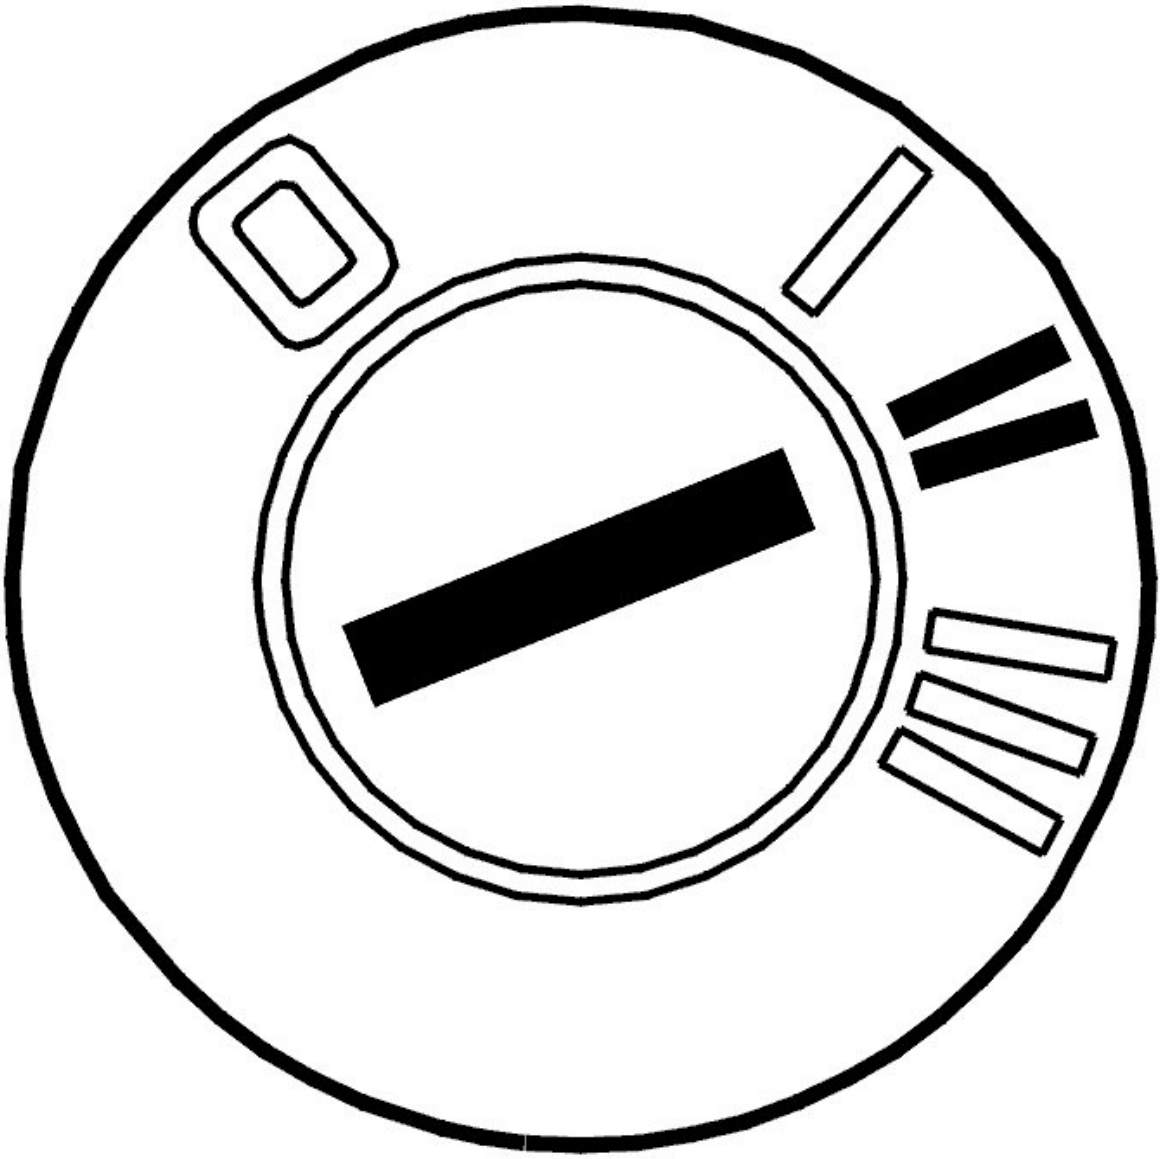
Hint: The transmission has torque controlled adaptive pressure control. Pressure control means that the transmission regulates the pressure itself during each gear shift. This avoids harsh gear shifting. Each gear shift is evaluated by the control module and stored in the memory. This allows for compensation for wear and tear in the transmission and clutch. It is important that the adaptation in the memory is reset after the transmission has been repaired. This is to ensure normal operation. The oil is replaced during repair; the "Transmission oil change" counter must be reset. If the counter is not reset when the fluid is drained and replaced, there is a risk that a diagnostic trouble code (DTC) will be stored in incorrect circumstances.

Note! This applies only if the transmission or one of the components in the transmission have been replaced.



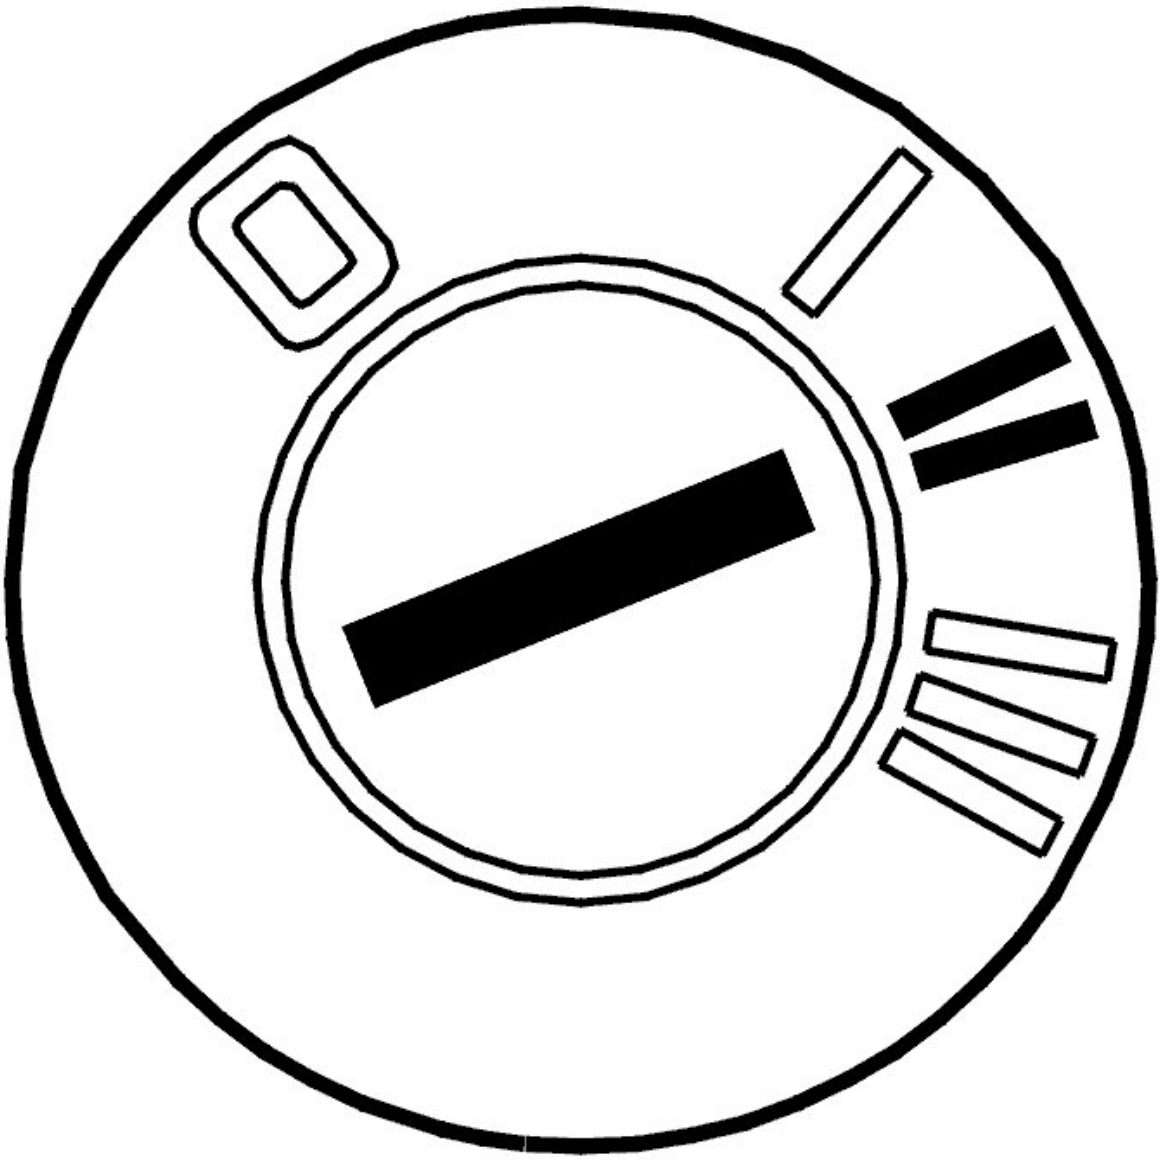
- Ignition on.

Click on the VCT2000 symbol to reset the adaptation and counter.

Continue - Verification

Verification

Hint: After carrying out the repair, check that the fault has been remedied.



- Ignition on
- Gear selector in position P
- Activate solenoid S1.

The current should oscillate between 0 and approximately 1.5 A.

Does the current oscillate?

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition

Shift solenoids S1, S2, S3, S4 and S5 operate in tandem to control gear-shifting. The solenoids are controlled by power stages in the transmission control module (TCM). The transmission control module (TCM) opens the power stages to activate the solenoids and sends a voltage through the circuit. Diagnostic trouble codes (DTCs) TCM-0001, TCM-0007, TCM-0101 TCM-0107 or TCM-010A are stored (depending on the solenoid)if the transmission control module (TCM) registers that the signal in circuits S1, S2, S3, S4 or S5 is too high when the solenoid should not be activated.

Substitute value

- The transmission control module (TCM) "Emergency mode I" program has been initiated.

Possible source

- Short-circuit to supply voltage in the signal cable.
- Internal fault in the control module.

Fault symptom[s]

- General orange warning lamp lit.
- Malfunction indicator lamp (MIL) lit.
- Harsh gear shifting.
- No shifting.
- No lock-up function.

Signal Too High

Signal too high

Resetting the adaptation and oil quality counter

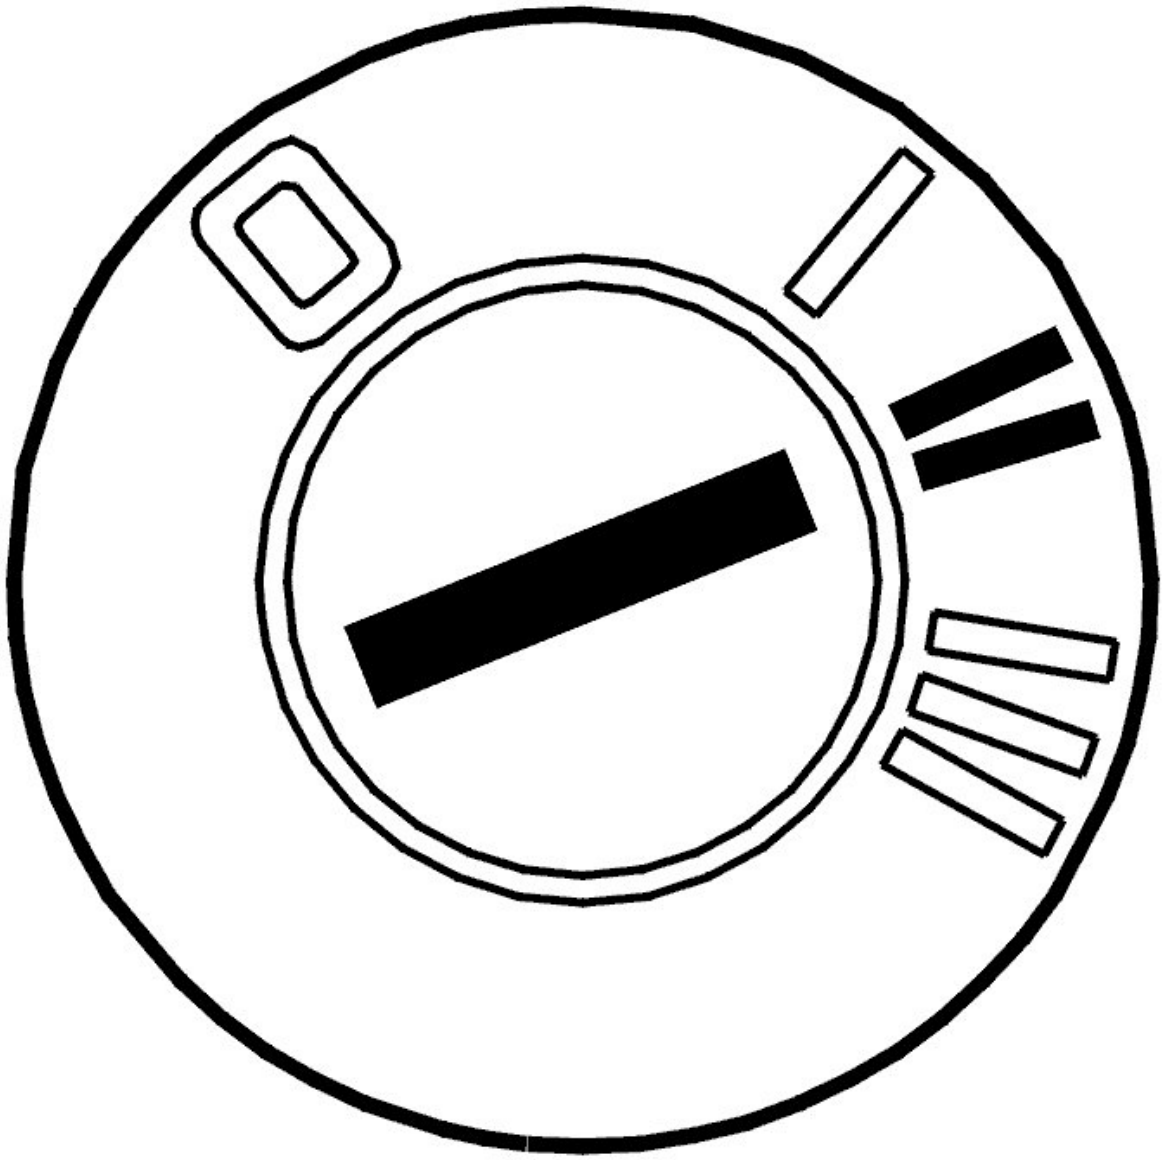
Resetting the adaptation

Resetting adaptation and the counter for "Transmission oil change"

Hint: The transmission has torque controlled adaptive pressure control. Pressure control means that the transmission regulates the pressure itself

during each gear shift. This avoids harsh gear shifting. Each gear shift is evaluated by the control module and stored in the memory. This allows for compensation for wear and tear in the transmission and clutch. It is important that the adaptation in the memory is reset after the transmission has been repaired. This is to ensure normal operation. The oil is replaced during repair; the "Transmission oil change" counter must be reset. If the counter is not reset when the fluid is drained and replaced, there is a risk that a diagnostic trouble code (DTC) will be stored in incorrect circumstances.

Note! This applies only if the transmission or one of the components in the transmission have been replaced.



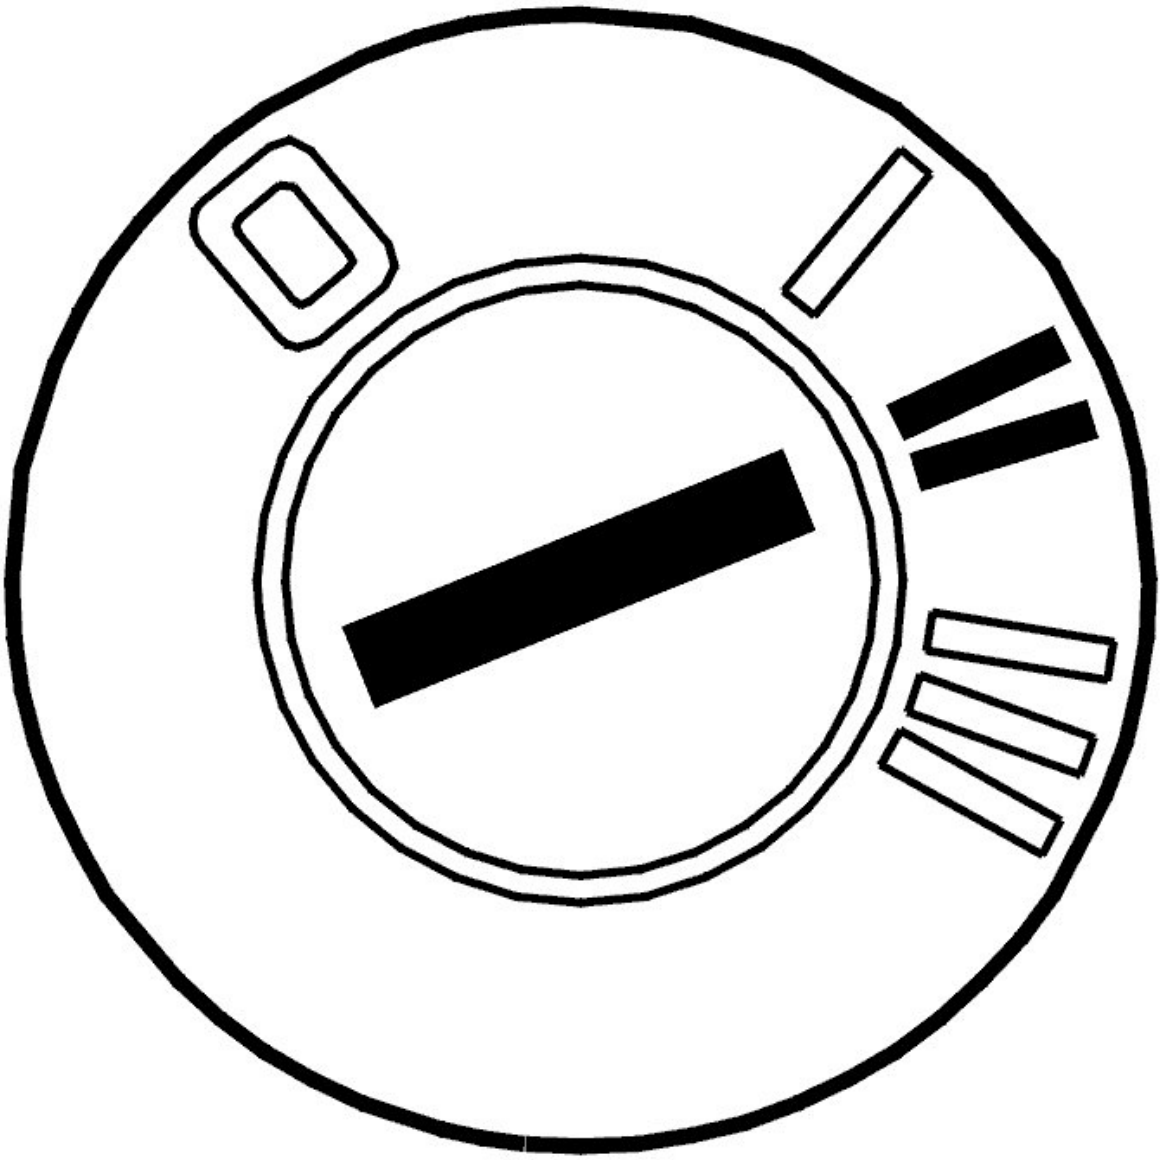
- Ignition on.

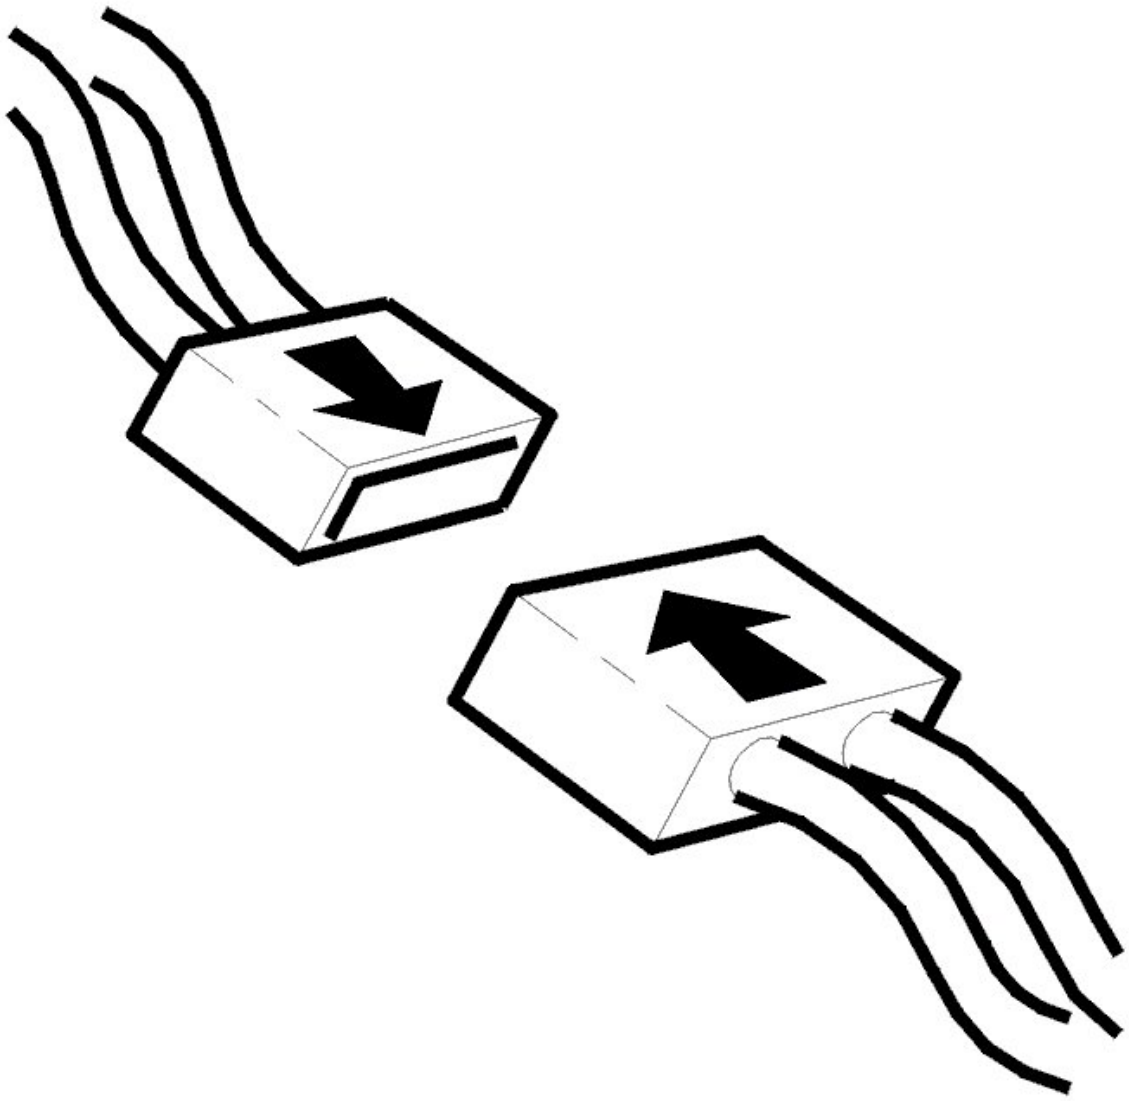
Click on the VCT2000 symbol to reset the adaptation and counter.

Continue - Verification

Verification

Hint: After the repair it is necessary to check that the fault has been rectified.





- Ignition off.
- Wait for at least 90 seconds.
- Connect the connectors, install the components etc.
- Ignition on.
- Gear selector in position P.
- Activate solenoid S2.

The value should change between OFF and ON.

Does the value change?

Yes - VERIFIED

No - VERIFICATION FAILED

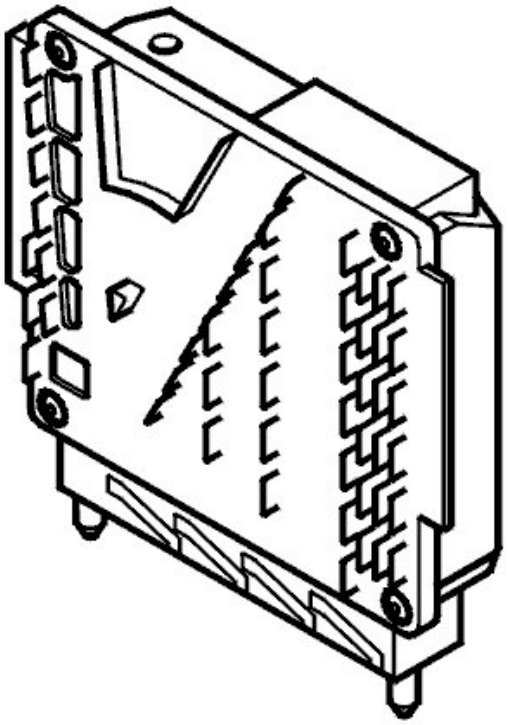
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition



Shift solenoids S1, S2, S3, S4 and S5 operate in tandem to control gear-shifting. The solenoids are controlled by power stages in the transmission control module (TCM). The transmission control module (TCM) opens the power stages to activate the solenoids and sends a voltage through the circuit. Diagnostic trouble codes (DTCs) TCM-0002, TCM-0008, TCM-0102, TCM-0108 or TCM-010B are stored (depending on the solenoid) if the transmission control module (TCM) registers that the signal in circuits S1, S2, S3, S4 or S5 is missing when the solenoid is activated.

Substitute value
- The transmission control module (TCM) "Emergency mode I" program has been initiated.

Possible source
- Contact resistance in terminals.
- Open-circuit in the signal cable.
- Defective solenoid.
- Internal fault in the control module.

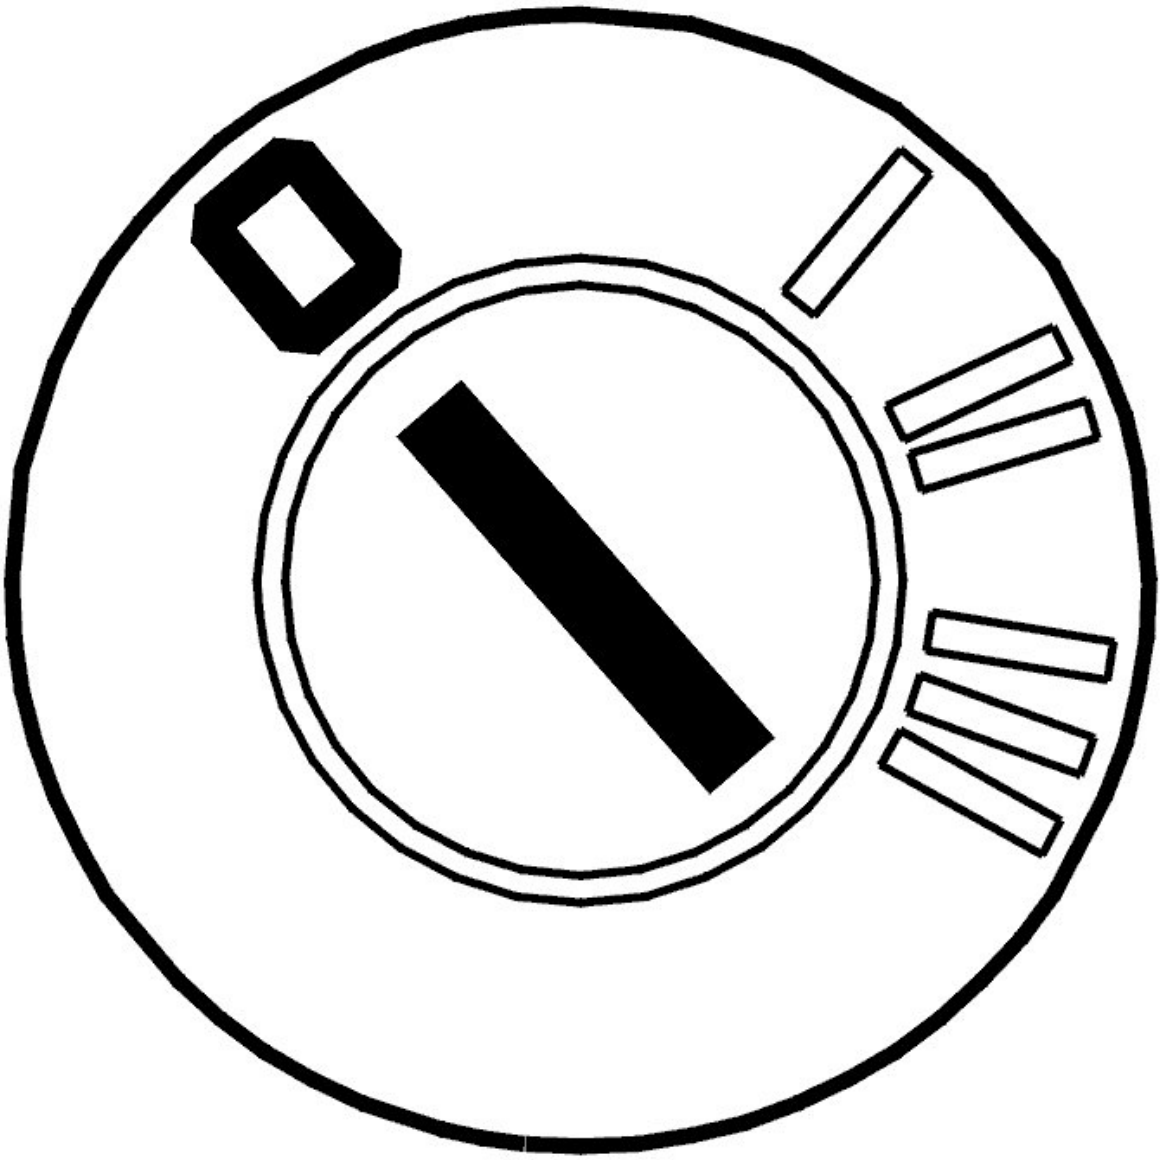
Fault symptom[s]
- General orange warning lamp lit.
- Malfunction indicator lamp (MIL) lit.
- Harsh gear shifting.
- No shifting.
- No lock-up function.

Signal Missing

Signal missing

Checking the temperature sensor

Hint: In some cases, the diagnostic trouble code (DTC) may be caused by a defective oil temperature sensor. Check the function of the oil temperature sensor first.



- Ignition off
- Read off the oil temperature.

Check that the function of the temperature sensor is OK. Test drive the car to increase the temperature of the transmission fluid. Read off the temperature again. Check that the temperature has increased.

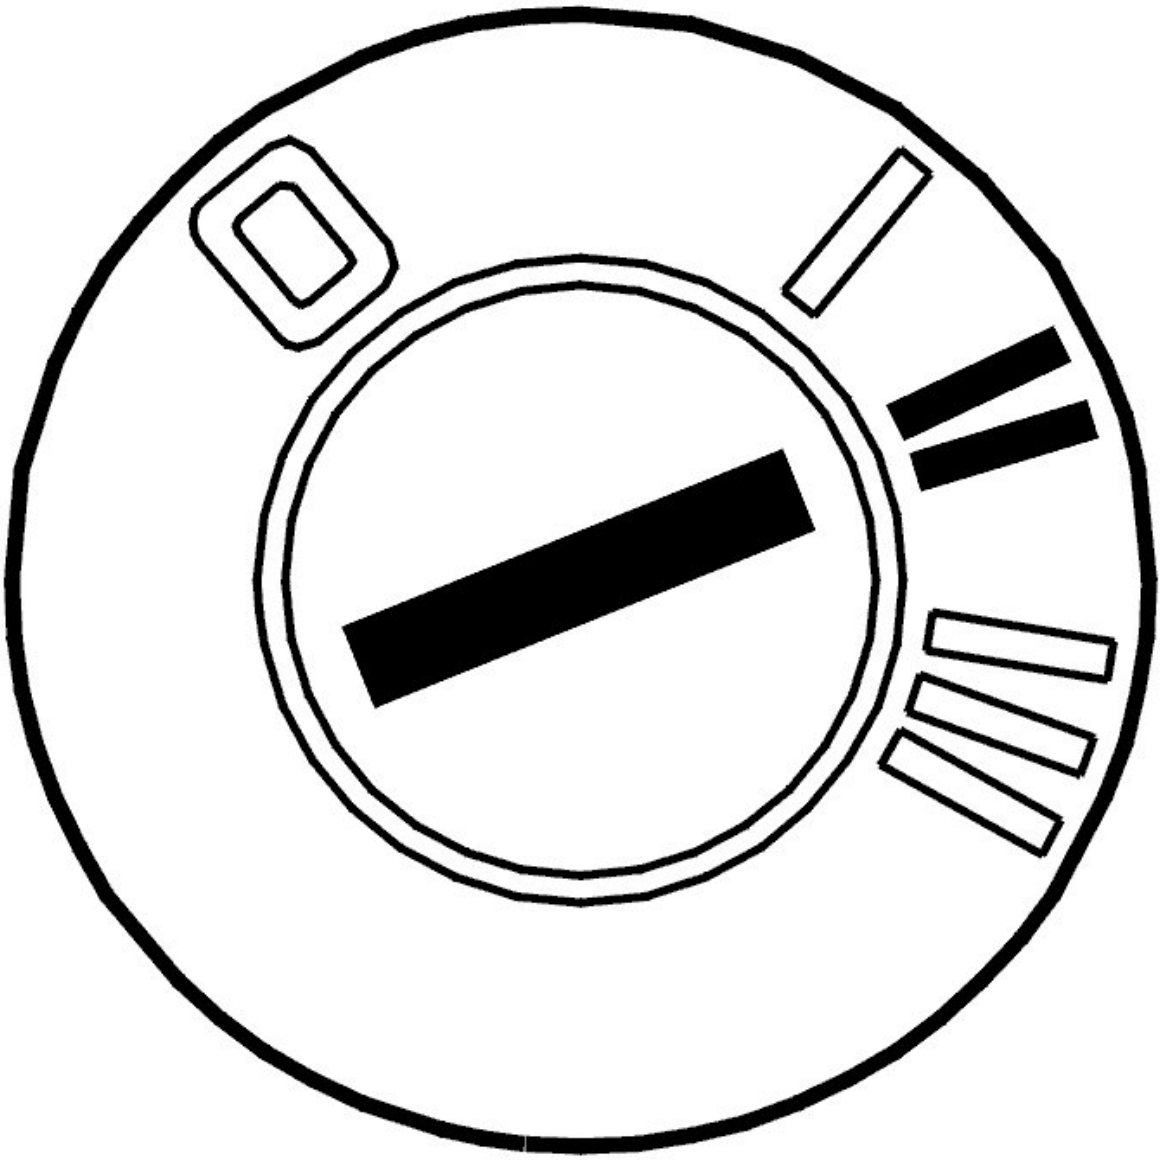
Hint: If the temperature is outside its permitted range, fault-trace the temperature sensor.

Is the oil temperature within its permitted range?

Yes - Checking shift solenoid S2

No - Checking transmission fluid temperature sensor

Checking shift solenoid S2



- Ignition on
- Gear selector in position P
- Activate solenoid S2.

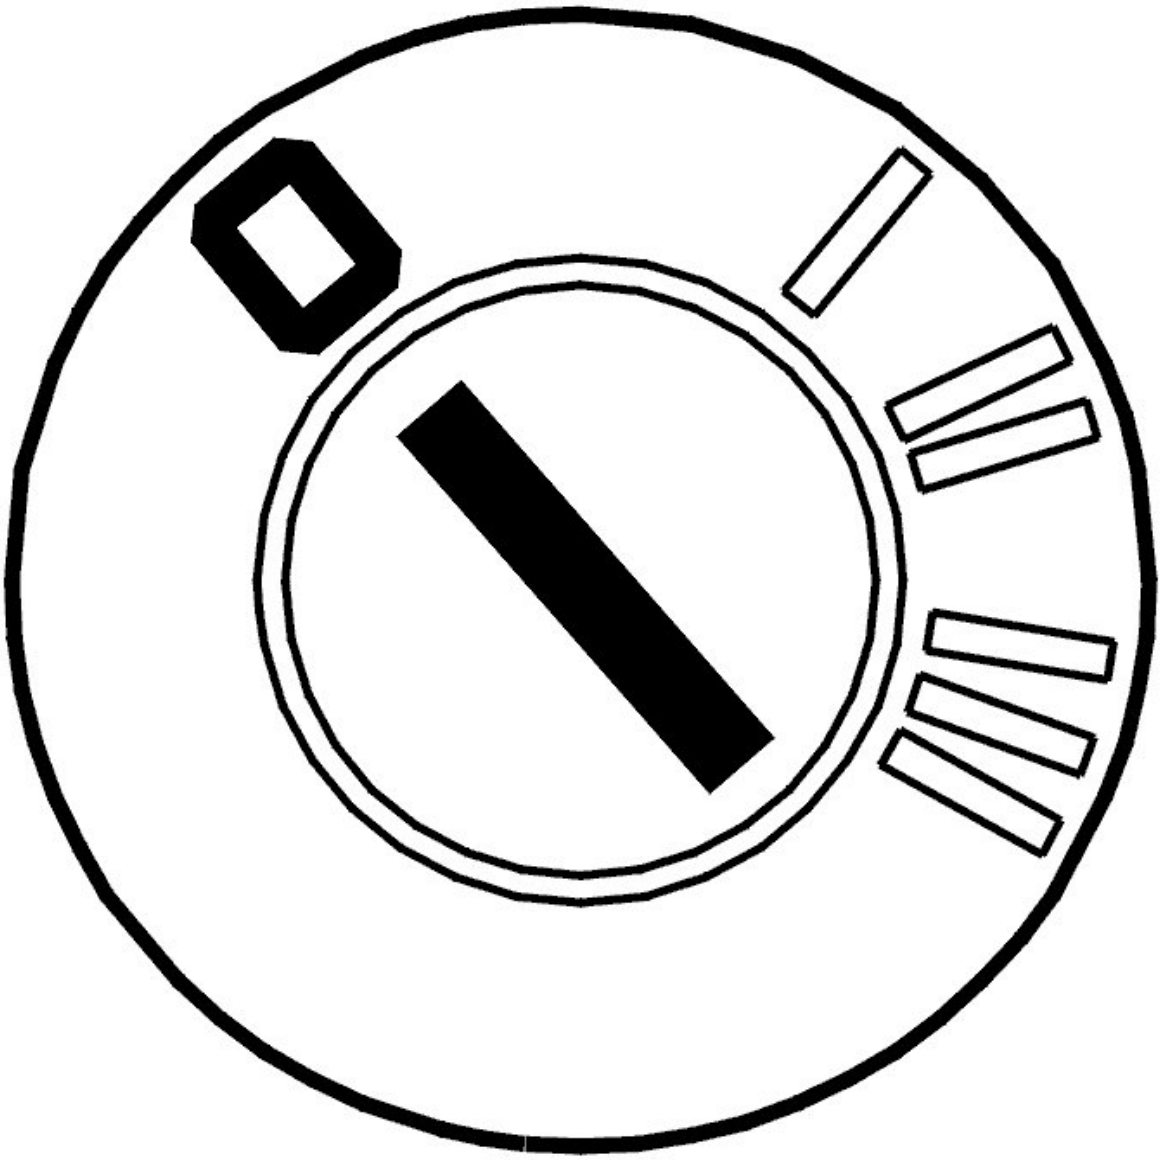
The current should oscillate between 0 and approximately 1.5 A.

