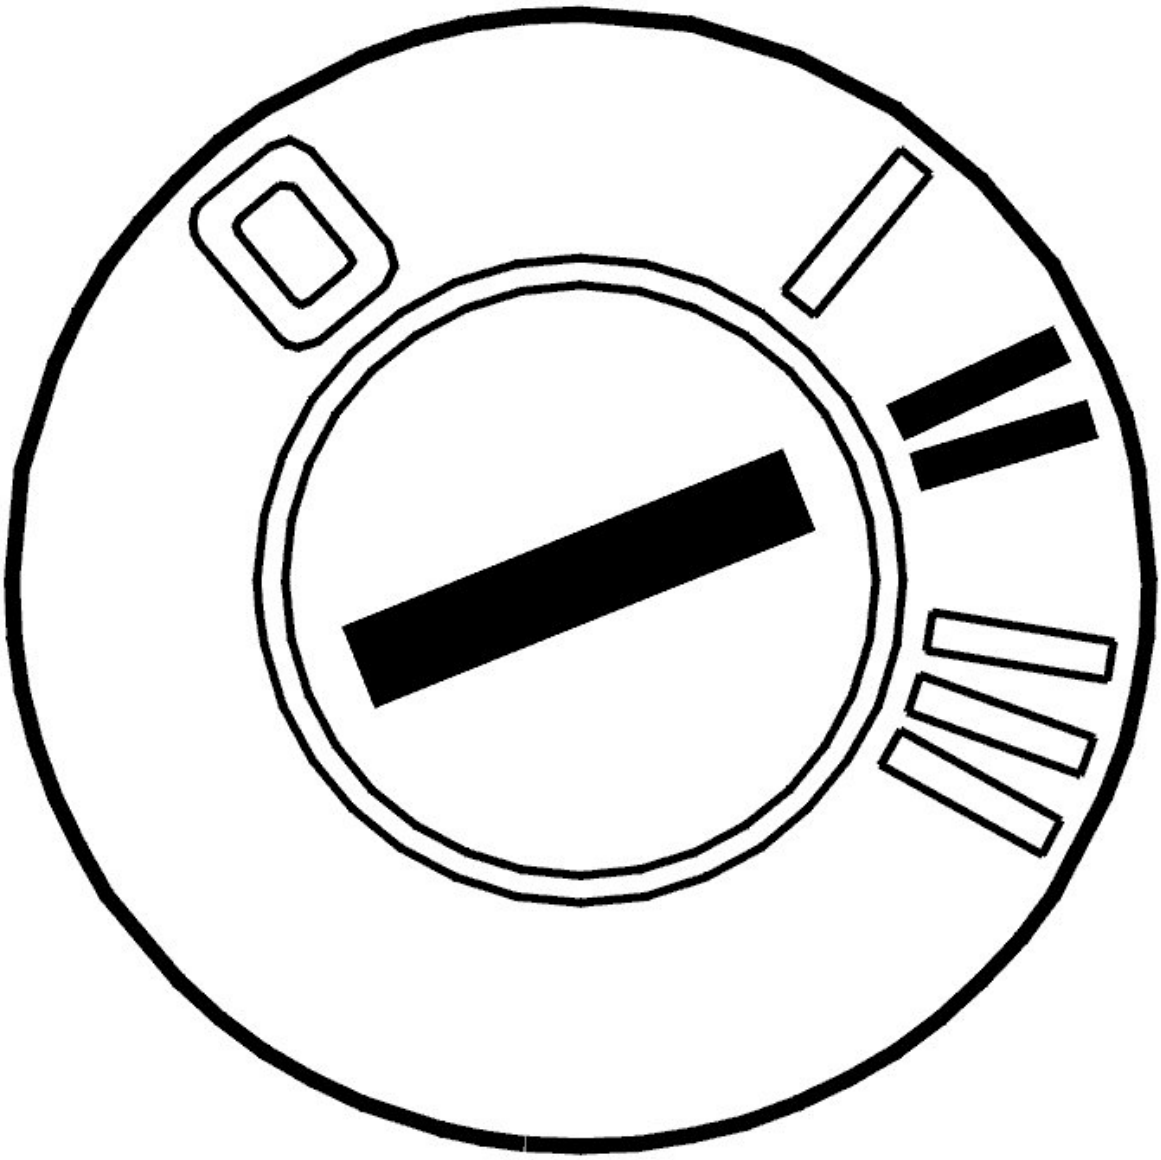


Continue - Verification

Verification

Hint: After rectifying a fault, a verification should be carried out.





- Reinstall the connectors, components etc.
- Ignition on.

Note! For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

- Erase diagnostic trouble codes (DTCs) in all control modules.
- Ignition off.
- Ignition on.
- Start the vehicle. Allow the vehicle to run for 10 minutes. Start the engine. Allow the engine to run at idle speed for 10 minutes
- Read out the diagnostic trouble codes in the vehicle via the DIAGNOSTICS tab.

Does the diagnostic trouble code (DTC) for faulty communication return?

Yes - Fault-tracing information

No - Fault Found

Fault-tracing information

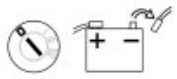
Checking short-circuiting to ground/voltage in CAN-net



- Ignition off.
- Disconnect the battery negative lead.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Checking for a short-circuit to ground

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #3 and #4 (ground). Measurement is shown in the figure. The resistance should be above 1 kohms.
- #11 and #4 (ground). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and ground.

Checking for a short-circuit to voltage

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #3 and #16 (voltage). Measurement is shown in the figure. The resistance should be above 1 kohms.
- #11 and #16 (voltage). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and voltage cable.
Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

Hint: Part the CAN-net at suitable points to decide where a short-circuit may be found.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy as necessary.

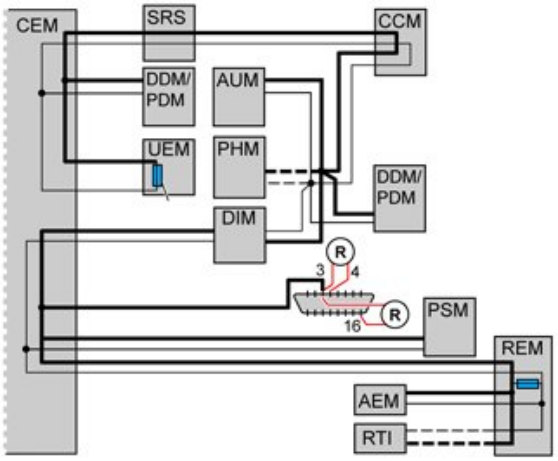
Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

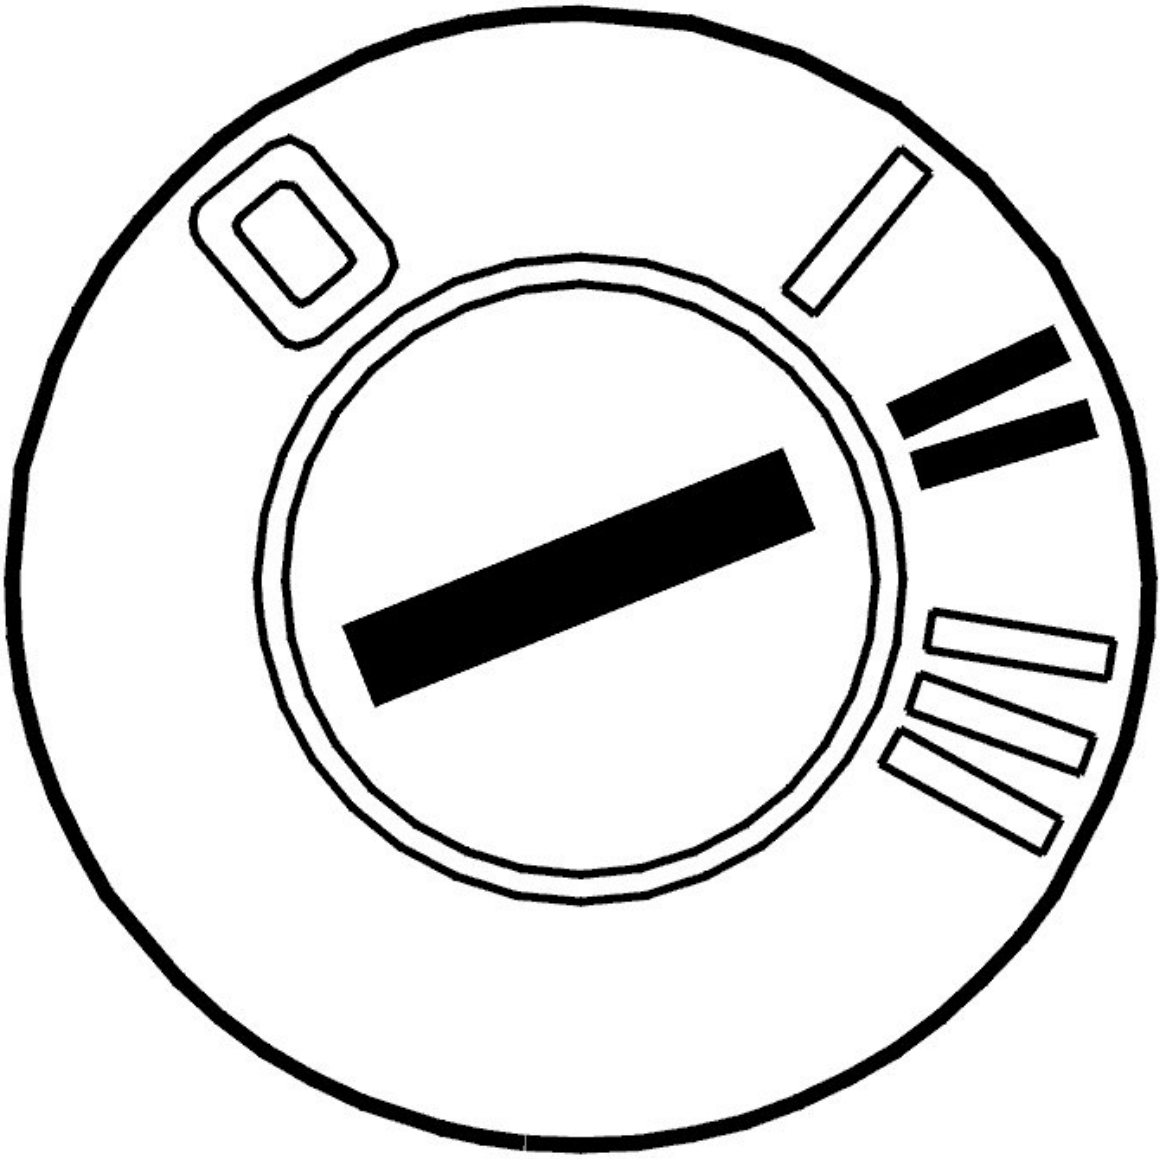


Was a fault detected?

Yes - Verification

No - Checking the amount of traffic on the LS-CAN

Checking voltage-drop in cable for CAN-H and CAN-L, respectively



- Connect the battery.
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

In principle, the voltage measured in each cable in the CAN-net shall be the same at each control module in the network. This means that the voltage-drop in the cable for CAN-H and CAN-L, respectively, between the control modules should be very low. If there is a voltage-difference in the CAN-lines between the diagnostics socket/Central electronic module (CEM) and a control module due to, e.g., contact resistance in a connector or branching, communication may be lost/interfered with. Check if there is voltage-drop in the cable for CAN-H and CAN-L between the diagnostics socket/Central electronic module (CEM) and the control module where there is problem with communication.
Carry out the following:
Measure voltage between the following connections on the OBDII-box/diagnostics socket.
- #3 and corresponding connection on relevant control module for CAN-H. The voltage shall be lower than 50 mV.
- #11 and corresponding connection on relevant control module for CAN-L. The voltage shall be lower than 50 mV.

If voltage is too high, this indicates too high contact resistance in cable, connector, or branching. Check the circuit between the diagnostics socket and control module in question for contact resistance and oxidation.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy wiring as necessary.

General information

Note! Figures shown are only examples.

Hint: For general information about CAN-troubleshooting, see:

- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

General about CAN-related diagnostic trouble codes.
CEM-DF01 - DF17can only be stored in Central electronic module (CEM). These diagnostic trouble codes are stored when an electric fault is detected in CAN-lines. Start with these diagnostic trouble codes first.
CEM-1AXX only stored in Central electronic module (CEM). One diagnostic trouble code for every control module on the CAN-net. These diagnostic trouble codes indicate that Central electronic module (CEM) does not receive any reply from other control modules.
XXX-E000 (HS-CAN)/E001 (LS-CAN) can be stored in all CAN-connected control modules. These diagnostic trouble codes indicate that the control module has detected interference on the CAN-net.
XXX-E003 can be stored in all CAN-connected control modules except in Central electronic module (CEM). The control modules on the CAN-net listen for a message (identity number) that is sent out at regular intervals from Central electronic module (CEM). This diagnostic trouble code indicates that the control module has not received any identity number, or that the expected number is not correct. Interference on the CAN-net can

also store this diagnostic trouble code.

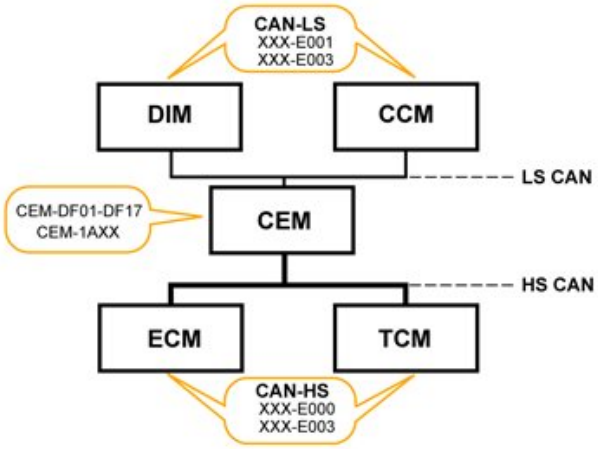
Note! In case of CAN-related faults, it is likely that a combination of above diagnostic trouble codes occur.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

If diagnostic trouble codes (DTCs) for communication faults can be read off from a control module, the fault is probably intermittent.
Intermittent fault in the voltage supply and ground to a control module on the CAN network results in the Central electronic module (CEM) storing a diagnostic trouble code (DTC) for an open-circuit in communication with the control module where the voltage supply does not work. There will probably not be a diagnostic trouble code (DTC) in the control module where the open-circuit in the voltage supply occurred as the control module cannot store a diagnostic trouble code (DTC) when it is not supplied with power.

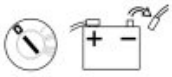
Note! Central electronic module (CEM) should not be replaced in case of CAN-fault, unless troubleshooting reveals that Central electronic module (CEM) has an internal fault.

Caution! During this fault-tracing use the wiring diagram to provide support when taking readings.



Continue - Checking resistance in CAN-net

Checking resistance in CAN-net



- Ignition off
- Disconnect the battery negative lead
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #3 and #11. The resistance should be approx. 55 - 65 ohms.
- If resistance is approx. 120 ohms, this indicates open circuit in the circuit so that only one terminating resistor (120 ohms) has been measured.
- If resistance is above 1 kohms this indicates open circuit/high contact resistance somewhere in the circuit.
- If resistance is below 55 ohms this indicates short-circuiting/contact resistance between the CAN-lines somewhere in the circuit.

Hint: For LS-CAN (Low Speed), terminating resistors are located in Upper electronic module (UEM) and Rear electronic module (REM).

Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

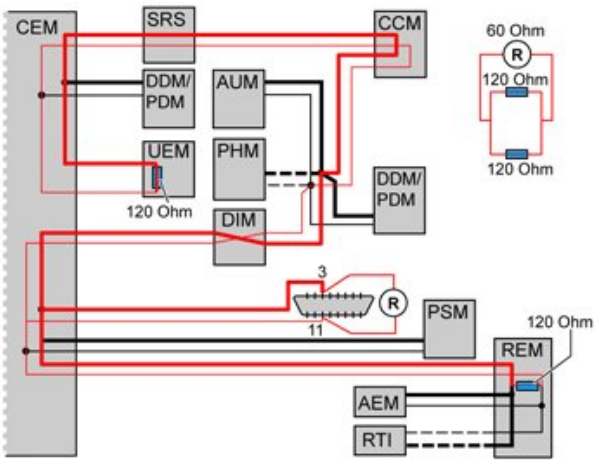
Note! Resistance measurement measures only main lines in the CAN-net (in circuit where both terminating resistors are found), not branches to certain control modules. See wiring diagram for vehicle model in question. Open circuit on branching without a terminating resistor cannot be detected with this measurement. However, short-circuiting on a branch can be detected. To measure resistance in the CAN-net to control modules located in a branching of their own, the measurement shall be done against the CAN-net at that control module. The values shall be as above.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy as necessary.