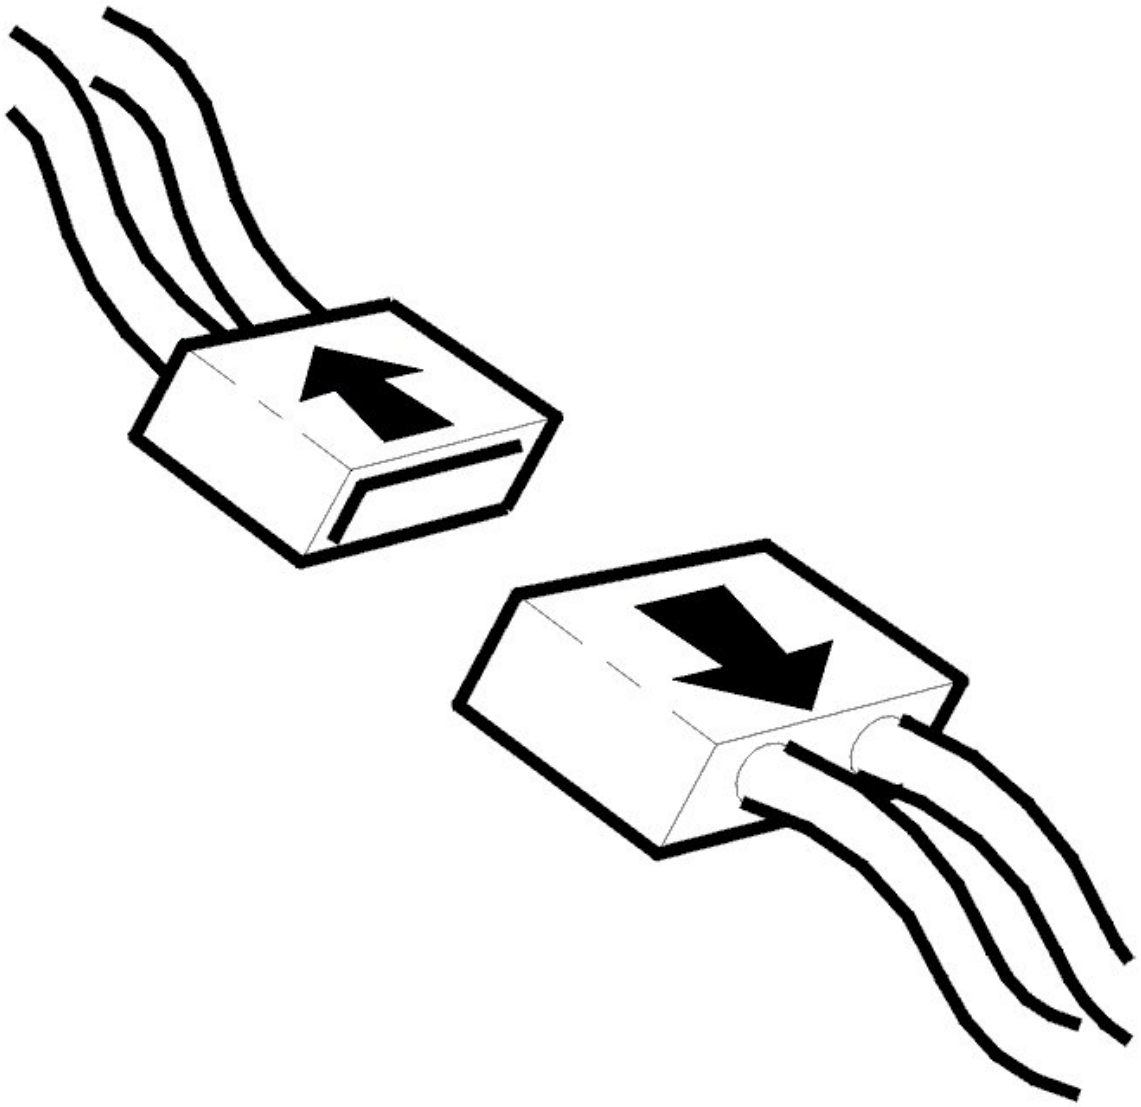
Does the current oscillate?

Yes - Intermittent fault

No - Checking resistance

Checking resistance



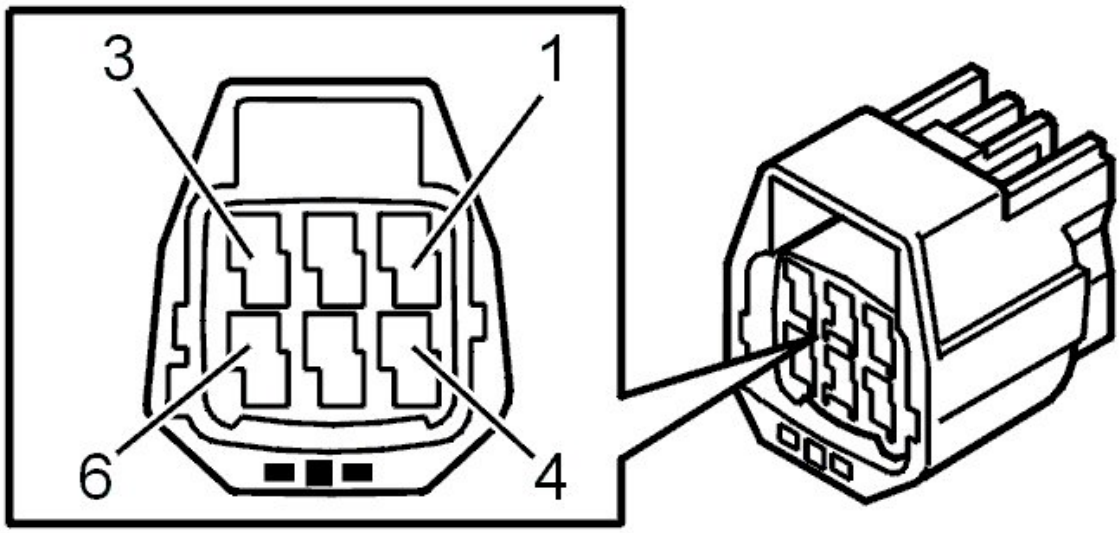


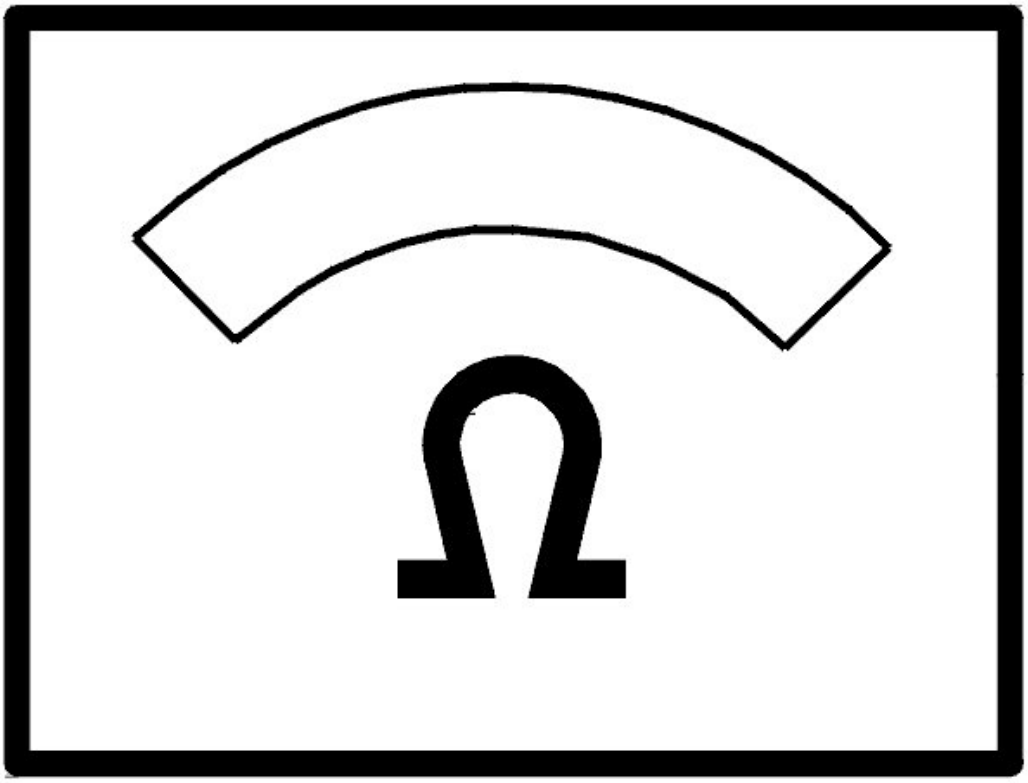
- Ignition off
- Disconnect transmission connector C.

Check solenoid S2. Measure the resistance between transmission connector terminal #C2 and the transmission housing. The resistance should be 11-15 ohms at 20°C.

Other information:

- To disconnect the transmission connectors, see Connectors transmission, disconnecting / connecting See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Wiring Harness/Service and Repair/Procedures
- For information about signals, see Signal description. Transmission control module (TCM), AW50/51 AWD, AW55-50/51SN See: Transmission Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Description. Transmission Control Module (TCM).





Was the resistance OK?

Yes - Checking the wiring

No - Checking the wiring and component

Checking the wiring

- For information about signals, see Signal description. Transmission control module (TCM), AW50/51 AWD, AW55-50/51SN See: Transmission Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Description. Transmission Control Module (TCM).

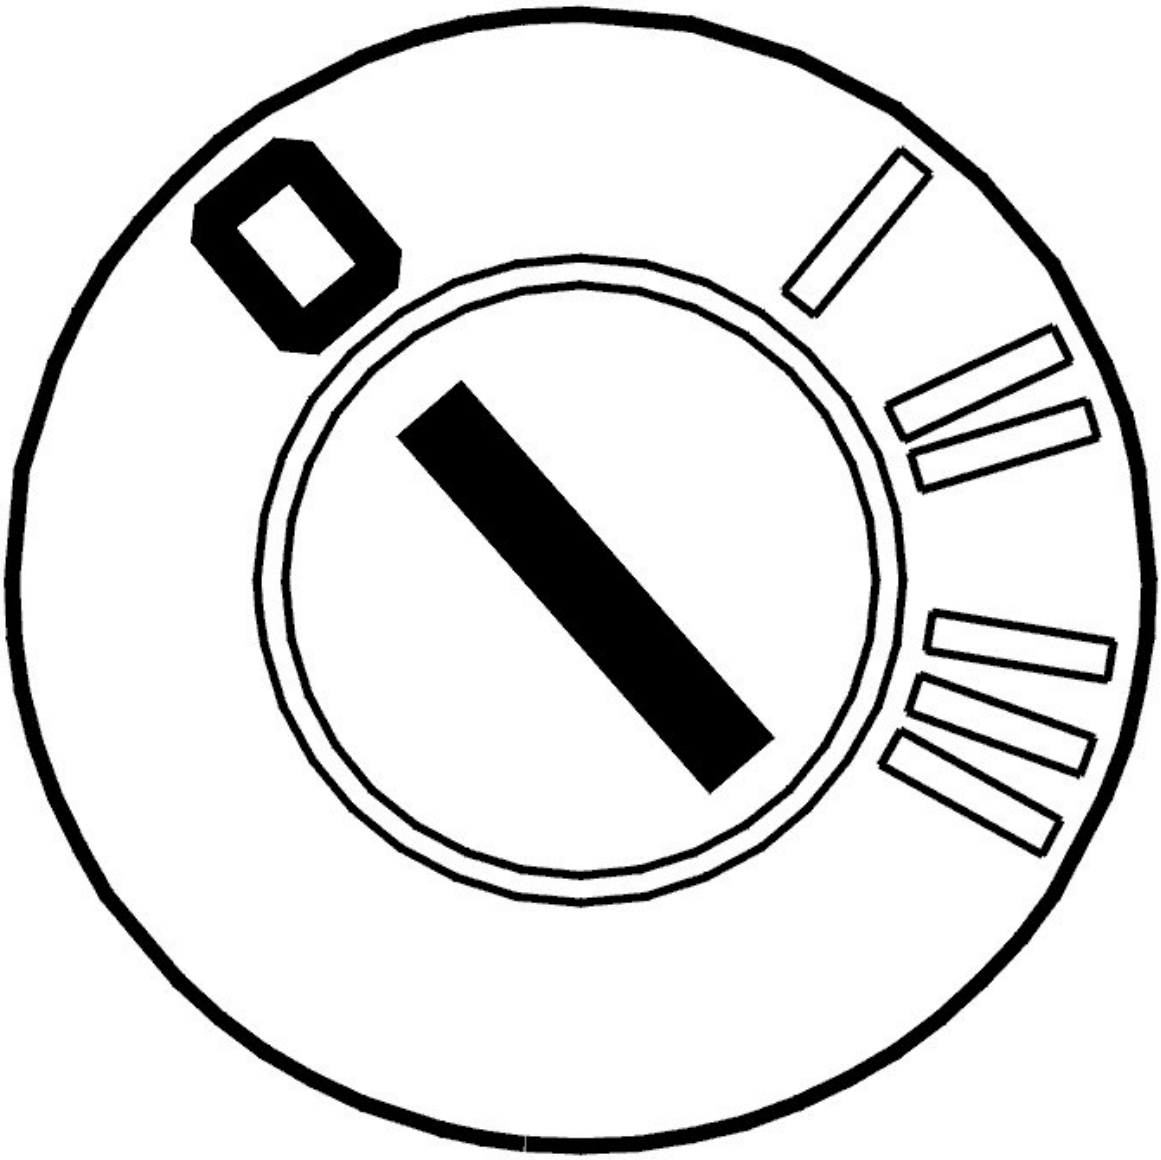
Was the resistance OK?

Yes - No Fault Found

No - Verification

Checking the wiring and component



- Ignition off
- Open the control system.

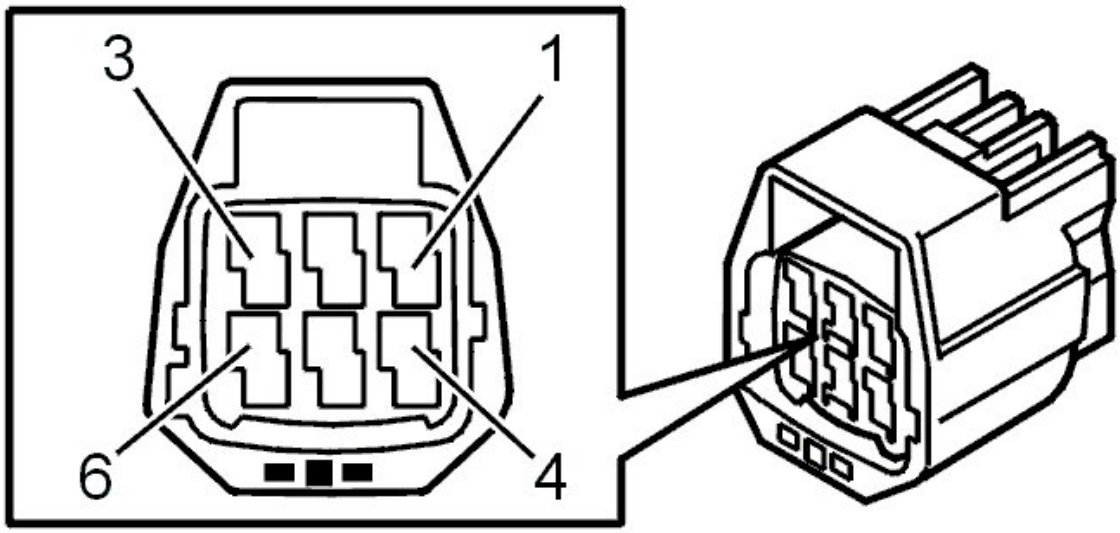
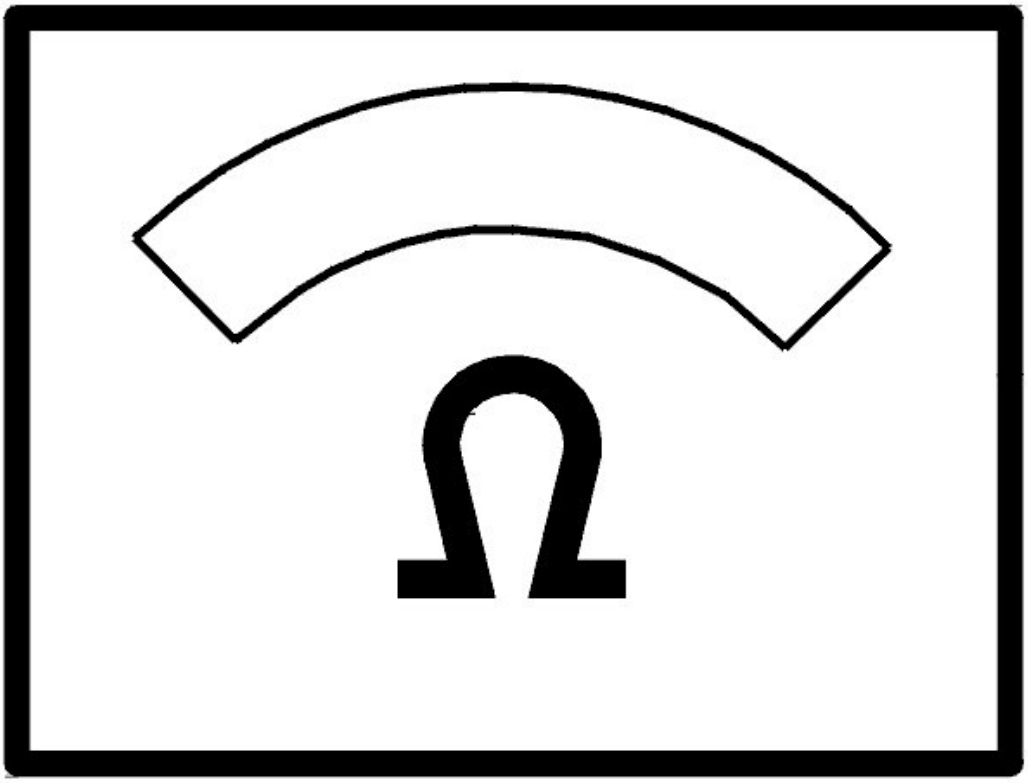
Check the cable between transmission connector terminal #C2 (transmission side) and the connector for solenoid S2. Check for a short-circuit to ground according to Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault.
Check solenoid S2 by measuring the resistance between the terminal pin on solenoid S2 and the transmission housing. The resistance should be 11-15 ohms at 20°C.
Remedy as necessary.

Other information:

- To disconnect the transmission connectors, see Connectors transmission, disconnecting / connecting See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Wiring Harness/Service and Repair/Procedures
- To open the control system and to check or replace solenoid S2, see Solenoid control system, replacing See: Transmission Control Systems/Actuators and Solenoids - Transmission and Drivetrain/Actuators and Solenoids - A/T/Shift Solenoid/Service and Repair/Solenoid Control System, Replacing
- To replace the cable harness for the control system, see Wiring harness / oil temperature sensor, replacing See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Wiring Harness/Service and Repair/Removal and Replacement
- For information about signals, see Signal description. Transmission control module (TCM), AW50/51 AWD, AW55-50/51SN See: Transmission Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Description. Transmission Control Module (TCM).





Select Continue when the fault has been remedied.

Continue - Resetting the adaptation and oil quality counter

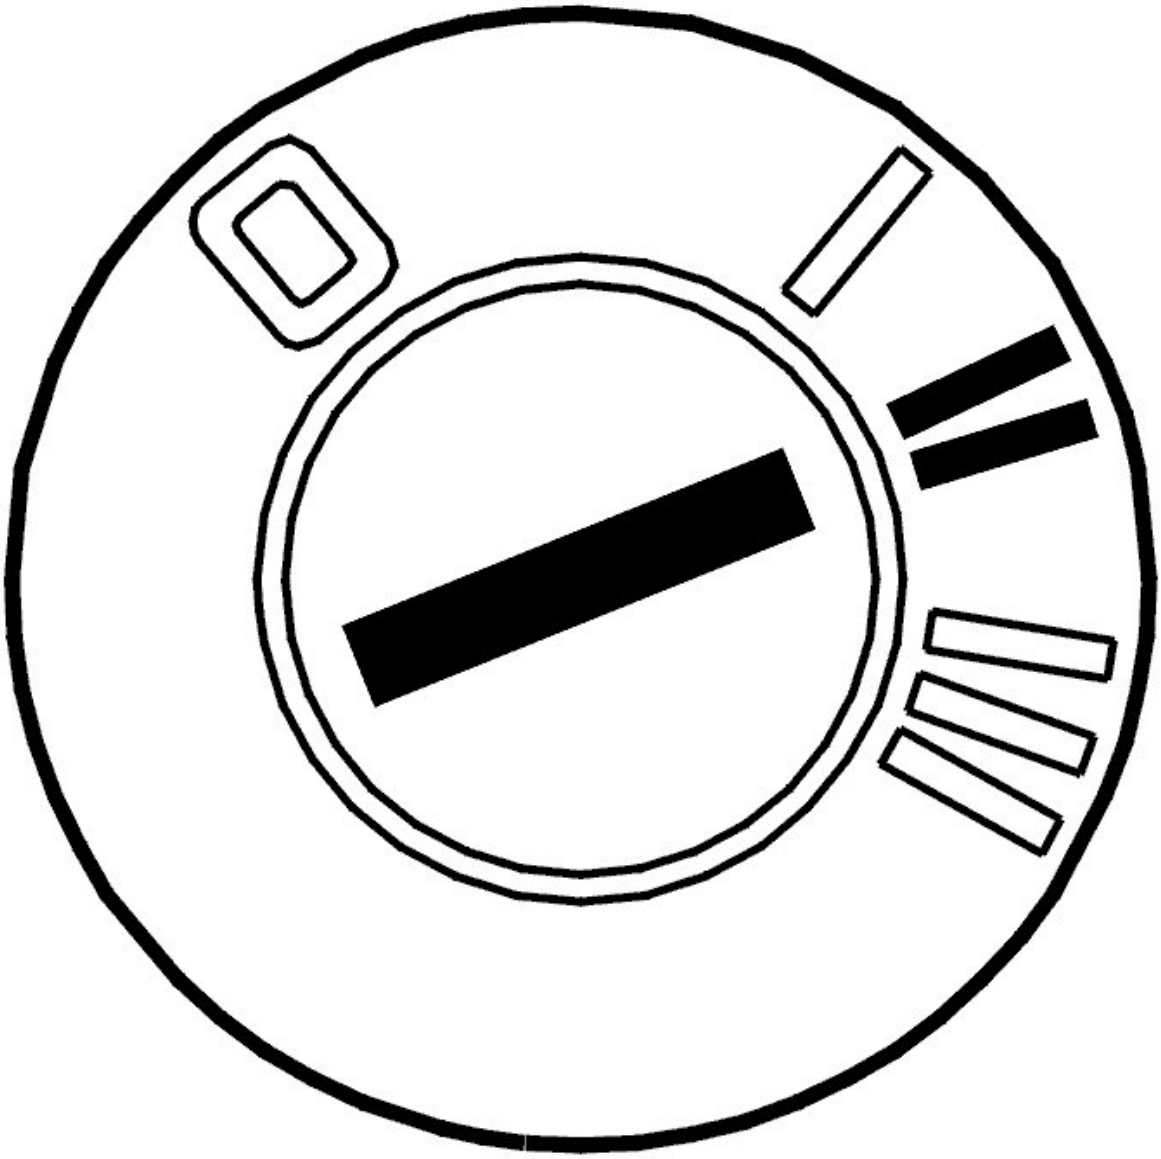
Resetting the adaptation and oil quality counter

Resetting the adaptation

Resetting adaptation and the counter for "Transmission oil change"

Hint: The transmission has torque controlled adaptive pressure control. Pressure control means that the transmission regulates the pressure itself during each gear shift. This avoids harsh gear shifting. Each gear shift is evaluated by the control module and stored in the memory. This allows for compensation for wear and tear in the transmission and clutch. It is important that the adaptation in the memory is reset after the transmission has been repaired. This is to ensure normal operation. The oil is replaced during repair; the "Transmission oil change" counter must be reset. If the counter is not reset when the fluid is drained and replaced, there is a risk that a diagnostic trouble code (DTC) will be stored in incorrect circumstances.

Note! This applies only if the transmission or one of the components in the transmission have been replaced.



- Ignition on.

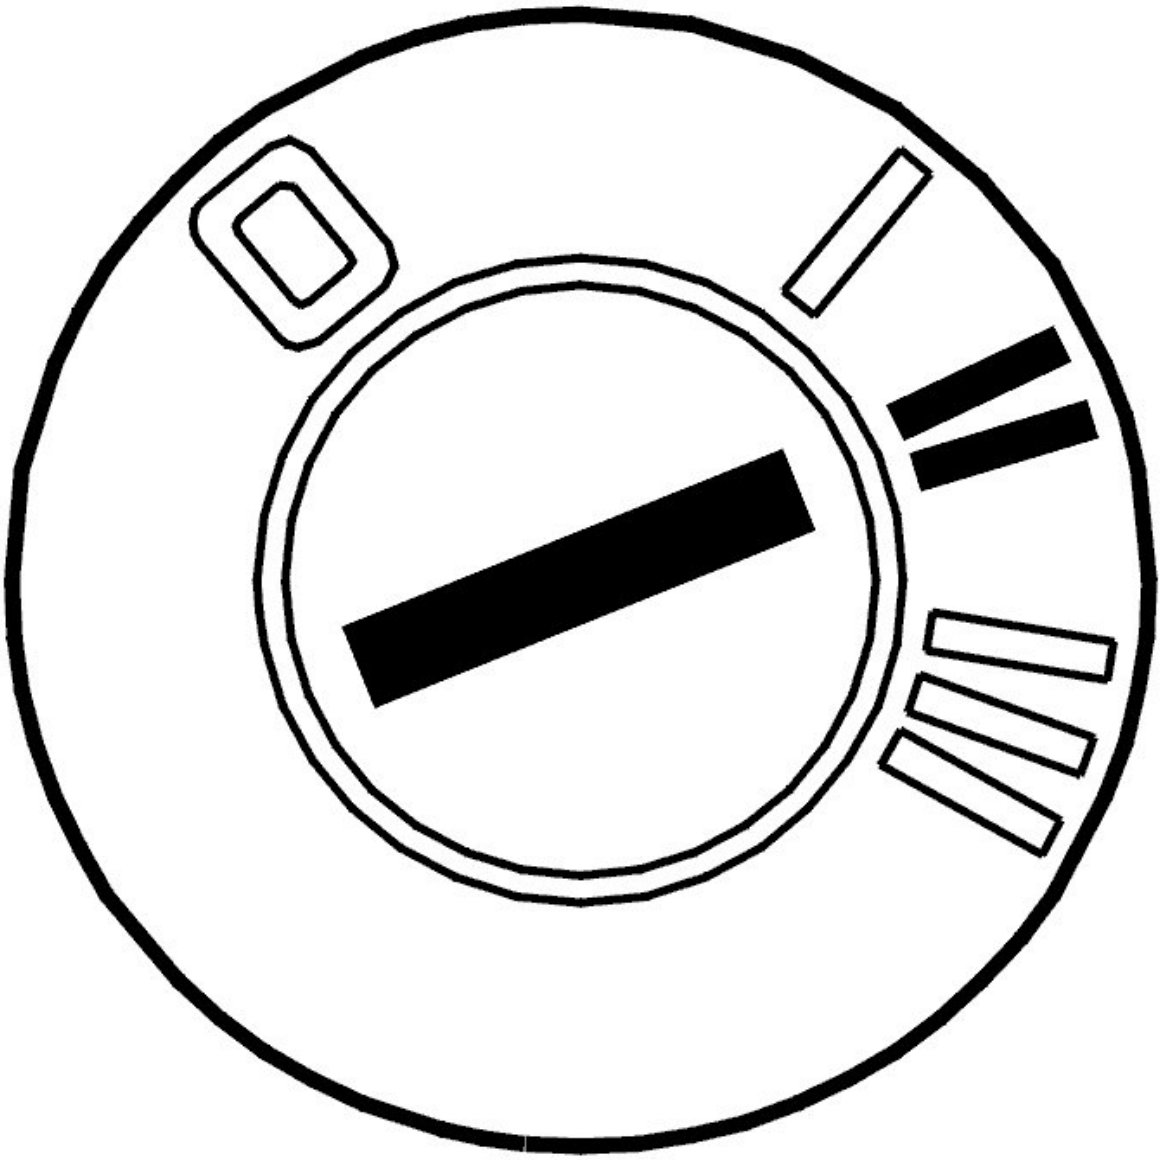
Click on the VCT2000 symbol to reset the adaptation and counter.

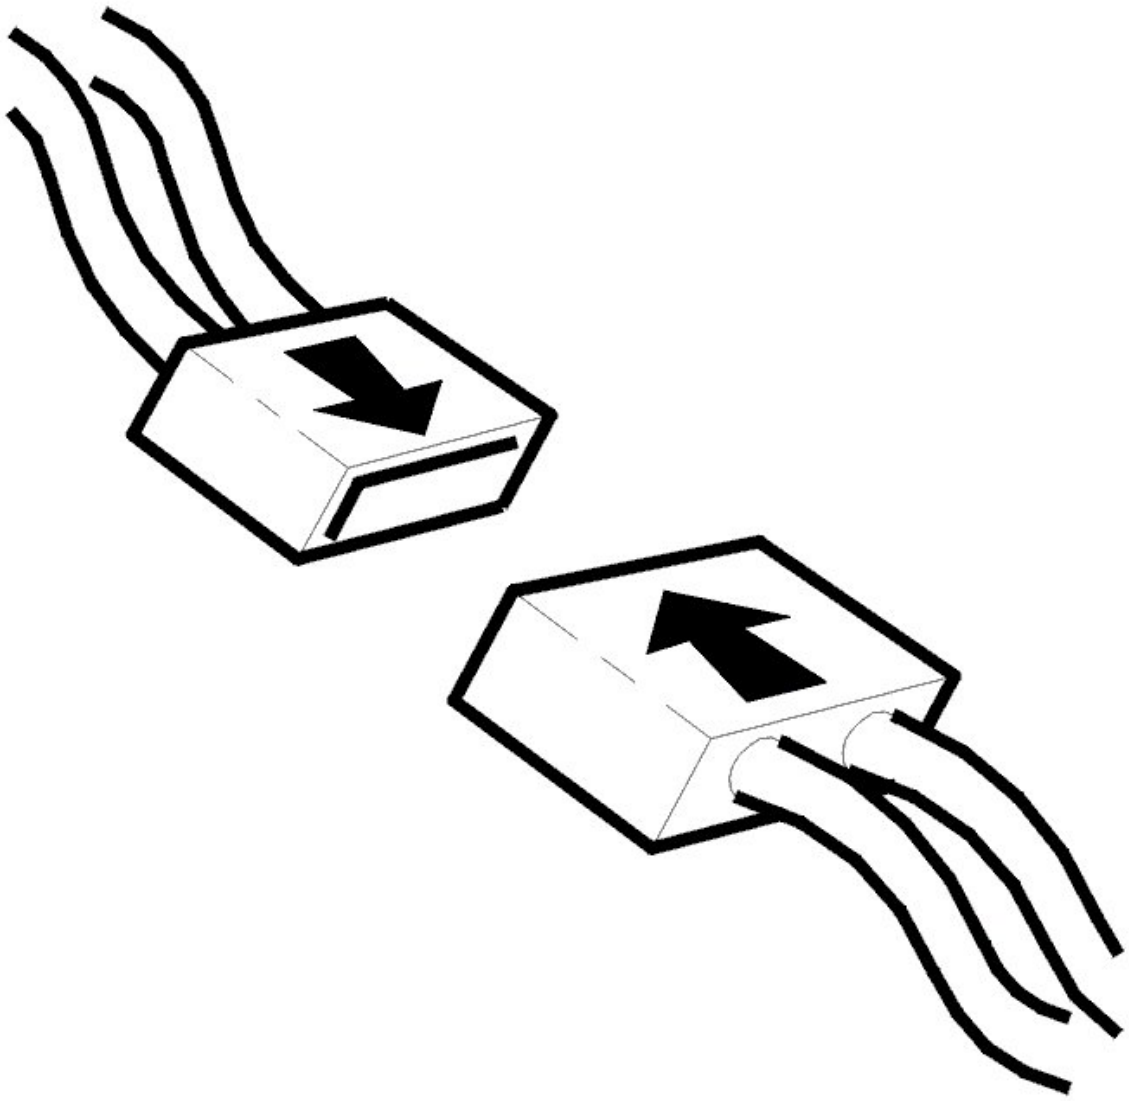
Continue - Verification

Verification

Verification

Hint: After carrying out the repair, check that the fault has been remedied.





- Ignition off.
- Reinstall the components, reconnect the connectors etc.
- Ignition on.
- Gear selector in position P.

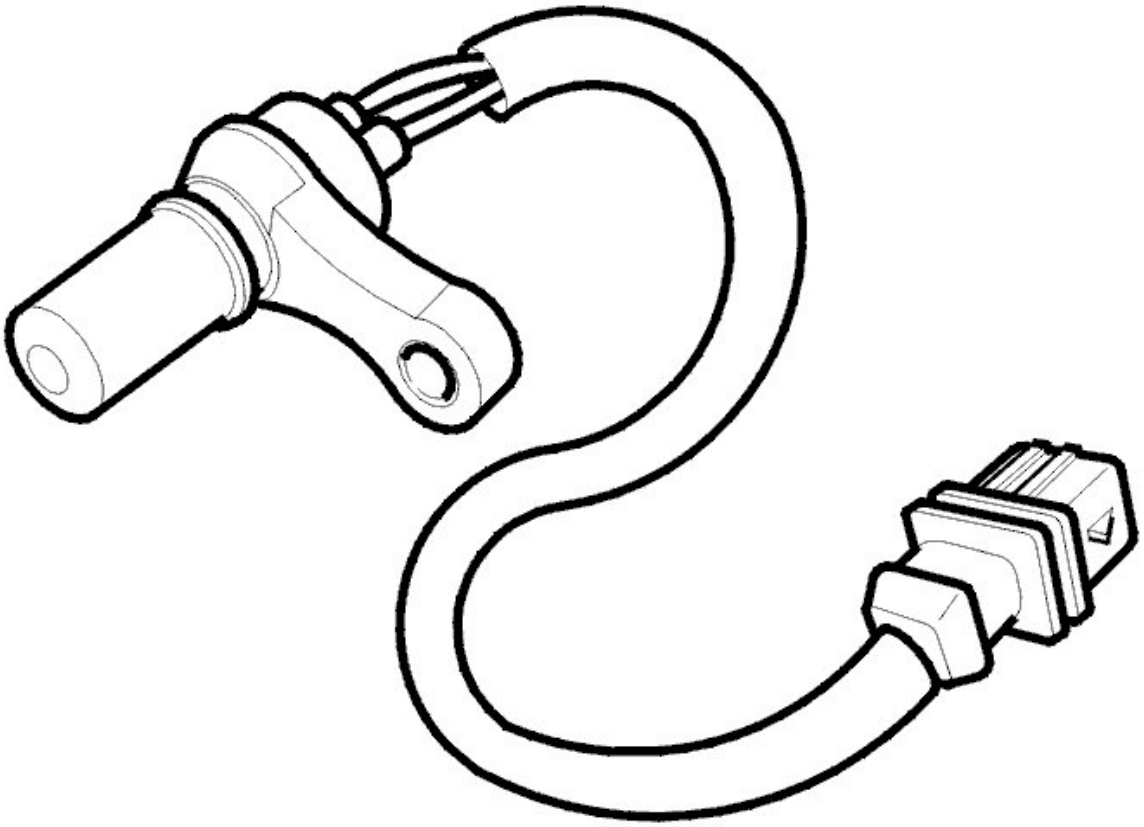
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition



Diagnostic trouble code (DTC) TCM-001F is stored if the control module registers that the signal from the speed sensor is missing.

Substitute value
- None.

Possible source
- Contact resistance in the terminals.
- Open-circuit in the power supply.
- Open-circuit in the signal cable.
- Defective speed sensor.

Fault symptom[s]
- General orange warning lamp lit.
- Malfunction indicator lamp (MIL) lit.
- No lock-up function.
- Harsh gear shifting.

Hint: Harsh gear shifting can be caused by:
- No reduction of the line pressure when shifting.
- No reduction of the line pressure when moving the gear selector between positions P-R, N-R and N-D.
- No request for torque limiting to the engine control module (ECM) when shifting.

Signal Missing. Intermittent Fault

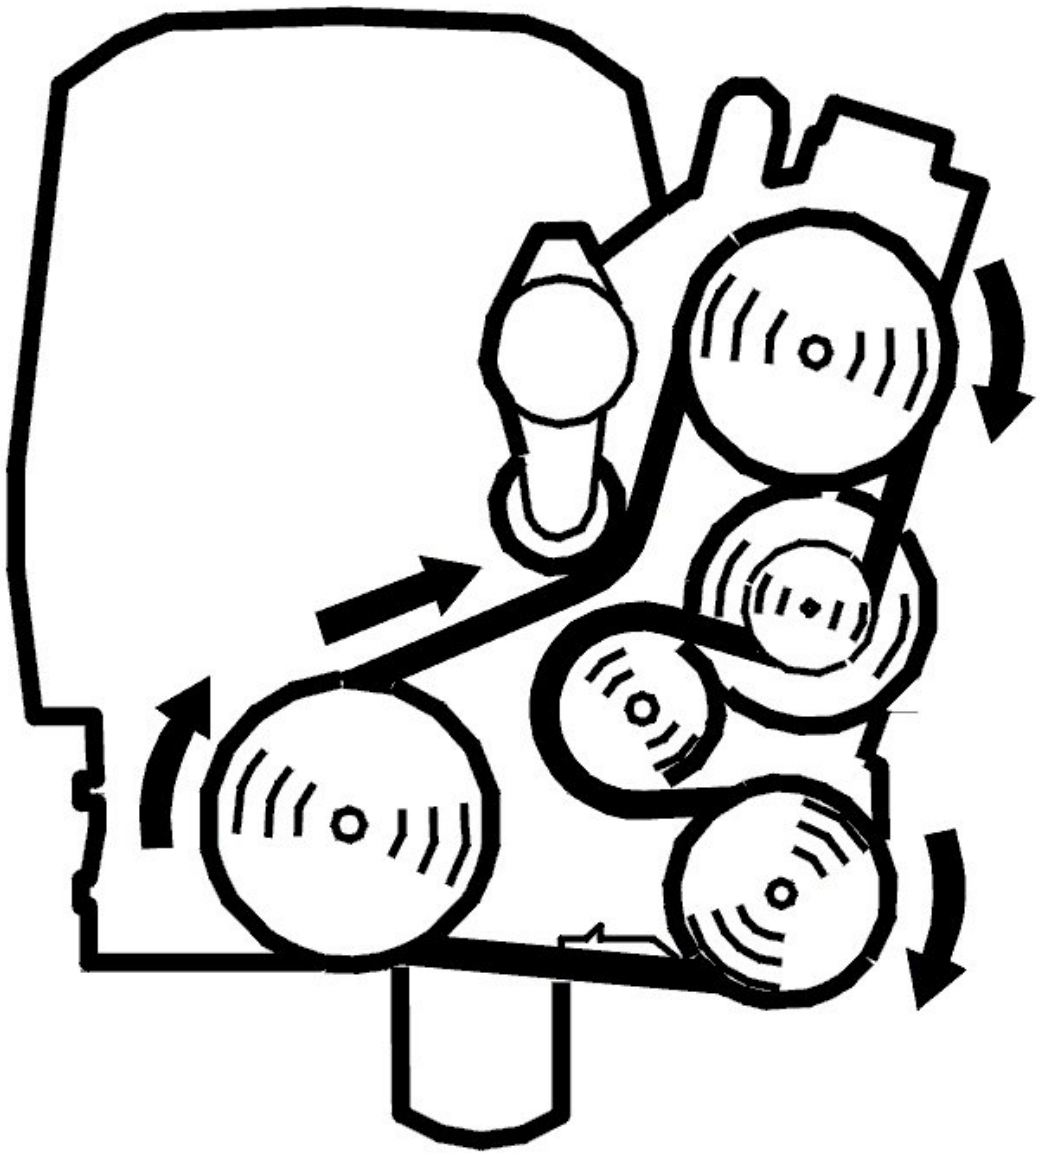
Signal Missing. Permanent Fault

Signal missing. Permanent fault

Checking the vehicle speed sensor (VSS) signal



- Ignition off
- Check the transmission control module (TCM) and speed sensor connectors. Check for contact resistance and oxidation according to Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault. Remedy if necessary
- Raise the car so that the drive wheels are clear of the ground
- Start the engine. Allow the engine to idle
- Move the gear selector to position D so that the drive wheels begin to rotate
- Read off the transmission speed.

Depress the accelerator pedal (AP) and check that the speed is updated.

Note! Ensure that the wheels are not rotating when the gear selector is moved.

Note! Diagnostic trouble codes (DTCs) may be stored in the ABS system when the rear wheels are stationary and the front wheels rotate. Erase any diagnostic trouble codes (DTCs) stored in the ABS system after fault-tracing.

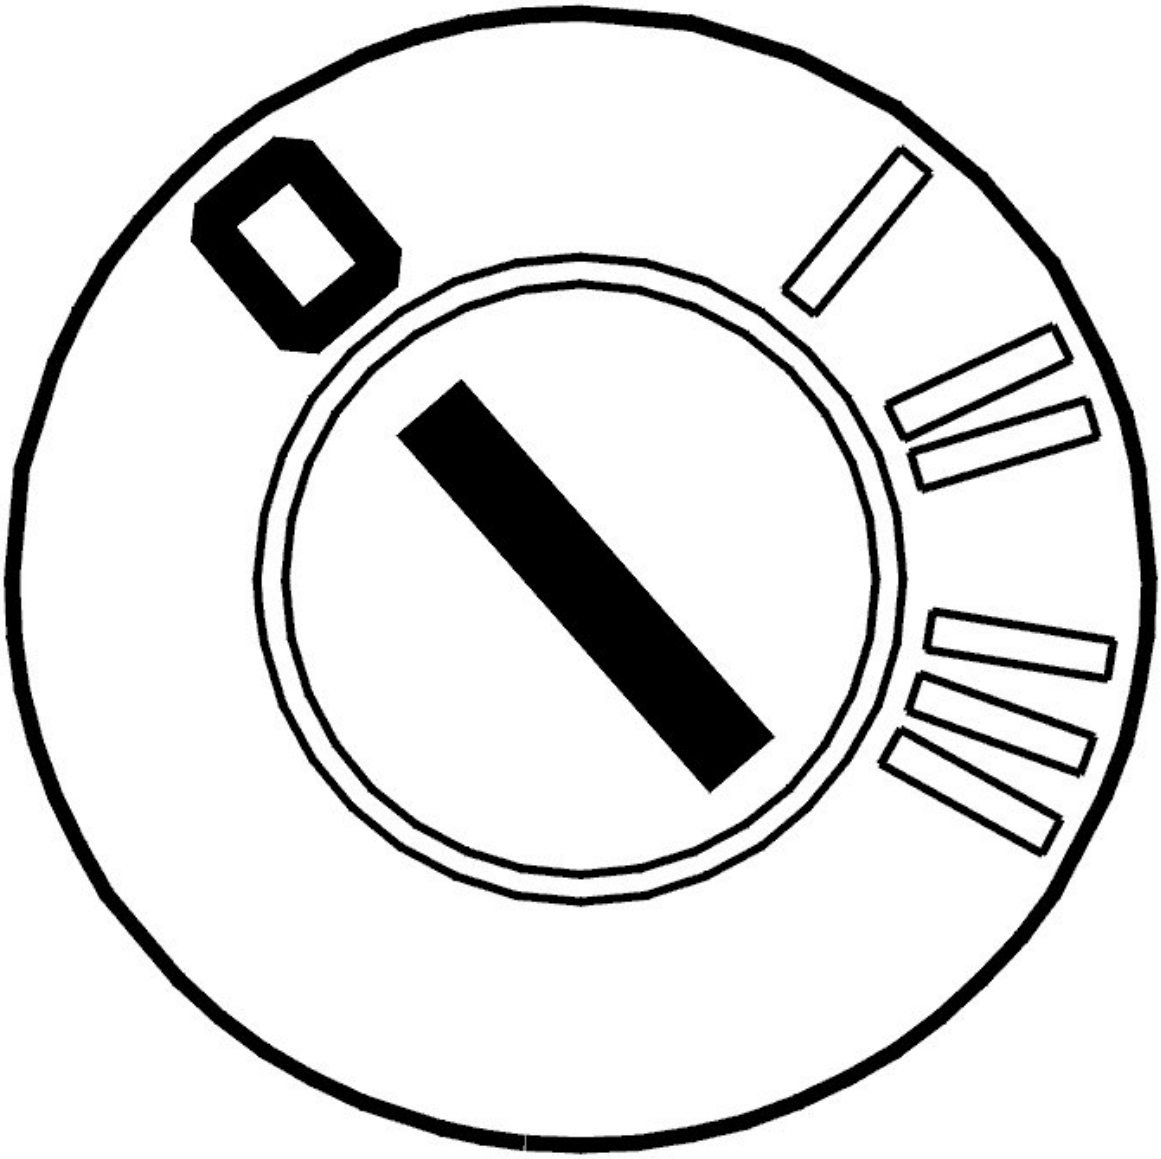
If the speed is updated, the cause of the fault was probably contact resistance or oxidation in the control module or vehicle speed sensor (VSS) connectors.

Was the speed updated?

Yes - No Fault Found

No - Checking wiring and sensors

Checking wiring and sensors



- Ignition off
- Connect the breakout box.

Check the power supply cable between transmission control module (TCM) terminal #A57 (#A57) and transmission output speed sensor connector

terminal #A4. Check for an open-circuit according to Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault.
Check the signal cable between transmission control module (TCM) terminal #A39 (#A39) and transmission output speed sensor connector terminal #A3. Check for an open-circuit according to Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault.

Hint: With the control module connected, the ignition on and a voltmeter connected between transmission output speed sensor connector terminals #A3 and #A4 (control module side), the voltage must be approximately 1-3 V below Ubat.

Remedy as necessary.

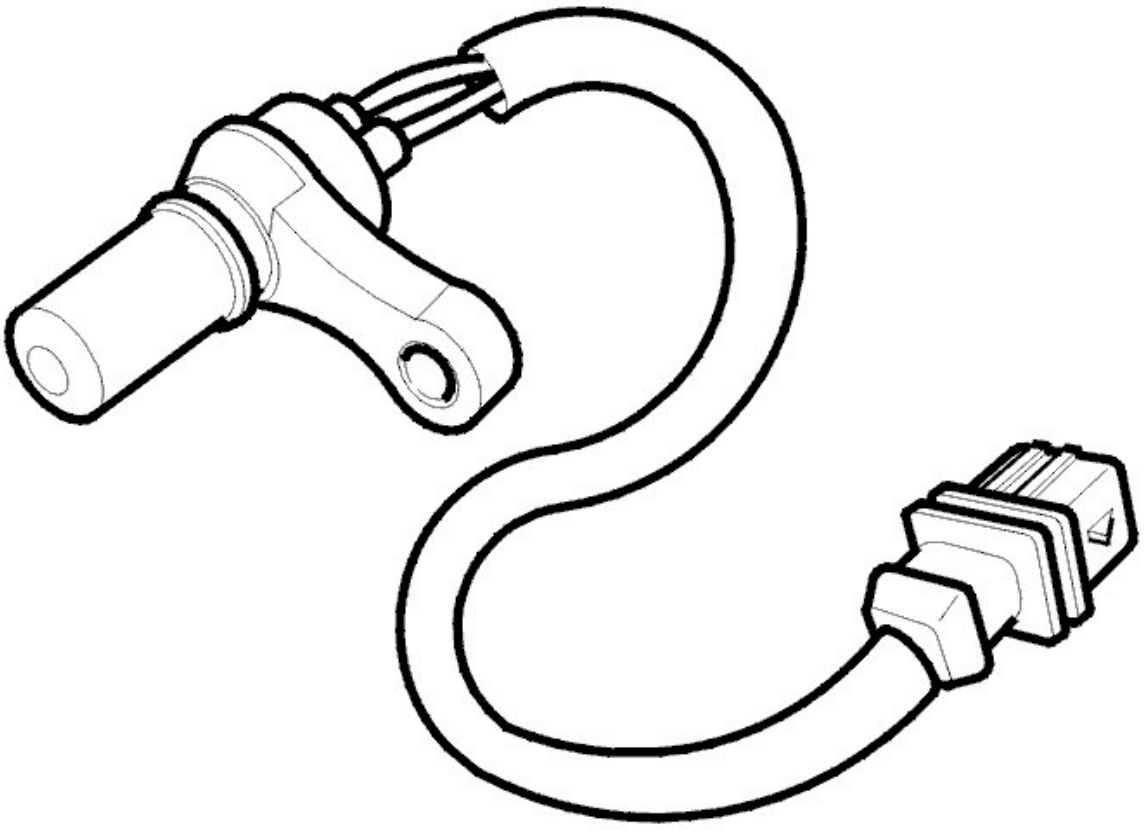
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition



The automatic transmission control module (TCM) receives speed signals from the ABS control module and from the the speed sensor on the transmission. The transmission control module (TCM) uses the signals to select the correct gear. The control module derives and compares the speed signal from the ABS system with the transmission speed and the engine speed (RPM) at the transmission. Diagnostic trouble code (DTC)

TCM-0020 is stored if the control module registers that the speed signal from the ABS system does not correspond with the transmission speed or the engine speed (RPM).

Substitute value
- None.

Possible source
- Contact resistance in the terminals.
- Open-circuit, short-circuit to ground or short-circuit to supply voltage in the power supply.
- Open-circuit, short-circuit to ground or short-circuit to supply voltage in the signal cable.
- Defective speed sensor.

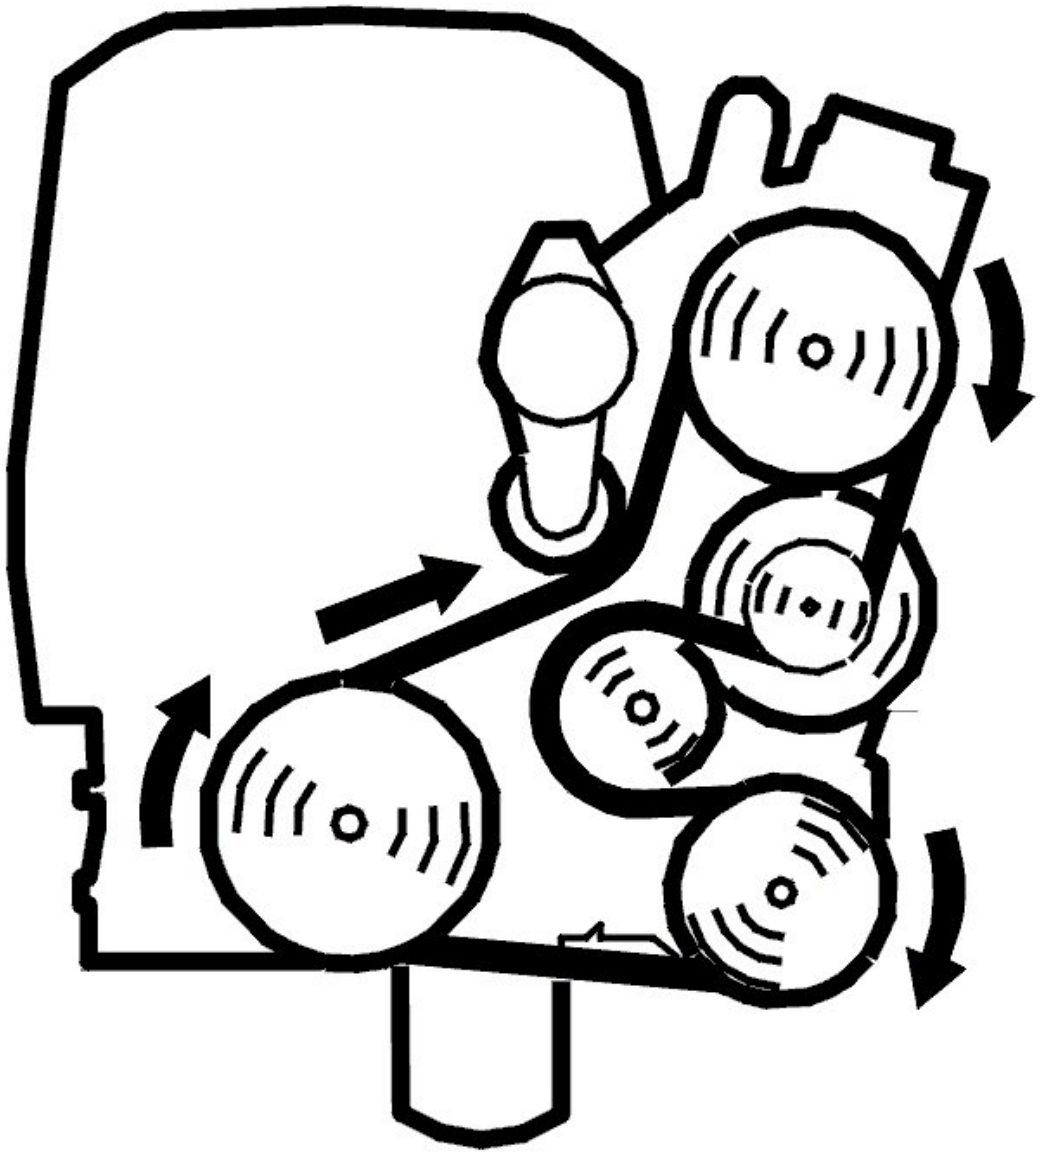
Fault symptom[s]
- General orange warning lamp lit.
- Malfunction indicator lamp (MIL) lit.
- No lock-up function.
- Harsh gear shifting.

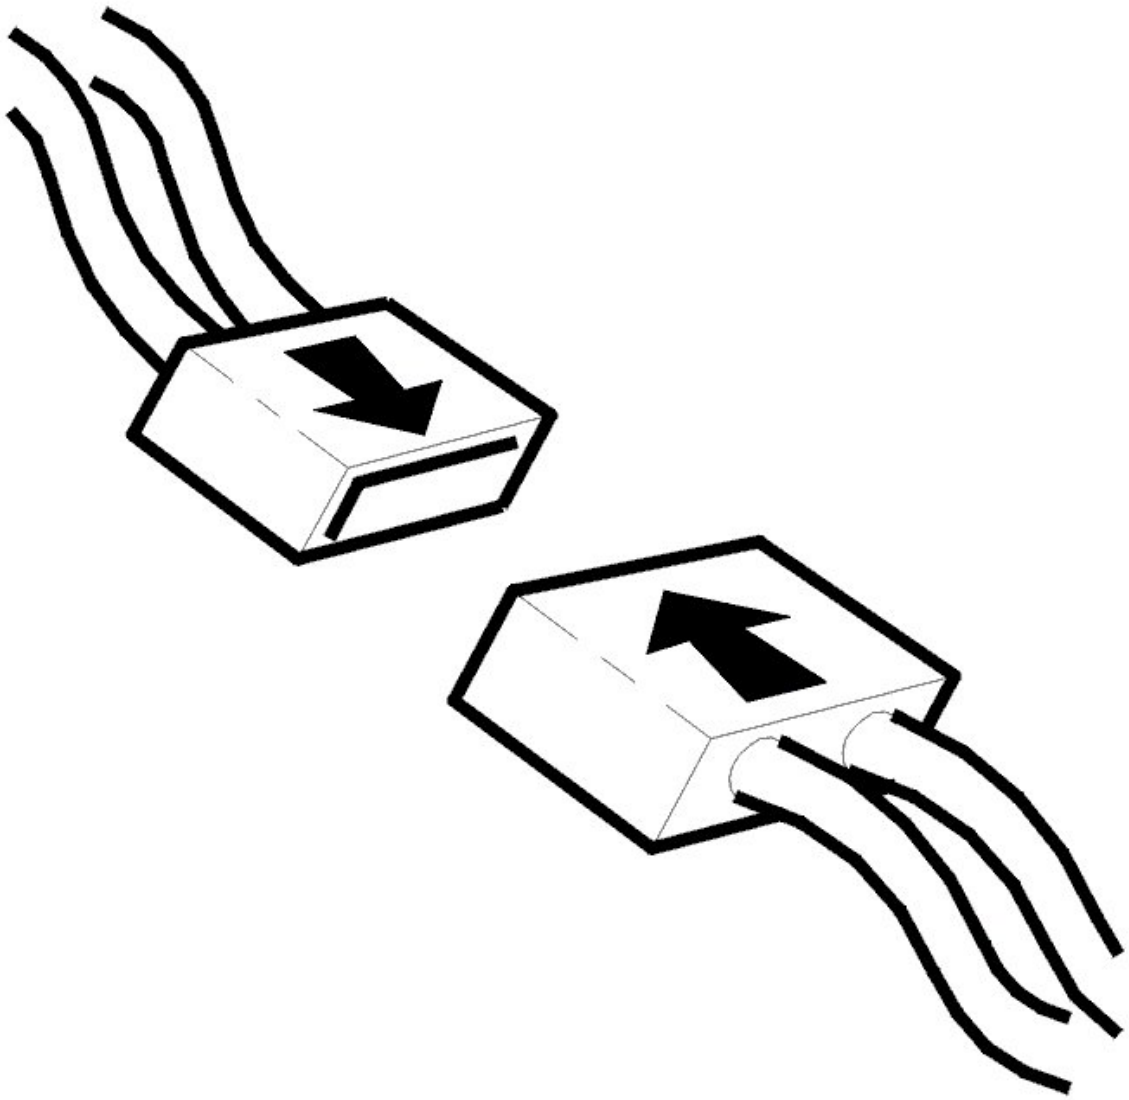
Hint: Harsh gear shifting can be caused by:
- No reduction of the line pressure when shifting.
- No reduction of the line pressure when moving the gear selector between positions P-R, N-R and N-D.
- No request for torque limiting to the engine control module (ECM) when shifting.

Faulty Signal. Permanent Fault

Faulty signal. Permanent fault

Checking the transmission output speed sensor signal





- Ignition off
- Check the control module and transmission output speed sensor connectors. Check for contact resistance and oxidation according to Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault
- Reinstall the components, reconnect the connectors etc.
- Raise the car so that the drive wheels can rotate freely
- Engine idling
- Gear selector in position D
- Read off the transmission output speed signal.

Check that the speed increases with engine speed (RPM). If the speed is updated, the cause of the fault was loose connections in the control module or vehicle speed sensor (VSS) connectors.

Note! A diagnostic trouble code (DTC) may be stored in the ABS system when the rear wheels are stationary and the front wheels rotate. Erase any diagnostic trouble codes (DTCs) in the ABS system after completing fault-tracing.

Diagnostic trouble code (DTC) information

Condition

The transmission speed signal is transmitted by a sensor on the transmission. The transmission control module (TCM) uses the signal to determine the input shaft speed after the torque converter. This signal is used to compare the transmission speed and vehicle speed. The transmission control module (TCM) uses this comparison to calculate gear-shift timing. Engine speed (RPM) and vehicle speed data affects the adjustment of system pressure, lock-up function control and engine torque reduction. The result is smooth gear-shifting. The control module calculates and compares the transmission speed, engine speed (RPM) and speed at the transmission. Diagnostic trouble code (DTC) TCM-0023 is stored if the control module registers that the speed (RPM) signal is missing.

Substitute value
- The transmission control module (TCM) "Emergency mode I" program has been initiated.

Possible source
- Contact resistance in the terminals.
- Open-circuit on power supply.
- Open-circuit in signal cable.
- Defective input speed sensor.

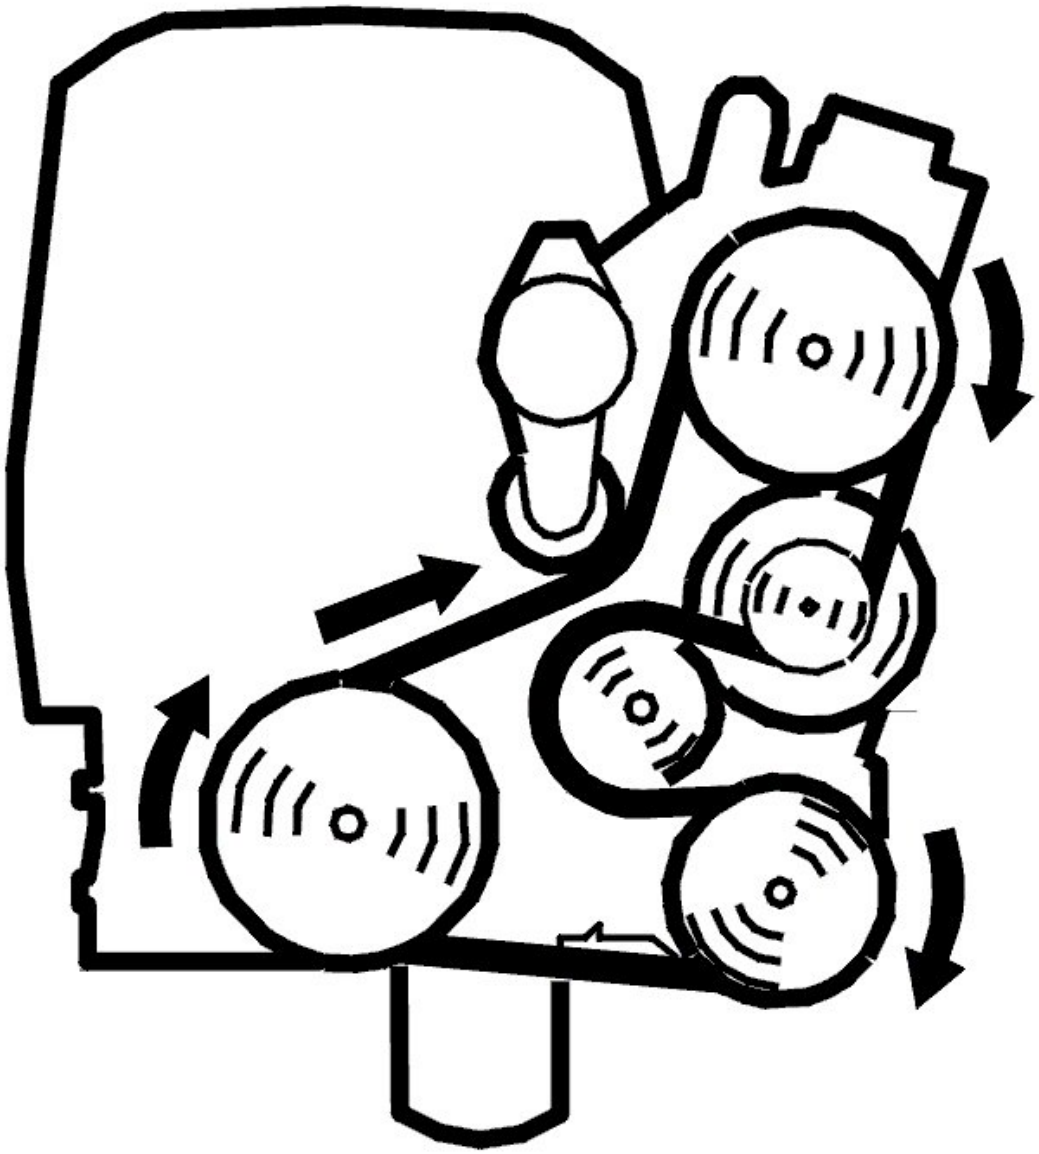
Fault symptom[s]
- General orange warning lamp lit.
- Malfunction indicator lamp (MIL) lit.
- No lock-up function.
- Harsh gear shifting.

Hint: Harsh gear shifting can be caused by:
- No reduction of line pressure when shifting.
- No reduction of line pressure when moving the gear selector between positions P-R, N-R and N-D.
- No torque limiting request to engine control module (ECM) when shifting.

Signal Missing. Permanent Fault

Signal missing. Permanent fault

Checking the transmission input speed sensor signal



- Gear selector in position P
- Start the engine. Allow the engine to idle
- Read off the transmission input speed.

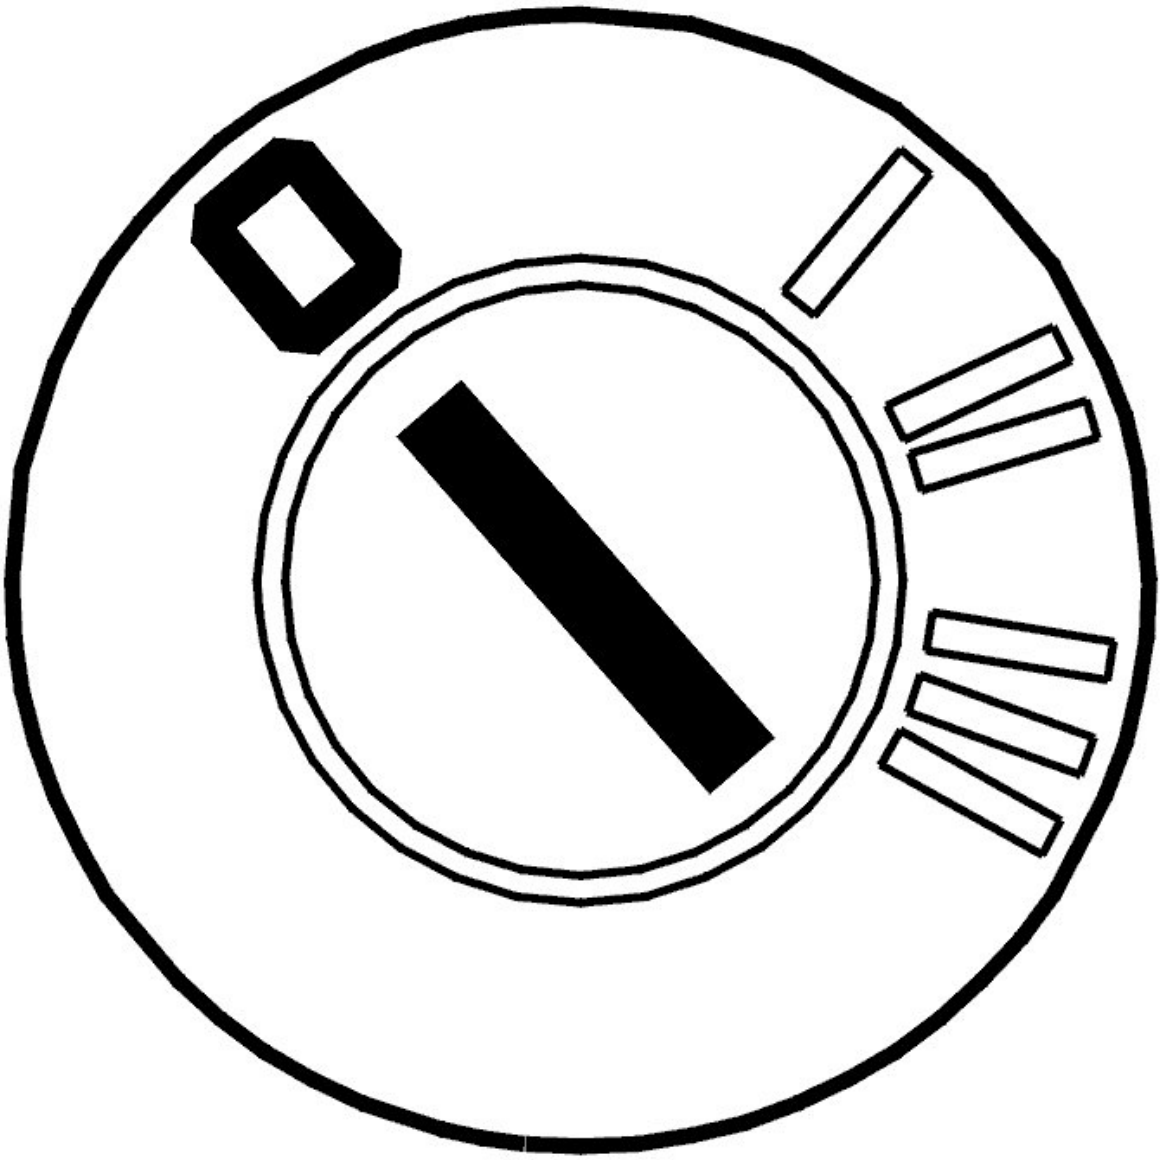
Check that the transmission speed is updated.
Compare with the engine speed (RPM).

Is the speed updated?

Yes - No Fault Found

No - Checking wiring and sensors

Checking wiring and sensors



- Ignition off.

Check the transmission connector. Check for contact resistance and oxidation. See Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault.
Check the power supply cable between transmission control module (TCM) terminal #A59 (#A59) and transmission connector terminal #A2. Check for an open-circuit according to Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault.
Check the signal cable between transmission control module (TCM) terminal #A41 (#A41) and transmission connector terminal #A1. Check for an open-circuit according to Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault.

Hint: With the control module connected, the ignition on and a voltmeter connected between transmission connector terminals #A1 and #A2 (control module side), the voltage must be 1-3 V below Ubat.

Remedy as necessary.

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

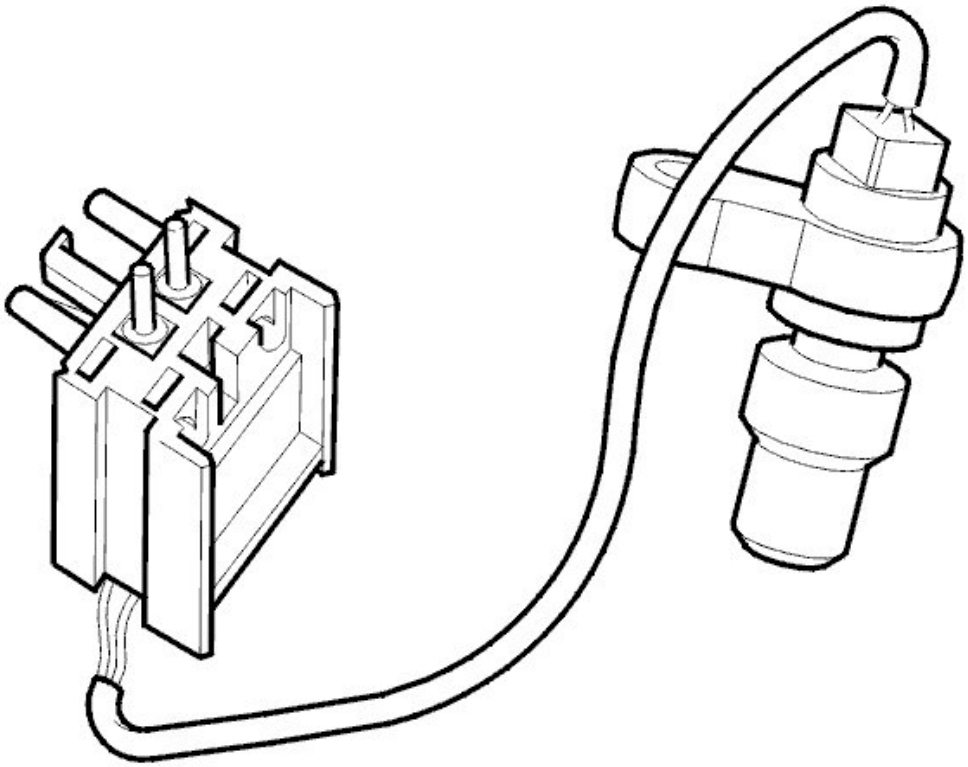
Condition



The transmission speed signal is transmitted by a sensor on the transmission. The transmission control module (TCM) uses the signal to determine the input shaft speed after the torque converter. This signal is used to compare the transmission speed and the vehicle speed. The transmission control module (TCM) uses this comparison to calculate the gear-shift timing. Engine speed (RPM) and vehicle speed data affects the adjustment of the system pressure, lock-up function control and engine torque reduction. The result is smooth gear-shifting. The control module calculates and compares the transmission speed, the engine speed (RPM) and the speed at the transmission. Diagnostic trouble code (DTC) TCM-0024 is stored if the control module registers a faulty signal when vehicle speed is above approximately 25 km/h.

Substitute value
- The transmission control module (TCM) "Emergency mode I" program has been initiated.

Possible source
- Contact resistance in the terminals.
- Open-circuit, short-circuit to ground or short-circuit to supply voltage in the power supply.
- Open-circuit, short-circuit to ground or short-circuit to supply voltage in the signal cable.
- Defective engine speed (RPM) sensor.

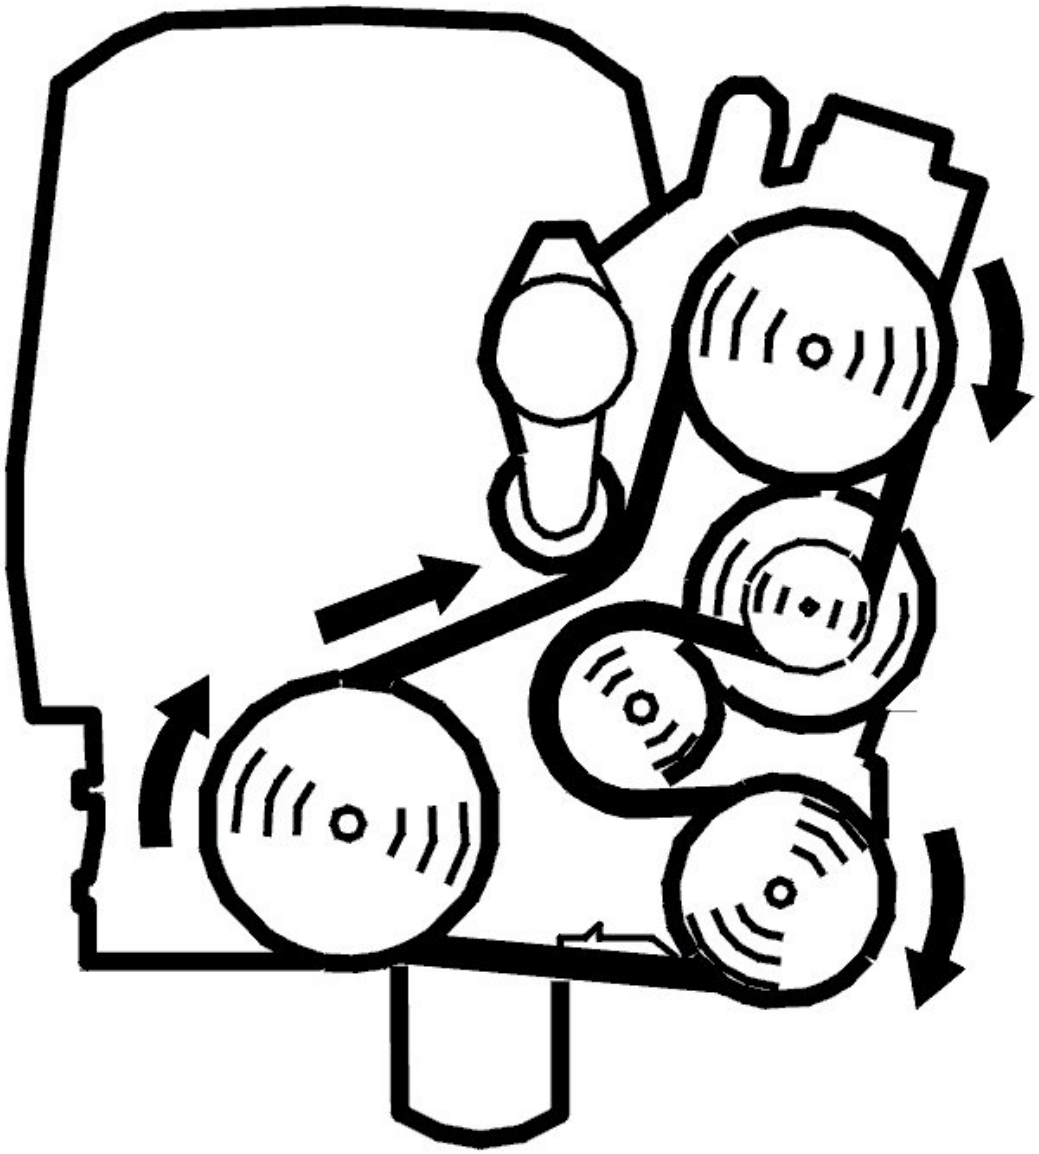
Fault symptom[s]
- General orange warning lamp lit.
- Malfunction indicator lamp (MIL) lit.
- No lock-up function.
- Harsh gear shifting.