Other information

- Battery, disconnecting See: Starting and Charging/Battery/Service and Repair/Procedures/Battery, Disconnecting
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

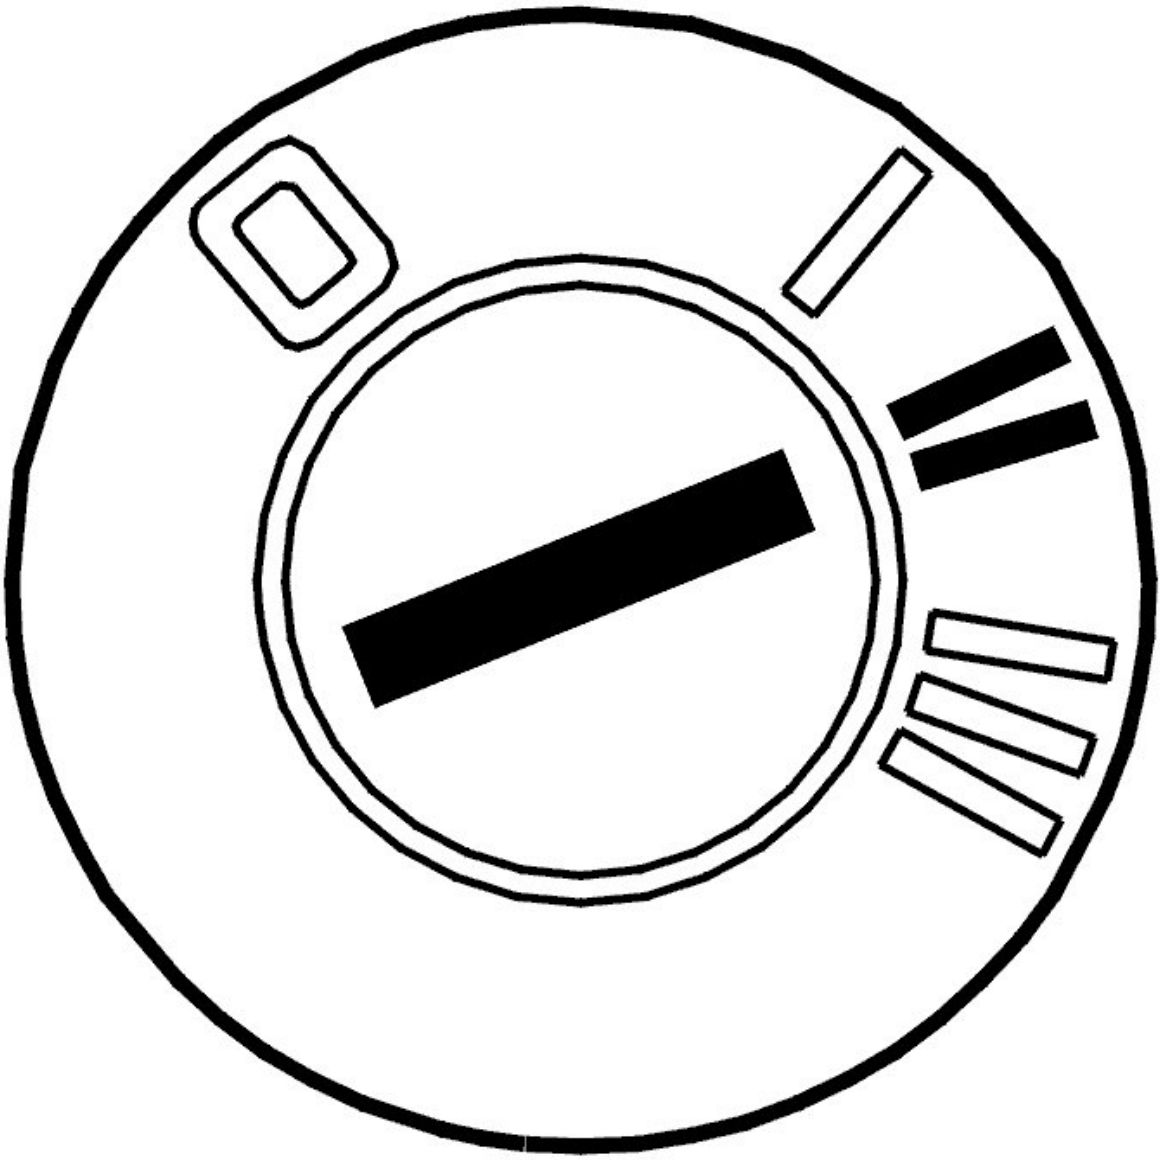


Was a fault detected?

Yes - Verification

No - Checking short-circuiting to ground/voltage in CAN-net

Checking the amount of traffic on the LS-CAN



- Connect the battery
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
Faults in the CAN network may be due to a control module sending faulty messages that disrupt normal communication. When messages are sent incorrectly, this results in a considerable increase in the amount of traffic on the CAN network. The load can be checked by reading the average value of the voltage on the CAN cables in relation to ground.
For further information, see the wiring diagram.
Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #3 and #4 (ground). The voltage should be approx: 2,8 - 3,2 V.
- #11 and #4 (ground). The voltage should be approx: 1,8 - 2,2 V.
- #3 and #11. The voltage shall be between approx. 0.55-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Hint: DiCE Error Frame Finder can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools: **951 3010** (memory card) as well as associated TJ 20402.

- Ignition on.
- Connect DiCE Error Frame Finder to the diagnostics socket.
- Note the blue LED-indicator. The indicator flashes to show detection of fault messages.

Note! Certain interference may occur without any real fault!

Cable fault

- Shake the cables lightly and pull lightly on the connections during the check to locate any fault. Note the blue LED-indicator.

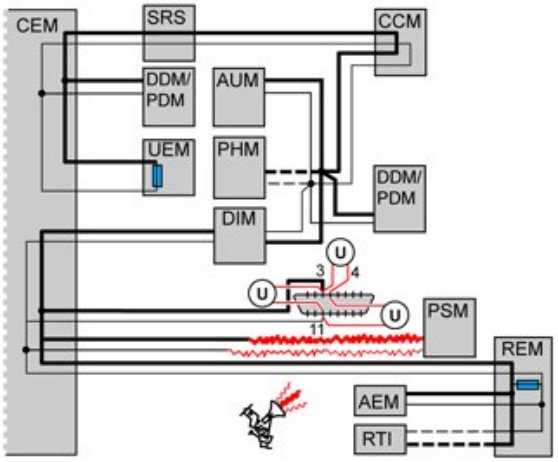
"Chatting" control modules

- "Chatting" control modules may be difficult to find and troubleshooting may take time. Let the vehicle stand with DiCE connected for an extended time period. Afterwards, activate functions to provoke a malfunction. It may take up to several hours before the fault messages are sent. When the indicator starts to flash, remove the fuse for one control module at a time until the indicator stops flashing. When the indicator stops flashing, restore the fuse for the relevant control module and check that the indicator starts to flash again. Then it is likely that the problem is identified.

Remedy wiring as necessary.

Other information

- Battery, disconnecting See: Starting and Charging/Battery/Service and Repair/Procedures/Battery, Disconnecting
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals



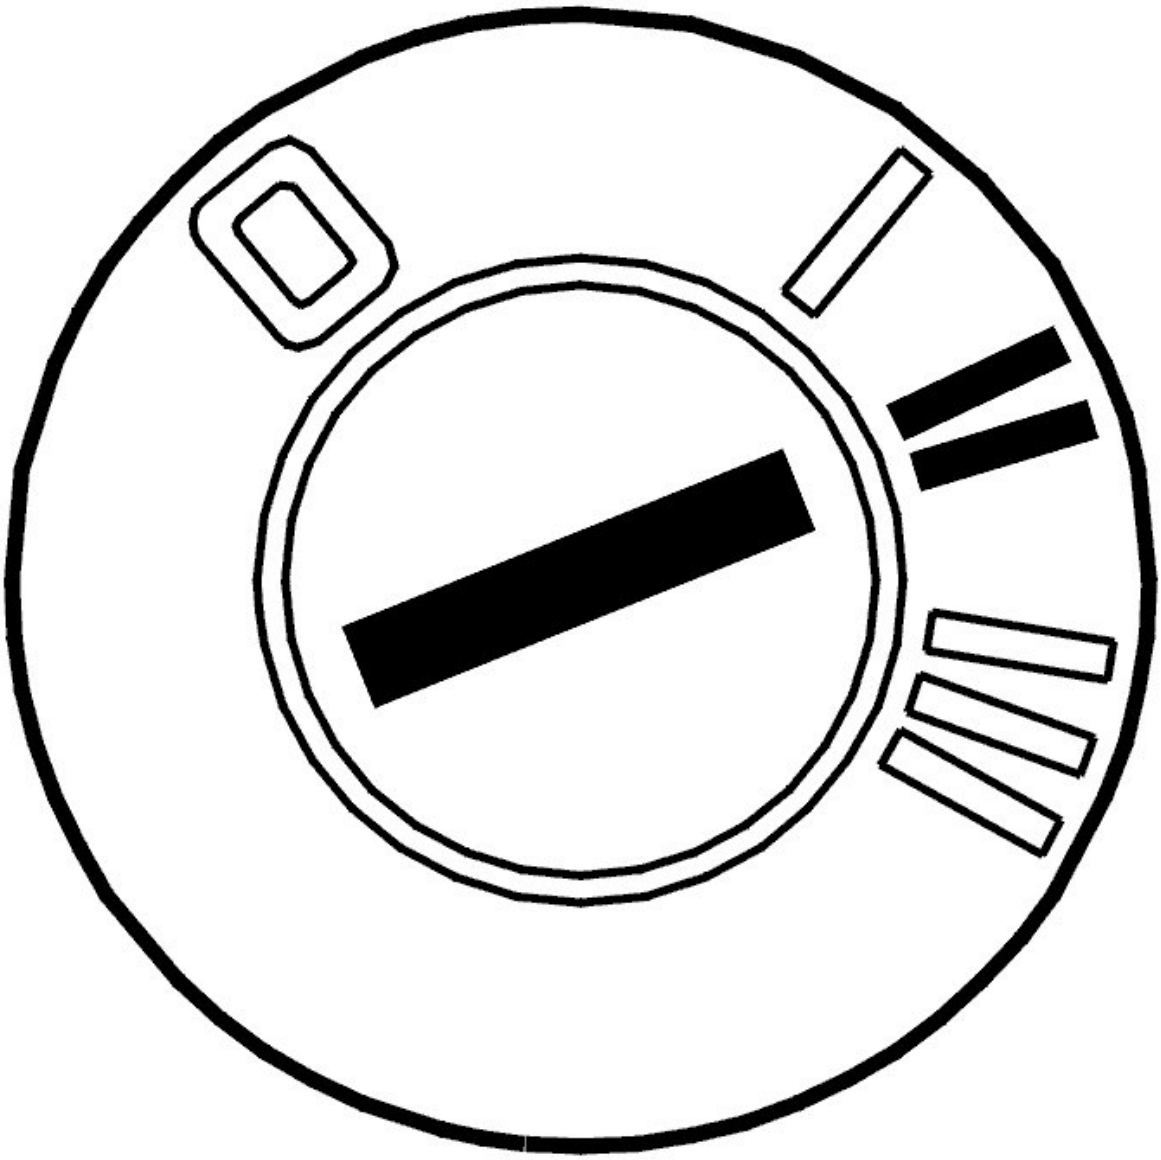
Was a fault detected?

Yes - Identifying a control module in the CAN network

No - Checking voltage-drop in cable for CAN-H and CAN-L, respectively

---

Identifying a control module in the CAN network



Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:

- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Hint: DiCE Error Frame Finder can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools: **951 3010** (memory card) as well as associated TJ 20402. If the load on the CAN network is too high, this may be due to a control module transmitting faulty messages on the CAN network. This is called a disruptive control module. The fault may also be due to an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The fault may occur without any of the control modules storing a diagnostic trouble code (DTC). The voltage can be measured between the CAN cables in order to check the load on the CAN network.

Note! It is not necessarily the control module that has set the diagnostic trouble code that communicates incorrectly. Faulty messages can come from any control module in the same section of the CAN network. However, faulty communication in one network cannot affect the communication on the other network. In other words, faulty communication on the LS-CAN cannot disrupt communication on the HS-CAN and vice versa.

- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Check communication/load on CAN-net by measuring voltage between CAN-L and CAN-H. Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #3 and #11. The average value of the voltage must be approximately 0.6-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

In order to identify which control module has faulty communication, cut the power supply to one control module at a time. Check the voltage in the CAN cables again. The easiest way to cut the power supply is to remove the fuse(s) for the relevant control module. Repeat until the voltage

between the CAN wiring drops to the normal level.

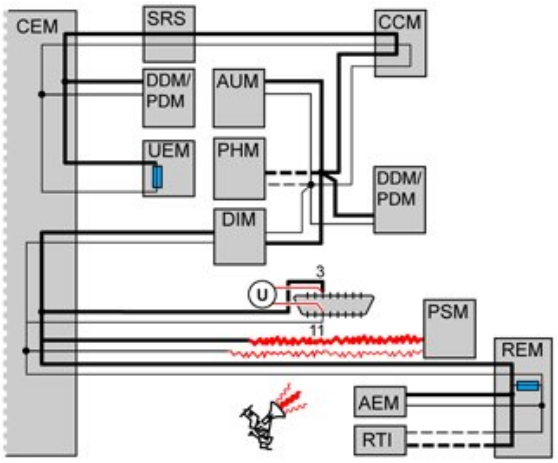
Note! When connecting and disconnecting certain control modules, diagnostic trouble codes (DTCs) may be stored in other control modules.

Hint: When the suspected defective control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the malfunction appears and disappears. Switch off the ignition between each check.

Note! Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.

A control module that is communicating incorrectly must be replaced. See Repairing and installing/Removing, replacing and installing.