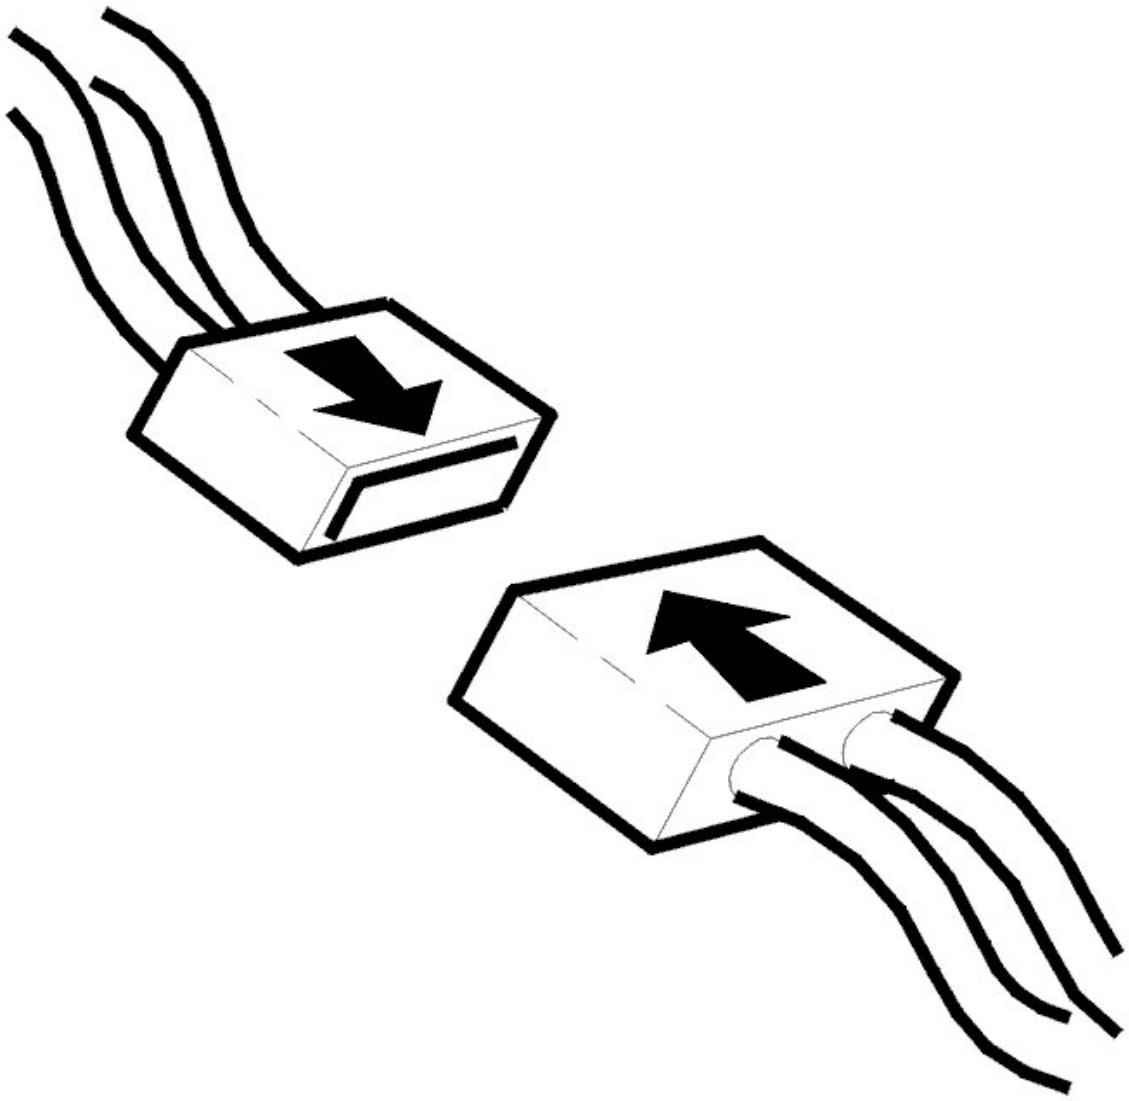
Hint: Harsh gear shifting can be caused by:
- No reduction of the line pressure when shifting.
- No reduction of the line pressure when moving the gear selector between positions P-R, N-R and N-D.
- No request for torque limiting to the engine control module (ECM) when shifting.

Faulty Signal. Permanent Fault

Faulty signal. Permanent fault

Checking the transmission input speed sensor signal





- Ignition off
- Check the transmission control module (TCM) and transmission connectors. Check for contact resistance and oxidation according to Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault. Remedy if necessary
- Reinstall the components, reconnect the connectors etc.
- Gear selector in position P
- Start the engine. Allow the engine to idle
- Read off the transmission input speed.

Check that the transmission input speed is updated.
Compare with the engine speed (RPM).
If the transmission speed increases, the cause of the fault was loose connections in the control module or transmission speed sensor connectors.

Other information:

- To disconnect the transmission control module (TCM), see Transmission control module (TCM), replacing, B5244T5, AW55-50/51SN, B5254T2, AW55-50/51SN, B5254T2, AW50/51 AWD See: Transmission Control Systems/Relays and Modules - Transmission and Drivetrain/Relays and Modules - A/T/Control Module/Service and Repair

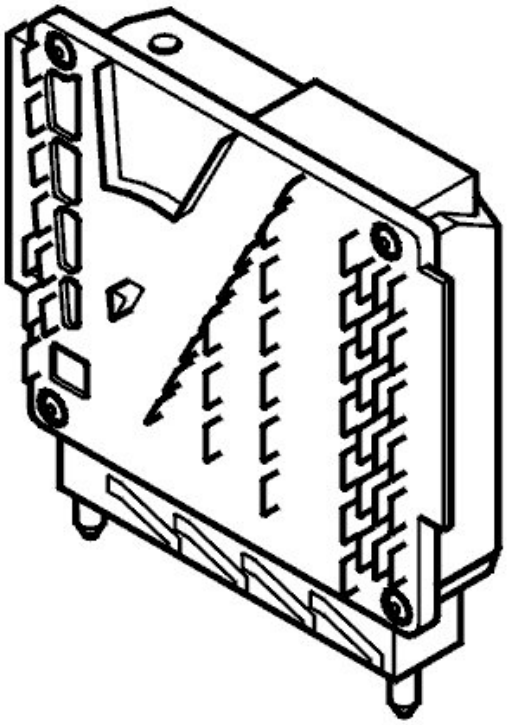
FAULT FOUND - Fault Found

Diagnostic Trouble Code (DTC) Information

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

Diagnostic trouble code (DTC) information

Condition



The transmission control module (TCM) calculates the ratio between the transmission input speed and the vehicle speed. There is a specific ratio for each gear. Diagnostic trouble code (DTC) TCM-0027 is stored if the control module registers that the ratio deviates by more than 10 % when the oil temperature is above +20°C and throttle opening exceeds 3 %.

Substitute value
- The transmission control module (TCM) "Emergency mode I" program has been initiated.

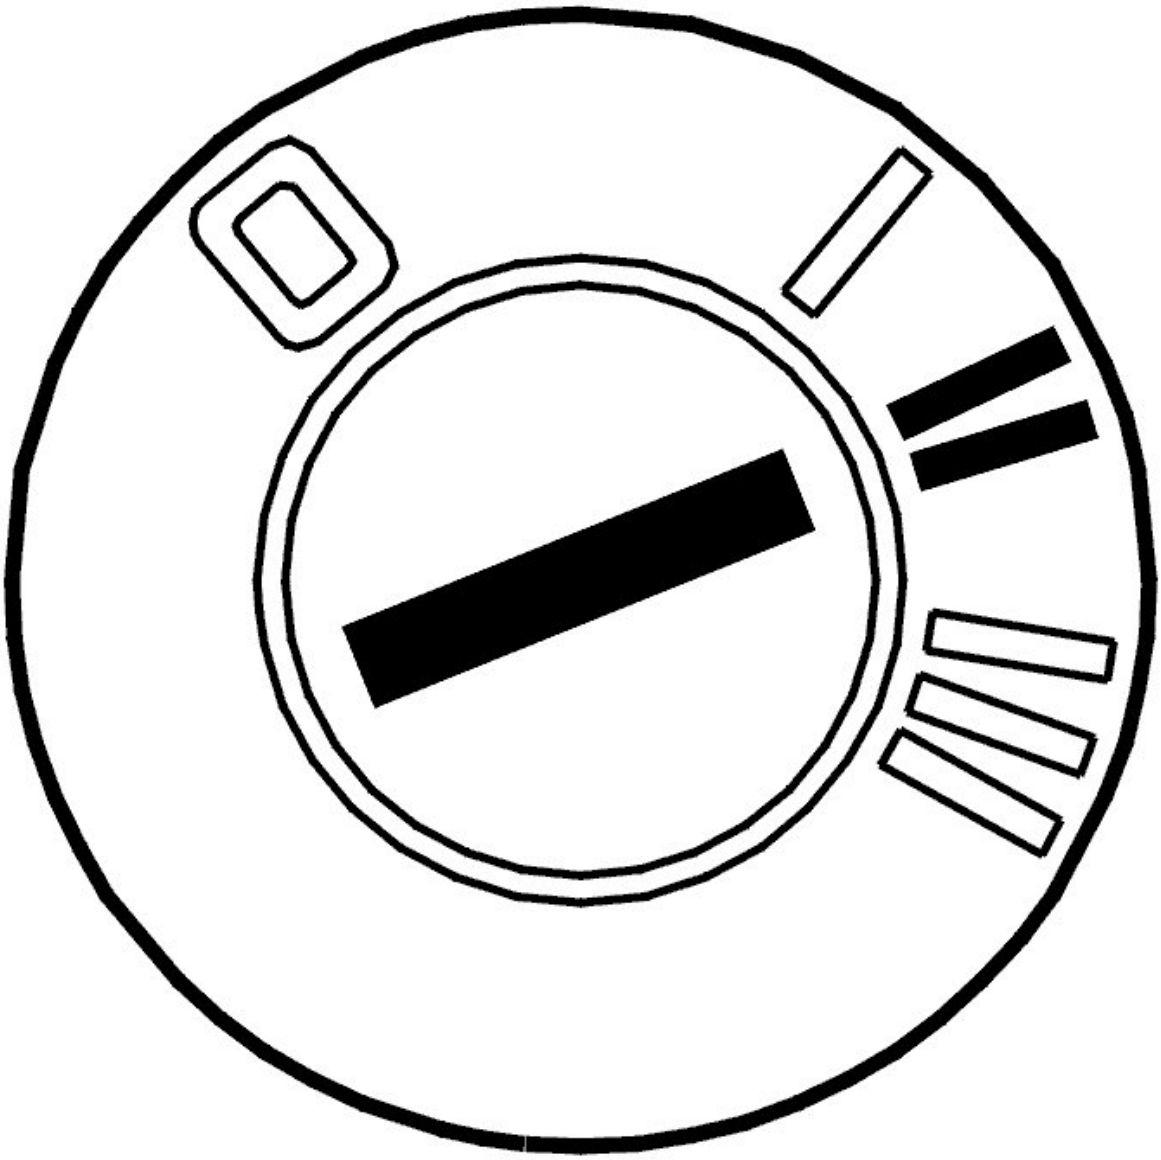
Possible source
- Contact resistance in the circuit for solenoids S1, S2, S3, S4, S5 and SLS.
- Solenoid S4 has jammed in the ON position.
- Mechanical fault in the transmission. Worn components in the transmission causing slippage or too low line pressure.

Fault symptom[s]
- General orange warning lamp lit.
- Malfunction indicator lamp (MIL) lit.
- No lock-up function.
- No shifting.
- Harsh gear shifting.

Incorrect Gear Ratio

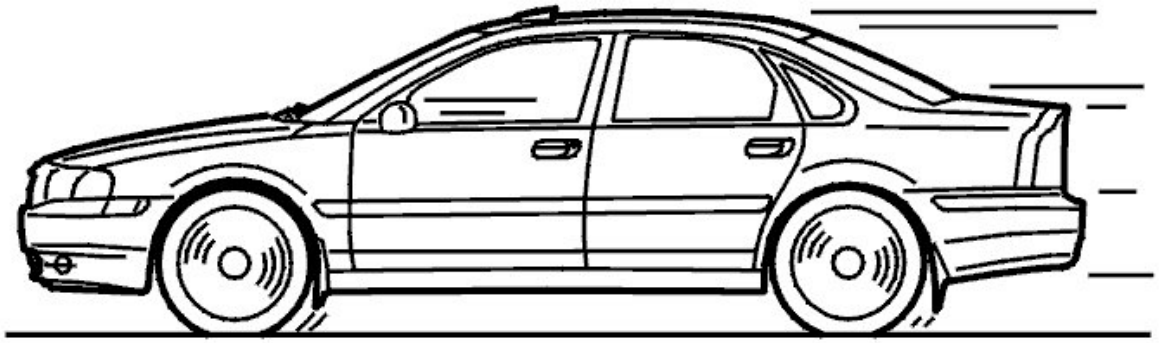
Incorrect gear ratio

Checking for contact resistance and oxidation



- Ignition off
- Check the transmission control module (TCM), transmission output speed sensor and transmission connectors. Check for contact resistance and oxidation. See Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault.

Test drive the car. See Test drive schedule, description, B5244T5, AW55-50/51SN, B5254T2, AW55-50/51SN, B5254T2, AW50/51 AWD See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Service and Repair/Procedures/Test Drive Schedule, Description.
When test driving, the oil temperature must be above 20°C. Check for transmission malfunction. Listen for mechanical noise from the transmission.



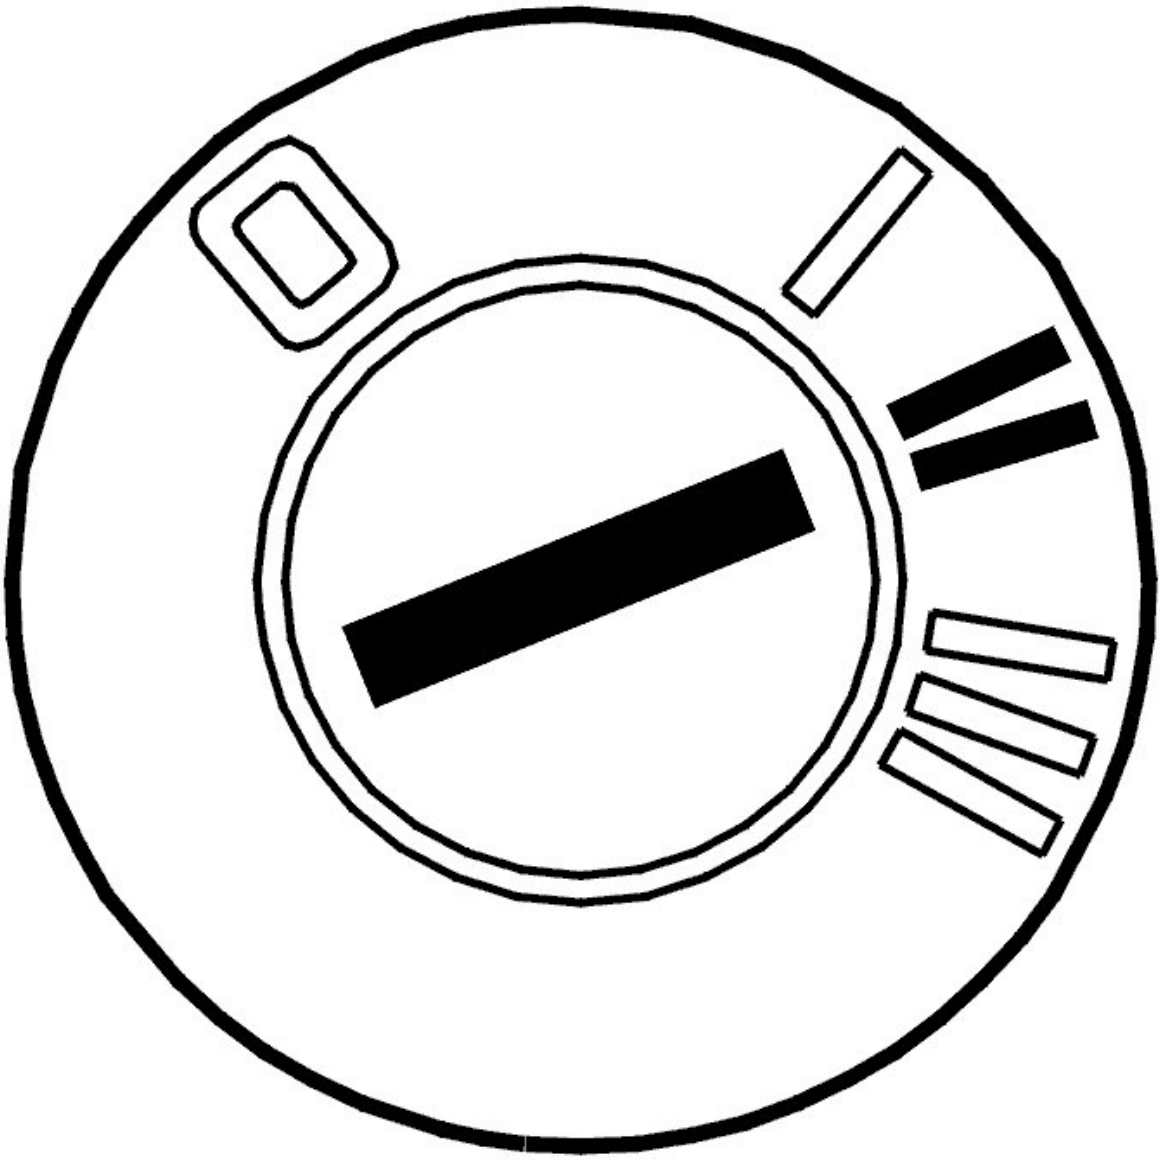
Is the function of the transmission OK?

Yes - Checking the oil quality and the oil level in the transmission

No - Replacing the transmission

Checking the oil quality and the oil level in the transmission

Note! Transmission fluid quality and level are extremely important for transmission function. Therefore it is imperative that these are correct. In addition the oil level is dependent on oil temperature.



- Ignition on
- Read off the oil temperature.

Check the oil level. If the oil level is low check for leakage. Top up with oil.
Check the quality of the oil.
Replace the transmission fluid if the fluid smells burnt.
Check the transmission fluid for metal swarf. Take a sample using the dip stick.
Replace the transmission if the transmission fluid contains metal swarf.

Other information:

- To replace the transmission fluid, see Transmission fluid, replacing See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Service and Repair/Removal and Replacement/Transmission Fluid, Replacing
- To check the level, see Oil level, checking See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Service and Repair/Procedures/Transmission Oil Level - Checking
- To check the quality of the transmission fluid, see the relevant service procedure.

Select an alternative below:

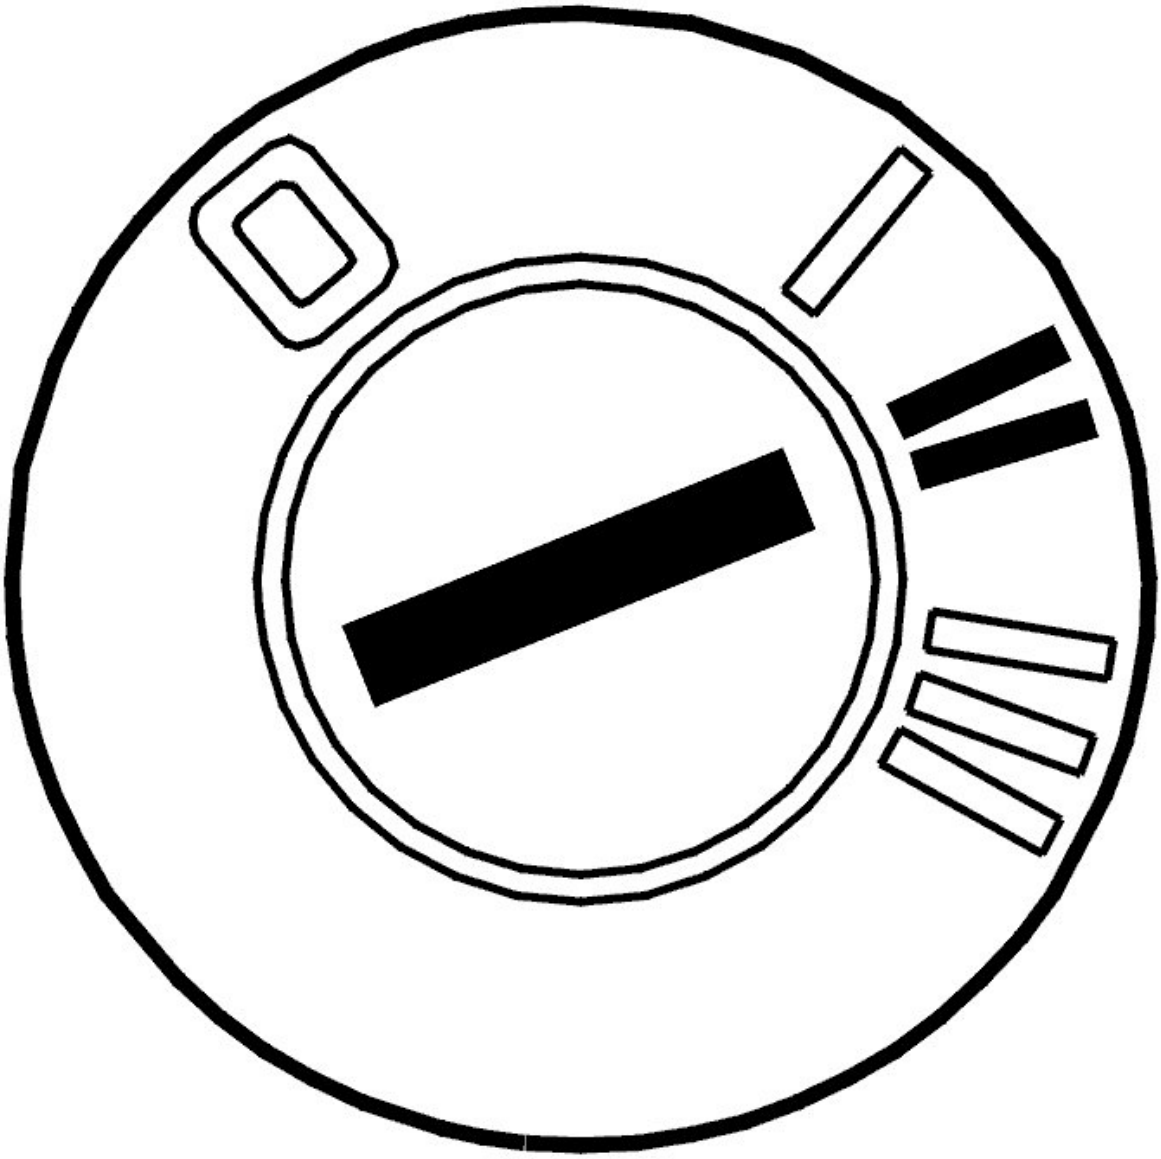
1. No fault detected
2. Transmission fluid replaced, the level was low or quality was poor
3. The transmission fluid contains metal swarf.

1 - Checking the adjustment of the gear-shift position sensor

2 - Resetting the oil quality counter

3 - Replacing the transmission

Checking the adjustment of the gear-shift position sensor



- Ignition on
- Read off the position of the gear-shift position sensor.

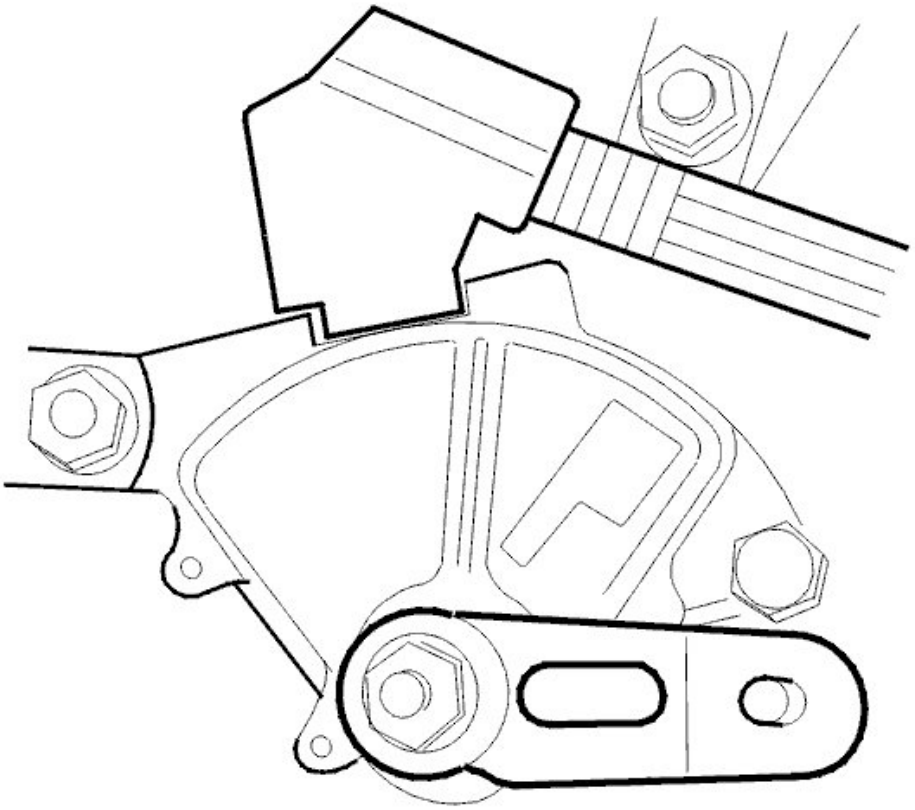
Move the gear selector around the different gear positions a number of times. Check that the gear position is updated. The selected position must be the same as that displayed in VIDA. If the display shows an undefined position (OR for example) the transmission cable needs adjusting.

Note! An undefined position may be displayed between the fixed gear positions. This is not a fault.

Remedy as necessary.

Other information

- To adjust the mechanical transmission cable, see the relevant service procedure.



Is the gear-shift position sensor incorrectly adjusted?

Yes - Verification

No - Checking the transmission output speed sensor signal

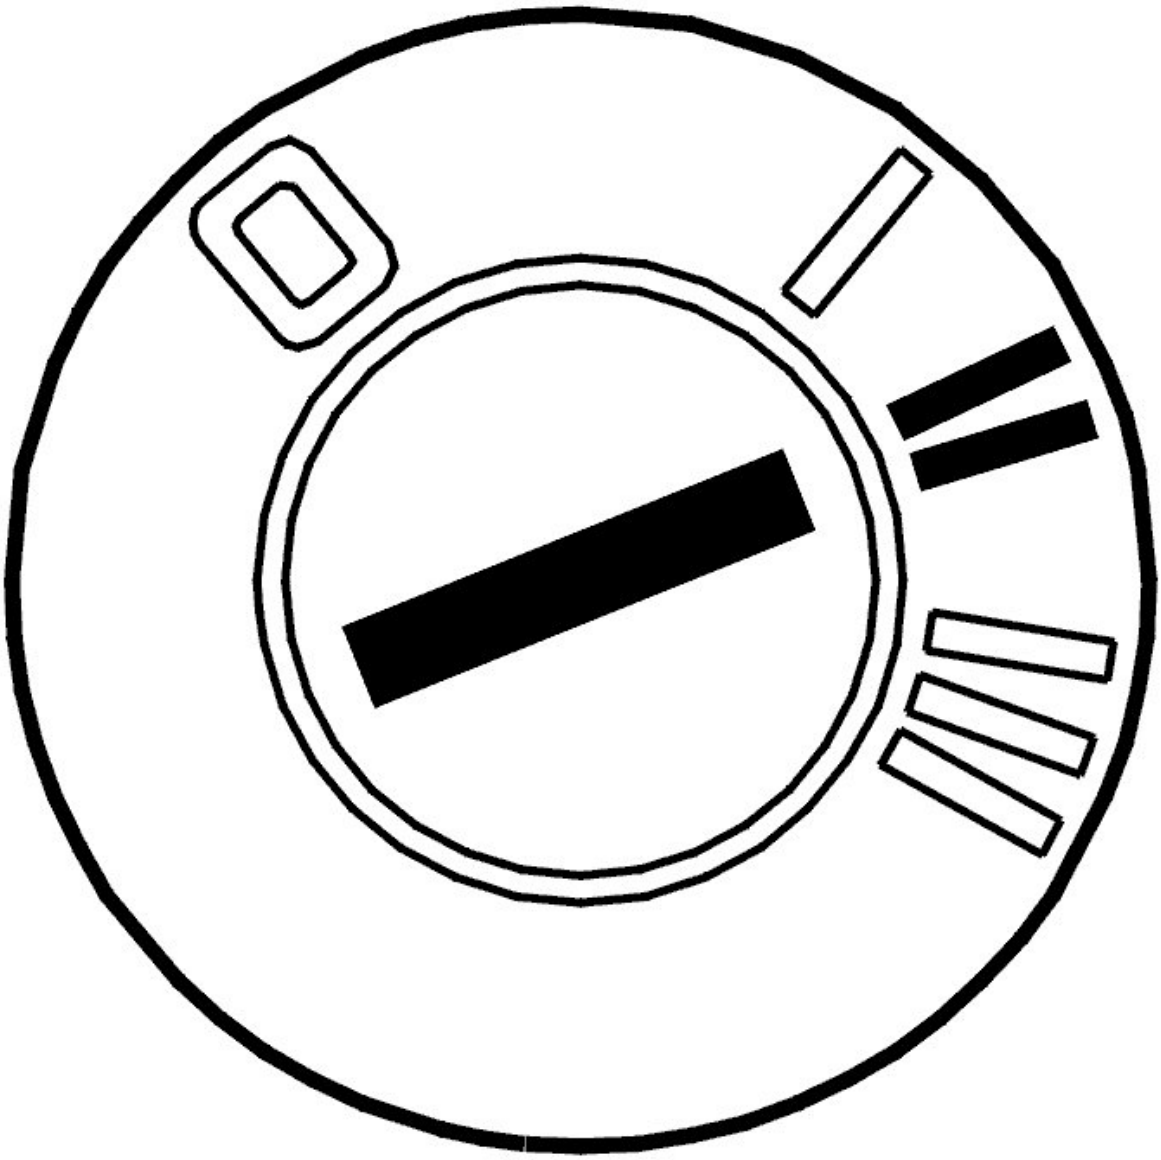
Resetting the oil quality counter

Resetting Transmission fluid change counter

Resetting Transmission fluid change counter

Hint: The transmission control module (TCM) has a counter for the oil quality. The counter counts up if the transmission is exposed to too high a load or an ambient temperature that is too high. If the counter is not reset when the oil is drained or changed, there is a risk that a diagnostic trouble code (DTC) will be stored in faulty circumstances. Therefore it is important that the "Transmission oil change" counter is reset.

Note! This applies only when the transmission fluid is changed and when the fluid is changed when repairs are carried out to the transmission temperature sensor.



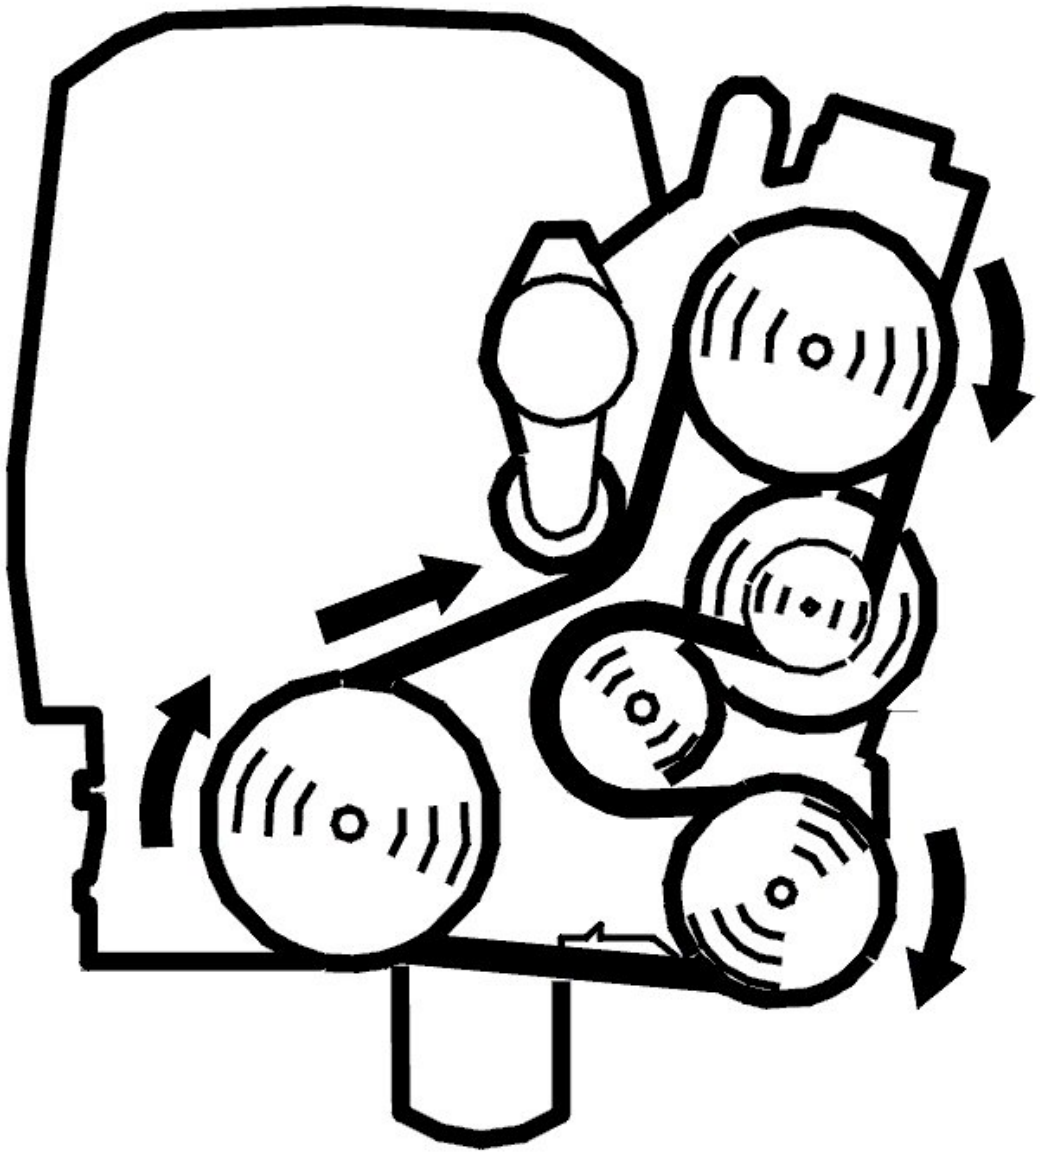
- Ignition on.

Reset the counter by clicking on the VCT 2000 symbol.

Continue - **DONE**

DONE - Verification

Checking the transmission output speed sensor signal



- Ignition off
- Raise the car so that the drive wheels can rotate freely
- Start the engine and let it run at idle speed
- Gear selector in position D
- Read off the transmission output speed signal.

Check that the speed increases with engine speed (RPM).

Note! A diagnostic trouble code (DTC) may be stored in the ABS system when the rear wheels are stationary and the front wheels rotate. Erase any diagnostic trouble codes (DTCs) in the ABS system after completing fault-tracing.

Other information:

- To disconnect the transmission control module (TCM), see Transmission control module (TCM), replacing, B5244T5, AW55-50/51SN, B5254T2, AW55-50/51SN, B5254T2, AW50/51 AWD See: Transmission Control Systems/Relays and Modules - Transmission and Drivetrain/Relays and Modules - A/T/Control Module/Service and Repair

Continue - Verification

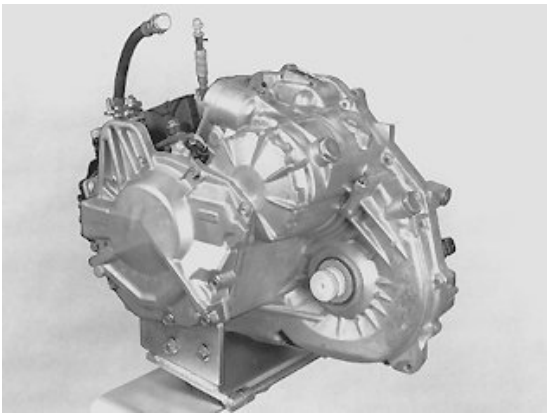
Replacing the transmission

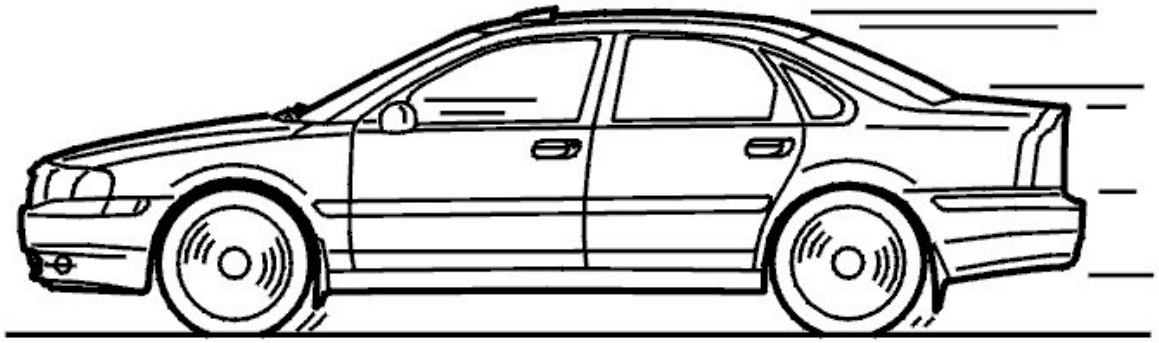
- Fault-tracing indicates an internal fault in the transmission. Replace the transmission. See Gearbox, removing See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Service and Repair/Removal and Replacement/Transmission, Removing and Installing the gearbox See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Service and Repair/Removal and Replacement/Transmission, Installation.



Continue - Verification

Test driving the transmission

Test drive the car. See Test drive schedule, description, B5244T5, AW55-50/51SN, B5254T2, AW55-50/51SN, B5254T2, AW50/51 AWD See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Service and Repair/Procedures/Test Drive Schedule, Description. When test driving, the oil temperature must be above 20°C.
Look out for any transmission malfunction.



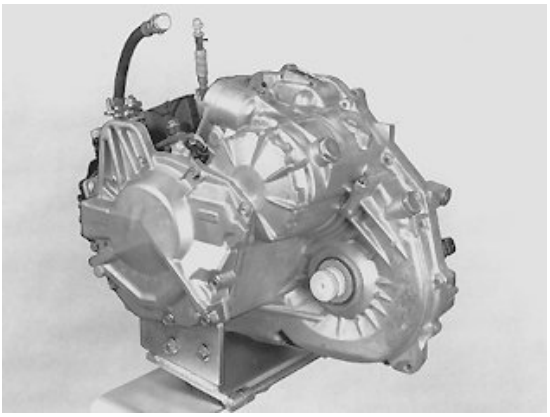
Is the transmission operating correctly?

Yes - Fault-tracing information

No - Replacing the transmission control system

Replacing the transmission control system

The previous tests indicate that there is a fault in the transmission control system.
Try a new control system. See Solenoid control system, replacing See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Service and Repair/Removal and Replacement/Automatic Transmission Components/Solenoid Control System, Replacing.



Select "Continue" when the fault has been remedied.