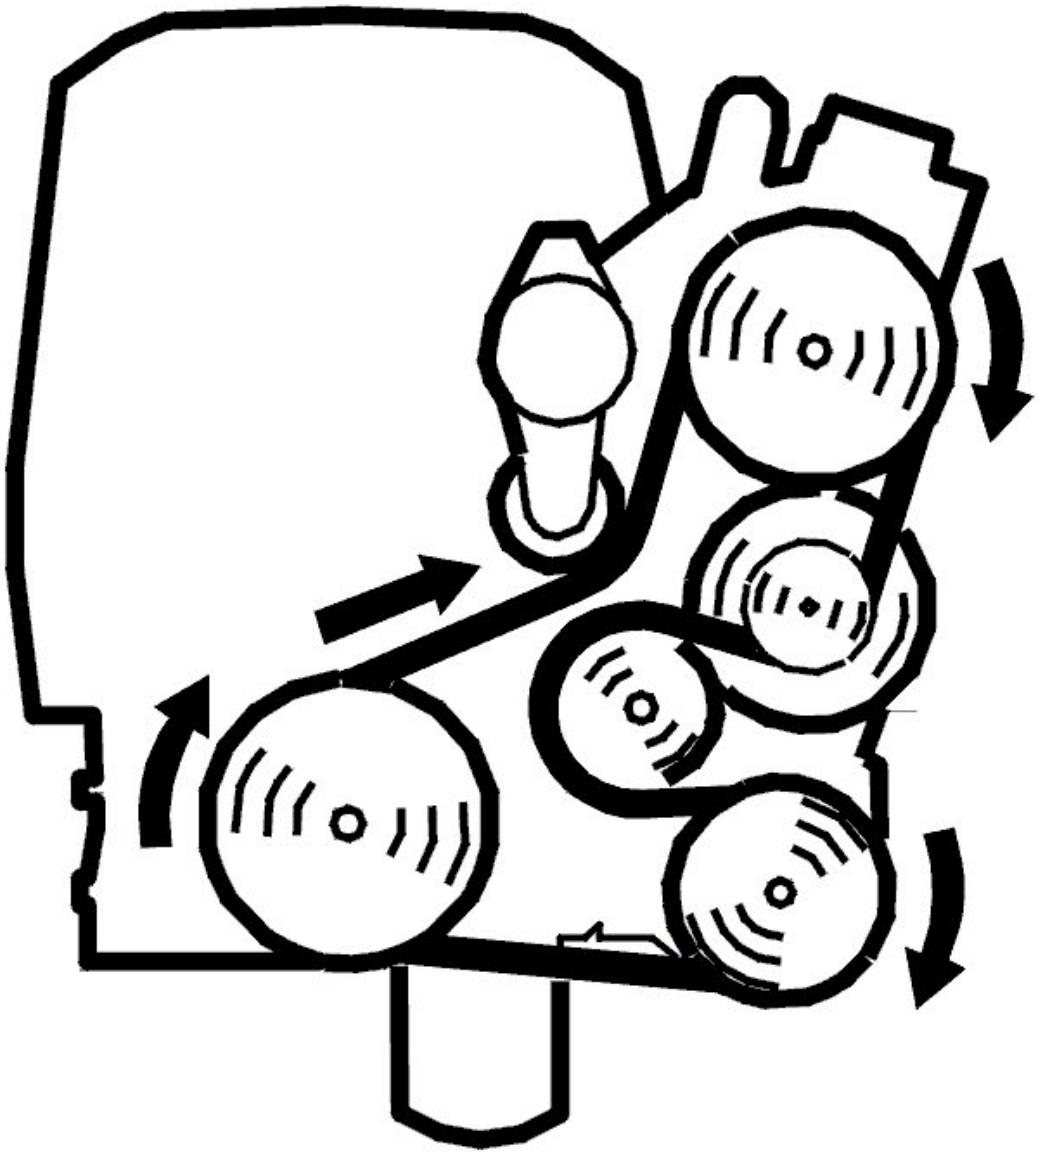
Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

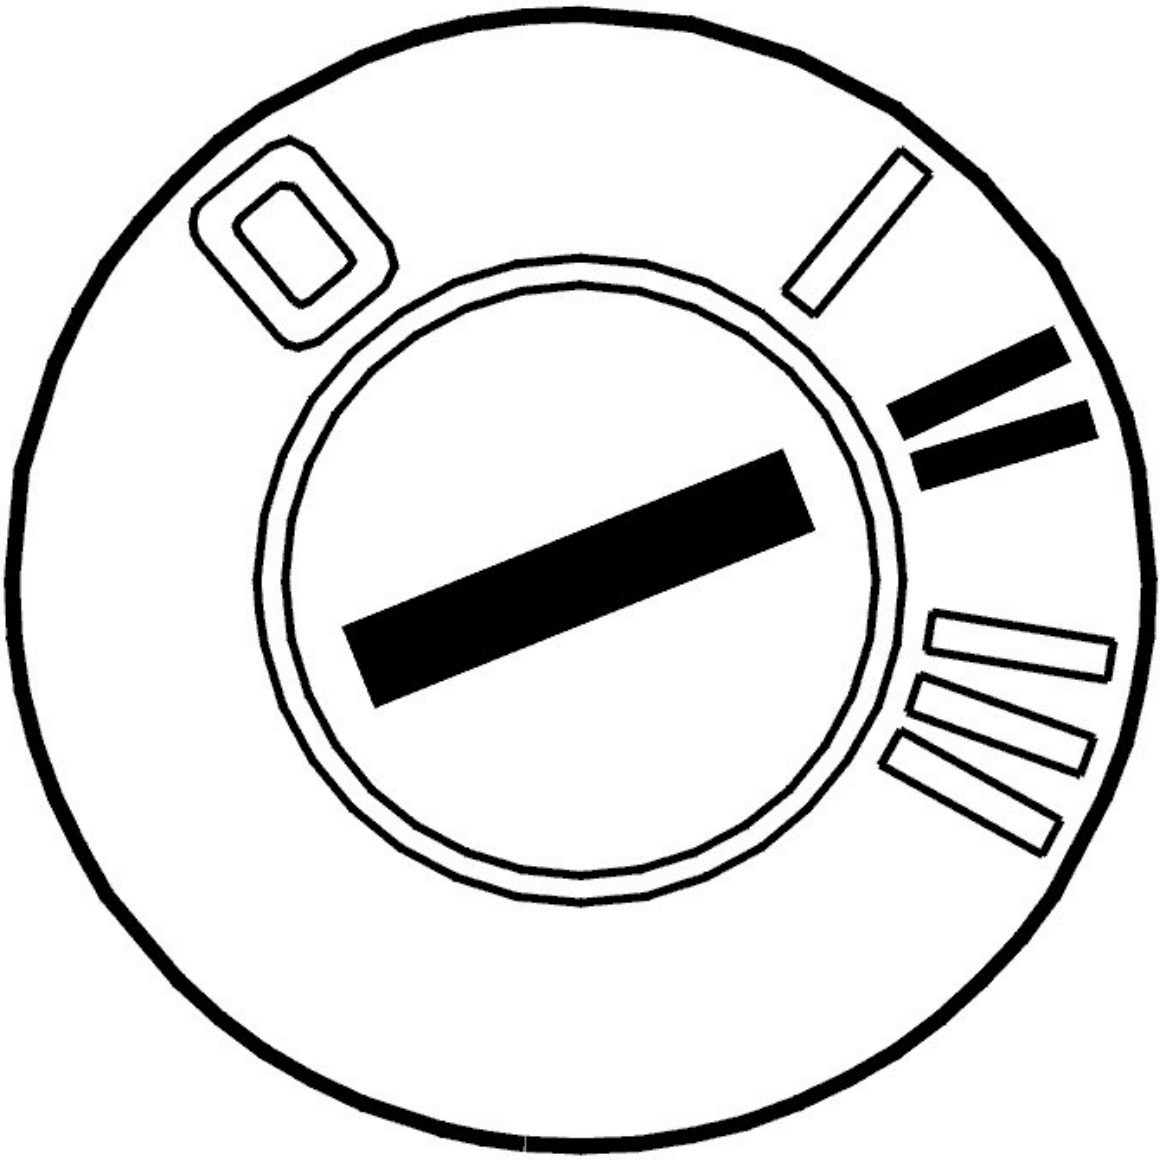


Continue - Verification

Verification

Hint: After rectifying a fault, a verification should be carried out.





- Reinstall the connectors, components etc.
- Ignition on.

Note! For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

- Erase diagnostic trouble codes (DTCs) in all control modules.
- Ignition off.
- Ignition on.
- Start the vehicle. Allow the vehicle to run for 10 minutes. Start the engine. Allow the engine to run at idle speed for 10 minutes
- Read out the diagnostic trouble codes in the vehicle via the DIAGNOSTICS tab.

Does the diagnostic trouble code (DTC) for faulty communication return?

Yes - Fault-tracing information

No - Fault Found

Fault-tracing information

Information

Fault-tracing information

The fault should have been detected and remedied. As this is not the case fault-tracing has failed.
Exit fault-tracing for this diagnostic trouble code (DTC) or make another attempt.

Do you want to exit fault-tracing?

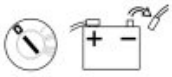
Yes - **FAULT-TRACING FAILED**

No - **Attempt New Test**

FAULT-TRACING FAILED - **FAULT-TRACING FAILED**

Attempt New Test - Signal missing

Checking short-circuiting to ground/voltage in CAN-net



- Ignition off.
- Disconnect the battery negative lead.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Checking for a short-circuit to ground

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #3 and #4 (ground). Measurement is shown in the figure. The resistance should be above 1 kohms.
- #11 and #4 (ground). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and ground.

Checking for a short-circuit to voltage

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #3 and #16 (voltage). Measurement is shown in the figure. The resistance should be above 1 kohms.
- #11 and #16 (voltage). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and voltage cable.
Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

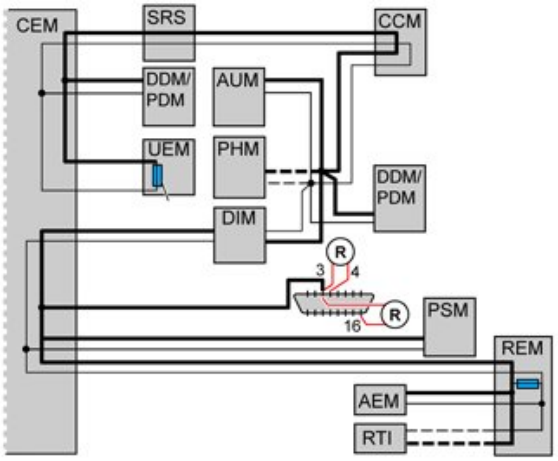
Hint: Part the CAN-net at suitable points to decide where a short-circuit may be found.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy as necessary.

Other information
- Battery, disconnecting See: Starting and Charging/Battery/Service and Repair/Procedures/Battery, Disconnecting
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

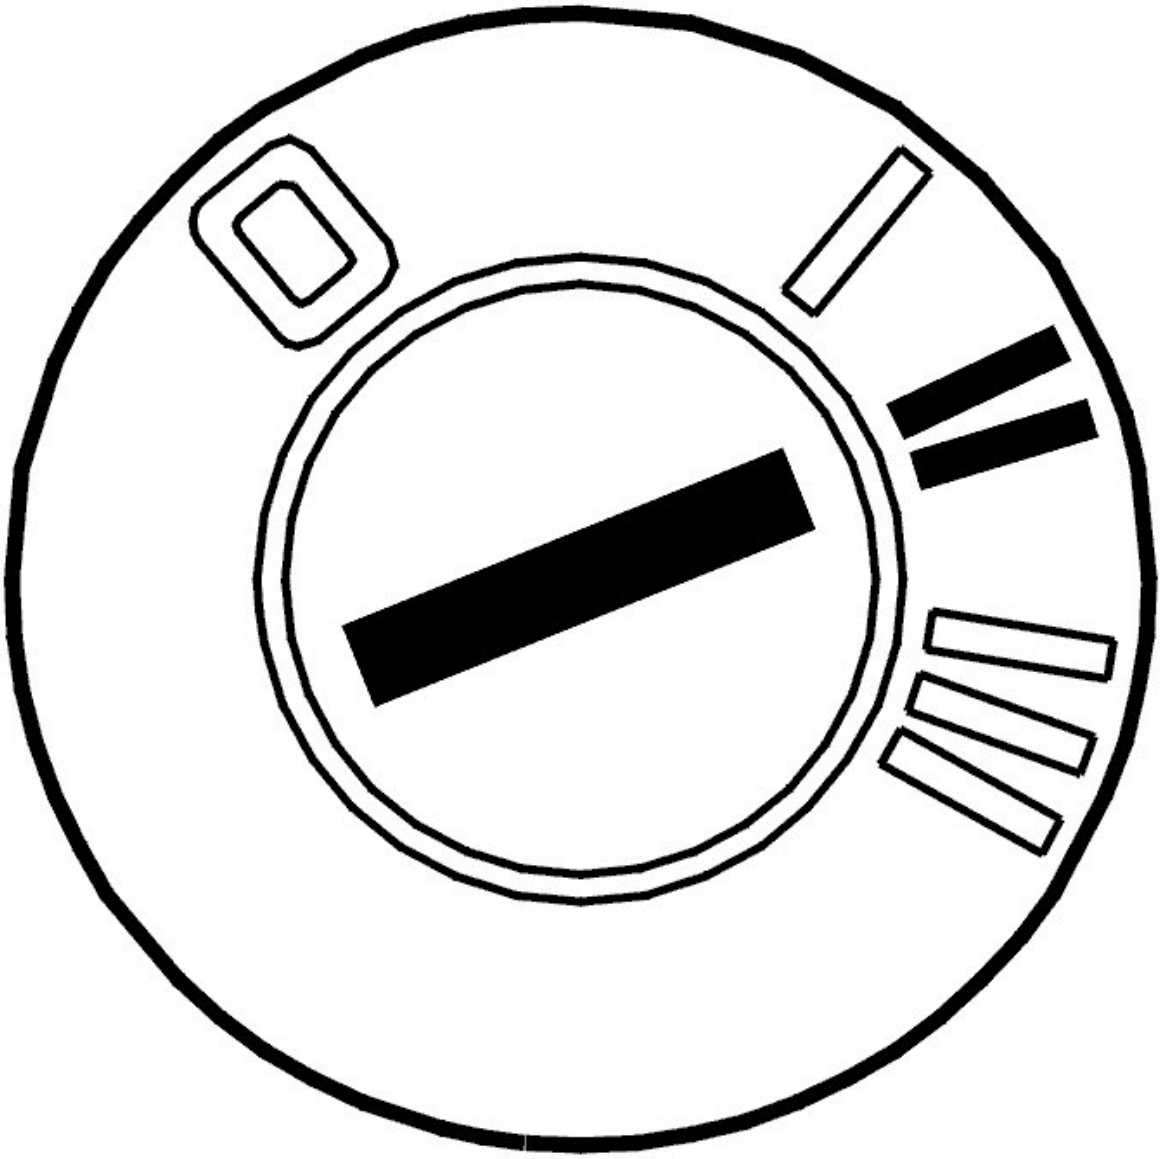


Was a fault detected?

Yes - Verification

No - Checking the amount of traffic on the LS-CAN

Checking voltage-drop in cable for CAN-H and CAN-L, respectively



- Connect the battery.
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

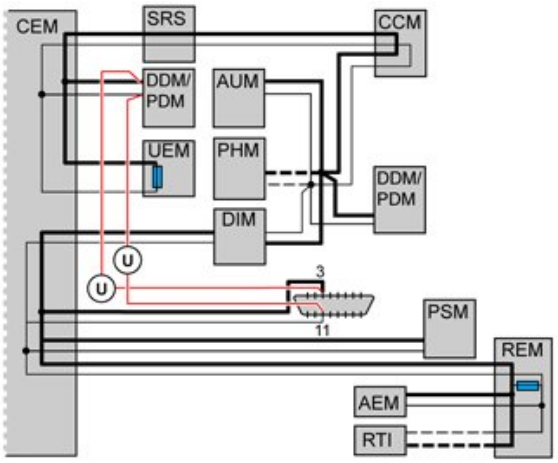
In principle, the voltage measured in each cable in the CAN-net shall be the same at each control module in the network. This means that the voltage-drop in the cable for CAN-H and CAN-L, respectively, between the control modules should be very low. If there is a voltage-difference in the CAN-lines between the diagnostics socket/Central electronic module (CEM) and a control module due to, e.g., contact resistance in a connector or branching, communication may be lost/interfered with. Check if there is voltage-drop in the cable for CAN-H and CAN-L between the diagnostics socket/Central electronic module (CEM) and the control module where there is problem with communication.
Carry out the following:
Measure voltage between the following connections on the OBDII-box/diagnostics socket.
- #3 and corresponding connection on relevant control module for CAN-H. The voltage shall be lower than 50 mV.
- #11 and corresponding connection on relevant control module for CAN-L. The voltage shall be lower than 50 mV.

If voltage is too high, this indicates too high contact resistance in cable, connector, or branching. Check the circuit between the diagnostics socket and control module in question for contact resistance and oxidation.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy wiring as necessary.