Continue - Resetting the adaptation and oil quality counter

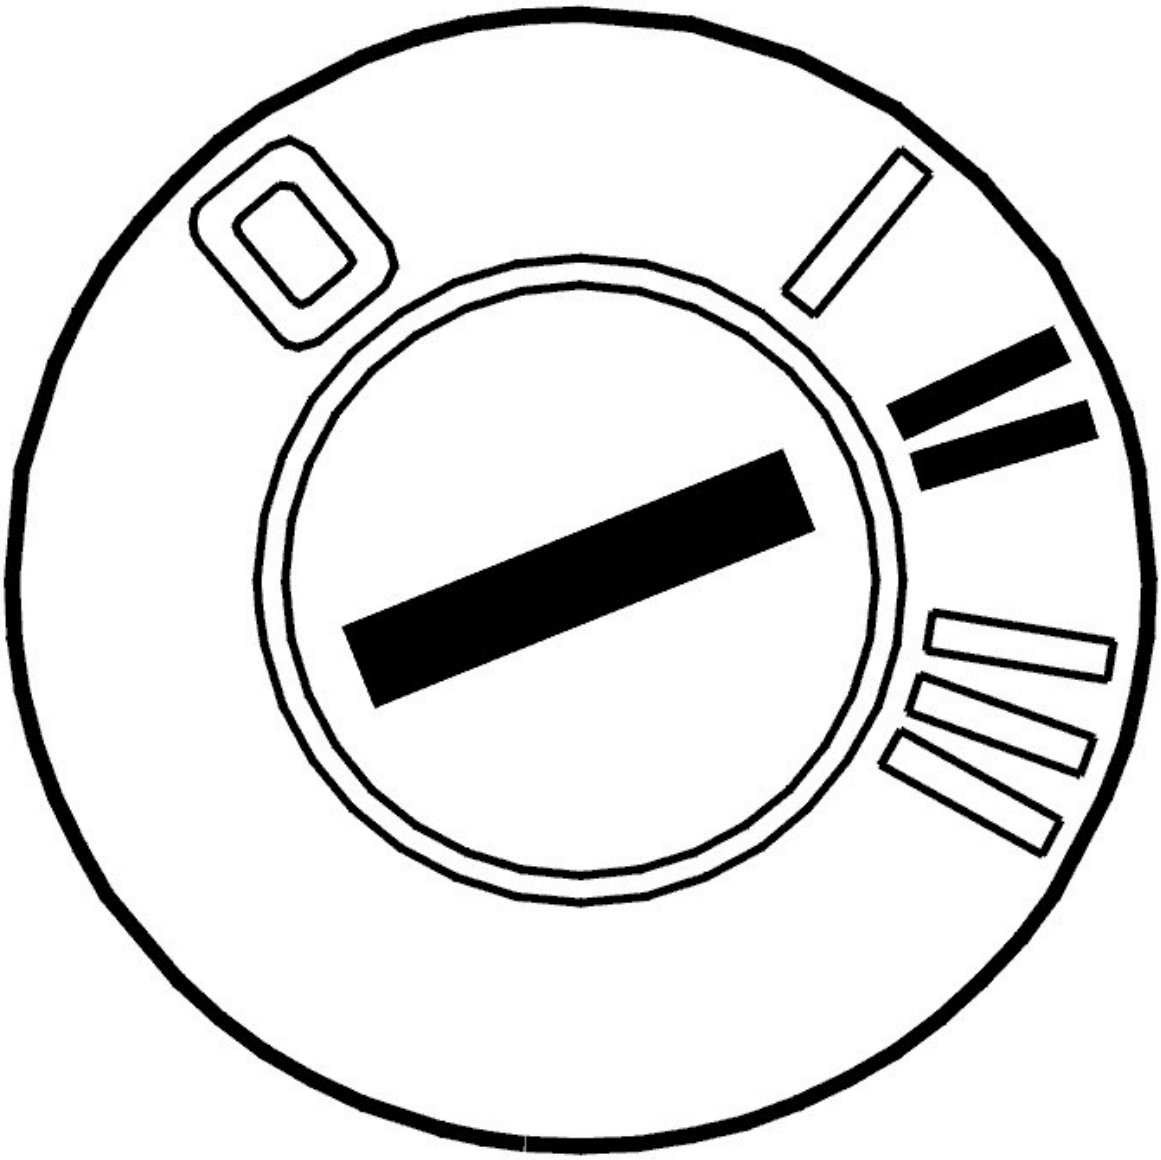
Resetting the adaptation and oil quality counter

Resetting the adaptation

Resetting adaptation and the counter for "Transmission oil change"

Hint: The transmission has torque controlled adaptive pressure control. Pressure control means that the transmission regulates the pressure itself during each gear shift. This avoids harsh gear shifting. Each gear shift is evaluated by the control module and stored in the memory. This allows for compensation for wear and tear in the transmission and clutch. It is important that the adaptation in the memory is reset after the transmission has been repaired. This is to ensure normal operation. The oil is replaced during repair; the "Transmission oil change" counter must be reset. If the counter is not reset when the fluid is drained and replaced, there is a risk that a diagnostic trouble code (DTC) will be stored in incorrect circumstances.

Note! This applies only if the transmission or one of the components in the transmission have been replaced.



- Ignition on.

Click on the VCT2000 symbol to reset the adaptation and counter.

Continue - DONE

DONE - Verification

Fault-tracing information

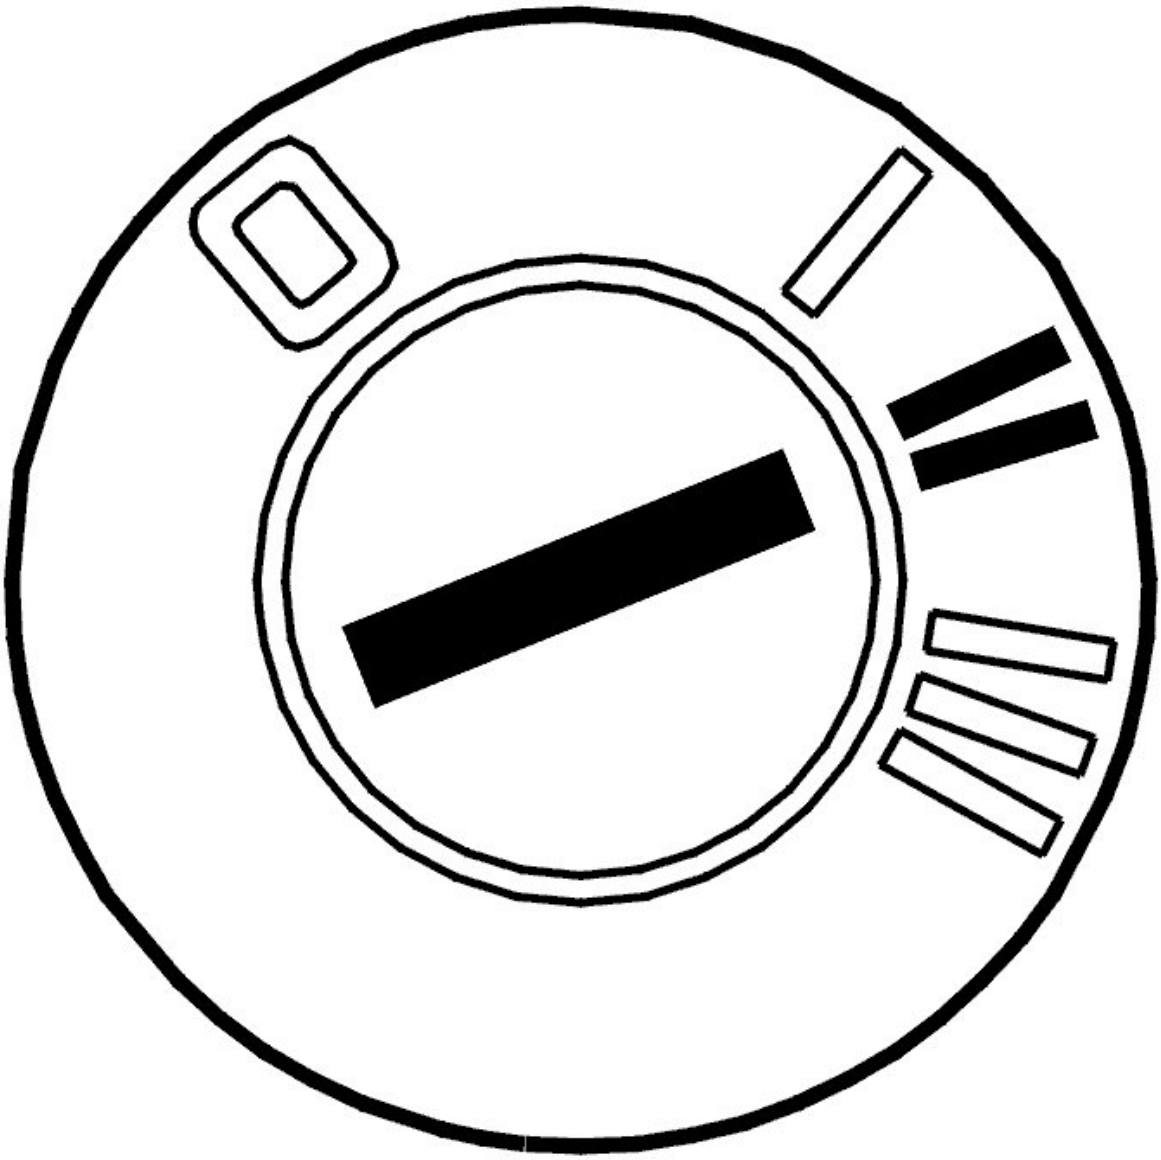
The control module has previously registered a fault. The fault is now no longer present. A test of the transmission function indicates that everything is now OK.

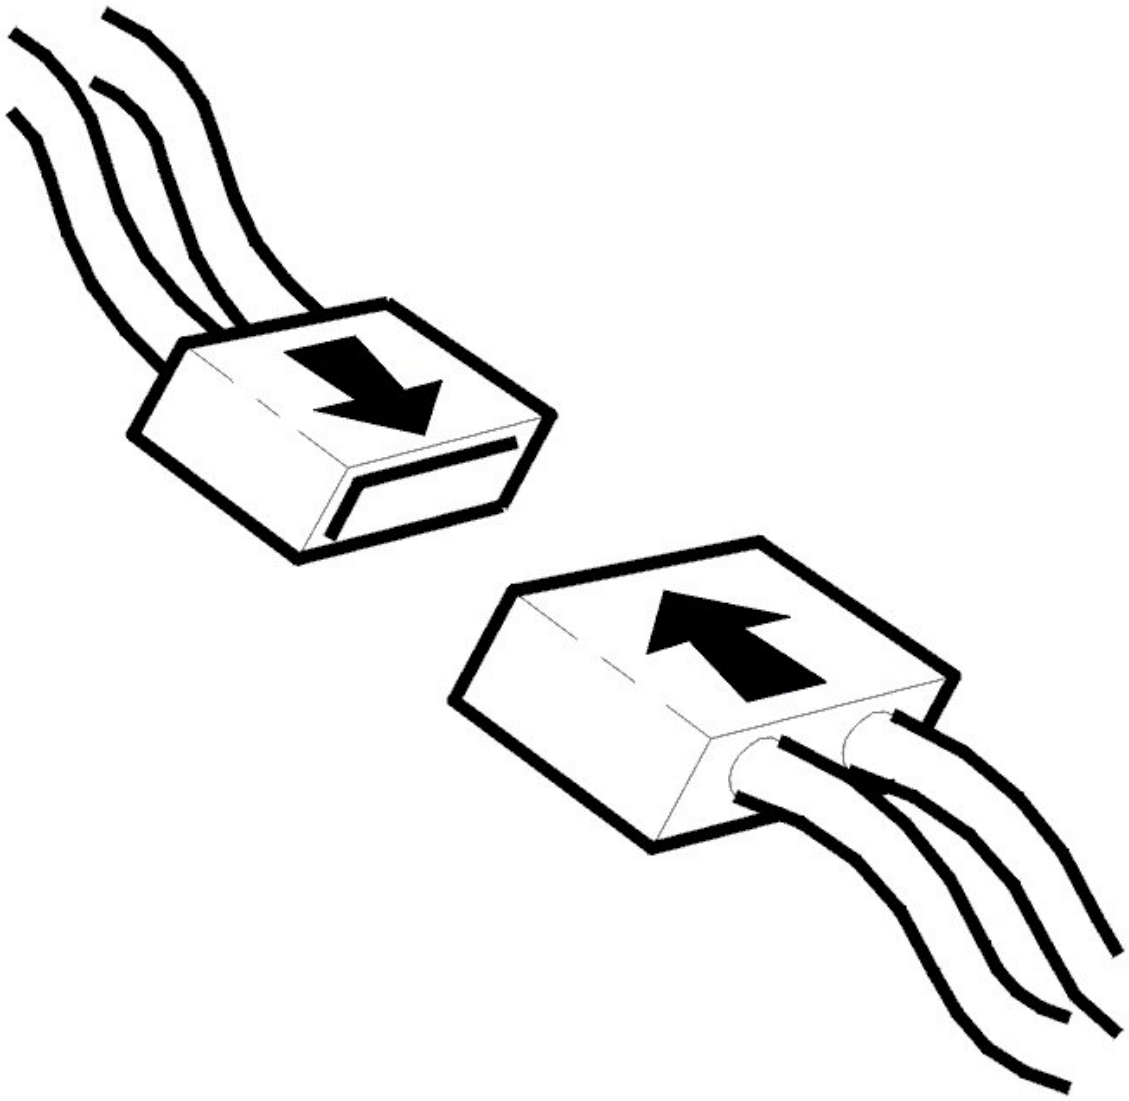
Continue - No Fault Found

Verification

Verification

Hint: After carrying out the repair, check that the fault has been remedied.





- Ignition off
- Reconnect the connectors, components, etc.
- Ignition on

Test drive the vehicle following: Test drive schedule, description See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Service and Repair/Procedures/Test Drive Schedule, Description
During the test drive, oil temperature should be over 20 °C.
Note any deviations in transmission function.

Does the transmission function flawlessly?

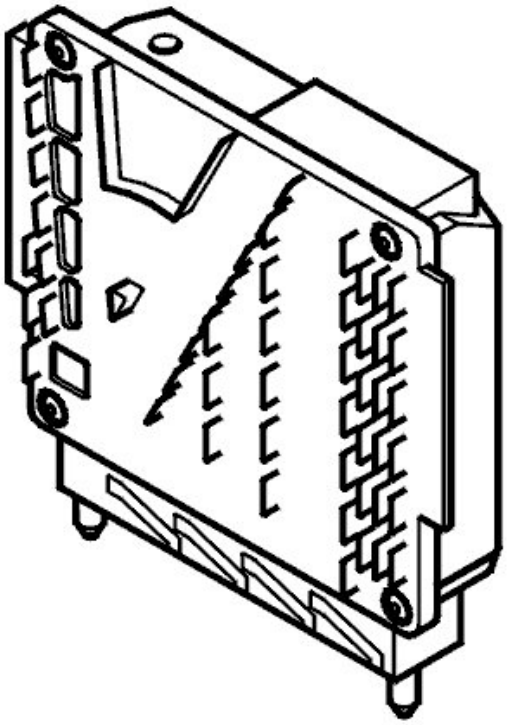
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition



The transmission control module (TCM) calculates the ratio between the transmission input speed and the vehicle speed. There is a specific ratio for each gear. Diagnostic trouble code (DTC) TCM-0028 is stored if the control module registers that the ratio deviates by more than 10 % when the oil temperature is above +20°C (68 °F) and throttle opening exceeds 3 %.

Substitute value

- The transmission control module (TCM) "Emergency mode I" program has been initiated.

Possible source

- Contact resistance in the circuit for solenoids S1, S2, S3, S4, S5 and SLS.
- Solenoid S1 has jammed in the OFF position.
- Mechanical fault in the transmission. Worn components in the transmission causing slippage or too low line pressure.

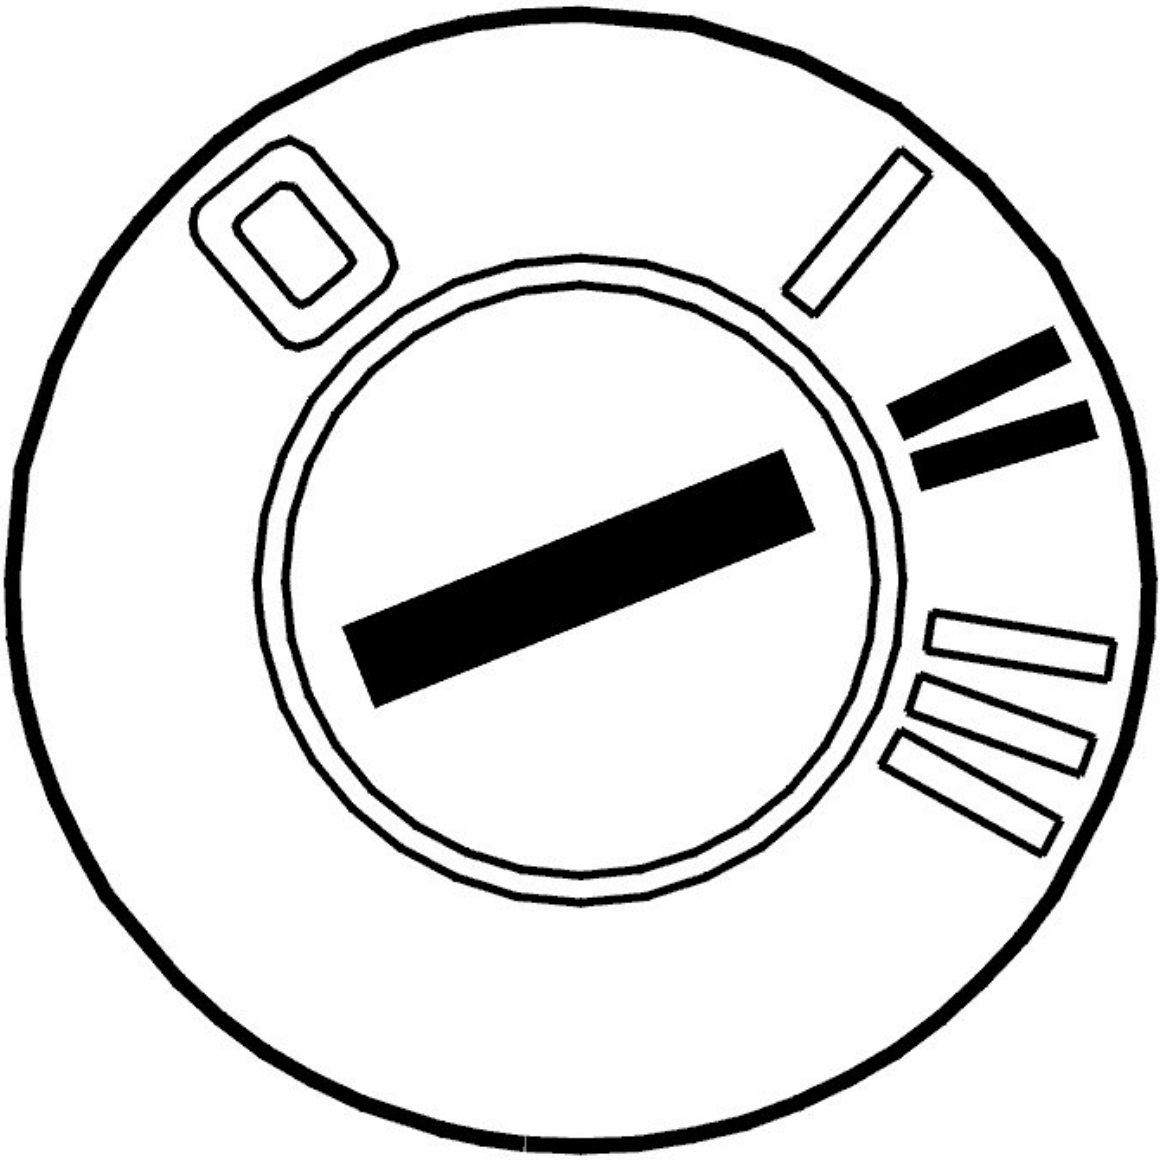
Fault symptom[s]

- General orange warning lamp lit.
- Malfunction indicator lamp (MIL) lit.
- No lock-up function.
- Harsh gear shifting.
- No shifting.

Incorrect Gear Ratio

Incorrect gear ratio

Checking the adjustment of the gear-shift position sensor



- Ignition on
- Read off the position of the gear selector.

Move the gear selector into all positions. Check that the gear-shift positions are updated.

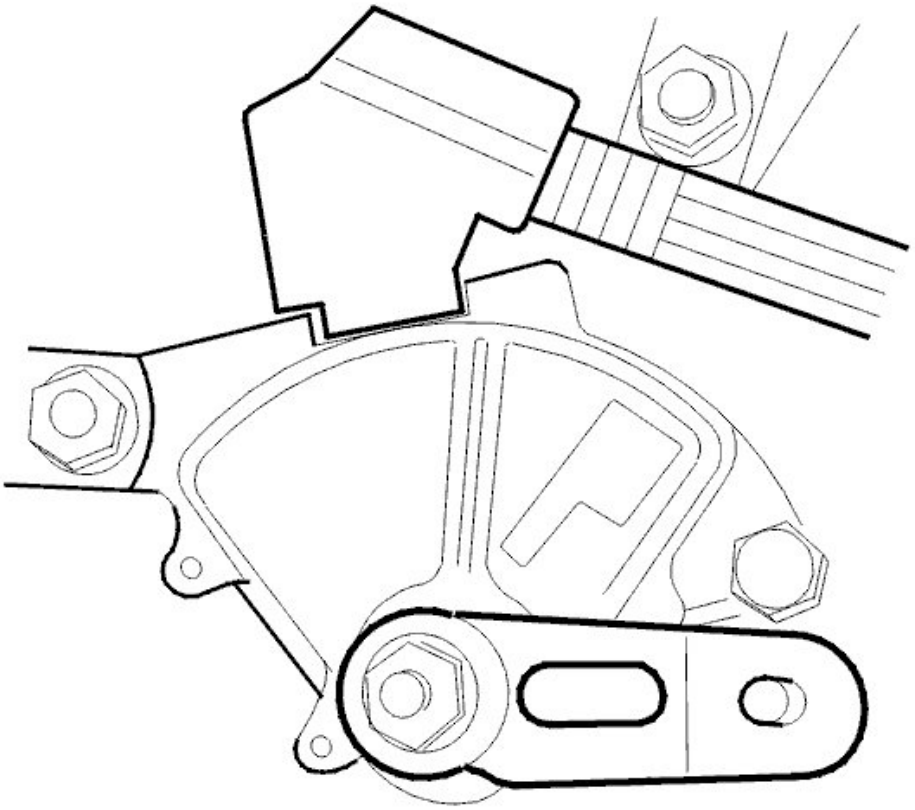
Note! Select the correct gear lever carrier from the list.

Hint: If the display shows an undefined position (O2 for example) the gear position sensor is incorrectly adjusted.

Remedy as necessary

Other information:

- Gear-shift position sensor, checking/adjusting See: Sensors and Switches - Computers and Control Systems/Transmission Position Switch/Sensor/Adjustments



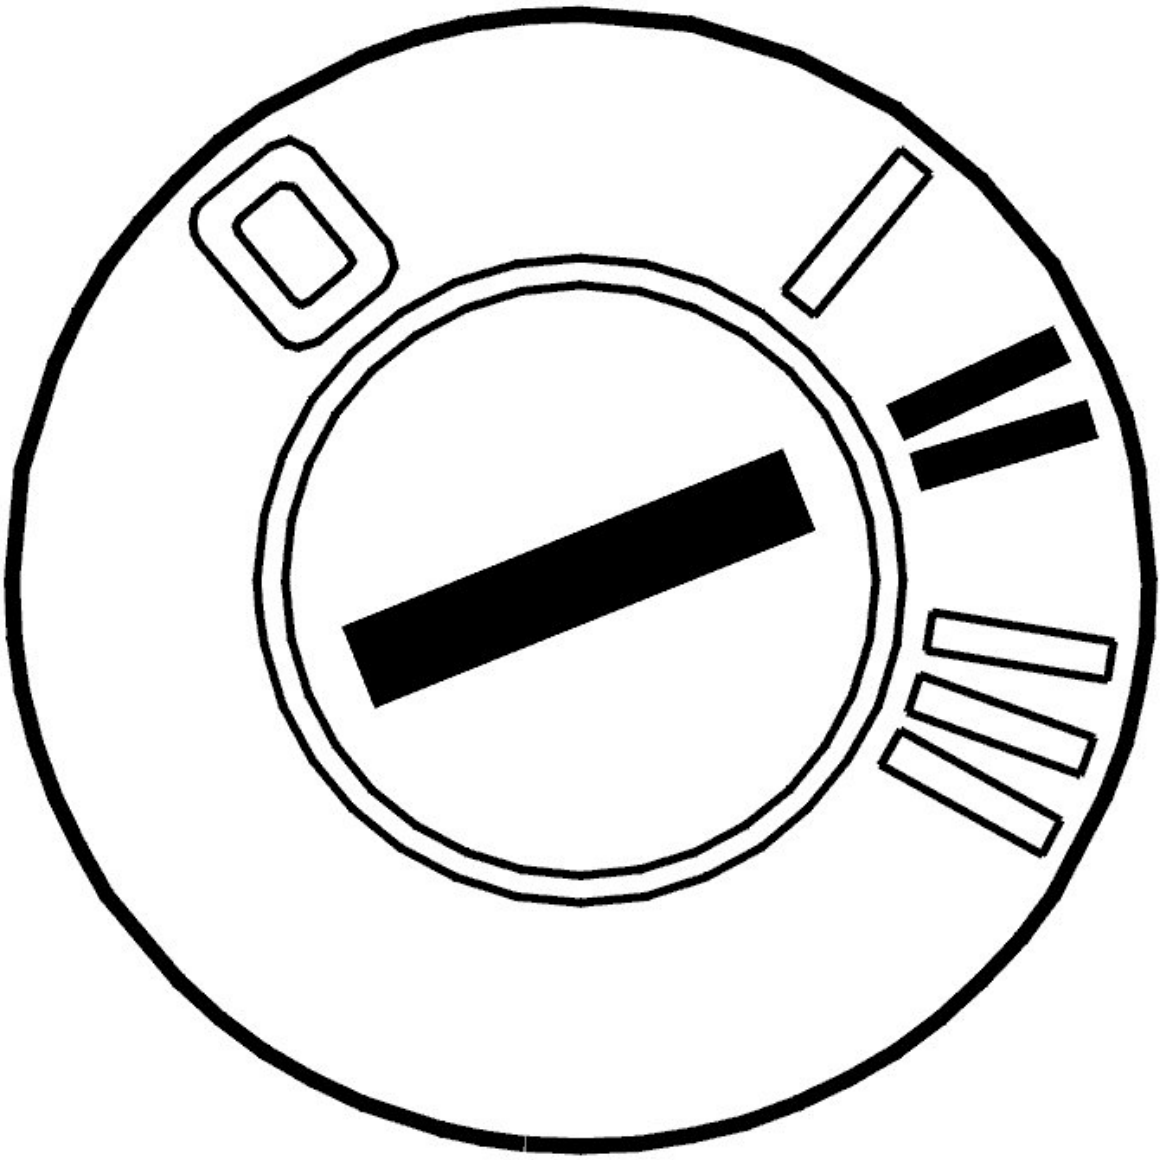
Is the gear-shift position sensor incorrectly adjusted?

Yes - Verification

No - Checking the quality and level of transmission fluid

Checking the quality and level of transmission fluid

Note! The quality and level of transmission fluid is vital to transmission function. It is therefore important that these are correct. Fluid level is also affected by its temperature.



- Ignition on
- Read the fluid temperature.

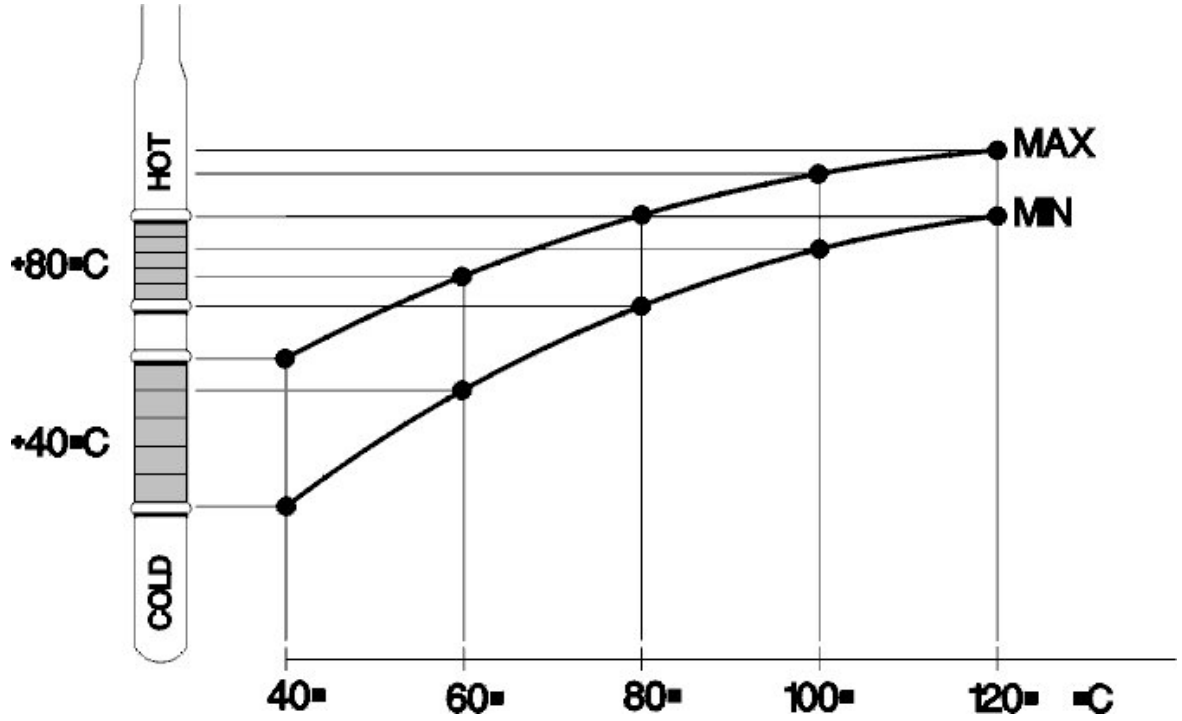
Check the transmission fluid level. If it is low, check the transmission for leaks and then top off the fluid.
Check the fluid quality.
If the fluid smells burnt, change the transmission fluid.
In addition, check the transmission fluid for an **abnormal** amount of particles by taking a sample with the dipstick.
If the transmission fluid contains an **abnormal** amount of particles, replace the transmission.

Other information

- Oil level, checking See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Service and Repair/Procedures/Transmission Oil Level - Checking
- Gearbox fluid, replacing See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Service and Repair/Removal and Replacement/Transmission Fluid, Replacing

Select an alternative below

1. No fault found.
2. Transmission fluid changed, level low or quality poor.
3. The transmission fluid contains an **abnormal** amount of particles.

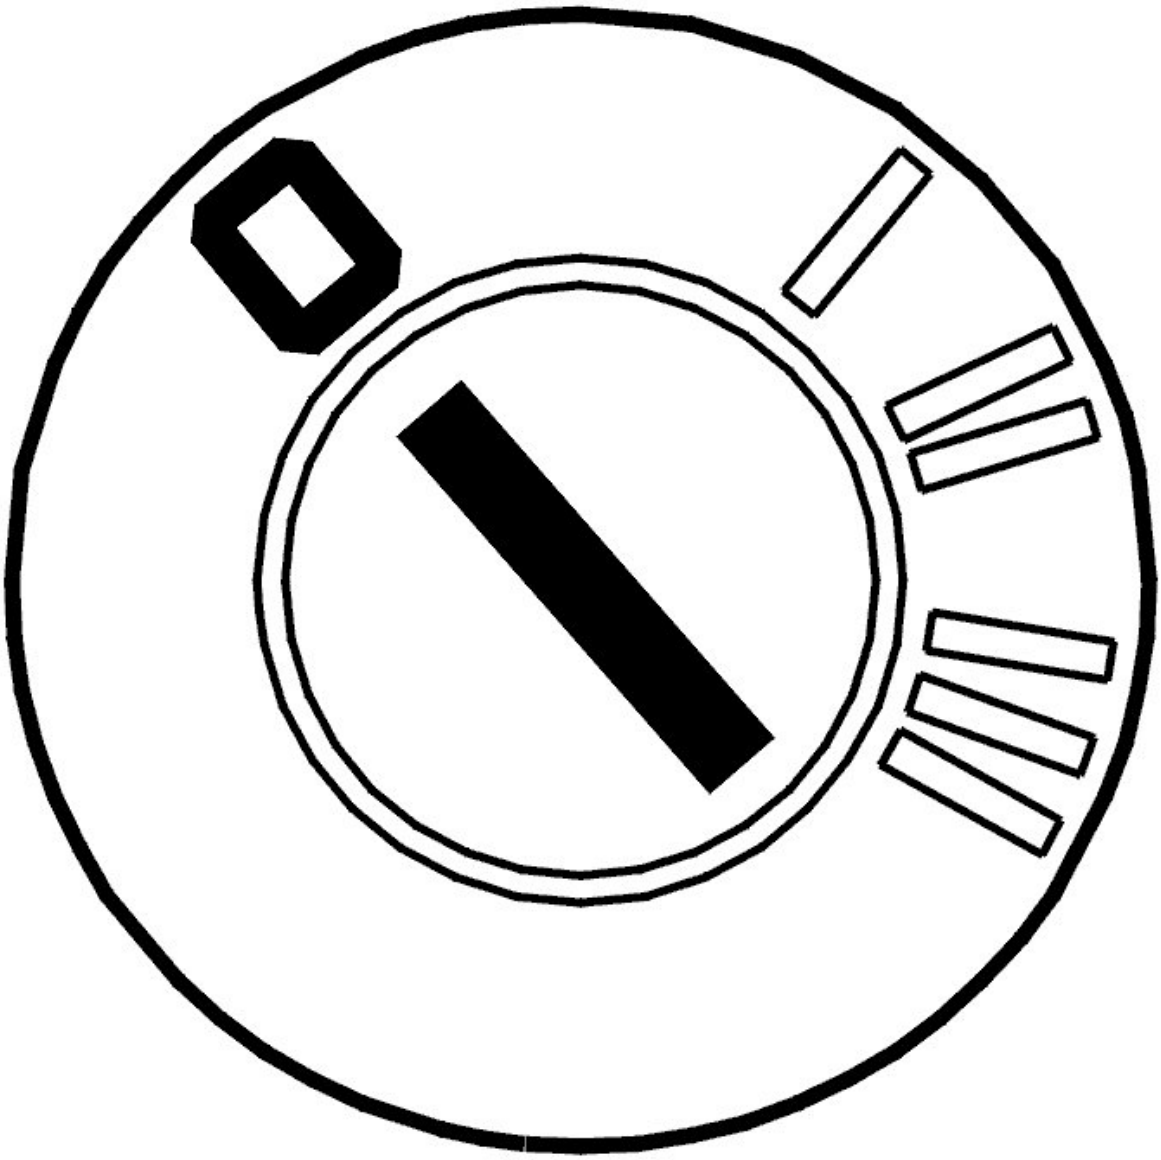


1 - Checking for contact resistance and oxidation

2 - Resetting adaptation and the fluid quality counter

3 - Replacing the gearbox

Checking for contact resistance and oxidation



- Ignition off

Check the transmission connectors and the control module connector for contact resistance and oxidation.

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition

The diagnostic trouble code (DTC) is stored if the control module repeatedly registers vibrations from slipping lock-up during a number of cycles.

Substitute value
- Slipping lock-up shuts off temporarily.

Possible source
- Poor quality transmission fluid.
- Glycol in the transmission fluid.
- Worn torque converter.
- Mechanical fault in the transmission.

Fault symptom[s]
- Cooling fluid consuption; High
- Vibrations
- Rough gear shift

The Transmission Jerks When Lock-Up Engages

The gearbox jerks when lock-up engages

Checking for the fault

Has the customer complained of vibrations?

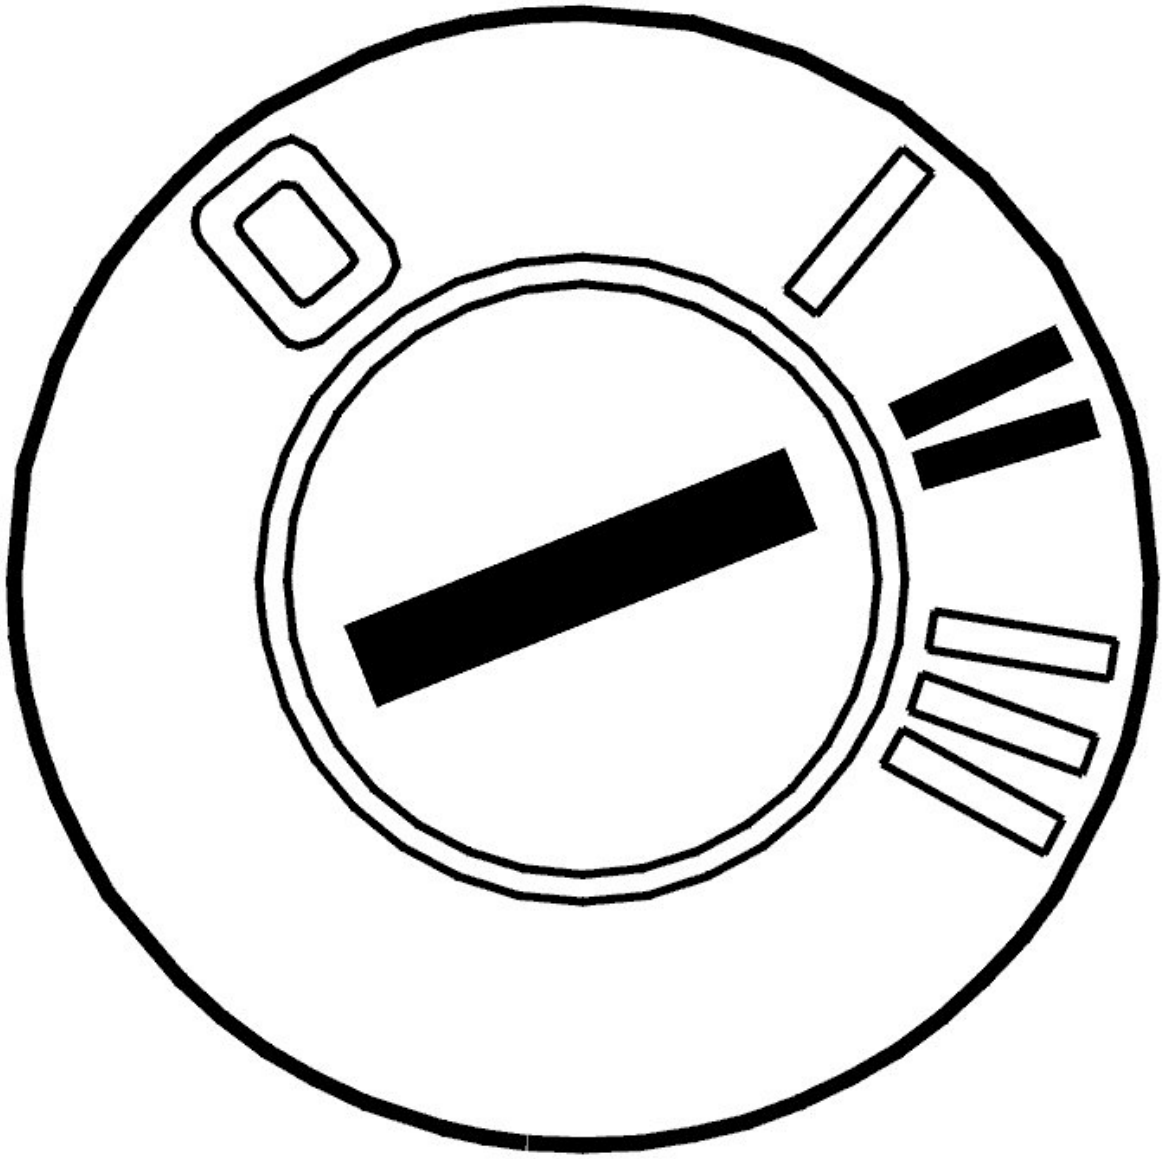
Yes - Checking oil quality and oil level in transmission

No - Fault-tracing without result

Checking oil quality and oil level in transmission

Note! Transmission fluid quality and level are extremely important for the function of the transmission. Therefore it is imperative that

these are correct. In addition the oil level is dependent on oil temperature.