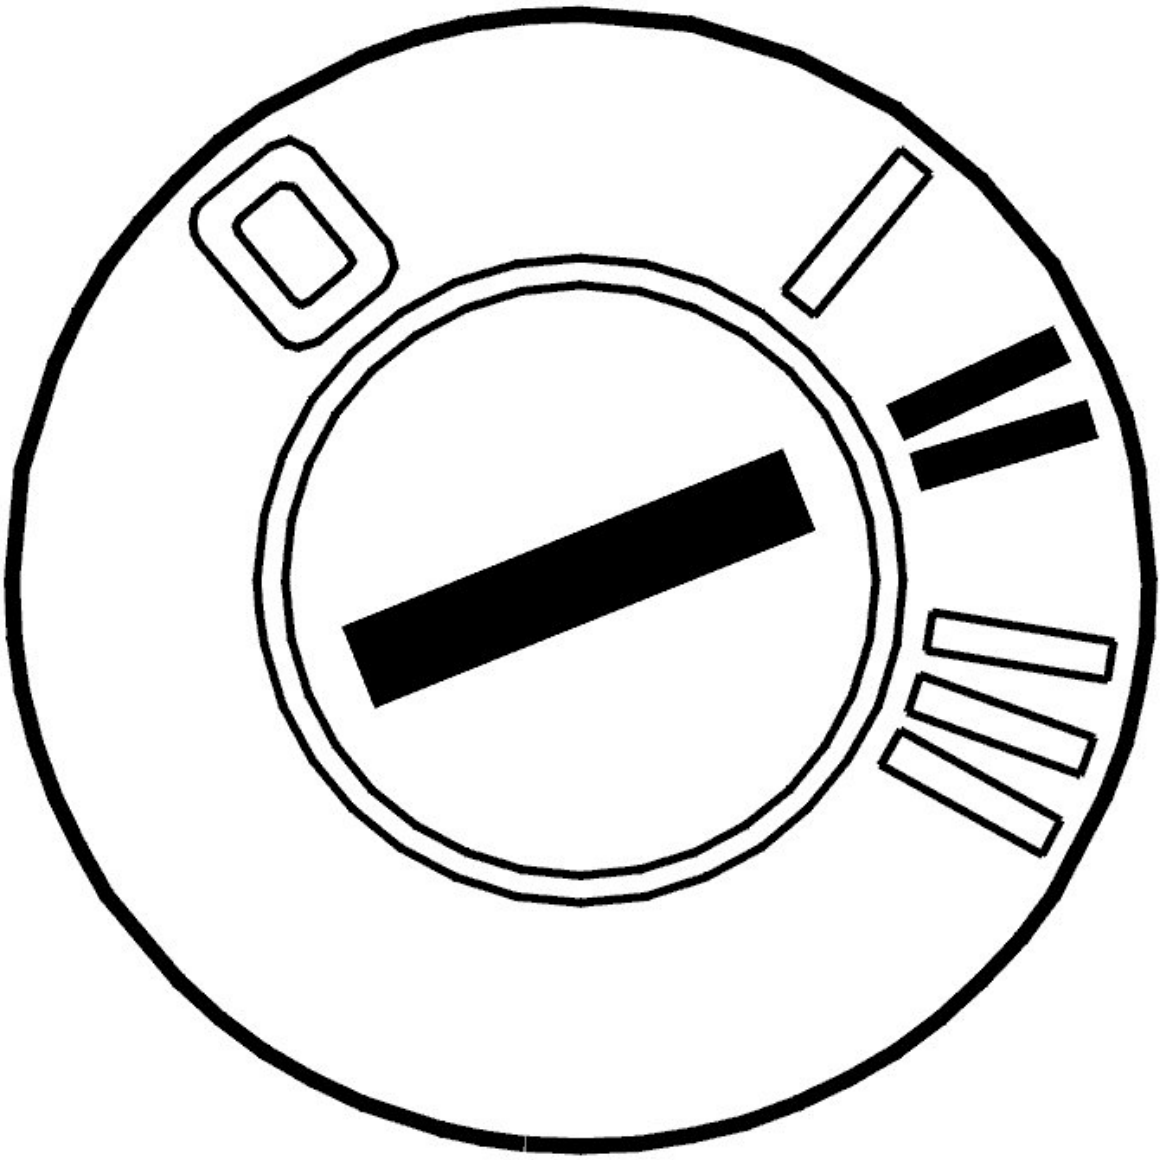
Other information
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

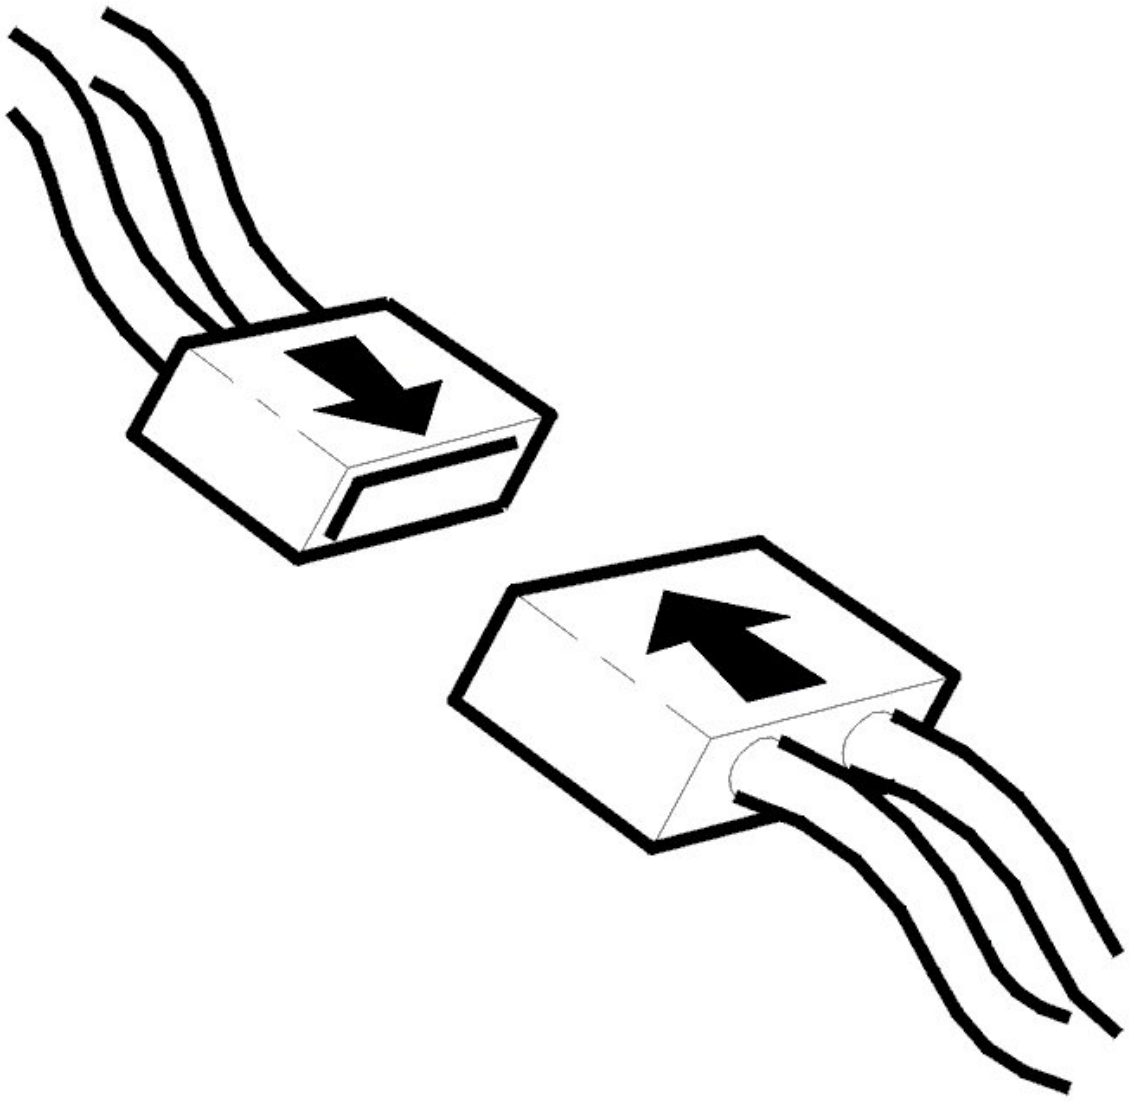


Continue - Verification

Checking the function of the road traffic information module (RTI)

Hint: After carrying out the repair, check that the fault has been remedied.





- Ignition off
- Reconnect the connectors. Reinstall the components
- Ignition on.

Check the power supply to the road traffic information module (RTI) by inserting and ejecting a DVD or CD.

Hint: This check can be made using either a CD or a DVD. The physical size of the discs is the same. The difference is that a CD will not be recognized by the system. However the insertion and ejection function can be checked.

Is the function OK?

Yes - Fault Found

No - Fault-tracing information

Fault-tracing information

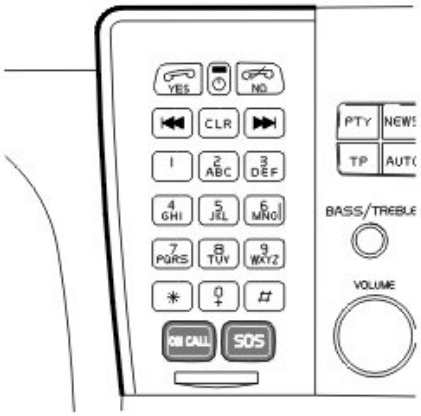
FAULT-TRACING FAILED - FAULT-TRACING FAILED

Attempt New Test - Checking the function of the road traffic information module (RTI)

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CEM-1A58

Condition



The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers that communication with the phone module (PHM) is not operating.
The diagnostic trouble code (DTC) can be diagnosed when the ignition has been on for more than 10 seconds.

Note! In the event of CEM-1A5X diagnostic trouble codes (DTCs), the central electronic module (CEM) must not be replaced as the diagnostic trouble code (DTC) indicates a communication fault in the controller area network (CAN).

Substitute value
- None.

Possible source
- No power supply to the phone module (PHM)
- Open-circuit in the ground lead for the phone module (PHM)
- Contact resistance in the terminals
- Open-circuit in the wiring for the CAN low speed network to the phone module (PHM)
- The phone module (PHM) is not intended for this vehicle (for example a used control module with different software/hardware).

Hint: If several diagnostic trouble codes (DTCs) are stored in the central electronic module (CEM) for communication faults with other control modules in the low speed network, this indicates a common fault in the controller area network (CAN). See the relevant wiring diagram.

Fault symptom[s]
- The phone is not working.
- The menu system does not operate.

Signal Missing

Signal missing

Checking the function of the phone module (PHM)

For further information about the fuse and terminal pin numbers, see the relevant Wiring Diagram.
Check that the phone module (PHM) is powered and grounded by pressing the ON/OFF button and then pressing the YES button.
The LED in the ON/OFF button must light.

Does the LED in the ON/OFF button light?

Yes - Checking communication with the phone module (PHM)

No - Checking the power supply and ground for the phone module (PHM)

Checking the power supply and ground for the phone module (PHM)

Check that the fuse for the control module is intact.
Check the power supply and the ground terminal for the phone module (PHM).
Remedy as necessary.

Other information:

- For information about fuse and terminal numbers, see the relevant Wiring Diagram.
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

Was a fault detected?

Yes - Checking the function of the phone module (PHM)

No - Signal missing

Checking communication with the phone module (PHM)

Hint: The CAN communication with the control module is probably OK if the control module ID can be read off. The fault is probably intermittent and may therefore be difficult to locate.

- Try to communicate with the phone module (PHM) by reading off the control module ID
- Click on the symbol for VCT2000 to begin reading off

Continue - Signal missing

Signal missing

General information

Note! Figures shown are only examples.

Hint: For general information about CAN-troubleshooting, see:

- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

General about CAN-related diagnostic trouble codes.
CEM-DF01 - DF17can only be stored in Central electronic module (CEM). These diagnostic trouble codes are stored when an electric fault is detected in CAN-lines. Start with these diagnostic trouble codes first.
CEM-1AXX only stored in Central electronic module (CEM). One diagnostic trouble code for every control module on the CAN-net. These diagnostic trouble codes indicate that Central electronic module (CEM) does not receive any reply from other control modules.
XXX-E000 (HS-CAN)/E001 (LS-CAN) can be stored in all CAN-connected control modules. These diagnostic trouble codes indicate that the control module has detected interference on the CAN-net.
XXX-E003 can be stored in all CAN-connected control modules except in Central electronic module (CEM). The control modules on the CAN-net listen for a message (identity number) that is sent out at regular intervals from Central electronic module (CEM). This diagnostic trouble code indicates that the control module has not received any identity number, or that the expected number is not correct. Interference on the CAN-net can also store this diagnostic trouble code.

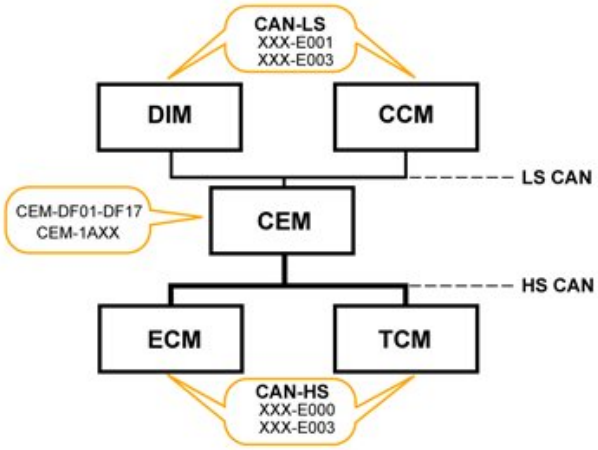
Note! In case of CAN-related faults, it is likely that a combination of above diagnostic trouble codes occur.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

If diagnostic trouble codes (DTCs) for communication faults can be read off from a control module, the fault is probably intermittent. Intermittent fault in the voltage supply and ground to a control module on the CAN network results in the Central electronic module (CEM) storing a diagnostic trouble code (DTC) for an open-circuit in communication with the control module where the voltage supply does not work. There will probably not be a diagnostic trouble code (DTC) in the control module where the open-circuit in the voltage supply occurred as the control module cannot store a diagnostic trouble code (DTC) when it is not supplied with power.

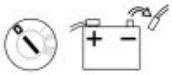
Note! Central electronic module (CEM) should not be replaced in case of CAN-fault, unless troubleshooting reveals that Central electronic module (CEM) has an internal fault.

Caution! During this fault-tracing use the wiring diagram to provide support when taking readings.



Continue - Checking resistance in CAN-net

Checking resistance in CAN-net



- Ignition off
- Disconnect the battery negative lead
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #3 and #11. The resistance should be approx. 55 - 65 ohms.
- If resistance is approx. 120 ohms, this indicates open circuit in the circuit so that only one terminating resistor (120 ohms) has been measured.
- If resistance is above 1 kohms this indicates open circuit/high contact resistance somewhere in the circuit.
- If resistance is below 55 ohms this indicates short-circuiting/contact resistance between the CAN-lines somewhere in the circuit.

Hint: For LS-CAN (Low Speed), terminating resistors are located in Upper electronic module (UEM) and Rear electronic module (REM).

Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

Note! Resistance measurement measures only main lines in the CAN-net (in circuit where both terminating resistors are found), not branches to certain control modules. See wiring diagram for vehicle model in question. Open circuit on branching without a terminating resistor cannot be detected with this measurement. However, short-circuiting on a branch can be detected. To measure resistance in the CAN-net to control modules located in a branching of their own, the measurement shall be done against the CAN-net at that control module. The values shall be as above.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they

work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy as necessary.

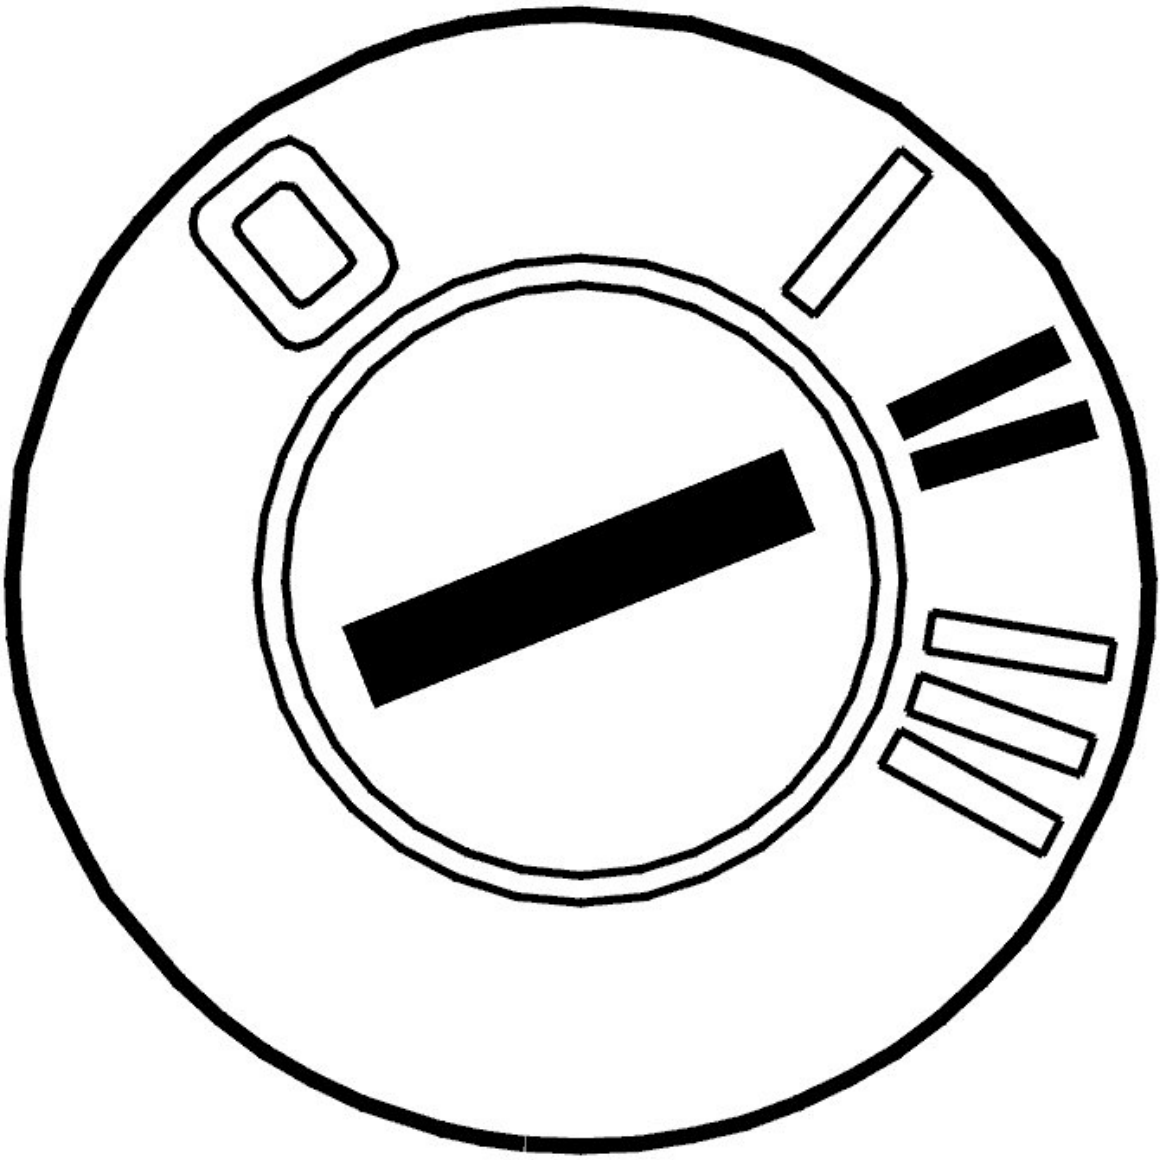
Was a fault detected?

Yes - Verification

No - Checking short-circuiting to ground/voltage in CAN-net

Checking the amount of traffic on the LS-CAN



- Connect the battery
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
Faults in the CAN network may be due to a control module sending faulty messages that disrupt normal communication. When messages are sent incorrectly, this results in a considerable increase in the amount of traffic on the CAN network. The load can be checked by reading the average value of the voltage on the CAN cables in relation to ground.
For further information, see the wiring diagram.
Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #3 and #4 (ground). The voltage should be approx: 2,8 - 3,2 V.
- #11 and #4 (ground). The voltage should be approx: 1,8 - 2,2 V.
- #3 and #11. The voltage shall be between approx. 0.55-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Hint: DiCE Error Frame Finder can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools: **951 3010** (memory card) as well as associated TJ 20402.

- Ignition on.
- Connect DiCE Error Frame Finder to the diagnostics socket.
- Note the blue LED-indicator. The indicator flashes to show detection of fault messages.

Note! Certain interference may occur without any real fault!

Cable fault

- Shake the cables lightly and pull lightly on the connections during the check to locate any fault. Note the blue LED-indicator.

"Chatting" control modules

- "Chatting" control modules may be difficult to find and troubleshooting may take time. Let the vehicle stand with DiCE connected for an extended time period. Afterwards, activate functions to provoke a malfunction. It may take up to several hours before the fault messages are sent. When the indicator starts to flash, remove the fuse for one control module at a time until the indicator stops flashing. When the indicator stops flashing, restore the fuse for the relevant control module and check that the indicator starts to flash again. Then it is likely that the problem is identified.

Remedy wiring as necessary.

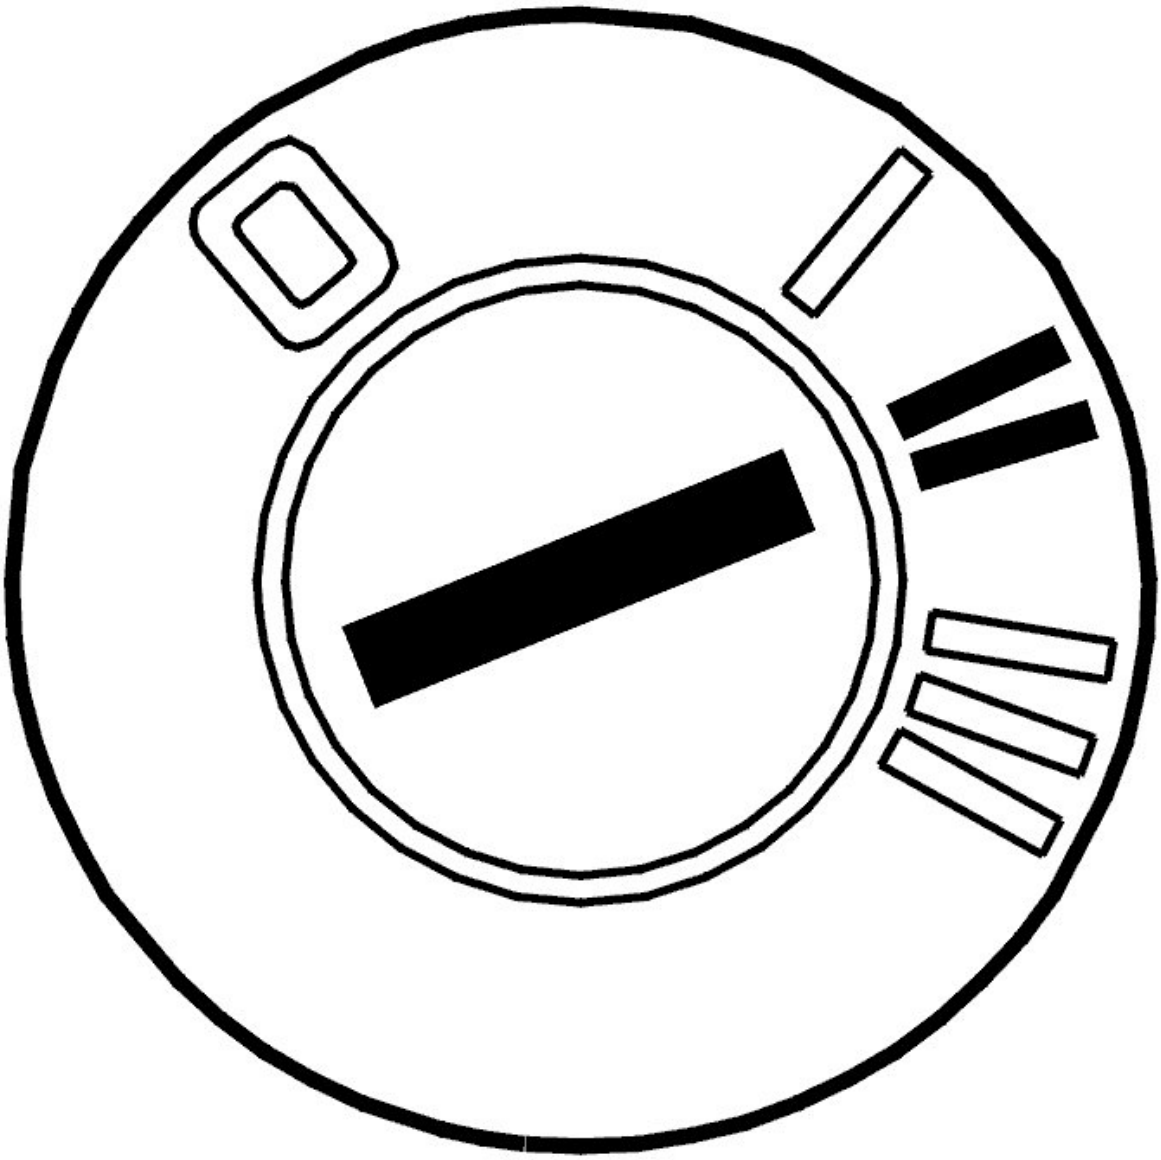
Identifying a control module in the CAN network



Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:

- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Hint: DiCE Error Frame Finder can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools: **951 3010** (memory card) as well as associated TJ 20402. If the load on the CAN network is too high, this may be due to a control module transmitting faulty messages on the CAN network. This is called a disruptive control module. The fault may also be due to an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The fault may occur without any of the control modules storing a diagnostic trouble code (DTC). The voltage can be measured between the CAN cables in order to check the load on the CAN network.

Note! It is not necessarily the control module that has set the diagnostic trouble code that communicates incorrectly. Faulty messages can come from any control module in the same section of the CAN network. However, faulty communication in one network cannot affect the communication on the other network. In other words, faulty communication on the LS-CAN cannot disrupt communication on the HS-CAN and vice versa.

- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Check communication/load on CAN-net by measuring voltage between CAN-L and CAN-H. Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #3 and #11. The average value of the voltage must be approximately 0.6-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

In order to identify which control module has faulty communication, cut the power supply to one control module at a time. Check the voltage in the CAN cables again. The easiest way to cut the power supply is to remove the fuse(s) for the relevant control module. Repeat until the voltage

between the CAN wiring drops to the normal level.

Note! When connecting and disconnecting certain control modules, diagnostic trouble codes (DTCs) may be stored in other control modules.

Hint: When the suspected defective control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the malfunction appears and disappears. Switch off the ignition between each check.

Note! Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.

A control module that is communicating incorrectly must be replaced. See Repairing and installing/Removing, replacing and installing.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Checking for a short-circuit to ground

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #3 and #4 (ground). Measurement is shown in the figure. The resistance should be above 1 kohms.
- #11 and #4 (ground). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and ground.

Checking for a short-circuit to voltage

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #3 and #16 (voltage). Measurement is shown in the figure. The resistance should be above 1 kohms.
- #11 and #16 (voltage). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and voltage cable.
Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

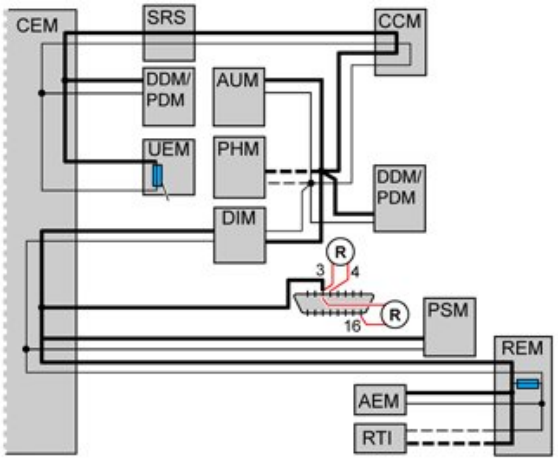
Hint: Part the CAN-net at suitable points to decide where a short-circuit may be found.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy as necessary.

Other information
- Battery, disconnecting See: Starting and Charging/Battery/Service and Repair/Procedures/Battery, Disconnecting
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

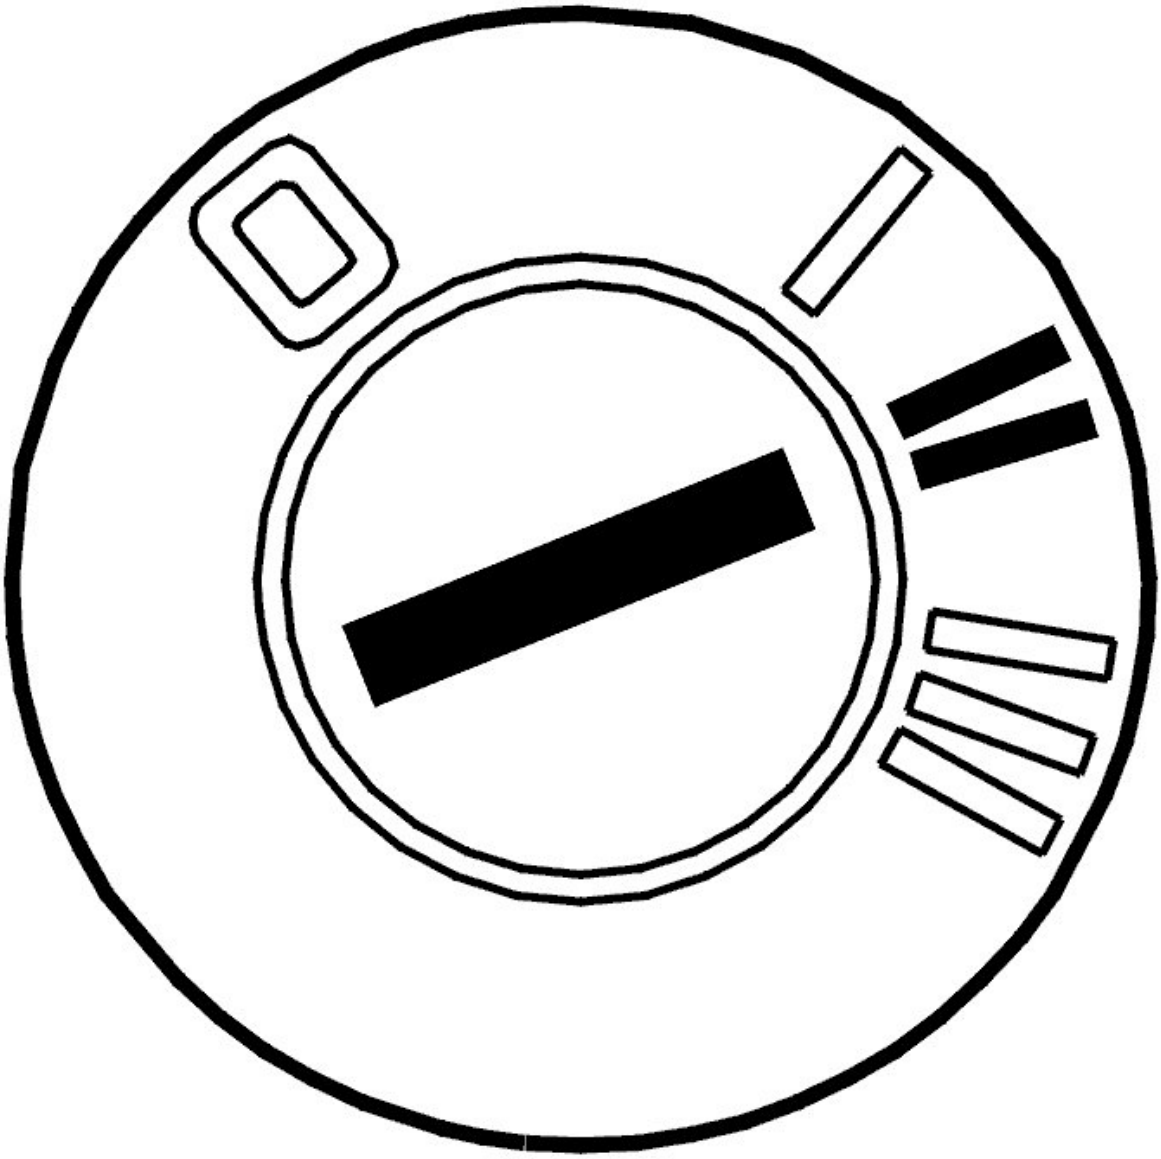


Was a fault detected?