- Ignition on.
- Read off the oil temperature.

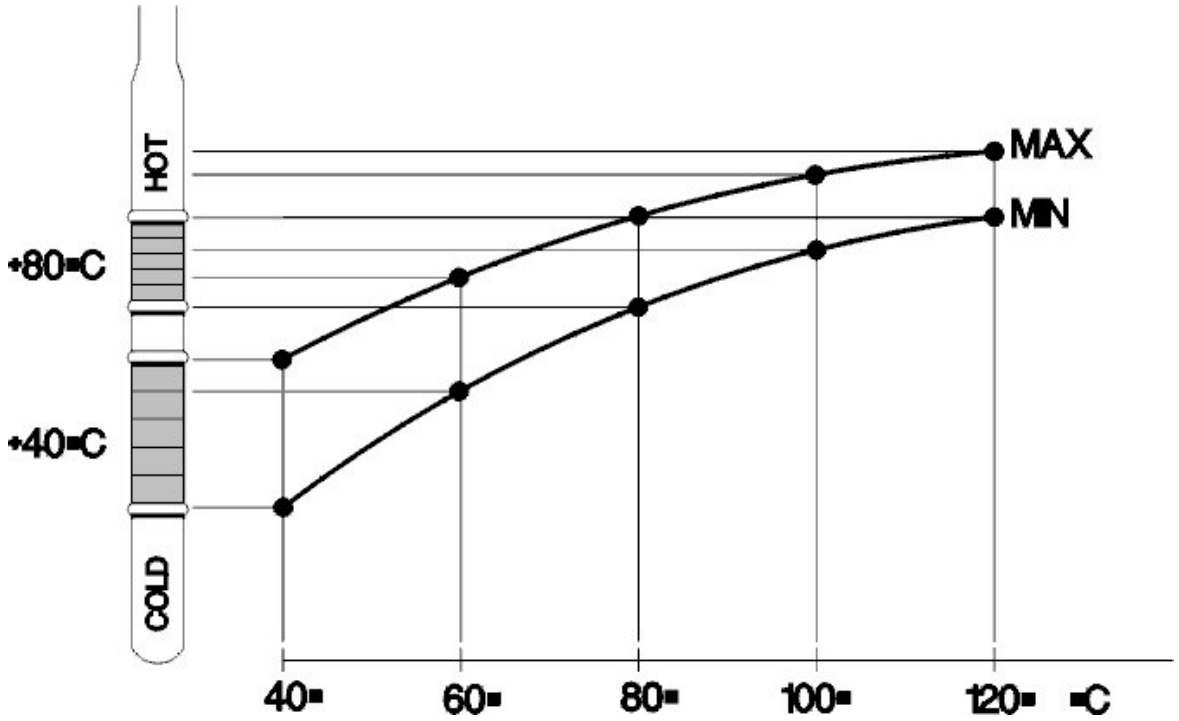
Check the oil level. If the oil level is low, check the transmission for leakage, then top up with oil.
Check the oil's quality.
If the oil smells burnt, change transmission oil.
Check the transmission fluid for metal swarf. Take a sample using the dip stick.
Replace the transmission if the transmission fluid contains metal swarf.

Other information:

- Gearbox fluid, replacing See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Service and Repair/Removal and Replacement/Transmission Fluid, Replacing
- Oil level, checking See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Service and Repair/Procedures/Transmission Oil Level - Checking
- Oil grade, checking See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Service and Repair/Procedures/Oil Grade, Checking

Select an alternative below:

1. No defect found.
2. Transmission oil changed, level low or quality poor.
3. The transmission fluid contains metal swarf.



1 - Checking the cooling system

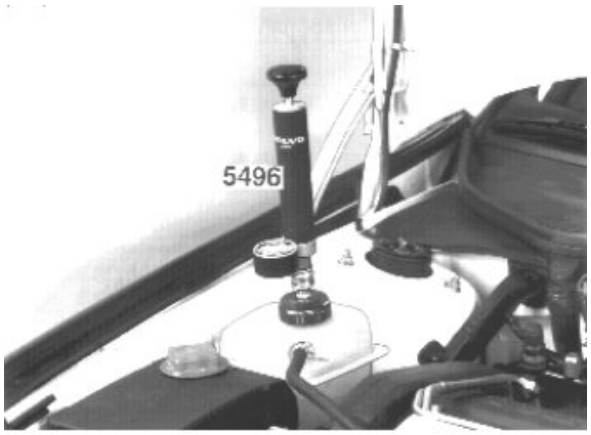
2 - Resetting the oil quality counter

3 - Replacing the gearbox

Checking the cooling system

- Perform the following check.

Test pressurization See: Engine, Cooling and Exhaust/Cooling System/Testing and Inspection



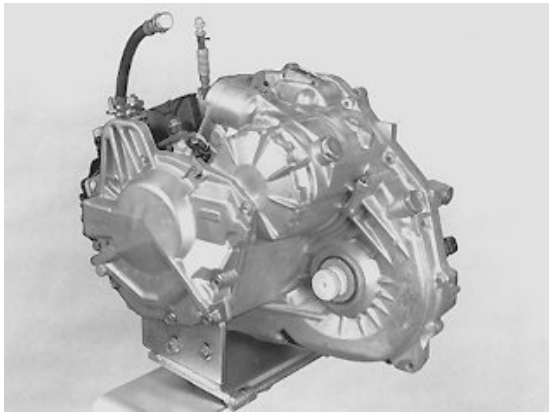
Does the pressure drop?

Yes - Checking the cooling system

No - Checking software

Replacing the gearbox

Earlier tests indicate that there is a fault in the transmission.
Replace transmission. See:
Gearbox, removing See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Service and Repair/Removal and Replacement/Transmission, Removing
Transmission, installing See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Service and Repair/Removal and Replacement/Transmission, Installation



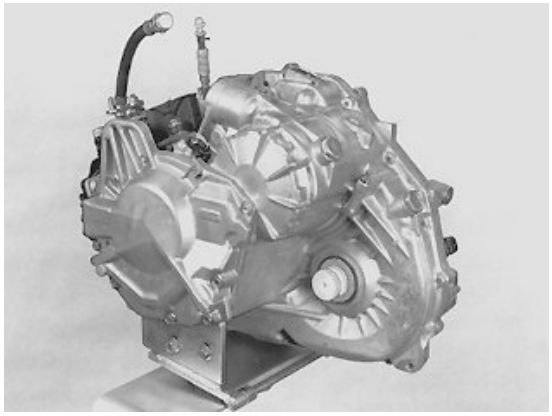
Continue - Resetting adaptation and the fluid quality counter

---

Checking software

Check that the control module has the latest version of the relevant software.

- If new software is available, download to the control module and then select Continue.
- If the control module already has the latest software select Continue.



Continue - Test driving the transmission

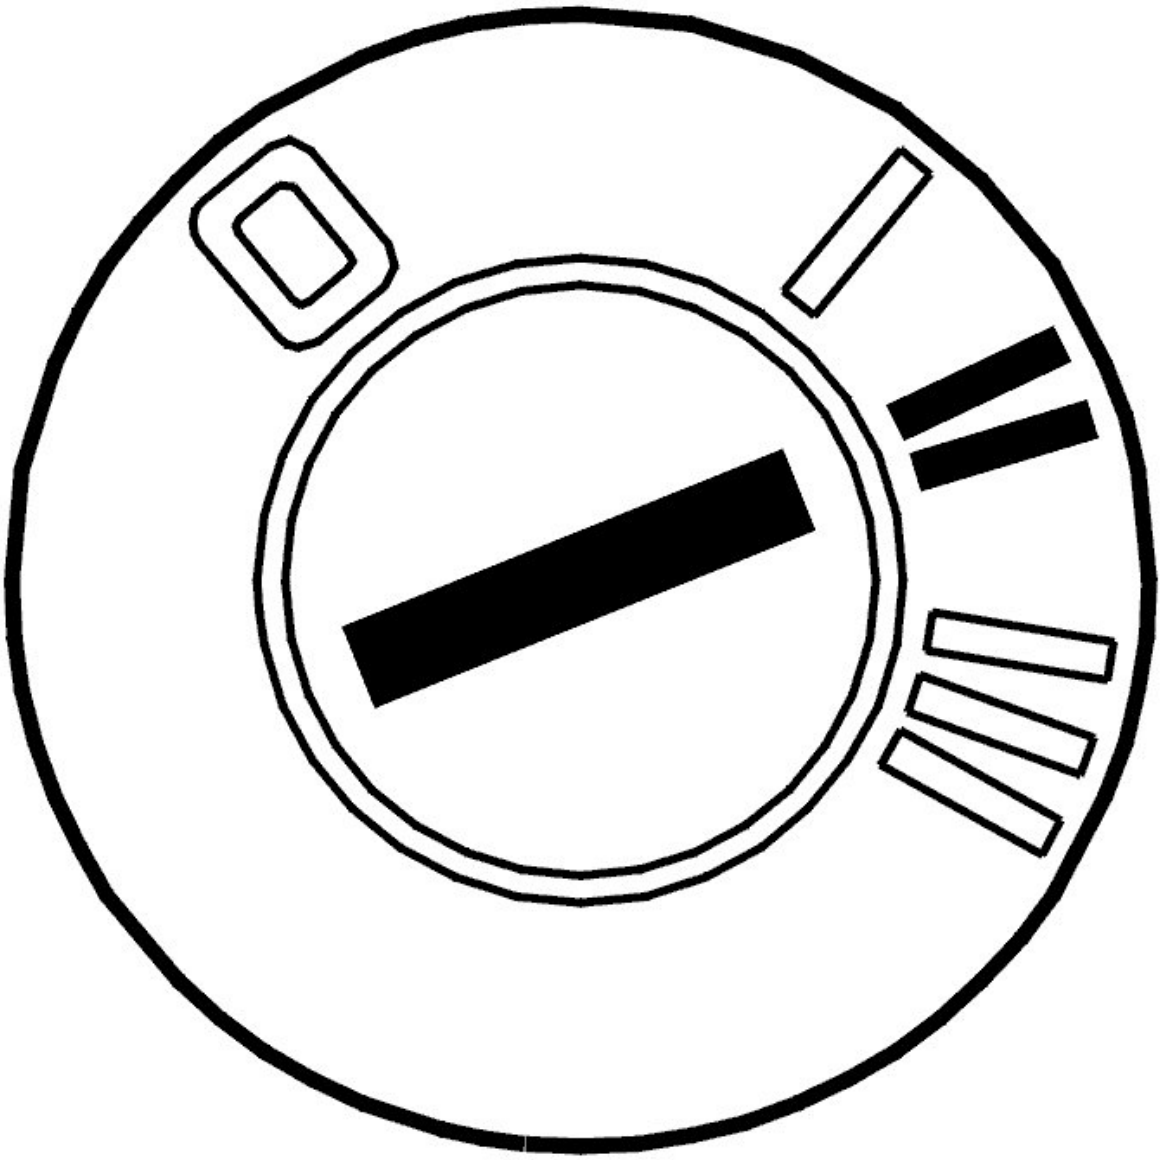
Resetting the oil quality counter

Resetting Transmission fluid change counter

Resetting Transmission fluid change counter

Hint: The transmission control module (TCM) has a counter for the oil quality. The counter counts up if the transmission is exposed to too high a load or an ambient temperature that is too high. If the counter is not reset when the oil is drained or changed, there is a risk that a diagnostic trouble code (DTC) will be stored in faulty circumstances. Therefore it is important that the "Transmission oil change" counter is reset.

Note! This applies only when the transmission fluid is changed and when the fluid is changed when repairs are carried out to the transmission temperature sensor.



- Ignition on.

Reset the counter by clicking on the VCT 2000 symbol.

Continue - DONE

DONE - Verification

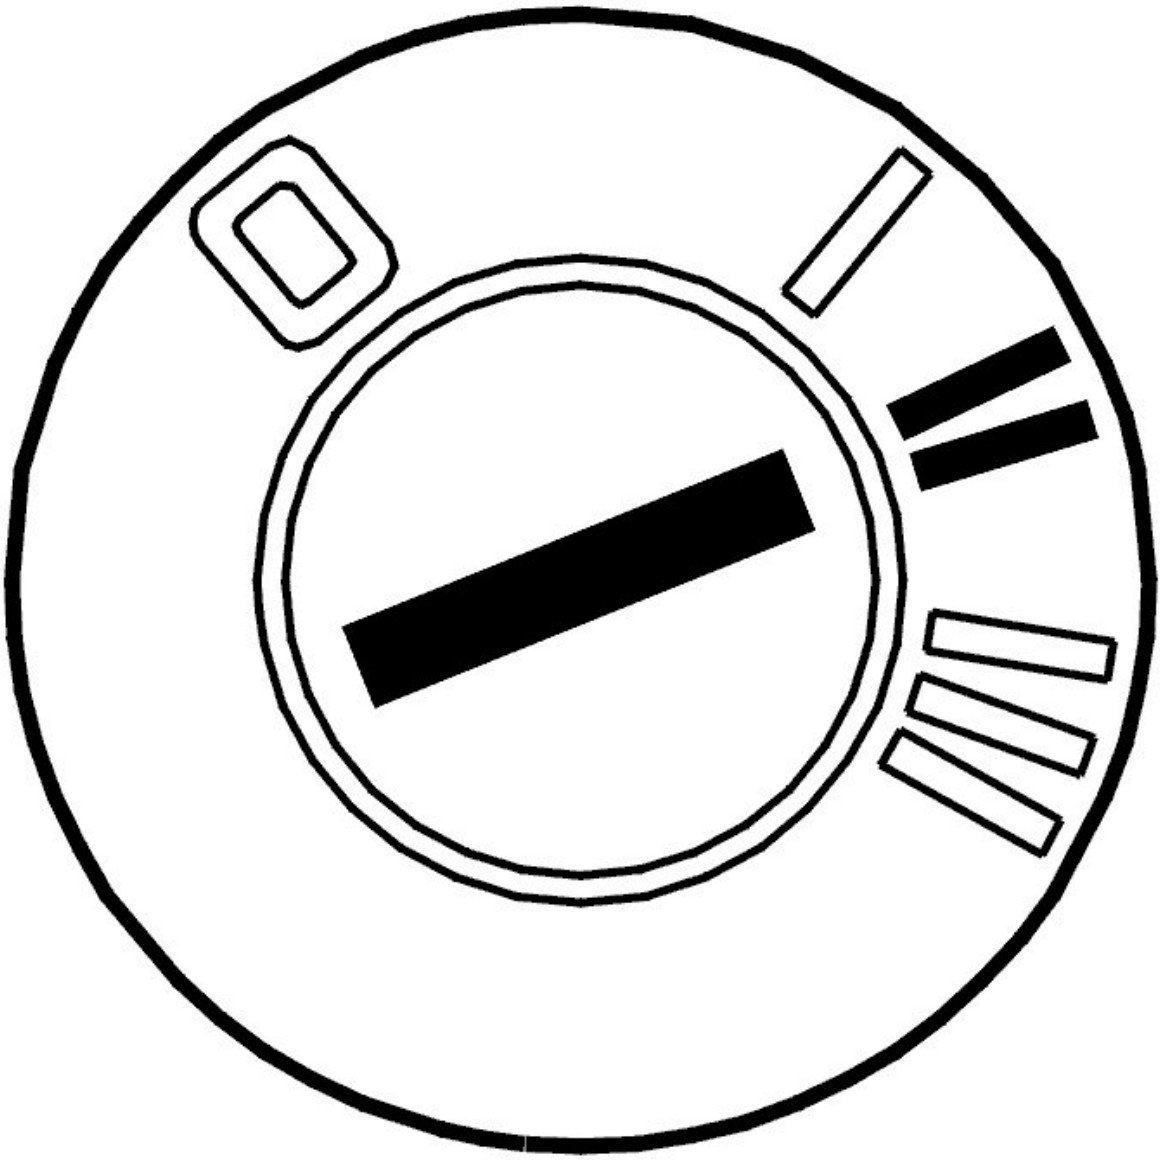
Resetting adaptation and the fluid quality counter

Resetting the adaptation

Resetting adaptation and the counter for "Transmission oil change"

Hint: The transmission has torque controlled adaptive pressure control. Pressure control means that the transmission regulates the pressure itself during each gear shift. This avoids harsh gear shifting. Each gear shift is evaluated by the control module and stored in the memory. This allows for compensation for wear and tear in the transmission and clutch. It is important that the adaptation in the memory is reset after the transmission has been repaired. This is to ensure normal operation. The oil is replaced during repair; the "Transmission oil change" counter must be reset. If the counter is not reset when the fluid is drained and replaced, there is a risk that a diagnostic trouble code (DTC) will be stored in incorrect circumstances.

Note! This applies only if the transmission or one of the components in the transmission have been replaced.



- Ignition on.

Click on the VCT2000 symbol to reset the adaptation and counter.

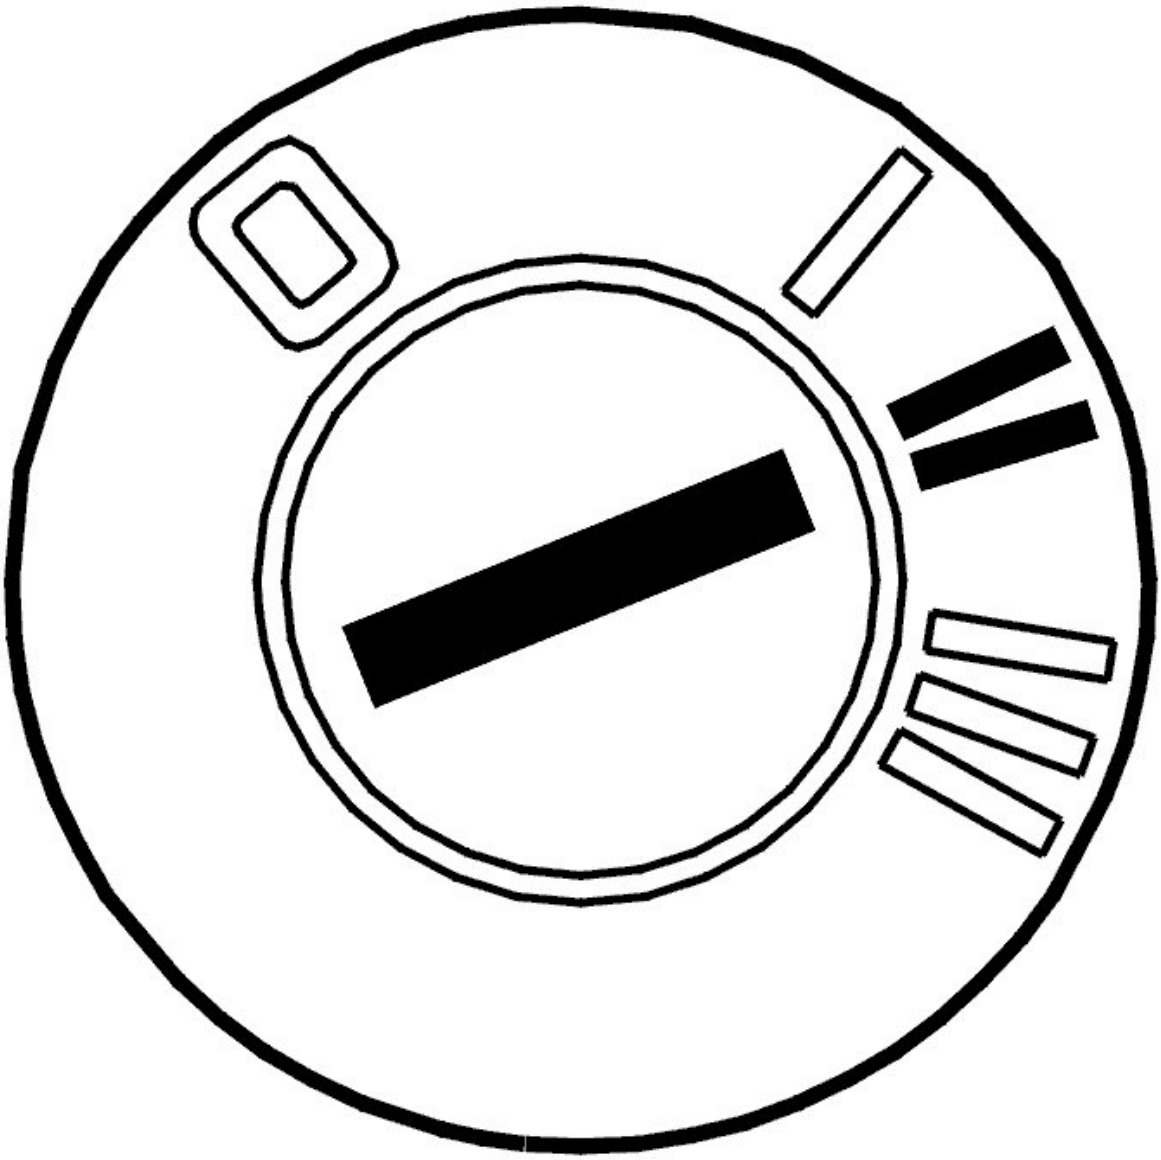
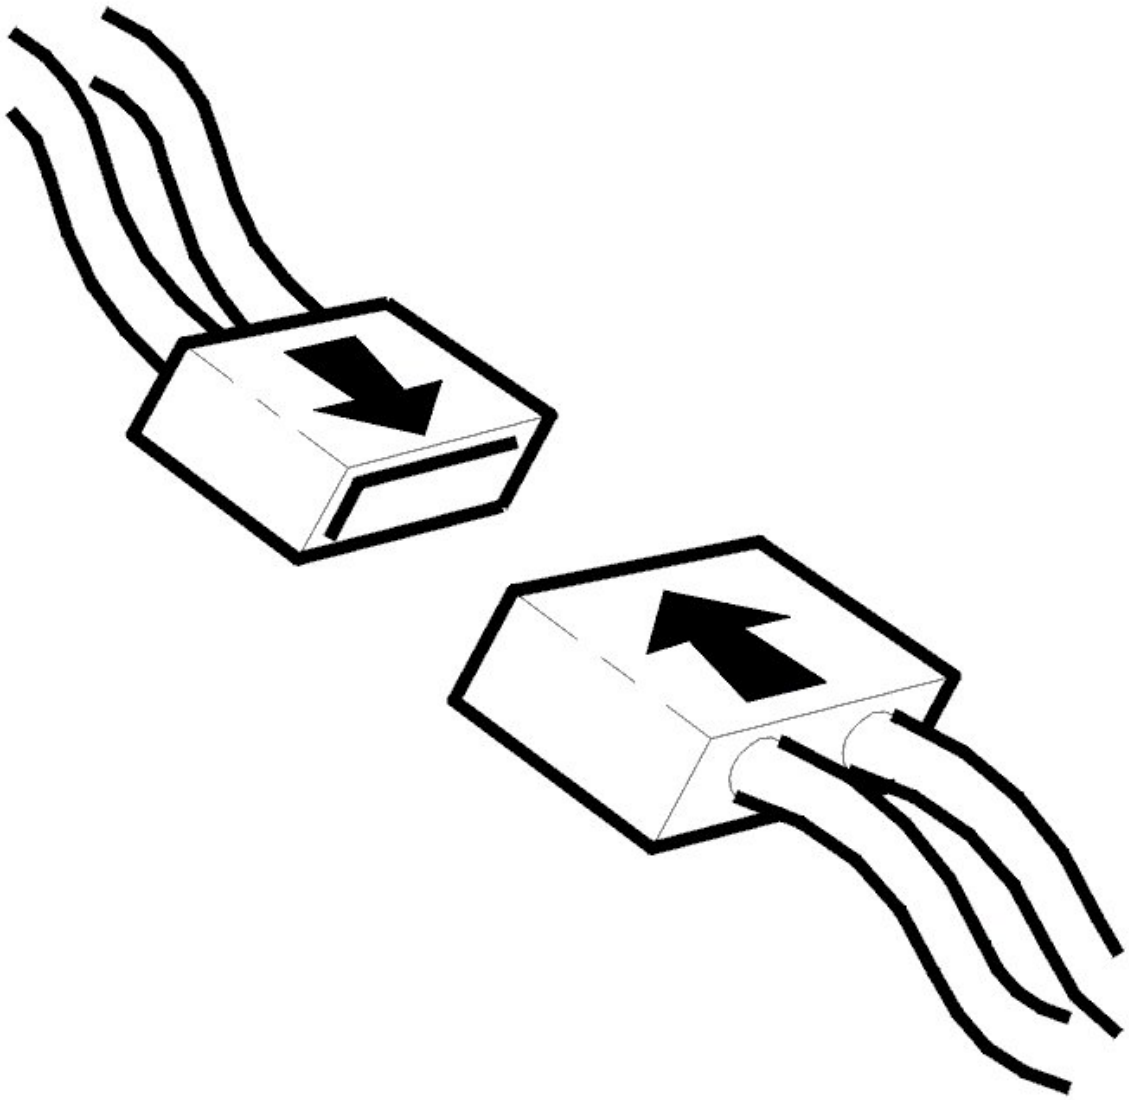
Hint: After carrying out the repair, check that the fault has been remedied.





- Ignition off.
- Reconnect the connectors, reinstall components etc.
- Ignition on.

Test drive the vehicle following:
Test-drive schedule TCM-002E AW55-50/51SN, AW55-50/51SN See: Diagnostic Trouble Code Tests and Associated Procedures/Manufacturer Code Charts/TCM Codes (Transmission Control Module)/TCM-002E/Test-Drive Schedule
During the test drive the oil temperature must be above 20°C.
Look out for any irregularities in the function of the transmission.

Is the transmission operating correctly?

Yes - VERIFIED

No - VERIFICATION FAILEDPAPER

VERIFICATION FAILED - Troubleshooting information

VERIFIED - Fault Found

Troubleshooting information

Information

Fault-tracing information

The fault should have been detected and remedied. As this is not the case fault-tracing has failed.

Exit fault-tracing for this diagnostic trouble code (DTC) or make another attempt.

Do you want to exit fault-tracing?

Yes - FAULT-TRACING FAILED

No - Attempt New Test

FAULT-TRACING FAILED - FAULT-TRACING FAILED

Attempt New Test - Checking for the fault

Fault-tracing without result

The diagnostic trouble code (DTC) indicates that a fault occurred previously but that the fault is no longer present.
No further corrective action is required if the diagnostic trouble code (DTC) is intermittent and does not recur.

Select "Continue" to exit.

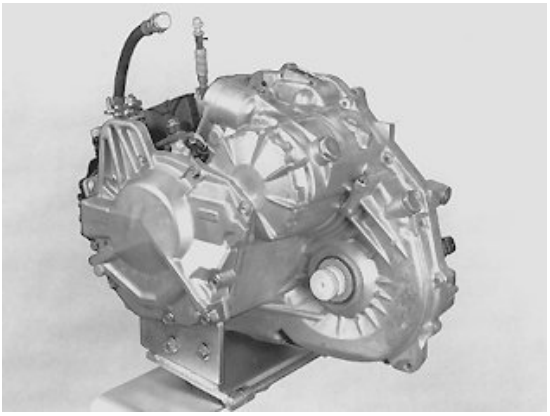
Continue - No Fault Found

Checking the cooling system

Ensure that the leak is the cause of the coolant coming in contact with the transmission oil by checking the quality of the oil.
If the quality of the transmission fluid had deteriorated due to leakage from the cooling system, replace the transmission, radiator, hoses and expansion tank as below.

Other information:

- Oil grade, checking, B5254T2, AW55-50/51SN, B5254T2, AW50/51 AWD See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Service and Repair/Procedures/Oil Grade, Checking
- Gearbox, removing See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Service and Repair/Removal and Replacement/Transmission, Removing
- Installing the gearbox See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Service and Repair/Removal and Replacement/Transmission, Installation
- Radiator / charge air cooler (CAC), replacement See: Fuel Delivery and Air Induction/Turbocharger/Intercooler/Service and Repair/Radiator / Charge Air Cooler (CAC), Replacement



Select "Continue" when you are ready.

Continue - Resetting adaptation and the fluid quality counter

---

Replacing the torque converter

- Ignition off.

Replace the torque converter.
Remedy as necessary.

Other information

- Replacing the sealing ring for the oil pump See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Seals and Gaskets/Service and Repair/Replacing the Sealing Ring For the Oil Pump

Continue - REPAIRED

Test driving the transmission

Test drive schedule, description See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Service and Repair/Procedures/Test Drive Schedule, Description Test drive schedule, description, B5244T5, AW55-50/51SN, B5254T2, AW55-50/51SN, B5254T2, AW50/51 AWD See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Service and Repair/Procedures/Test Drive Schedule, Description

Was any corrective action taken?

Yes - DONE

No - Replacing the torque converter

Test-Drive Schedule

Test-drive schedule TCM-002E AW55-50/51SN

Perform the following test-drive:

Note! Read through the whole document before starting to test-drive.

1. Check the oil temperature in the transmission via read-out. Suitable temperature range is 40-65 °C.
2. Start Activation of gear indication. See, Diagnostics/Vehicle communication/Advanced.

   Note! The activation only applies during one driving cycle.

3. Drive the vehicle with light load, approx. 60 km/h (37 mph) in 4th gear (engine speed approx. 1600 rpm). Check status of lock-up via control light IND.

   Hint: The problems occur at slipping lock-up (IND-light flashes).

4. When the IND-light flashes, throttle up slightly on a slight uphill grade. Pay attention to if a brief vibration occurs, and that slipping lock-up is turned off. The engine speed should increase by approx. 500 rpm.

   Vehicles with GearTronic lever carrier:
   1. Perform the same step as above once more with the gear lever in GearTronic-position with 4th gear selected. Try also to keep the engine in the same engine speed range as during the previous check. In this position, slipping lock-up will not be possible, only locked lock-up. Then the indicator light will be on with a steady glow.

   Vehicles with standard lever carrier:
   - Perform the same step as above but with the gear lever in position 3. Try also to keep the engine in the same engine speed range as during the previous check. In this position, slipping lock-up will not be possible, only locked lock-up. Then the indicator light will be on with a steady glow.
1. Check if the vibrations follow the speed or if they are brief vibrations.

Note! It is likely that no new diagnostic trouble code will be stored as the diagnosis requires that the malfunction occurs during a number of driving cycles to enable storing of the diagnostic trouble.

Perform one of the alternatives below:

1. Vibrations occur both at slipping and locked lock-up: replace transmission.
Gearbox, removing See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Service and Repair/Removal and Replacement/Transmission, Removing
Installing the gearbox See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Service and Repair/Removal and Replacement/Transmission, Installation
2. Vibrations only occur at slipping lock-up: replace torque converter.

3. Vibrations only occur at locked lock-up: replace transmission.
Gearbox, removing See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Service and Repair/Removal and Replacement/Transmission, Removing
Installing the gearbox See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Service and Repair/Removal and Replacement/Transmission, Installation

4. Vibrations follow the speed:

Investigate other components, such as tire imbalance and similar.

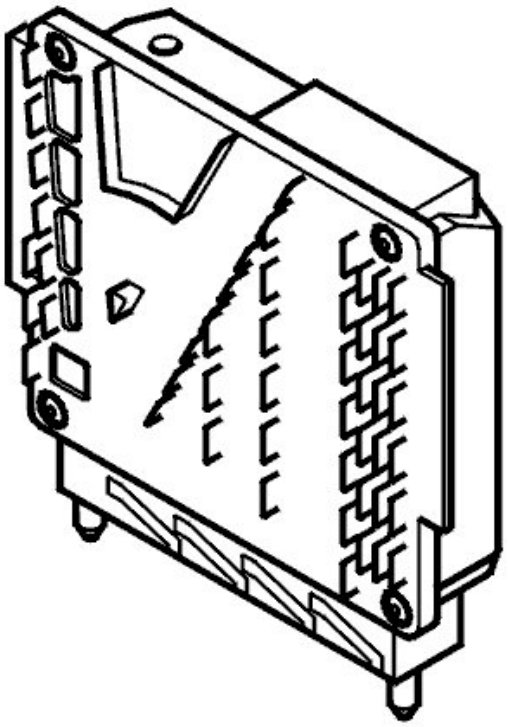
5. No vibrations can be detected:

No further troubleshooting is required.

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code information

Condition



The automatic transmission checks that lock-up is not engaged or slips by comparing the rpm signal from the transmission speed (rpm) sensor to the engine speed. The signals must then show the same calculated speed (rpm). If the control module detects that the engine speed (RPM) signals do not correspond with the programmed values, it means that lock-up is slipping or does not engage in the locked position. The diagnostic trouble code (DTC) is stored.

Substitute value

- Control unit help program "Emergency mode I" has started to work.

Possible source

- Poor quality transmission fluid.
- Water in the oil.
- Contact resistance in the connectors.
- Gear shift solenoid S4 is jammed in OFF position.
- Gear shift solenoid SLU is jammed in OFF position.
- Mechanical fault in the gearbox.

Fault symptom[s]

- Orange general warning lamp is on.
- Malfunction indicator light (MIL) is on.
- No lock up function.
- Rough gear shifts.

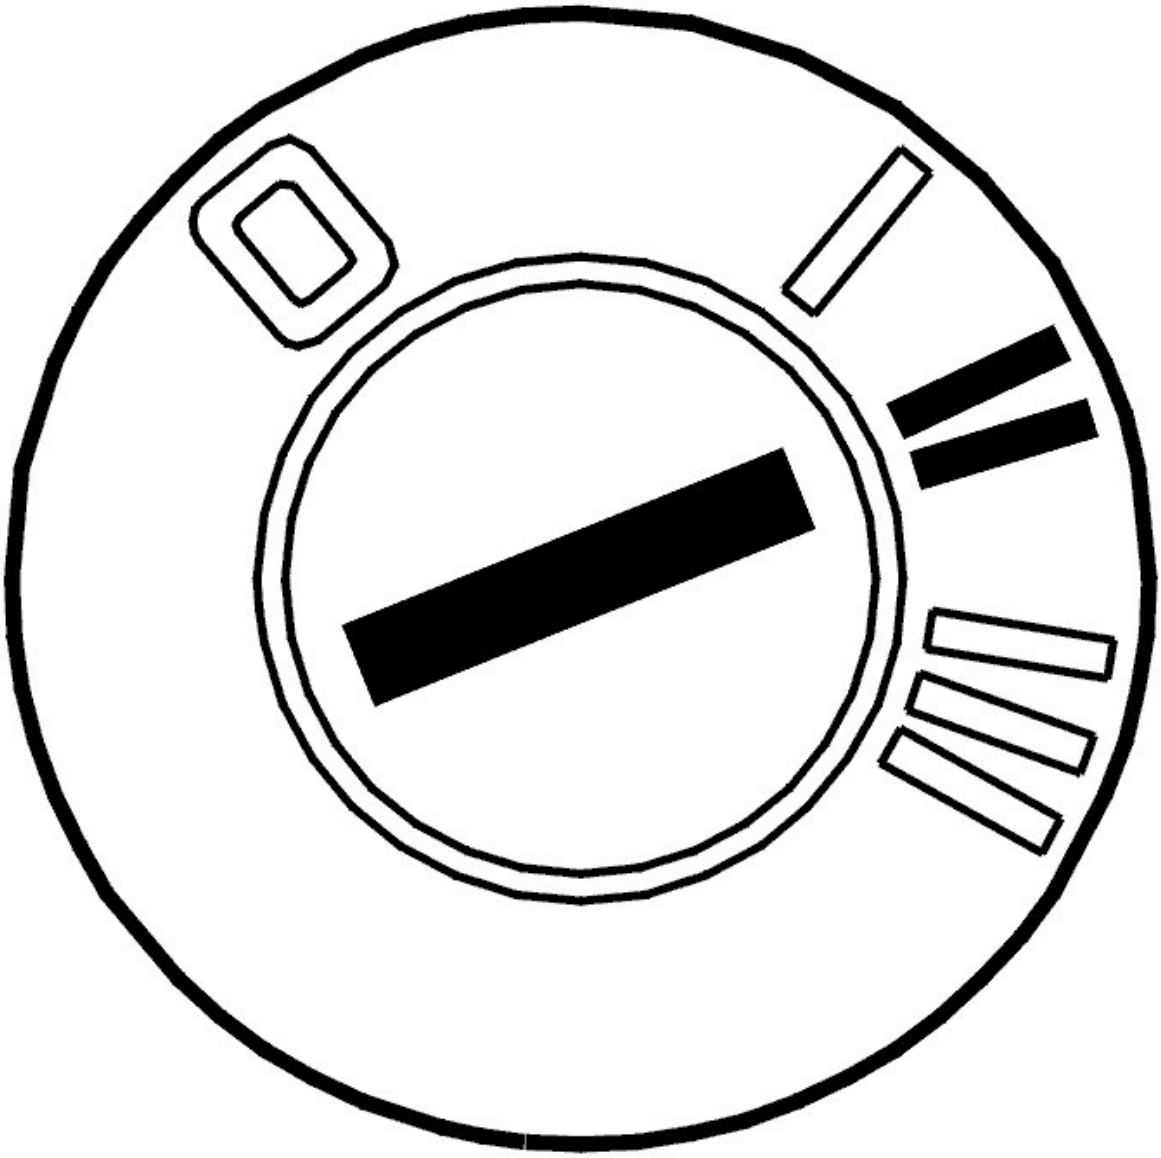
Slipping or Not Engaged

Slipping or not engaged

Checking the oil quality and the oil level in the transmission

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

Note! Transmission fluid quality and level are extremely important for transmission function. Therefore it is imperative that these are correct. In addition the oil level is dependent on oil temperature.



- Ignition on
- Read off the oil temperature.

Check the oil level. Check the transmission for leakage if the fluid level is low. Then top up with oil.
Check the quality of the oil.
Check the transmission fluid for metal swarf. Take a sample using the dip stick.

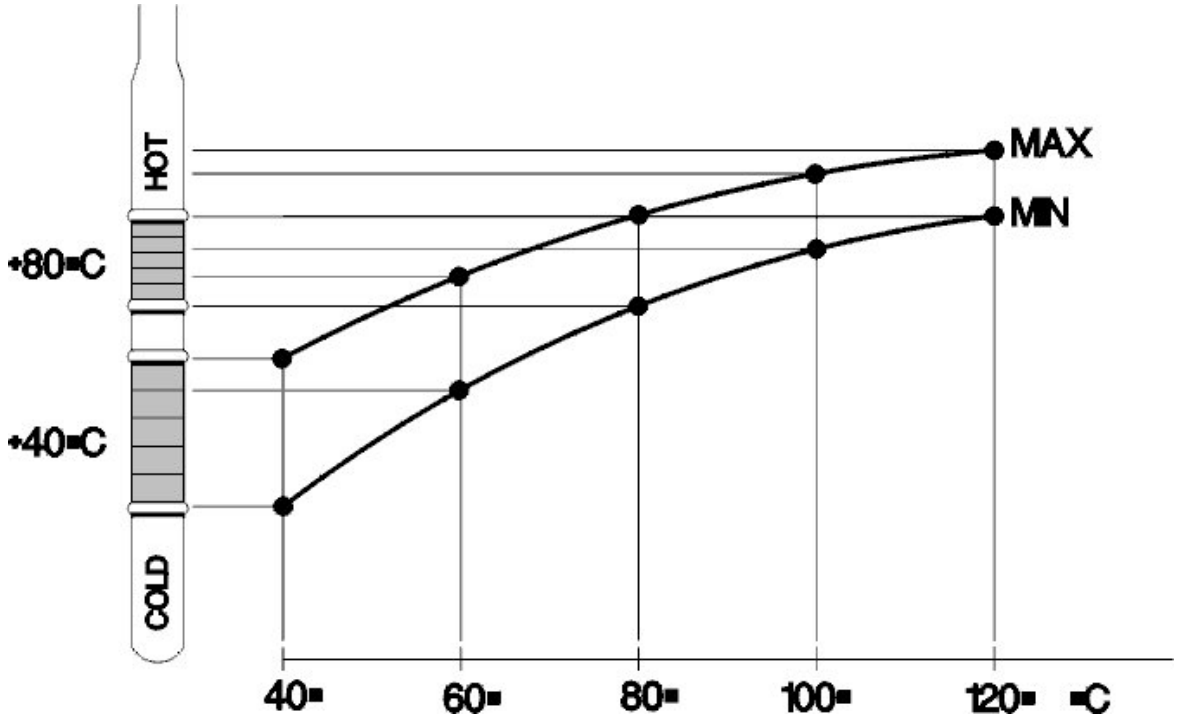
- Replace the transmission if the transmission fluid contains metal swarf
- Replace the transmission fluid if the fluid smells burnt.