Yes - Verification

No - Checking the amount of traffic on the LS-CAN

Checking voltage-drop in cable for CAN-H and CAN-L, respectively



- Connect the battery.
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

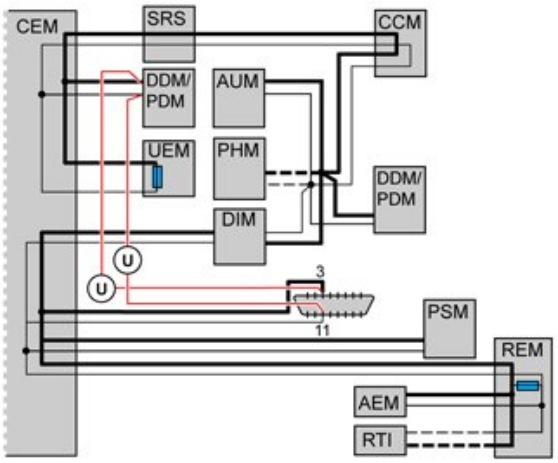
In principle, the voltage measured in each cable in the CAN-net shall be the same at each control module in the network. This means that the voltage-drop in the cable for CAN-H and CAN-L, respectively, between the control modules should be very low. If there is a voltage-difference in the CAN-lines between the diagnostics socket/Central electronic module (CEM) and a control module due to, e.g., contact resistance in a connector or branching, communication may be lost/interfered with. Check if there is voltage-drop in the cable for CAN-H and CAN-L between the diagnostics socket/Central electronic module (CEM) and the control module where there is problem with communication.
Carry out the following:
Measure voltage between the following connections on the OBDII-box/diagnostics socket.
- #3 and corresponding connection on relevant control module for CAN-H. The voltage shall be lower than 50 mV.
- #11 and corresponding connection on relevant control module for CAN-L. The voltage shall be lower than 50 mV.

If voltage is too high, this indicates too high contact resistance in cable, connector, or branching. Check the circuit between the diagnostics socket and control module in question for contact resistance and oxidation.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy wiring as necessary.

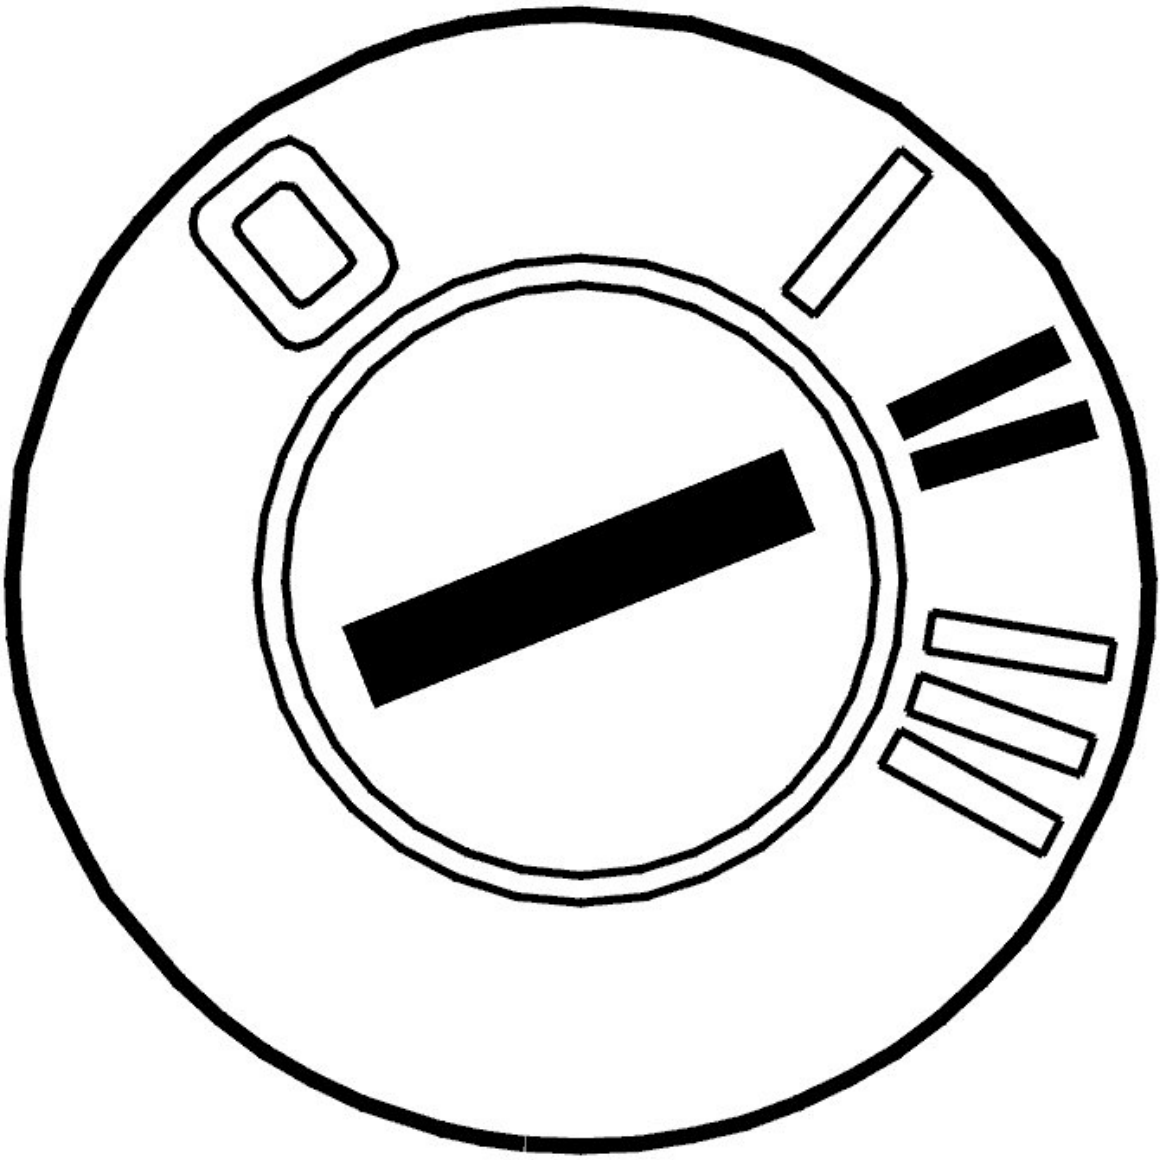
Other information
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

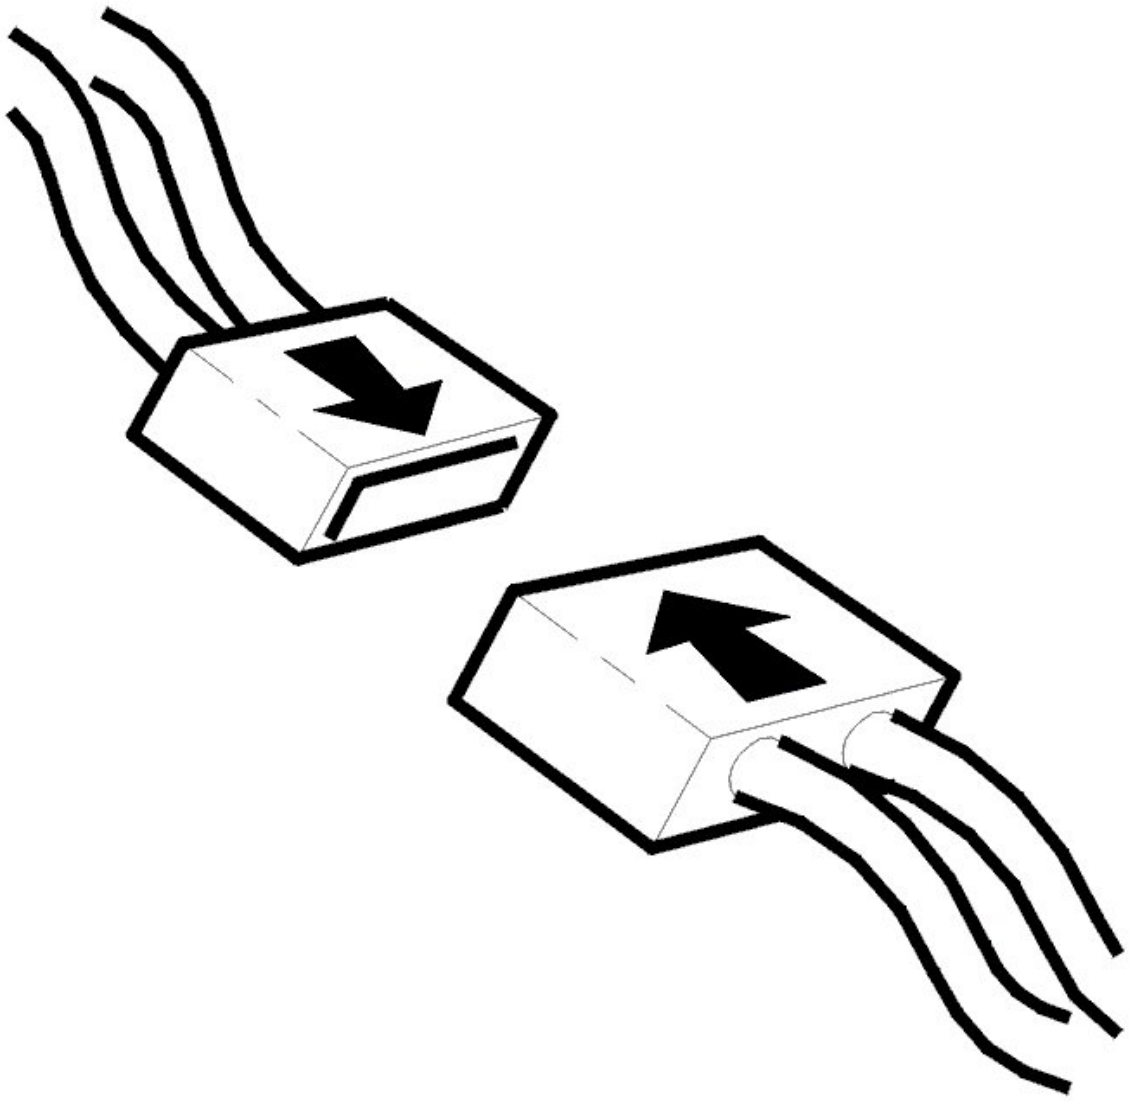


Continue - Verification

Checking the function of the phone module (PHM)

Hint: After carrying out the repair, check that the fault has been remedied.





- Ignition off
- Reconnect the connectors. Reinstall the components
- Ignition on.

Check that the phone module (PHM) is powered and grounded by pressing the ON/OFF button and then pressing the YES button. The LED in the ON/OFF button must light. A text message must appear in the display on the driver information module (DIM).

Does the LED in the ON/OFF button light?

Yes - Fault Found

No - Fault-tracing information

Fault-tracing information

Information

Fault-tracing information

The fault should have been detected and remedied. As this is not the case fault-tracing has failed.
Exit fault-tracing for this diagnostic trouble code (DTC) or make another attempt.

Do you want to exit fault-tracing?

Yes - FAULT-TRACING FAILED

No - Attempt New Test

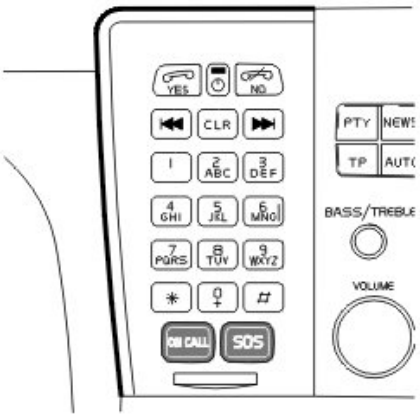
FAULT-TRACING FAILED - FAULT-TRACING FAILED

Attempt New Test - Checking the function of the phone module (PHM)

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CEM-1A59

Condition



The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers that communication with the audio module (AUM) is not operating.
The diagnostic trouble code (DTC) can be diagnosed when the ignition has been on for more than 10 seconds.

Note! In the event of CEM-1A5X diagnostic trouble codes (DTCs), the central electronic module (CEM) must not be replaced as the diagnostic trouble code (DTC) indicates a communication fault in the controller area network (CAN).

Substitute value
- None.

Possible source
- No power supply to the audio module (AUM)
- Open-circuit in the ground lead for the audio module (AUM)
- Contact resistance in the terminals
- Open-circuit in the wiring for the CAN low speed network to the audio module (AUM)
- The audio module (AUM) is not intended for this vehicle (for example a used control module with different software/hardware).

Hint: If several diagnostic trouble codes (DTCs) are stored in the central electronic module (CEM) for communication faults with other control modules in the low speed network, this indicates a common fault in the controller area network (CAN). See the relevant wiring diagram.

Fault symptom[s]
- The rheostat function on the audio system is not working.
- Cannot be controlled with the remote control.
- The radio buttons on the steering wheel do not function

Signal Missing

Signal missing

Checking the function of the audio module (AUM)

Check the power supply for the control module by switching on the radio or playing a CD. There must be sound from the radio or CD.

Note! Radio reception may be poor indoors. On certain cars, the radio reception may deteriorate if the trunk lid is open.

Is there sound from the radio?

Yes - Checking communication with the audio module (AUM)

No - Checking the power supply and ground for the audio module (AUM)

Checking the power supply and ground for the audio module (AUM)

Check the fuses for the main unit/audio module (AUM).

Note! If a fuse is blown, check the circuit after the fuse before replacing the fuse. Check for a short-circuit to ground. Then replace the fuse. For further information about the circuit after the fuse, see the relevant wiring diagram.

Check the connector for the main unit/audio module (AUM). Check for contact resistance and oxidation.
Check the power supply cable for the main unit/audio module (AUM). Check for an open-circuit.
Check the ground cable between the main unit/audio module (AUM) and the ground terminal. Check for an open-circuit. Also check the ground terminal. Check for contact resistance and oxidation.
Remedy as necessary.

- Connecting the breakout box, Audio control module See: Accessories and Optional Equipment/Cellular Phone/Communications Control Module/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box
- Signal specification, audio control module See: Accessories and Optional Equipment/Cellular Phone/Communications Control Module/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Specification
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

Was a fault detected?

Yes - Checking the function of the audio module (AUM)

No - Signal missing

Checking communication with the audio module (AUM)

Hint: The CAN communication with the control module is probably OK if the control module ID can be read off. The fault is probably intermittent and may therefore be difficult to locate.

- Try to communicate with the audio module (AUM) by reading off the control module ID
- Click on the symbol for VCT2000 to begin reading off

Continue - Signal missing

Signal missing

General information

Note! Figures shown are only examples.

Hint: For general information about CAN-troubleshooting, see:

- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

General about CAN-related diagnostic trouble codes.
CEM-DF01 - DF17can only be stored in Central electronic module (CEM). These diagnostic trouble codes are stored when an electric fault is detected in CAN-lines. Start with these diagnostic trouble codes first.
CEM-1AXX only stored in Central electronic module (CEM). One diagnostic trouble code for every control module on the CAN-net. These diagnostic trouble codes indicate that Central electronic module (CEM) does not receive any reply from other control modules.

XXX-E000 (HS-CAN)/E001 (LS-CAN) can be stored in all CAN-connected control modules. These diagnostic trouble codes indicate that the control module has detected interference on the CAN-net.
XXX-E003 can be stored in all CAN-connected control modules except in Central electronic module (CEM). The control modules on the CAN-net listen for a message (identity number) that is sent out at regular intervals from Central electronic module (CEM). This diagnostic trouble code indicates that the control module has not received any identity number, or that the expected number is not correct. Interference on the CAN-net can also store this diagnostic trouble code.

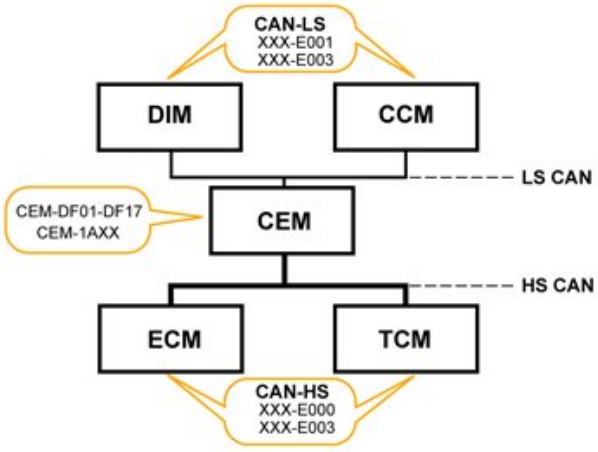
Note! In case of CAN-related faults, it is likely that a combination of above diagnostic trouble codes occur.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

If diagnostic trouble codes (DTCs) for communication faults can be read off from a control module, the fault is probably intermittent.
Intermittent fault in the voltage supply and ground to a control module on the CAN network results in the Central electronic module (CEM) storing a diagnostic trouble code (DTC) for an open-circuit in communication with the control module where the voltage supply does not work. There will probably not be a diagnostic trouble code (DTC) in the control module where the open-circuit in the voltage supply occurred as the control module cannot store a diagnostic trouble code (DTC) when it is not supplied with power.

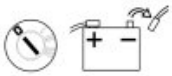
Note! Central electronic module (CEM) should not be replaced in case of CAN-fault, unless troubleshooting reveals that Central electronic module (CEM) has an internal fault.

Caution! During this fault-tracing use the wiring diagram to provide support when taking readings.



Continue - Checking resistance in CAN-net

Checking resistance in CAN-net



- Ignition off
- Disconnect the battery negative lead
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #3 and #11. The resistance should be approx. 55 - 65 ohms.
- If resistance is approx. 120 ohms, this indicates open circuit in the circuit so that only one terminating resistor (120 ohms) has been measured.
- If resistance is above 1 kohms this indicates open circuit/high contact resistance somewhere in the circuit.
- If resistance is below 55 ohms this indicates short-circuiting/contact resistance between the CAN-lines somewhere in the circuit.

Hint: For LS-CAN (Low Speed), terminating resistors are located in Upper electronic module (UEM) and Rear electronic module (REM).

Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

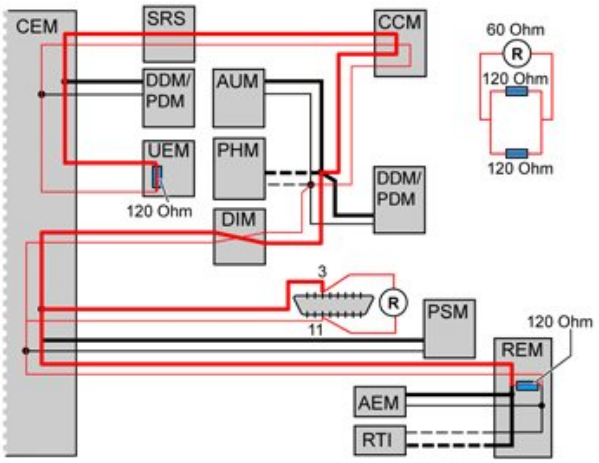
Note! Resistance measurement measures only main lines in the CAN-net (in circuit where both terminating resistors are found), not branches to certain control modules. See wiring diagram for vehicle model in question. Open circuit on branching without a terminating resistor cannot be detected with this measurement. However, short-circuiting on a branch can be detected. To measure resistance in the CAN-net to control modules located in a branching of their own, the measurement shall be done against the CAN-net at that control module. The values shall be as above.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy as necessary.

Other information

- Battery, disconnecting See: Starting and Charging/Battery/Service and Repair/Procedures/Battery, Disconnecting
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

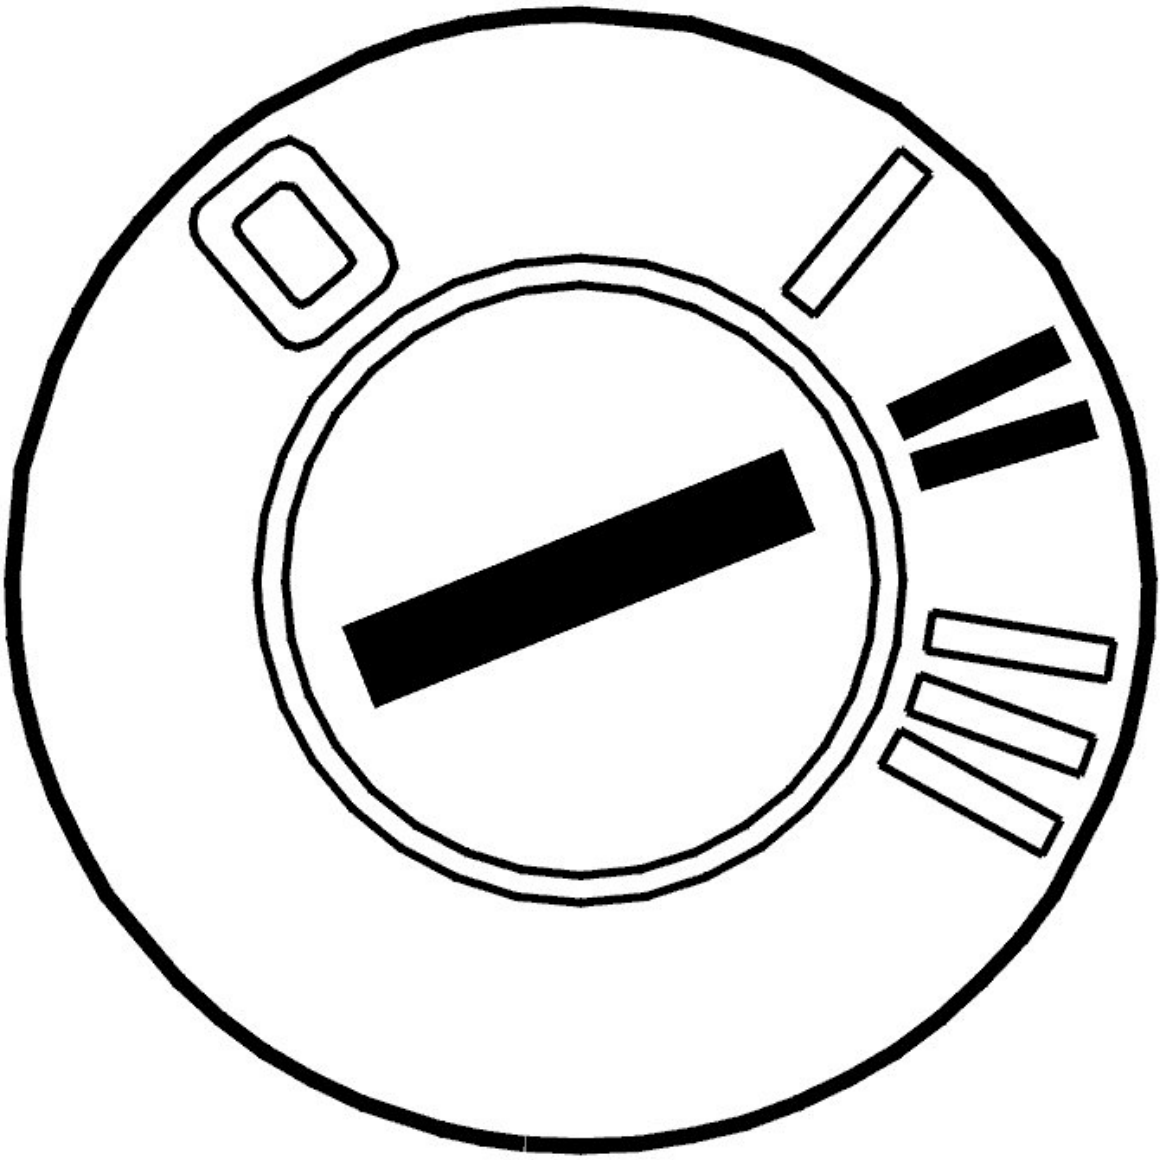


Was a fault detected?

Yes - Verification

No - Checking short-circuiting to ground/voltage in CAN-net

Checking the amount of traffic on the LS-CAN



- Connect the battery
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
Faults in the CAN network may be due to a control module sending faulty messages that disrupt normal communication. When messages are sent incorrectly, this results in a considerable increase in the amount of traffic on the CAN network. The load can be checked by reading the average value of the voltage on the CAN cables in relation to ground.
For further information, see the wiring diagram.
Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #3 and #4 (ground). The voltage should be approx: 2,8 - 3,2 V.
- #11 and #4 (ground). The voltage should be approx: 1,8 - 2,2 V.
- #3 and #11. The voltage shall be between approx. 0.55-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Hint: DiCE Error Frame Finder can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools: **951 3010** (memory card) as well as associated TJ 20402.

- Ignition on.
- Connect DiCE Error Frame Finder to the diagnostics socket.
- Note the blue LED-indicator. The indicator flashes to show detection of fault messages.

Note! Certain interference may occur without any real fault!

Cable fault

- Shake the cables lightly and pull lightly on the connections during the check to locate any fault. Note the blue LED-indicator.

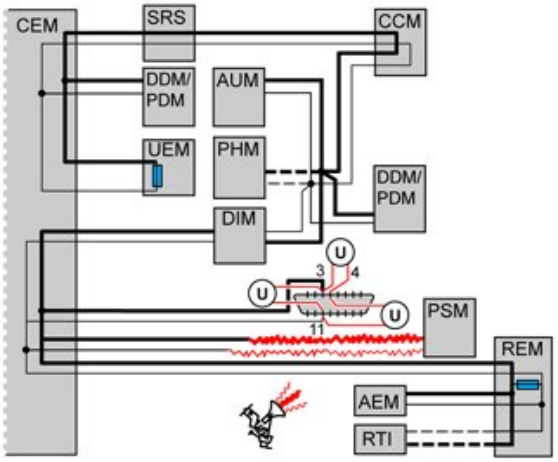
"Chatting" control modules

- "Chatting" control modules may be difficult to find and troubleshooting may take time. Let the vehicle stand with DiCE connected for an extended time period. Afterwards, activate functions to provoke a malfunction. It may take up to several hours before the fault messages are sent. When the indicator starts to flash, remove the fuse for one control module at a time until the indicator stops flashing. When the indicator stops flashing, restore the fuse for the relevant control module and check that the indicator starts to flash again. Then it is likely that the problem is identified.

Remedy wiring as necessary.

Other information

- Battery, disconnecting See: Starting and Charging/Battery/Service and Repair/Procedures/Battery, Disconnecting
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals



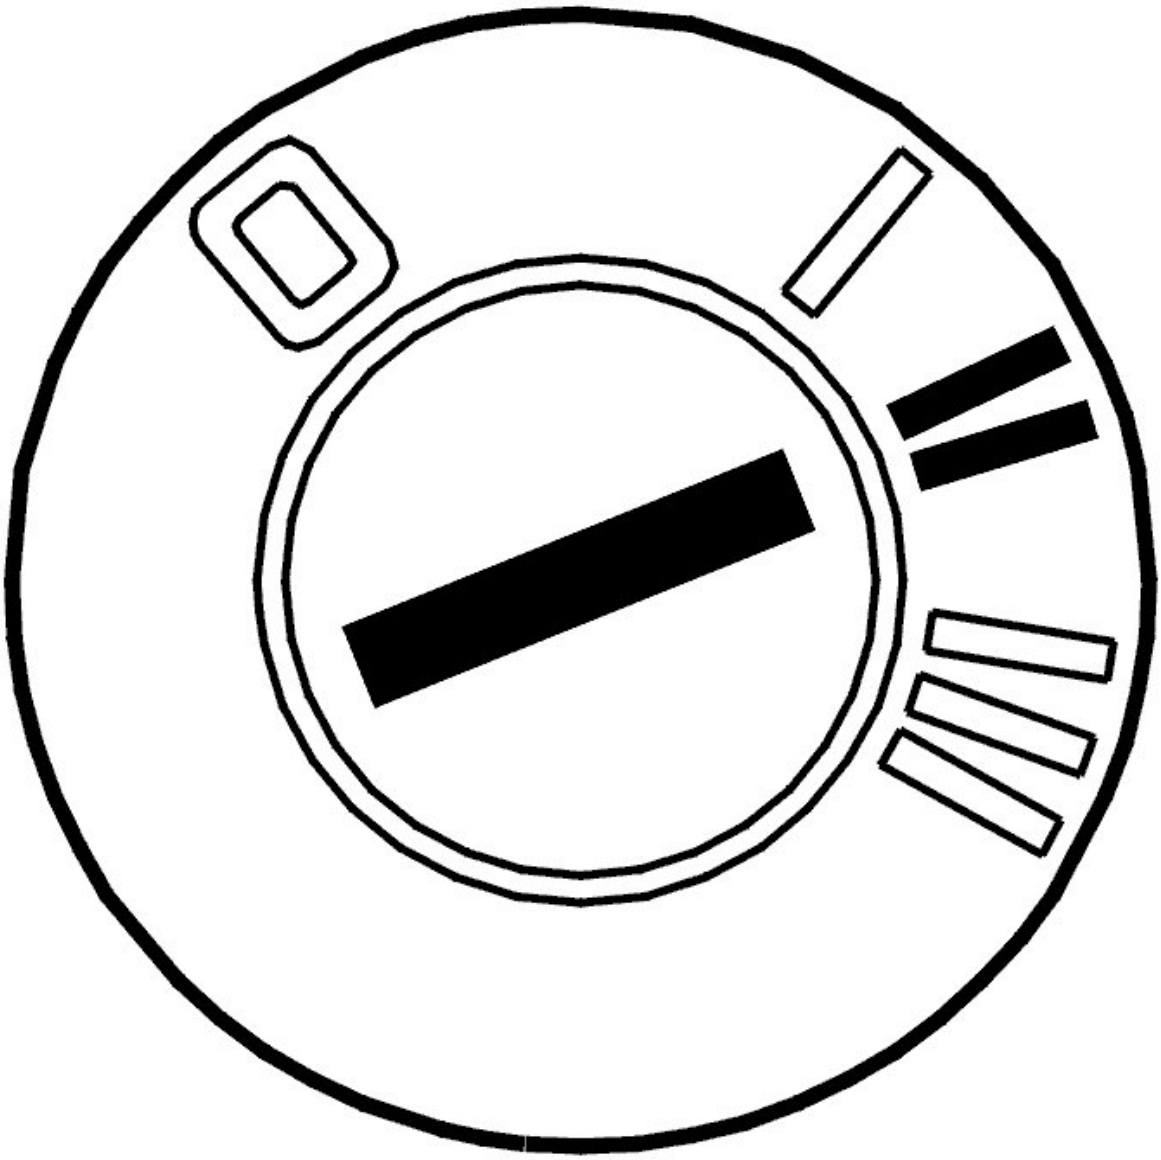
Was a fault detected?

Yes - Identifying a control module in the CAN network

No - Checking voltage-drop in cable for CAN-H and CAN-L, respectively

---

Identifying a control module in the CAN network



Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:

- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Hint: DiCE Error Frame Finder can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools: **951 3010** (memory card) as well as associated TJ 20402. If the load on the CAN network is too high, this may be due to a control module transmitting faulty messages on the CAN network. This is called a disruptive control module. The fault may also be due to an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The fault may occur without any of the control modules storing a diagnostic trouble code (DTC). The voltage can be measured between the CAN cables in order to check the load on the CAN network.

Note! It is not necessarily the control module that has set the diagnostic trouble code that communicates incorrectly. Faulty messages can come from any control module in the same section of the CAN network. However, faulty communication in one network cannot affect the communication on the other network. In other words, faulty communication on the LS-CAN cannot disrupt communication on the HS-CAN and vice versa.

- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Check communication/load on CAN-net by measuring voltage between CAN-L and CAN-H. Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #3 and #11. The average value of the voltage must be approximately 0.6-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

In order to identify which control module has faulty communication, cut the power supply to one control module at a time. Check the voltage in the CAN cables again. The easiest way to cut the power supply is to remove the fuse(s) for the relevant control module. Repeat until the voltage

between the CAN wiring drops to the normal level.

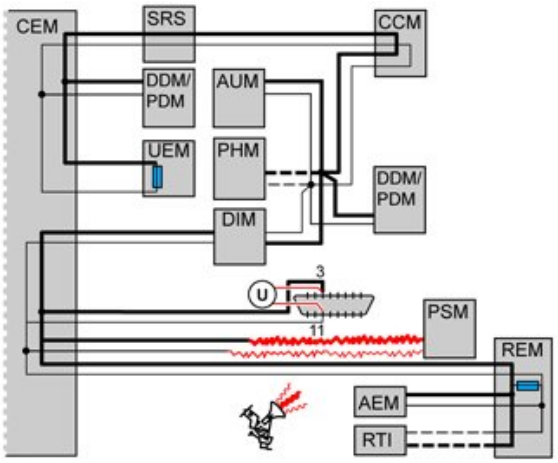
Note! When connecting and disconnecting certain control modules, diagnostic trouble codes (DTCs) may be stored in other control modules.

Hint: When the suspected defective control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the malfunction appears and disappears. Switch off the ignition between each check.

Note! Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.

A control module that is communicating incorrectly must be replaced. See Repairing and installing/Removing, replacing and installing.