Other information:

- Transmission fluid, replacing See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Service and Repair/Removal and Replacement/Transmission Fluid, Replacing
- Oil level, checking See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Service and Repair/Procedures/Transmission Oil Level - Checking
- Oil grade, checking, B5254T2, AW55-50/51SN, B5254T2, AW50/51 AWD See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Service and Repair/Procedures/Oil Grade, Checking

Select an alternative below:

1. No fault detected
2. Transmission fluid replaced, the level was low or quality was poor
3. The transmission fluid contains metal swarf.

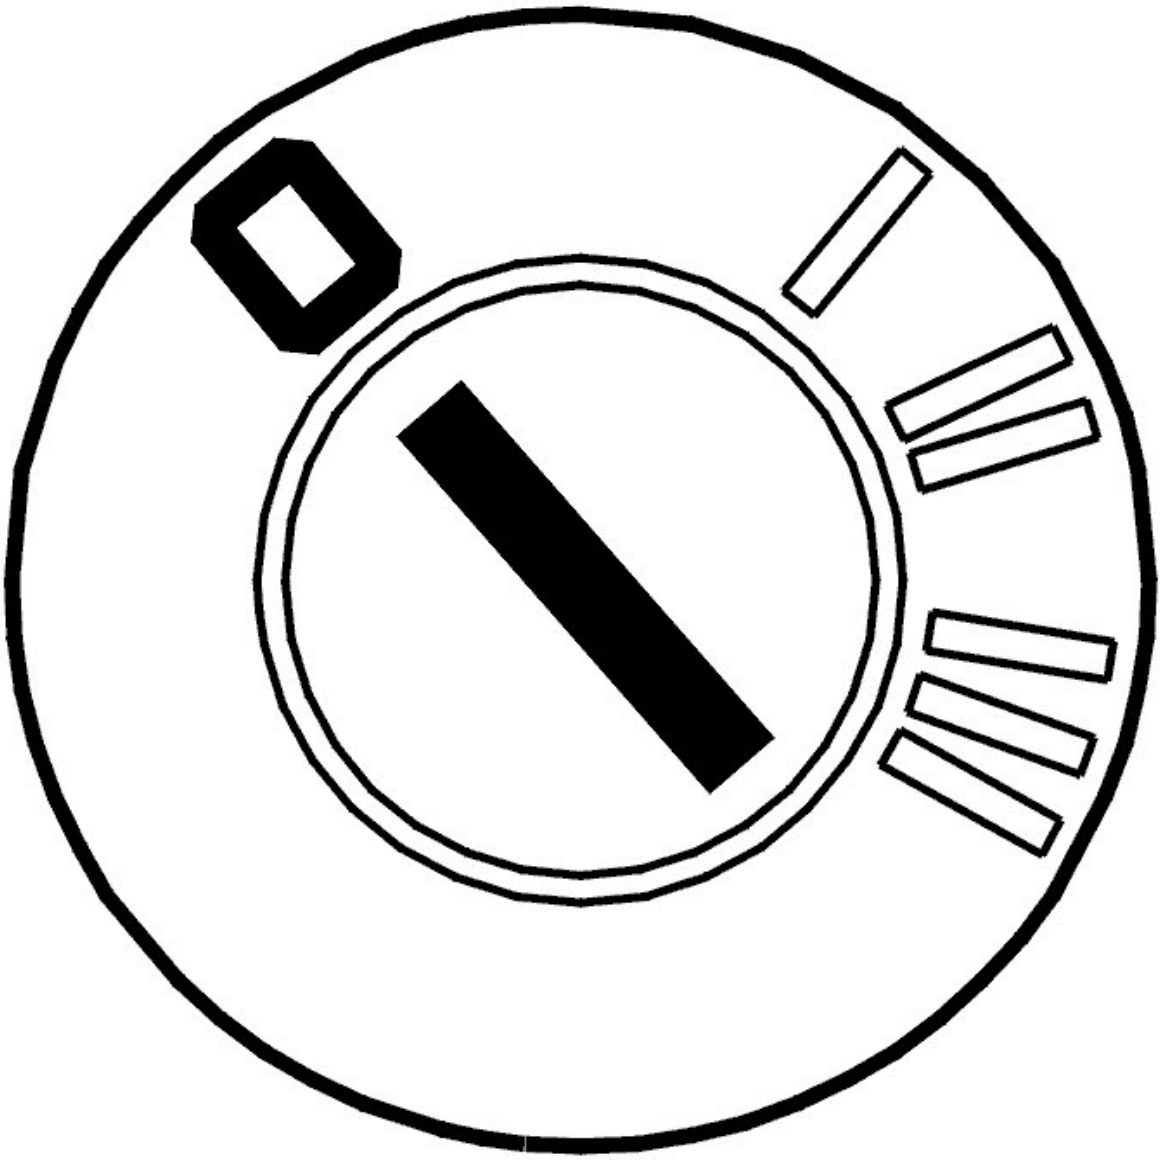


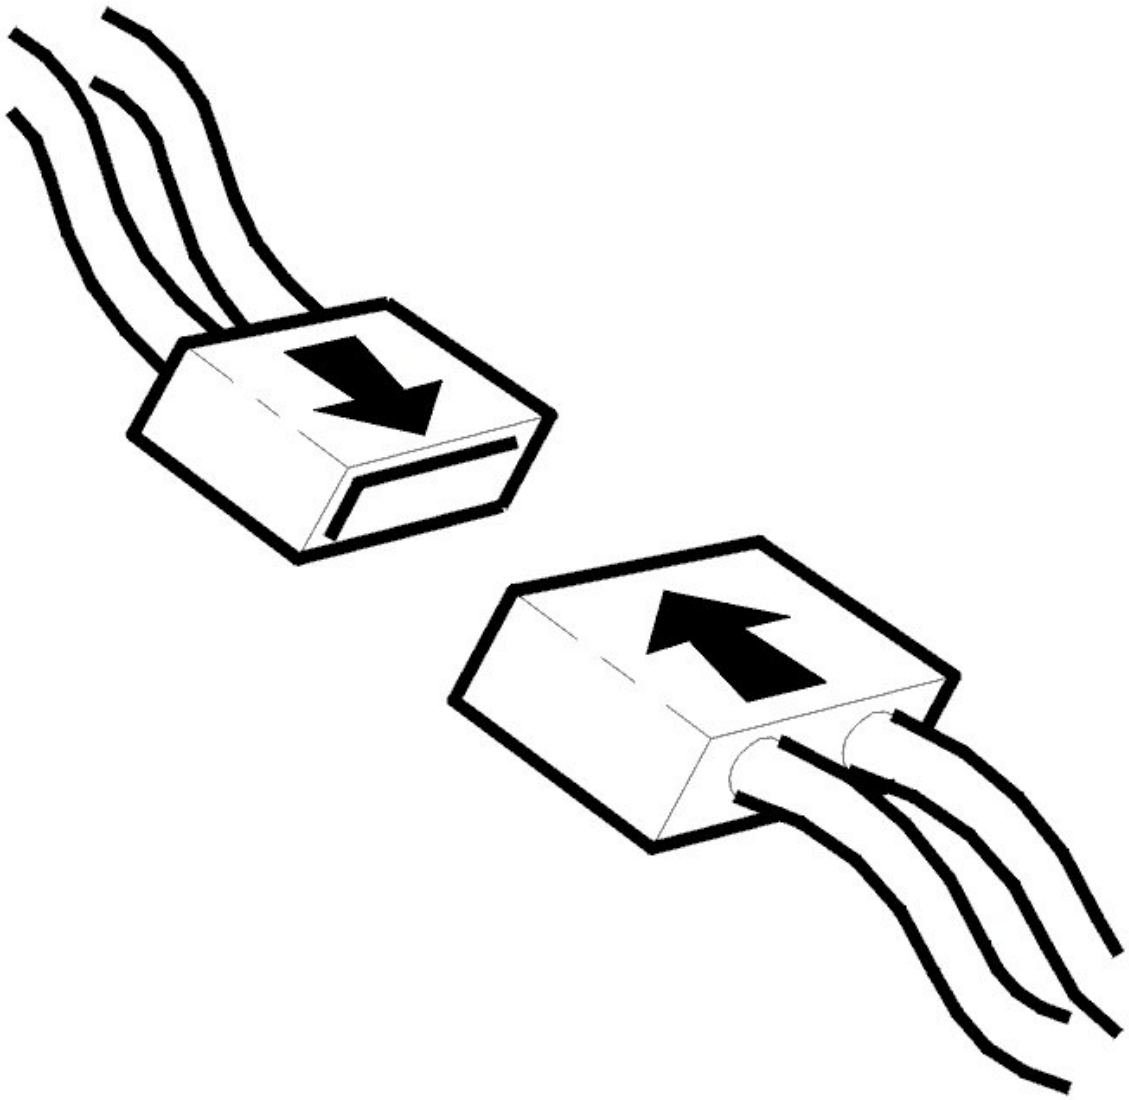
1 - Replacing the transmission control system

2 - Resetting the oil quality counter

3 - Replacing the transmission

Checking for contact resistance and oxidation





- Ignition off
- Check connectors and connections for contact resistance or oxidation.

Measure the resistance on the terminals for solenoid SLU. Check for an open-circuit. Check for a short-circuit to ground.
Remedy as necessary.

Other information

- Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault
- To access transmission connectors, see:

Connectors, transmission, disconnecting / connecting, B5244T5, AW55-50/51SN, B5254T2, AW55-50/51SN, B5254T2, AW50/51 AWD See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Wiring Harness/Service and Repair/Procedures

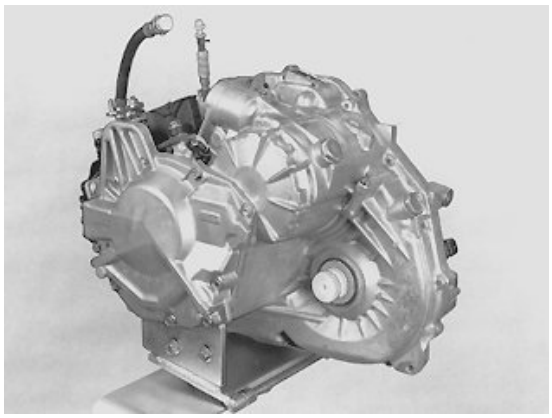
Replacing the transmission control system

- Perform the following check.

Test pressurization See: Engine, Cooling and Exhaust/Cooling System/Testing and Inspection

- Check the cooling system's pipes and connections to the automatic transmission. Check for leakage.



Does the pressure drop?

Yes - Checking the cooling system

No - Checking software

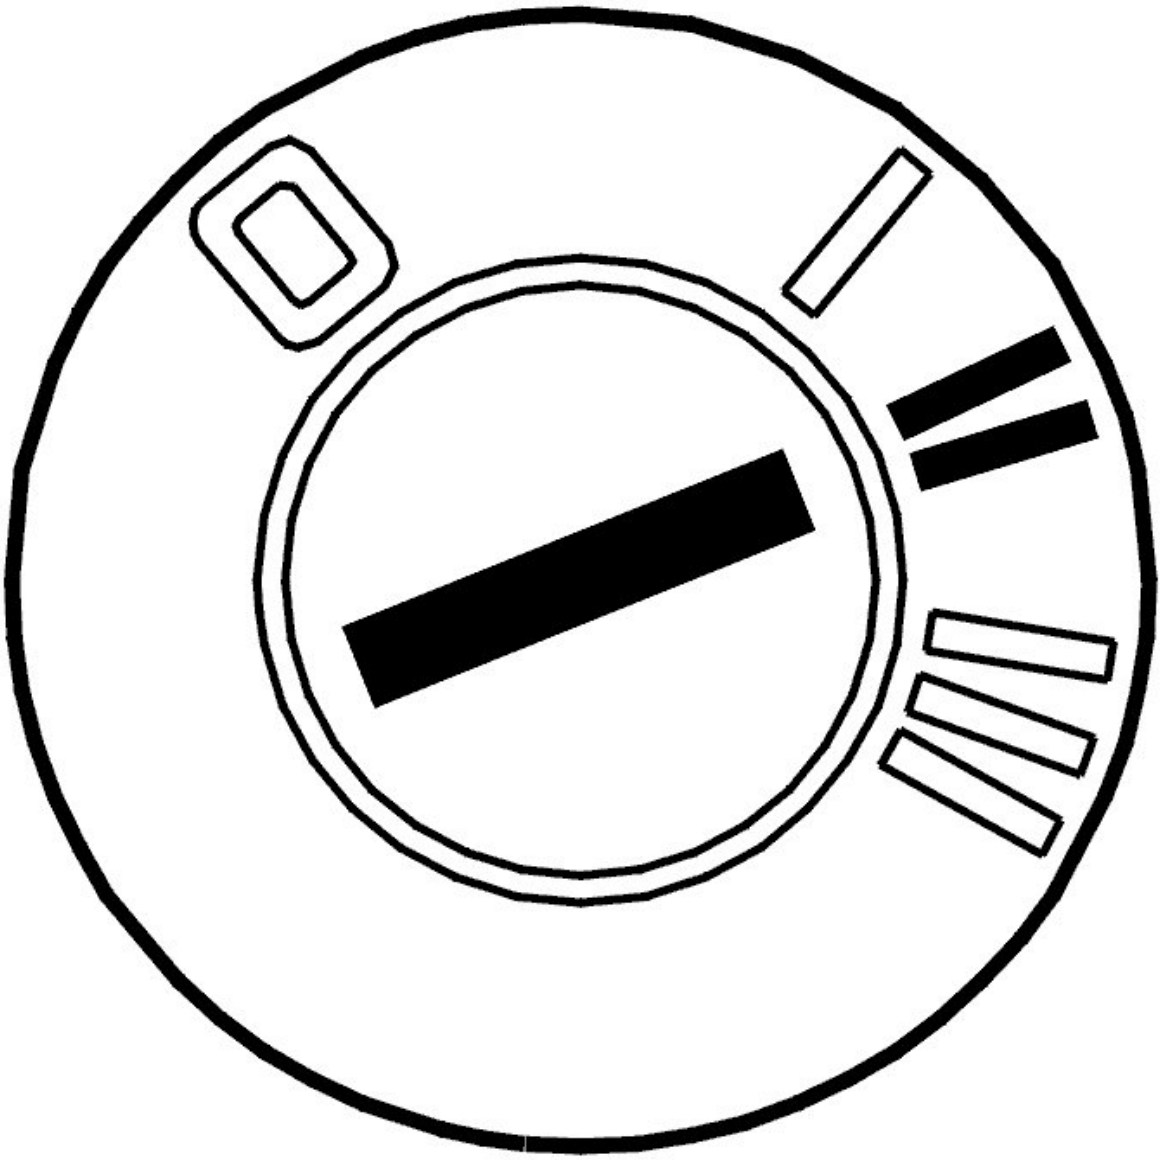
Resetting the oil quality counter

Resetting Transmission fluid change counter

Resetting Transmission fluid change counter

Hint: The transmission control module (TCM) has a counter for the oil quality. The counter counts up if the transmission is exposed to too high a load or an ambient temperature that is too high. If the counter is not reset when the oil is drained or changed, there is a risk that a diagnostic trouble code (DTC) will be stored in faulty circumstances. Therefore it is important that the "Transmission oil change" counter is reset.

Note! This applies only when the transmission fluid is changed and when the fluid is changed when repairs are carried out to the transmission temperature sensor.



- Ignition on.

Reset the counter by clicking on the VCT 2000 symbol.

Continue - DONE

DONE - Verification

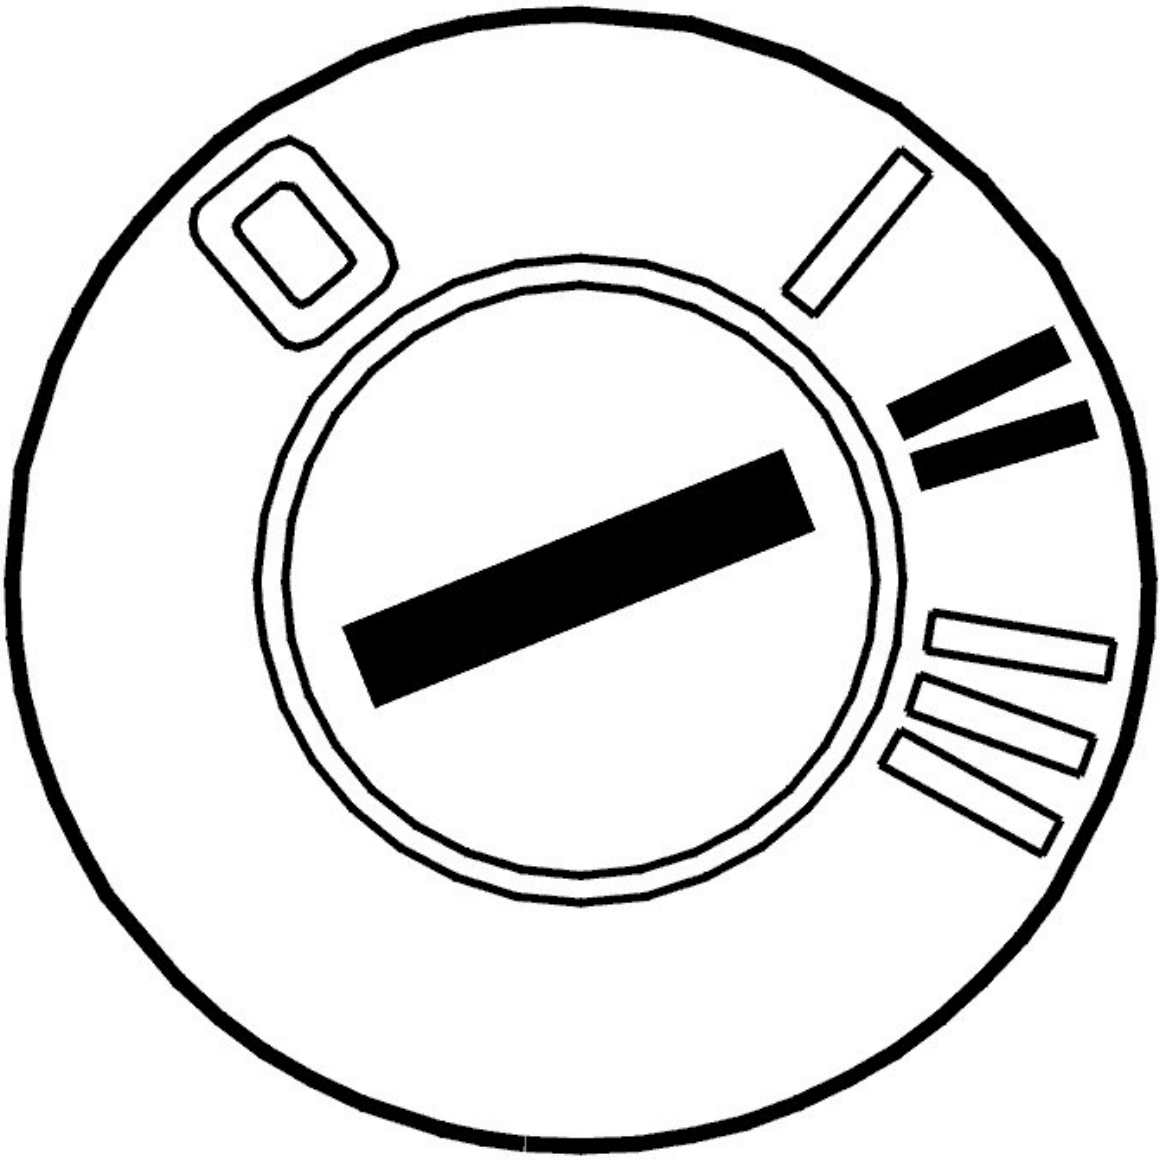
Resetting the adaptation and oil quality counter

Resetting the adaptation

Resetting adaptation and the counter for "Transmission oil change"

Hint: The transmission has torque controlled adaptive pressure control. Pressure control means that the transmission regulates the pressure itself during each gear shift. This avoids harsh gear shifting. Each gear shift is evaluated by the control module and stored in the memory. This allows for compensation for wear and tear in the transmission and clutch. It is important that the adaptation in the memory is reset after the transmission has been repaired. This is to ensure normal operation. The oil is replaced during repair; the "Transmission oil change" counter must be reset. If the counter is not reset when the fluid is drained and replaced, there is a risk that a diagnostic trouble code (DTC) will be stored in incorrect circumstances.

Note! This applies only if the transmission or one of the components in the transmission have been replaced.



- Ignition on.

Click on the VCT2000 symbol to reset the adaptation and counter.

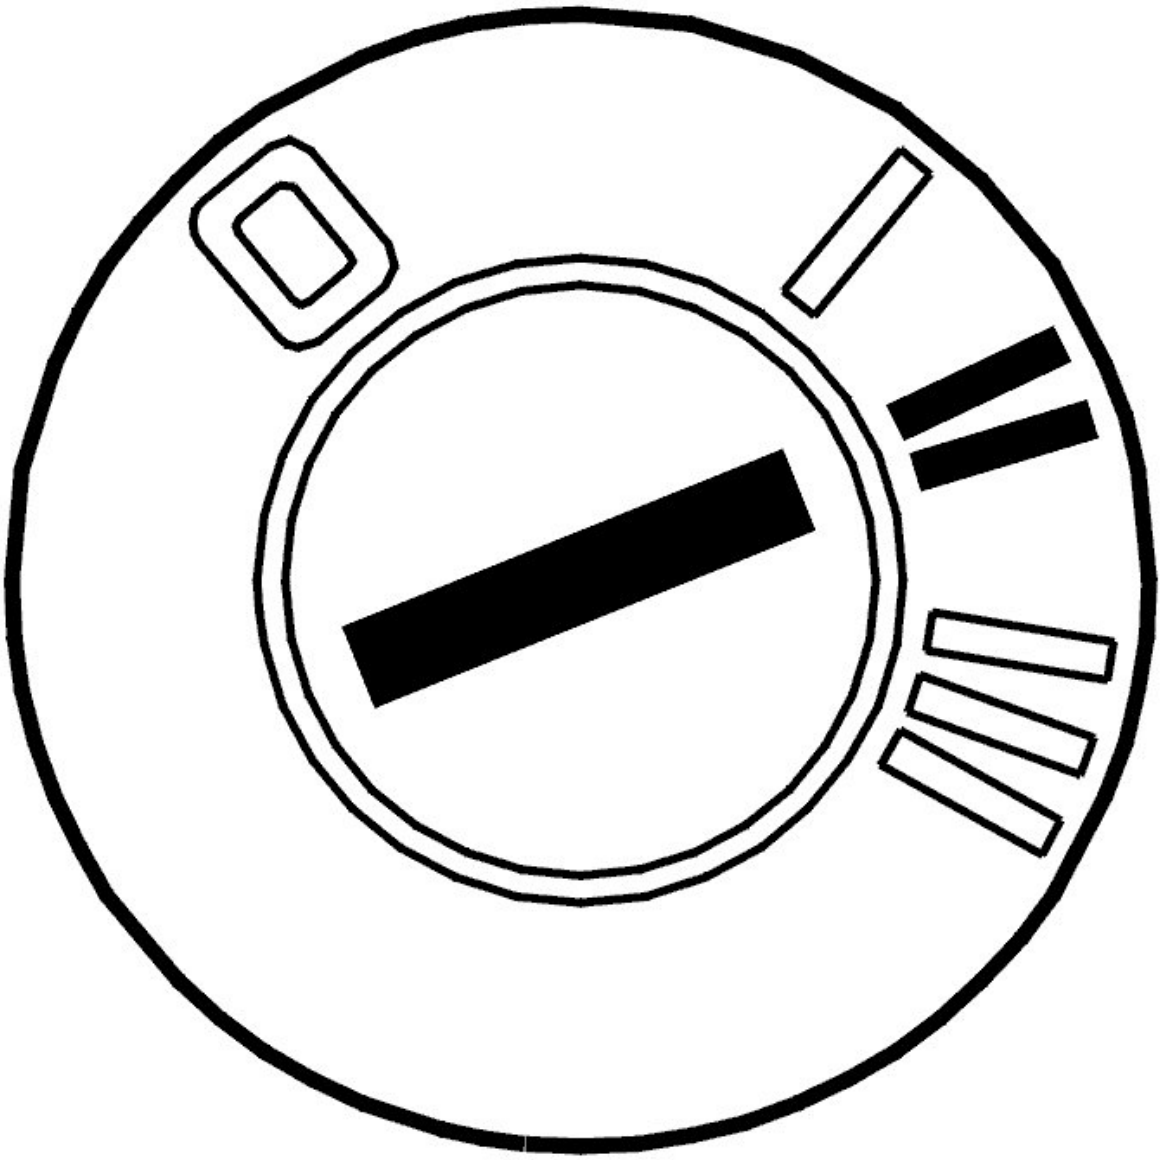
Continue - **DONE**

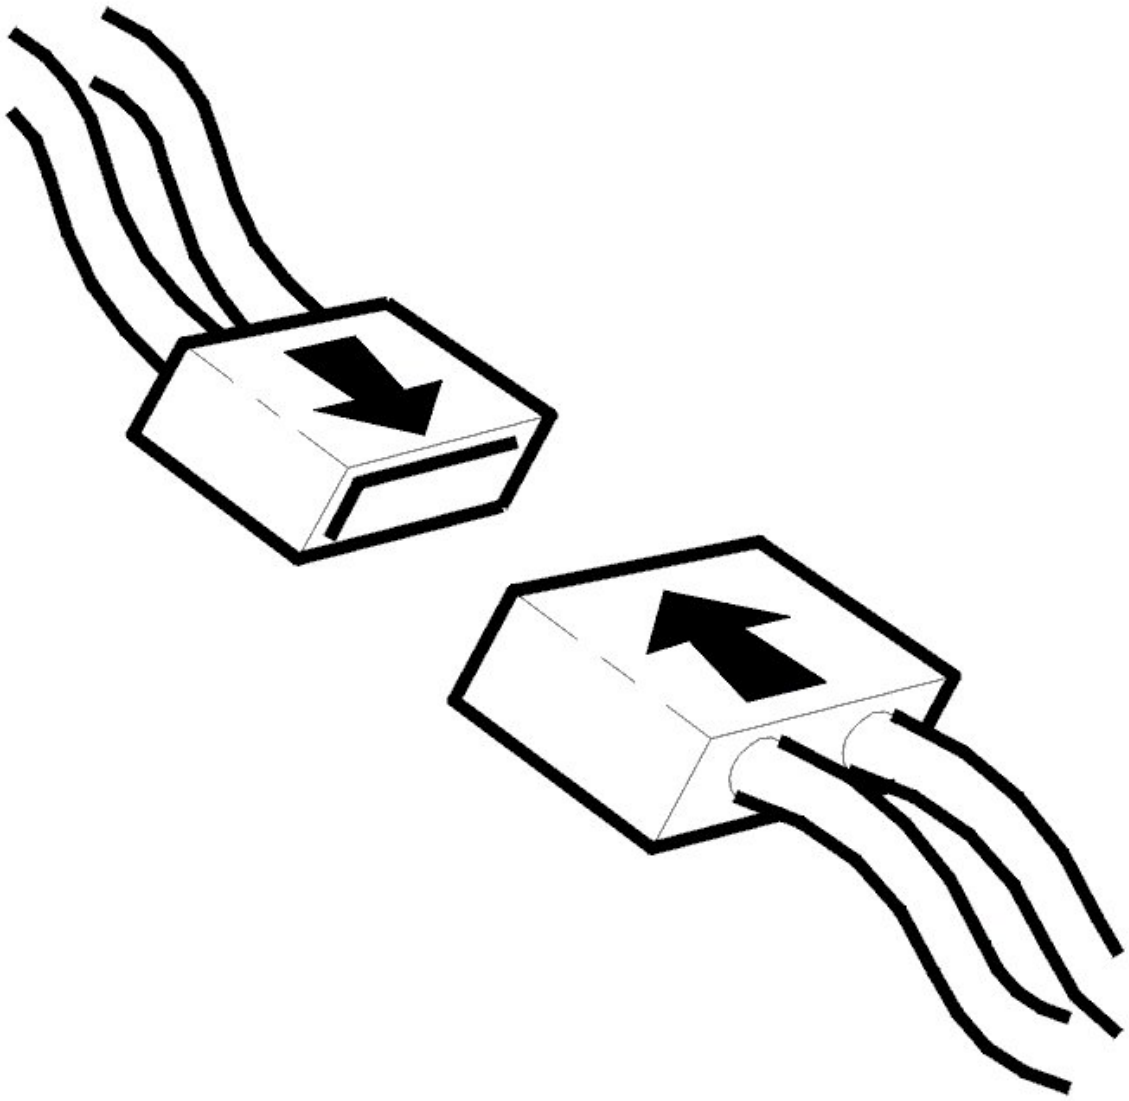
DONE - Verification

Verification

Verification

Hint: After carrying out the repair, check that the fault has been remedied.





- Ignition off
- Reconnect the connectors, components, etc.
- Ignition on

Test drive the vehicle following: Test drive schedule, description See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Service and Repair/Procedures/Test Drive Schedule, Description
During the test drive, oil temperature should be over 20 °C.
Note any deviations in transmission function.

Test-Drive Schedule

Test-drive schedule TCM-002F AW55-50/51SN

Note! Read through the whole test-drive schedule before starting to test-drive.

1. Check the oil temperature in the transmission. Suitable temperature range is approx. 40-100 °C.
2. Start Activation of gear indication. See, Diagnostics/Vehicle communication/Advanced.

   Note! The function is only active during the driving cycle in question.

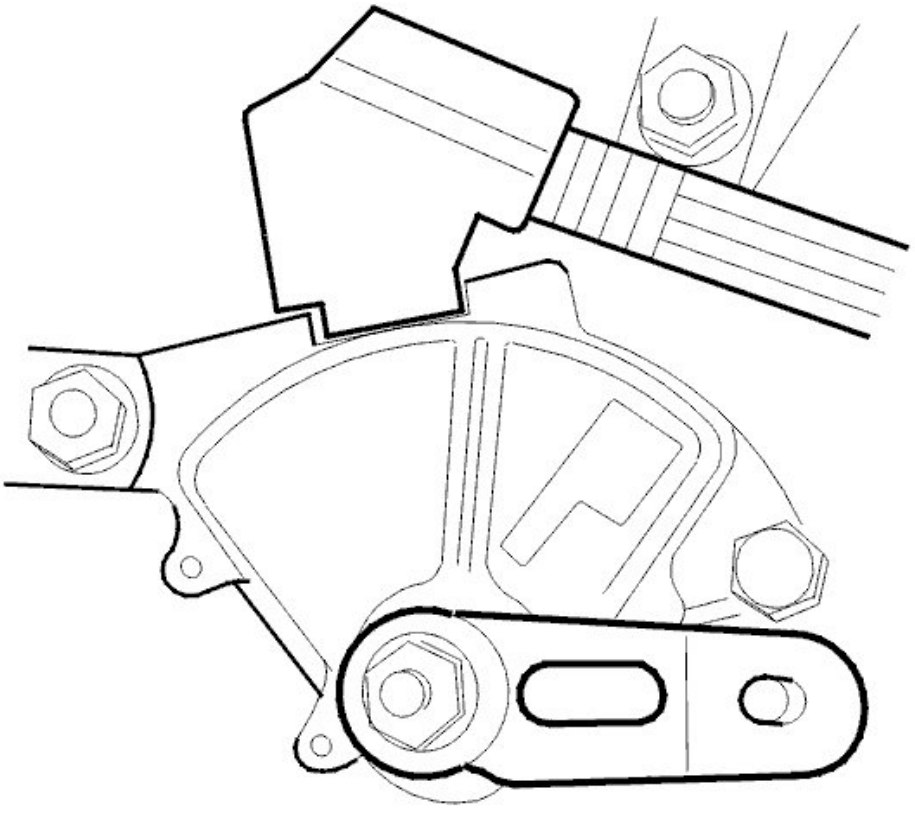
3. Activate tools to measure the rpm difference between the transmission's rpm sensor and the engine speed. See, Diagnostics/Vehicle communication/Advanced.
4. Drive the vehicle at approx. 60 km/h (37 mph) with the gear selector in lever position 3, alternatively manually selected position 3 if the vehicle is equipped with lever carrier with GearTronic. Check that the lock-up locks (indicated by steady glow from IND-light).
5. Press down the accelerator pedal and check if the difference in rpm between engine and transmission is greater than 100 rpm.
6. Perform the above check at other speeds and with other lever positions.

Note! Diagnostic trouble code is stored after approx. 20 sec. with an rpm difference that is greater than 100 rpm.

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition



The gear-shift position sensor signals provide the transmission control module (TCM) with data on the gear selector position. This is done by grounding a combination of signals A, B, C and PA inside the gear position sensor. Diagnostic trouble code (DTC) TCM-0039 is stored if the

transmission control module (TCM) registers an unacceptable combination of A, B, C and PA for a period of 10 seconds as shown below.

A	B	C	PA	
â¢	â¢	o	o	Diagnostic Trouble Code (DTC)
â¢	â¢	â¢	â¢	Diagnostic Trouble Code (DTC)
â¢	â¢	â¢	o	Diagnostic Trouble Code (DTC)
o	â¢	â¢	â¢	Diagnostic Trouble Code (DTC)
â¢	â¢	o	â¢	Diagnostic Trouble Code (DTC)
o	o	o	â¢	Diagnostic Trouble Code (DTC)

â€¢ = 0-2 V below battery voltage
o = ground

Substitute value
- The control module "Limp Home" program has been initiated.

Possible source
- Contact resistance in terminals.
- Short-circuit to supply voltage or ground in the signal cable.
- Open-circuit in the signal cable.
- Incorrectly adjusted gear-shift position sensor.
- Defective gear-shift position sensor.

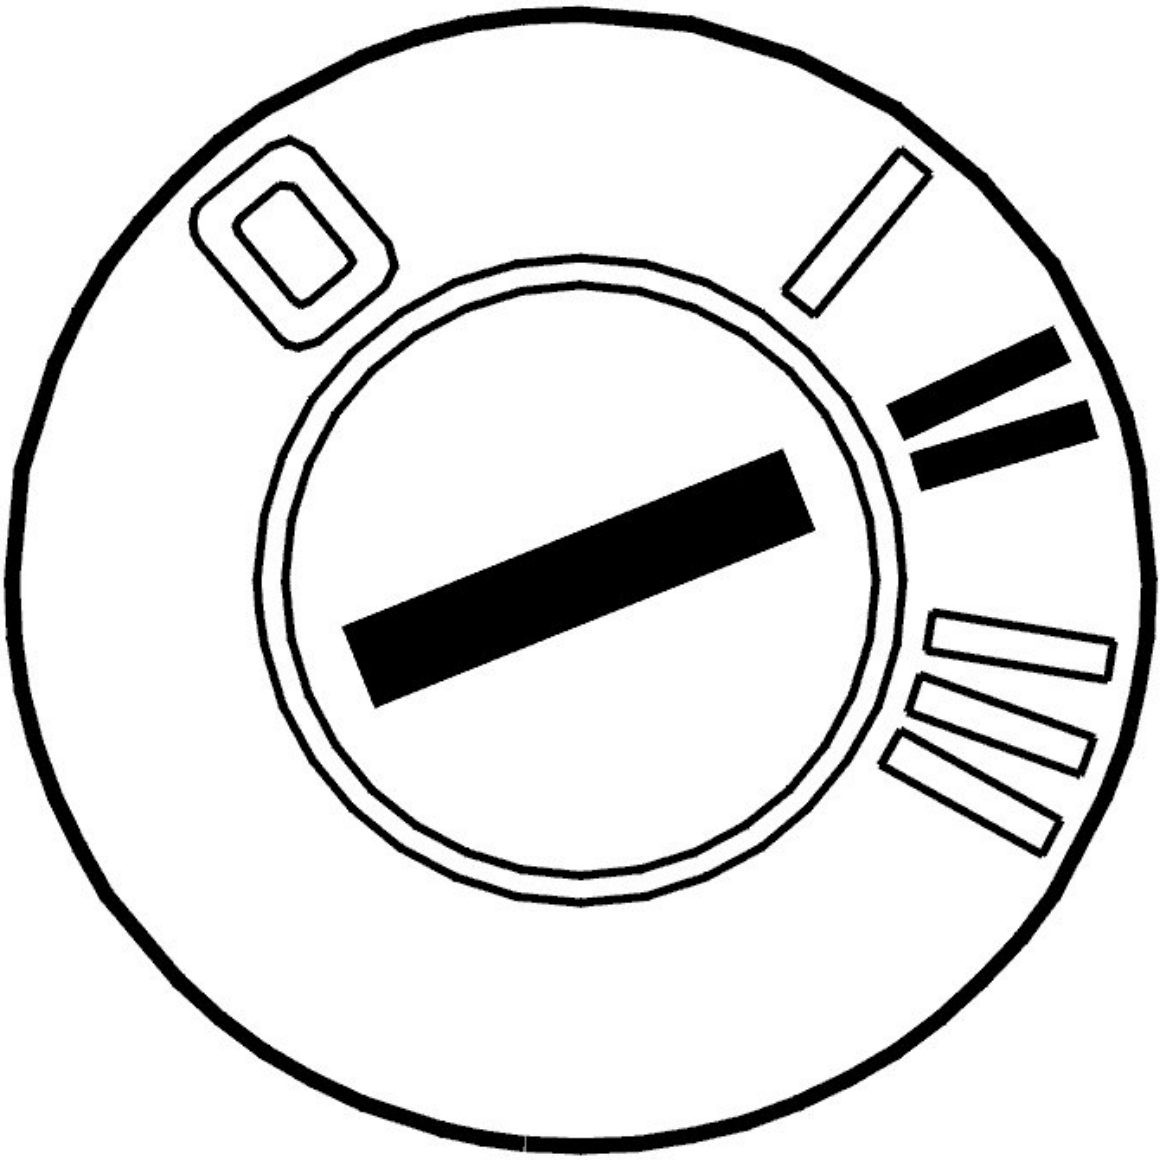
Fault symptom[s]
- General orange warning lamp lit.
- Malfunction indicator lamp (MIL) lit.
- No lock-up function.
- Harsh gear shifting.
- No shifting.

Caution! The gear-shift position sensor will malfunction if there is a short-circuit to supply voltage.