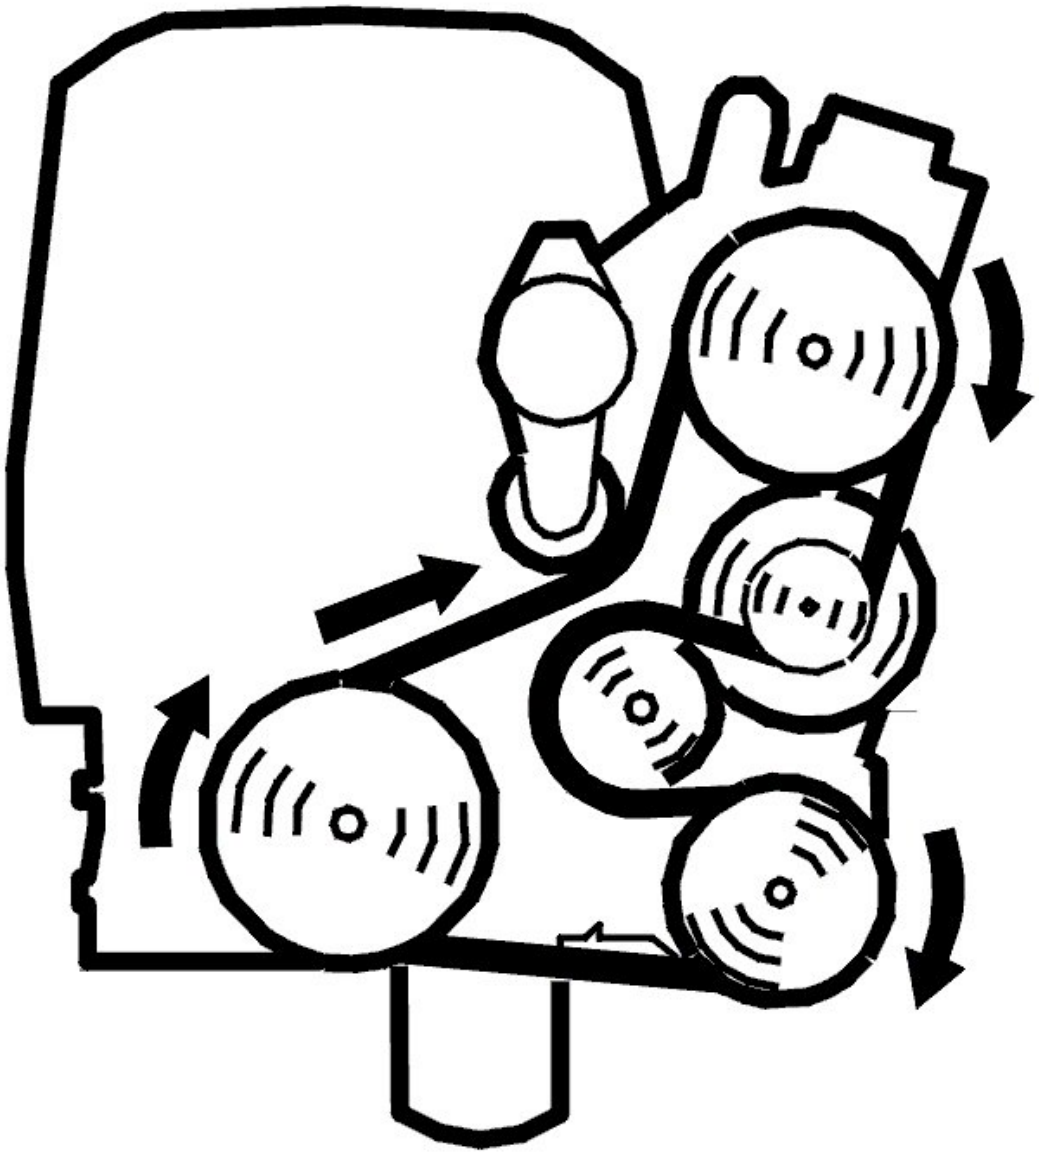
Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

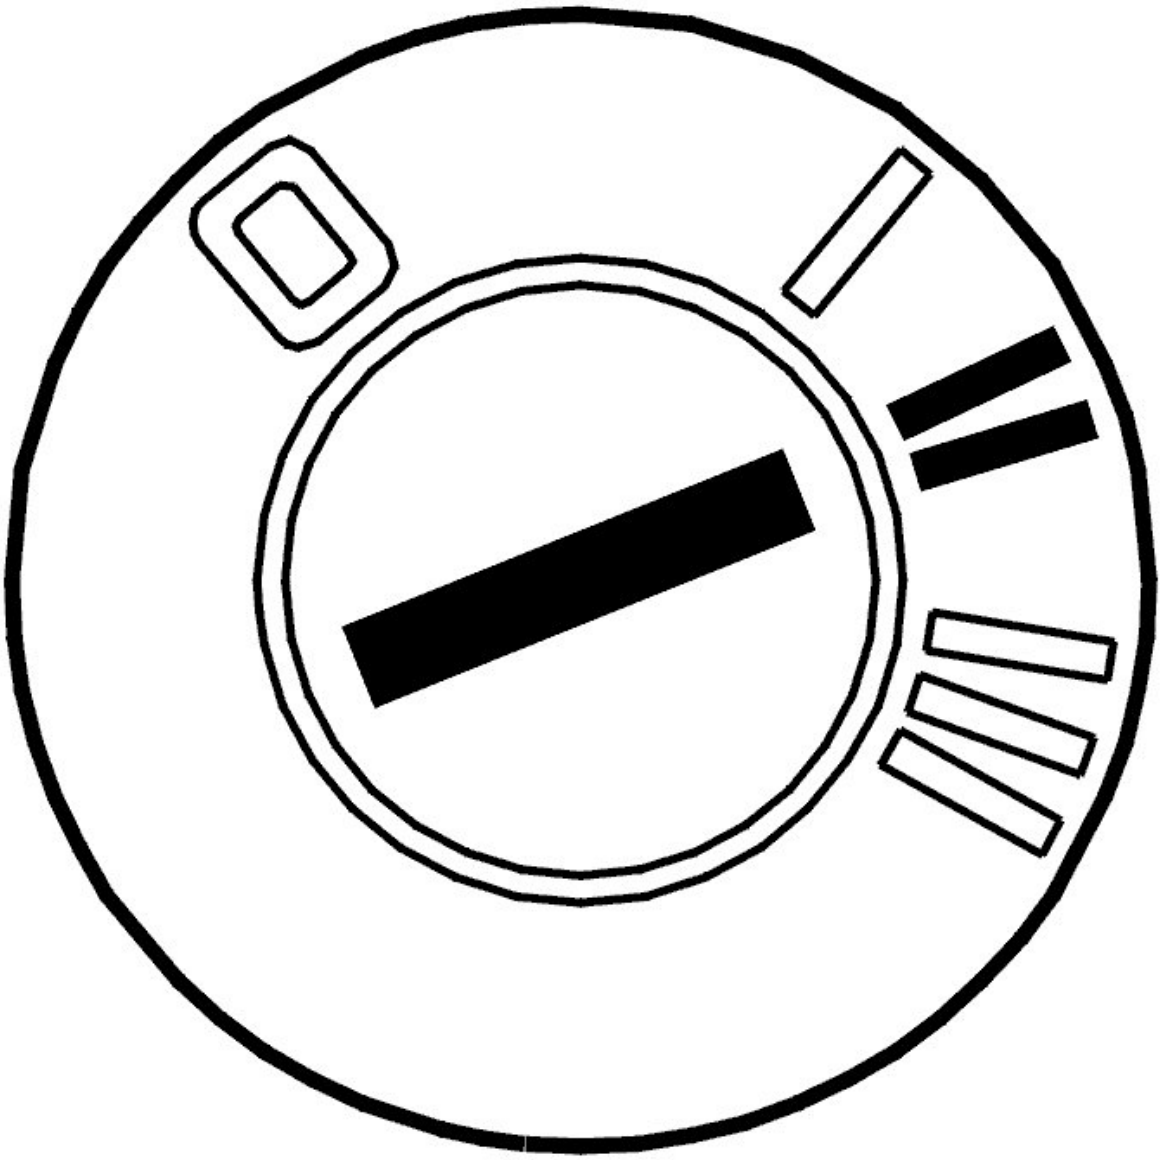


Continue - Verification

Verification

Hint: After rectifying a fault, a verification should be carried out.





- Reinstall the connectors, components etc.
- Ignition on.

Note! For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

- Erase diagnostic trouble codes (DTCs) in all control modules.
- Ignition off.
- Ignition on.
- Start the vehicle. Allow the vehicle to run for 10 minutes. Start the engine. Allow the engine to run at idle speed for 10 minutes
- Read out the diagnostic trouble codes in the vehicle via the DIAGNOSTICS tab.

Does the diagnostic trouble code (DTC) for faulty communication return?

Yes - Fault-tracing information

No - Fault Found

Fault-tracing information

Information

Fault-tracing information

The fault should have been detected and remedied. As this is not the case fault-tracing has failed.
Exit fault-tracing for this diagnostic trouble code (DTC) or make another attempt.

Do you want to exit fault-tracing?

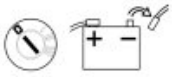
Yes - **FAULT-TRACING FAILED**

No - **Attempt New Test**

FAULT-TRACING FAILED - **FAULT-TRACING FAILED**

Attempt New Test - Signal missing

Checking short-circuiting to ground/voltage in CAN-net



- Ignition off.
- Disconnect the battery negative lead.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Checking for a short-circuit to ground

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #3 and #4 (ground). Measurement is shown in the figure. The resistance should be above 1 kohms.
- #11 and #4 (ground). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and ground.

Checking for a short-circuit to voltage

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #3 and #16 (voltage). Measurement is shown in the figure. The resistance should be above 1 kohms.
- #11 and #16 (voltage). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and voltage cable.
Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

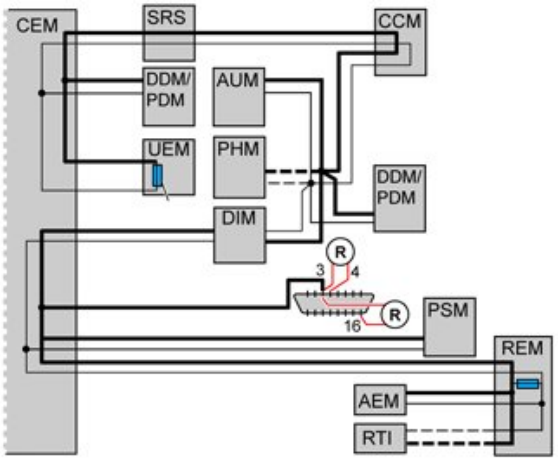
Hint: Part the CAN-net at suitable points to decide where a short-circuit may be found.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy as necessary.

Other information
- Battery, disconnecting See: Starting and Charging/Battery/Service and Repair/Procedures/Battery, Disconnecting
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

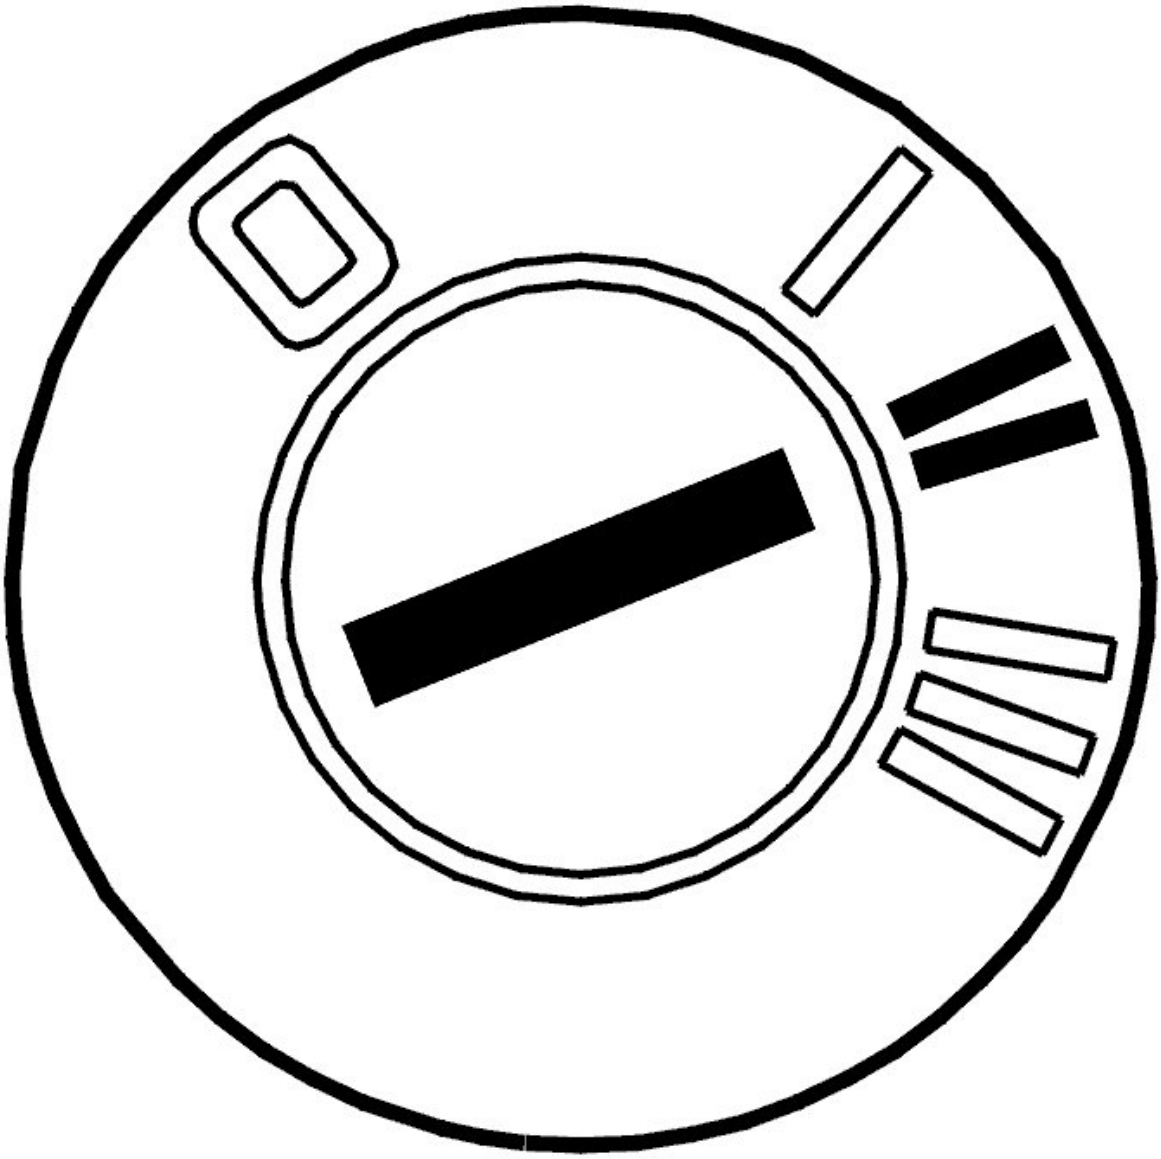


Was a fault detected?

Yes - Verification

No - Checking the amount of traffic on the LS-CAN

Checking voltage-drop in cable for CAN-H and CAN-L, respectively



- Connect the battery.
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

In principle, the voltage measured in each cable in the CAN-net shall be the same at each control module in the network. This means that the voltage-drop in the cable for CAN-H and CAN-L, respectively, between the control modules should be very low. If there is a voltage-difference in the CAN-lines between the diagnostics socket/Central electronic module (CEM) and a control module due to, e.g., contact resistance in a connector or branching, communication may be lost/interfered with. Check if there is voltage-drop in the cable for CAN-H and CAN-L between the diagnostics socket/Central electronic module (CEM) and the control module where there is problem with communication.
Carry out the following:
Measure voltage between the following connections on the OBDII-box/diagnostics socket.
- #3 and corresponding connection on relevant control module for CAN-H. The voltage shall be lower than 50 mV.
- #11 and corresponding connection on relevant control module for CAN-L. The voltage shall be lower than 50 mV.

If voltage is too high, this indicates too high contact resistance in cable, connector, or branching. Check the circuit between the diagnostics socket and control module in question for contact resistance and oxidation.