Faulty Signal

Faulty signal

Checking the adjustment of the gear-shift position sensor



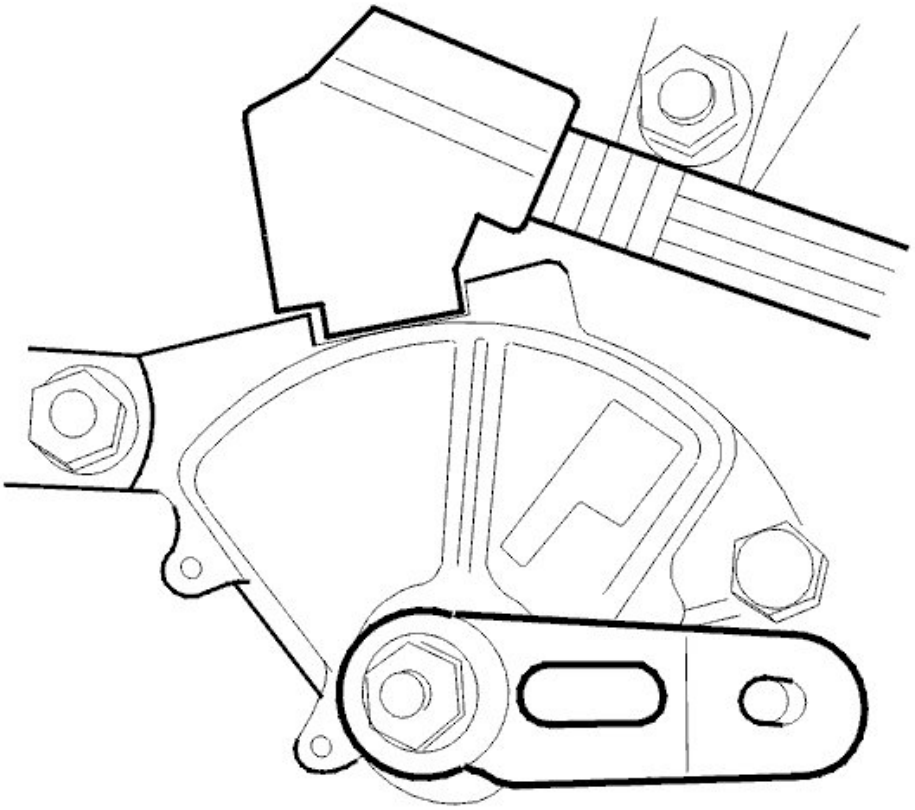
- Ignition on
- Read off the position of the gear selector.

Note! Select the correct gear selector assembly from the list.

Shift the gear selector to all gear positions several times. This is to check the function of the gear selector sensor.
The selected position must be the same as that displayed in VIDA. If the display shows an undefined position (OR for example) when a specific gear is selected, the transmission cable needs adjusting.

Note! An undefined position may be displayed between the fixed gear positions. This isnota fault.

Adjust the gear-shift position sensor if necessary according to Gear-shift position sensor, checking/adjusting See: Sensors and Switches - Computers and Control Systems/Transmission Position Switch/Sensor/Adjustments.

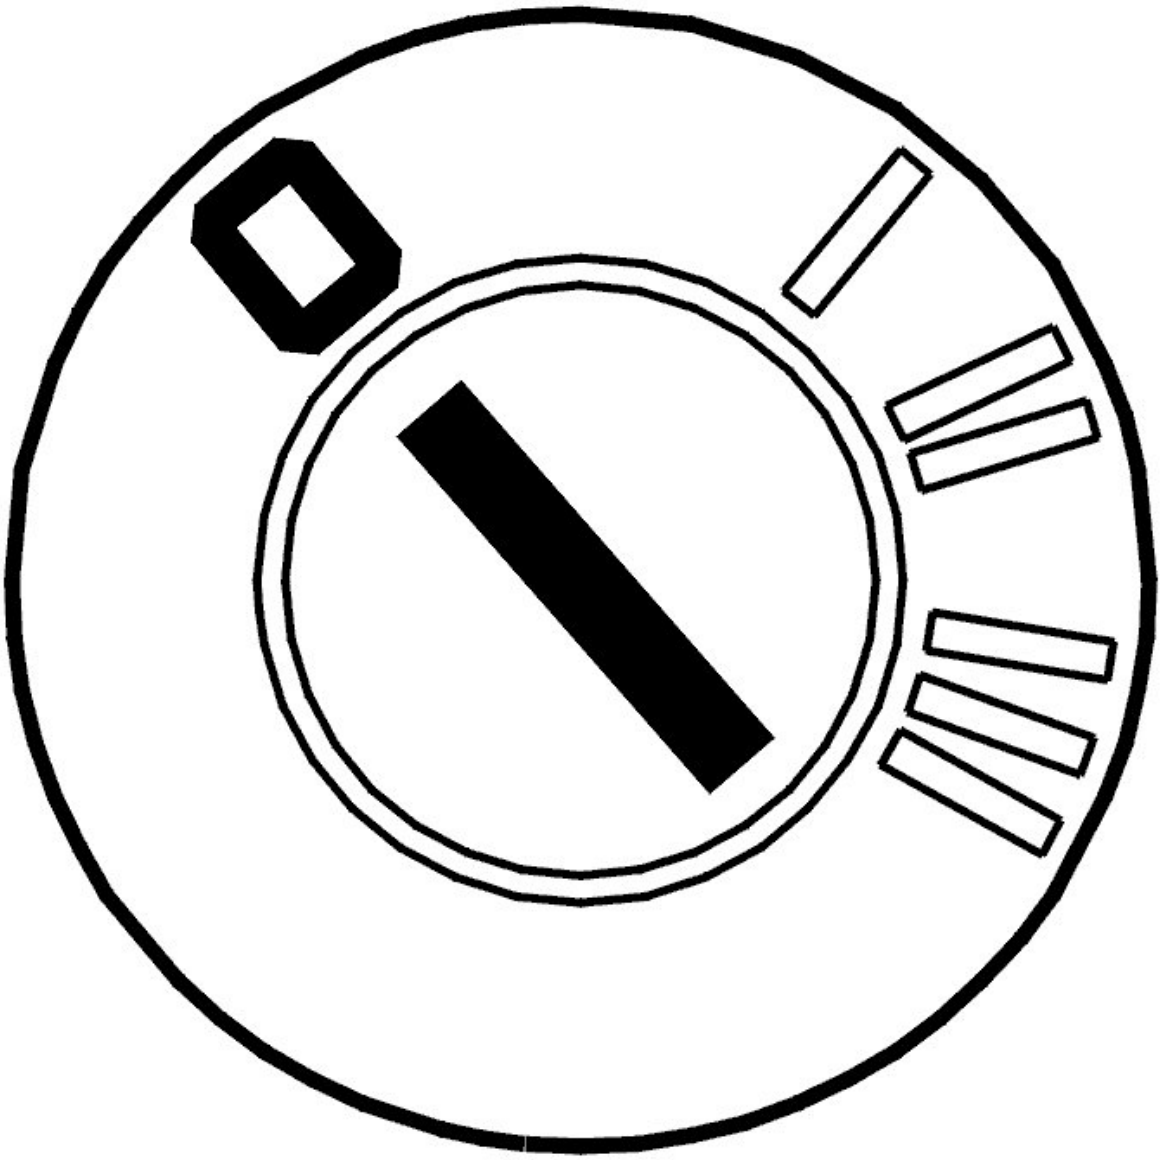


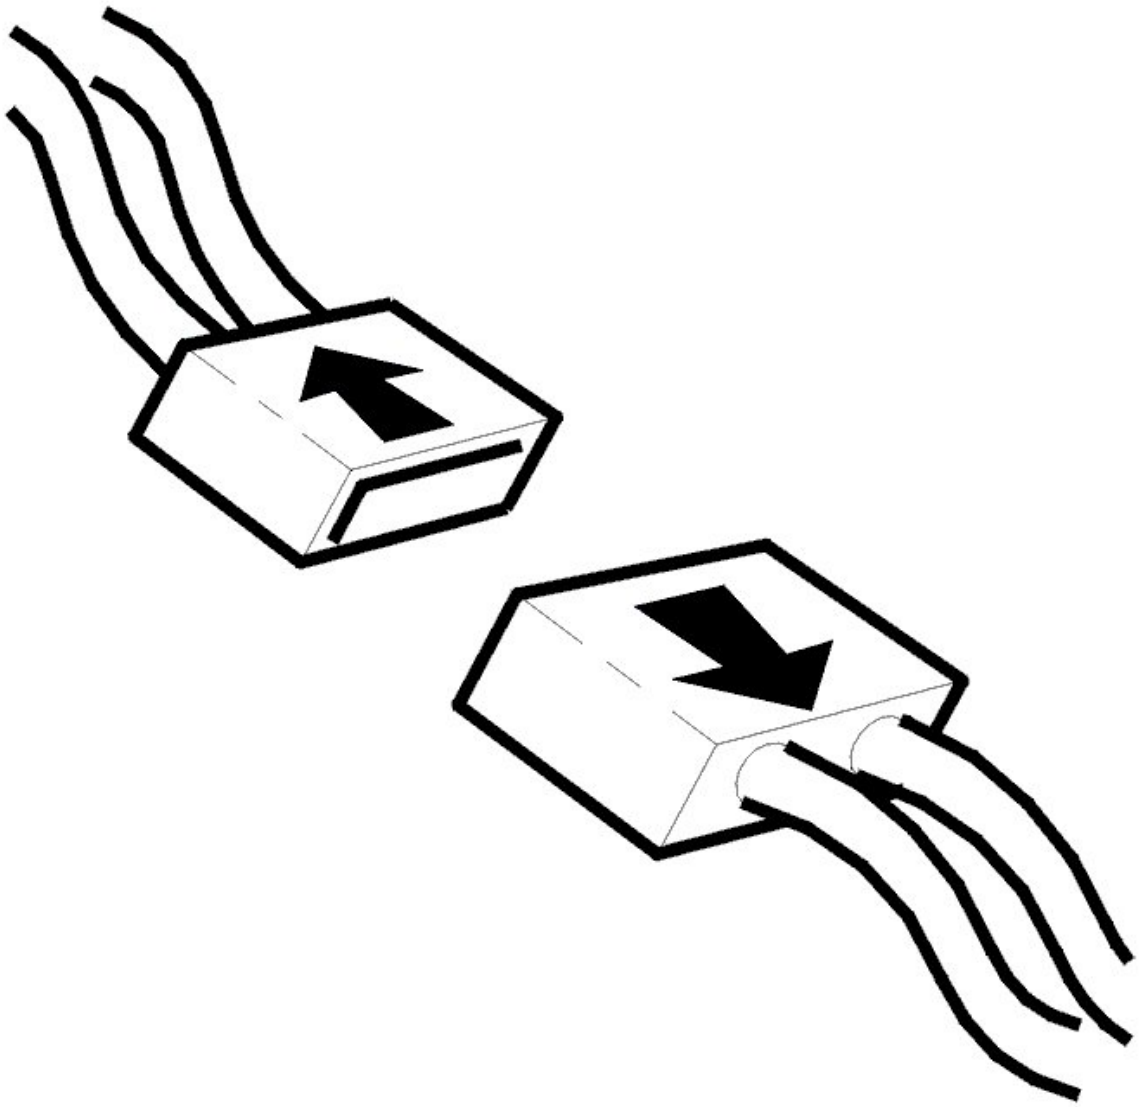
Is the gear-shift position sensor incorrectly adjusted?

Yes - Verification

No - Checking the wiring

Checking the wiring





- Ignition off
- Disconnect the transmission connector
- Connect the breakout box.

Check the wiring between the transmission connector (control module side):

- terminal #B5 and control module terminal #A46 (#A46) "A"
- terminal #B6 and control module terminal #B4 (#A64) "B"
- terminal #B7 and control module terminal #A45 (#A45) "C"
- terminal #B8 and control module terminal #B3 (#A63) "PA".

check for an open-circuit according to Checking wiring and terminals. Diagnostic Trouble Code (DTC) Information

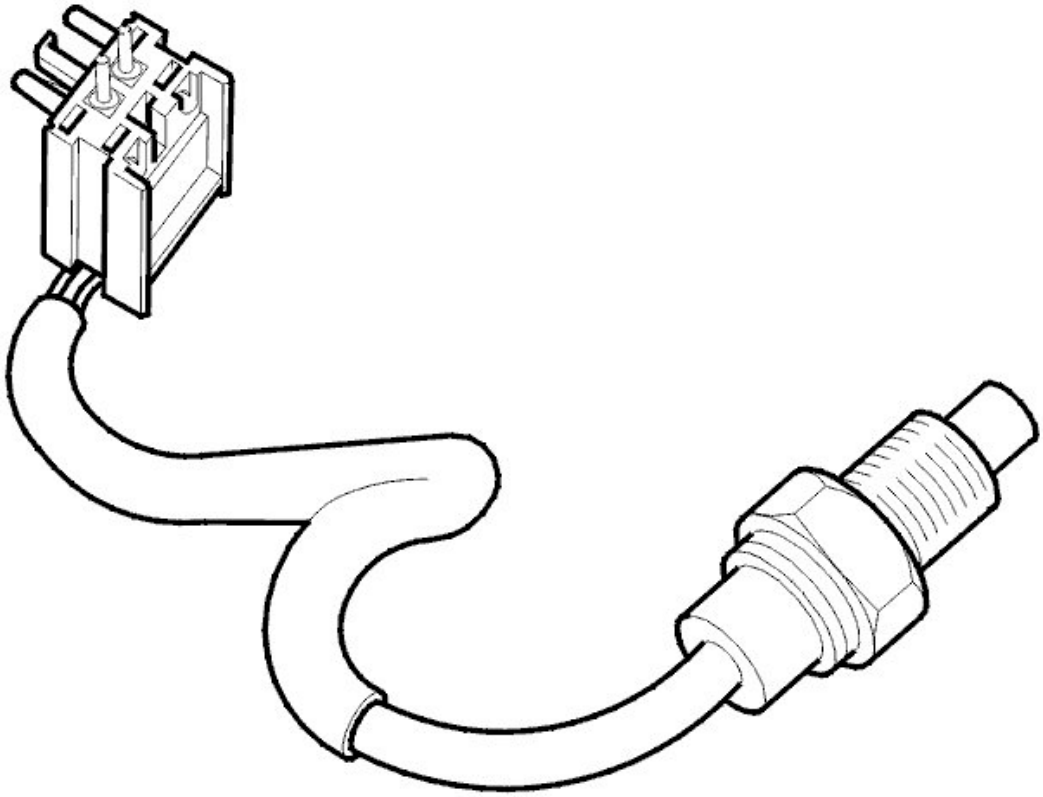
Diagnostic trouble code (DTC) information

Condition



The oil temperature sensor sends a signal to the transmission control module (TCM) which is used for functions such as temperature controlled lockup and initiating high-temperature programs. The sensor has an NTC (negative temperature coefficient) resistor. The signal (voltage) decreases with increasing oil temperature. Diagnostic trouble code (DTC) TCM-0042 is stored if the transmission control module (TCM) receives a signal from the oil temperature sensor corresponding to a temperature above approximately +150°C for approximately 2 minutes.

Substitute value
- No substitute values.

Possible source
- Contact resistance in terminals.
- Short-circuit to ground in signal cable.
- Defective oil temperature sensor.
- Mechanical fault in the transmission.
- The transmission has been exposed to extreme load and high ambient temperature.

Fault symptom[s]
- General orange warning lamp lit.

Temperature Too High

Temperature too high

Checking the wiring and component

The diagnostic trouble code (DTC) was caused by the transmission being subjected to high loads and high temperatures. It is therefore important to change transmission fluid and to check the function of the transmission.
Replace the oil according to Gearbox fluid, replacing See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Service and Repair/Removal and Replacement/Transmission Fluid, Replacing.

Continue - Resetting the oil quality counter

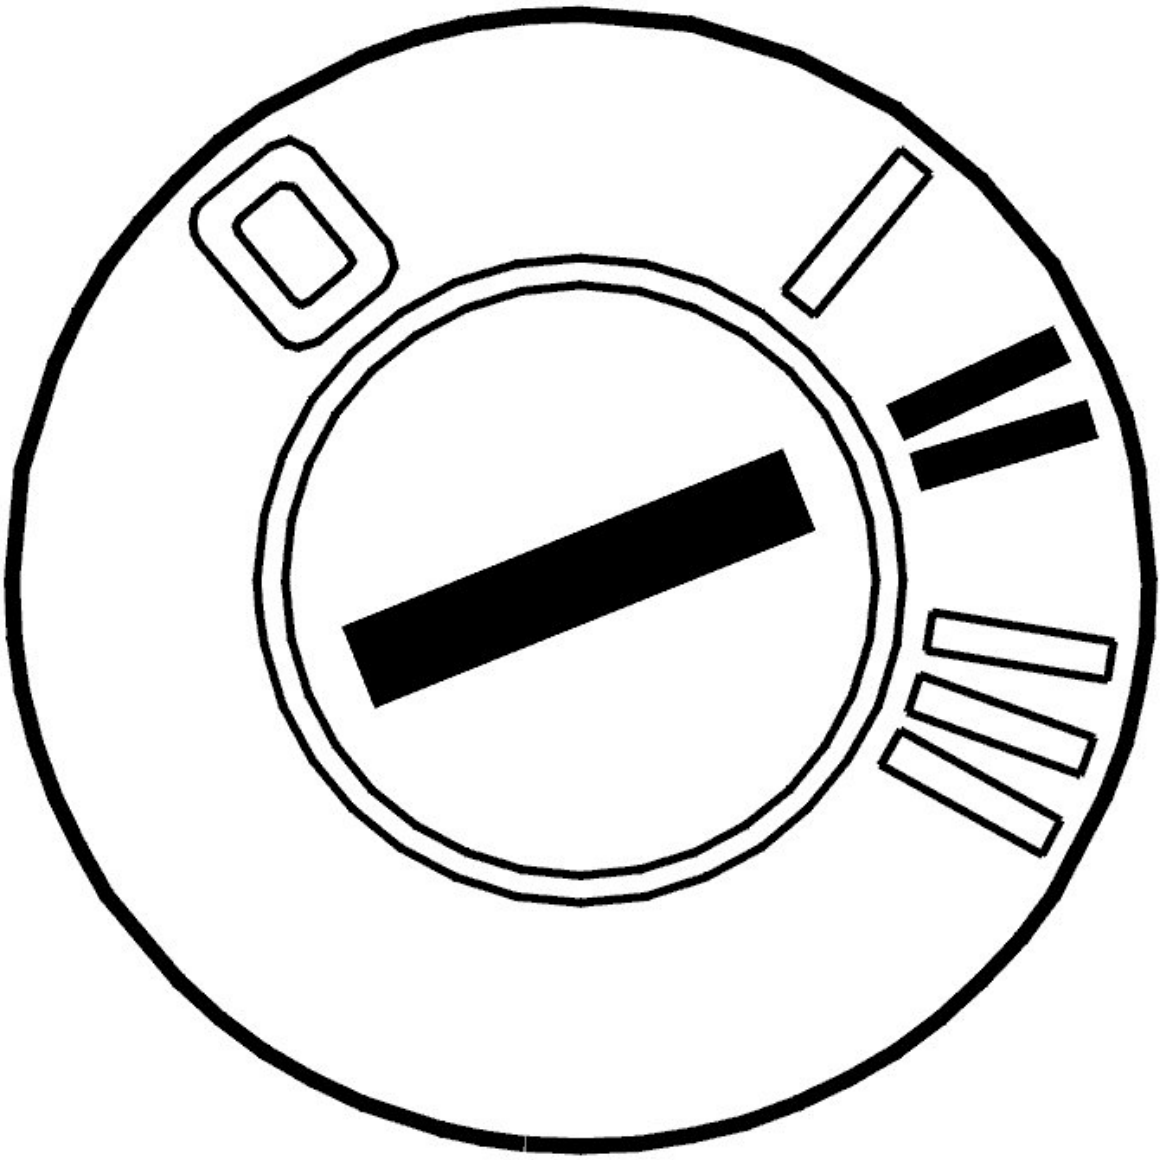
Resetting the oil quality counter

Resetting Transmission fluid change counter

Resetting Transmission fluid change counter

Hint: The transmission control module (TCM) has a counter for the oil quality. The counter counts up if the transmission is exposed to too high a load or an ambient temperature that is too high. If the counter is not reset when the oil is drained or changed, there is a risk that a diagnostic trouble code (DTC) will be stored in faulty circumstances. Therefore it is important that the "Transmission oil change" counter is reset.

Note! This applies only when the transmission fluid is changed and when the fluid is changed when repairs are carried out to the transmission temperature sensor.



- Ignition on.

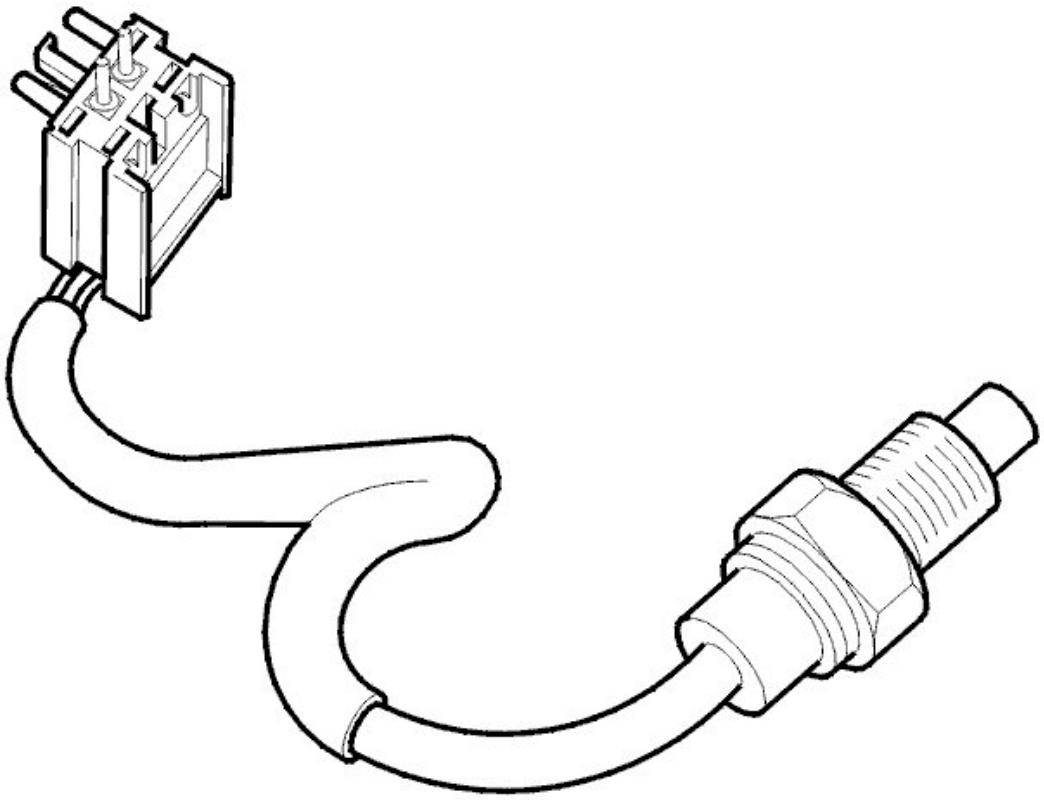
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition



The oil temperature sensor transmits a signal to the control module. This signal is used for functions such as temperature controlled lock-up and the engagement of high-temperature programs. The sensor has an NTC (negative temperature coefficient) resistor. The signal (voltage) decreases with increasing oil temperature. Diagnostic trouble code (DTC) TCM-0043 is stored if the control module receives too low a signal from the oil temperature sensor for approximately 20 seconds.

Substitute value
- No substitute values.

Possible source
- The power supply and signal cables are short-circuited to each other.
- Short-circuit to ground in the signal cable.
- Defective oil temperature sensor.

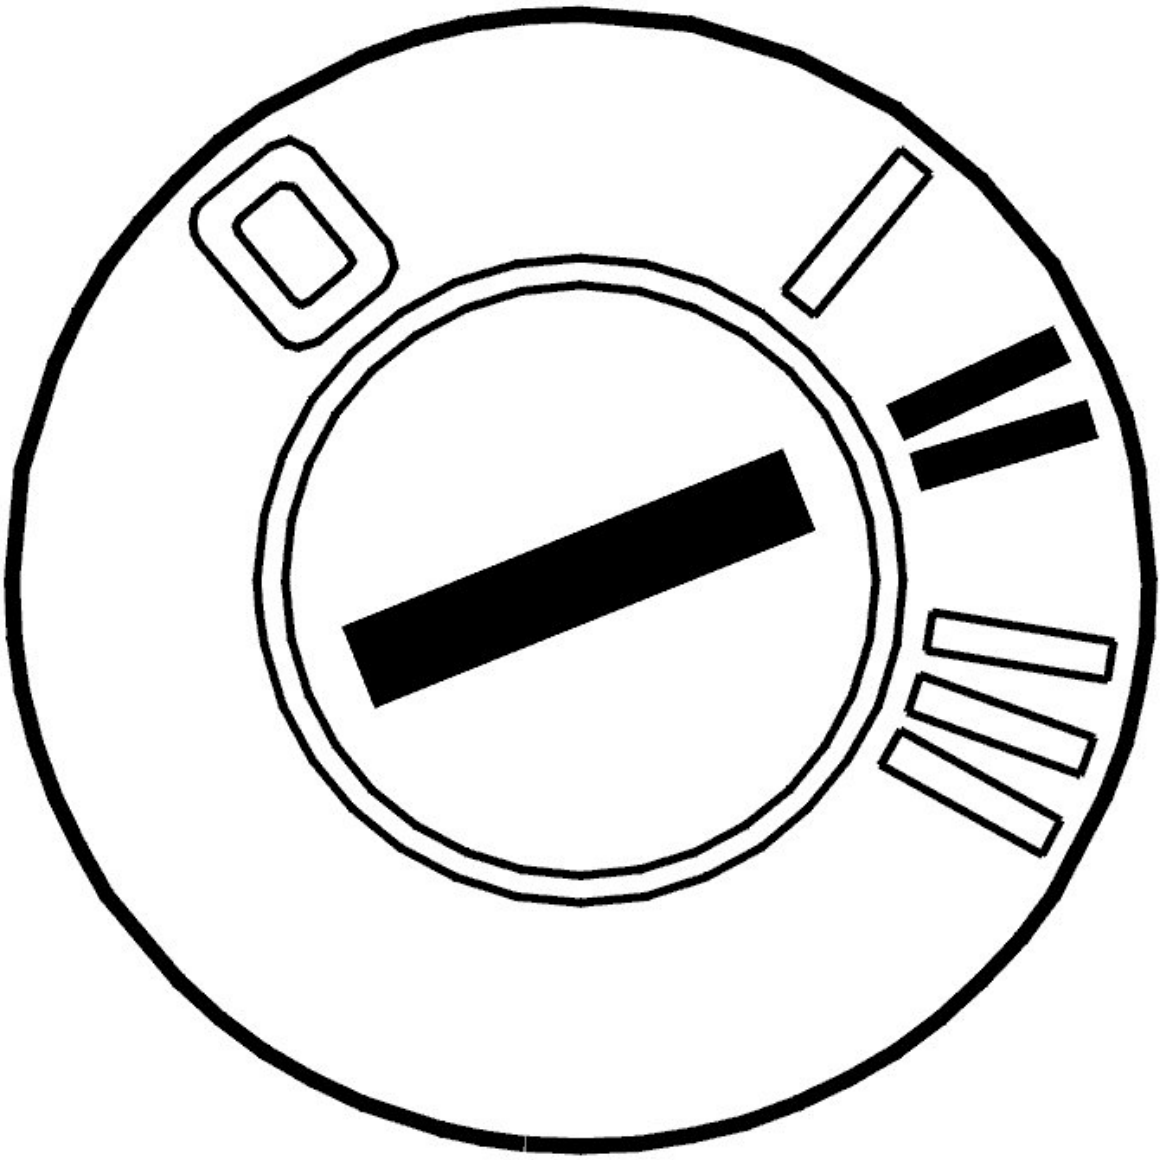
Fault symptom[s]
- General orange warning lamp lit.
- No lock-up function.
- Harsh gear shifting.

Hint: Harsh gear shifting can be caused by:
- No reduction of the line pressure when shifting.
- No reduction of the line pressure when moving the gear selector between positions P-R, N-R and N-D.
- No request for torque limiting to the engine control module (ECM) when shifting.

Signal Too Low

Signal too low

Checking the function of the oil temperature sensor



- Ignition on
- Read off the oil temperature.

Check that the temperature is within its permitted range.
Compare with the transmission temperature.

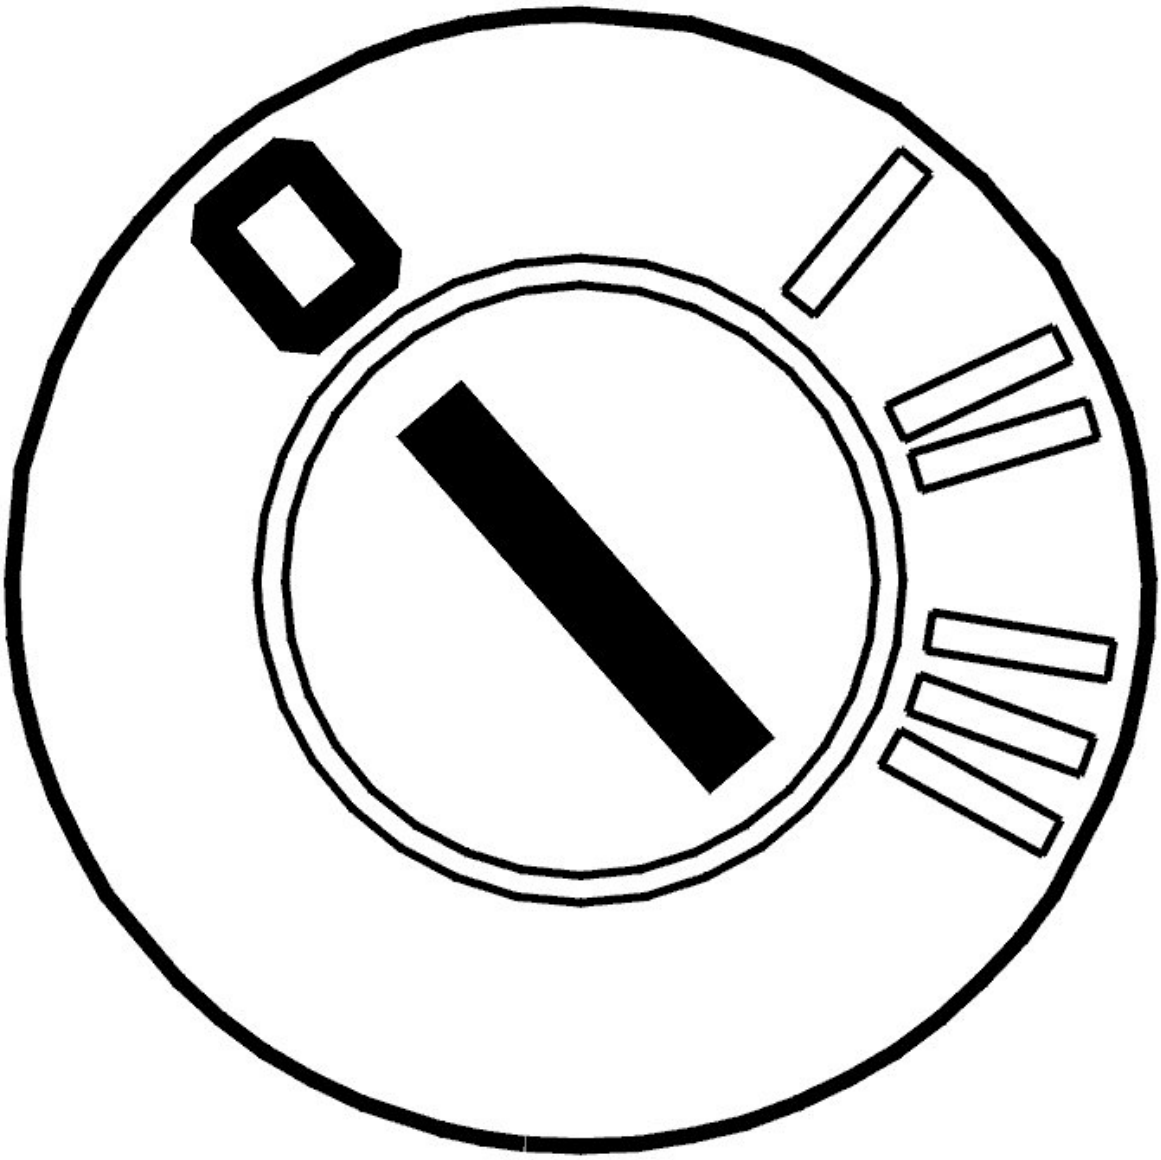
Note! The transmission temperature sensor is located inside the control system and may be affected by the heat given off by the solenoids.

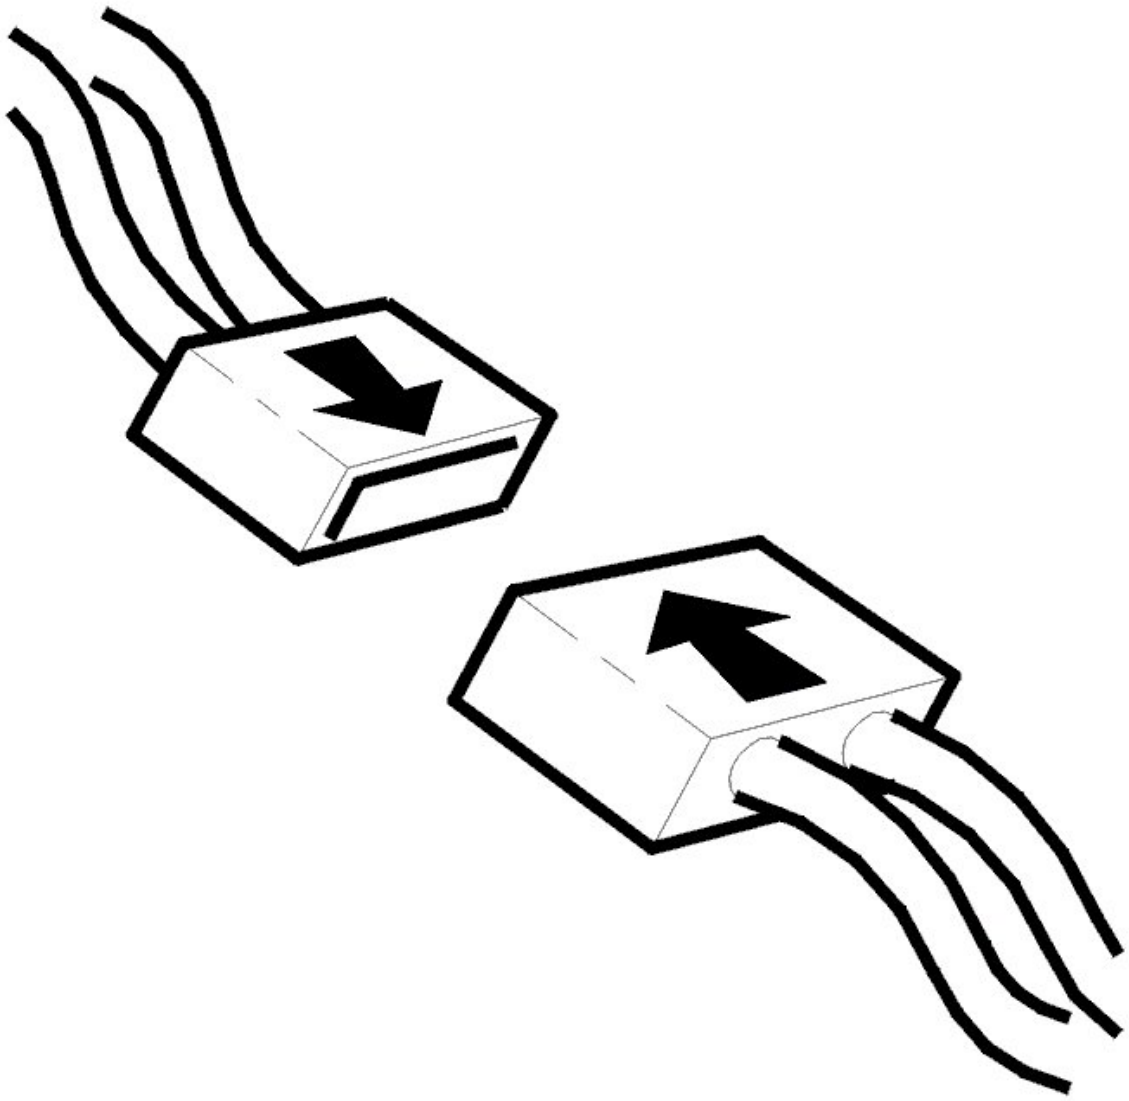
Was the transmission temperature within its permitted range?

Yes - Intermittent fault

No - Checking transmission fluid temperature sensor

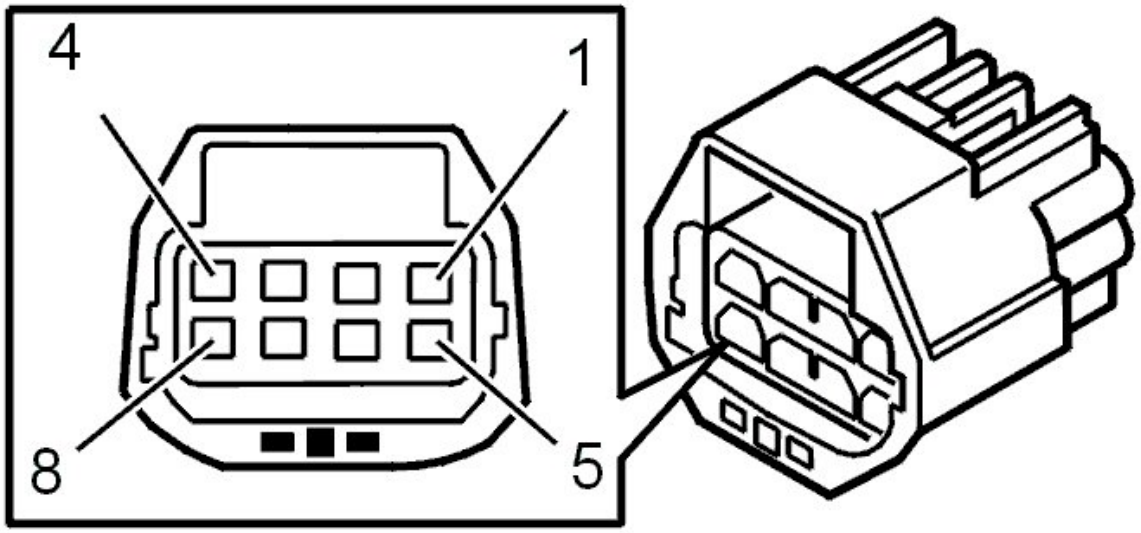
Checking transmission fluid temperature sensor





- Ignition off
- Transmission connector D disconnected.

Check the temperature sensor. Measure the resistance between transmission connector D terminals #D7 and #D8.
The resistance must be 4.5-6 kohms at 20°C.



Was the resistance OK?

Yes - Checking the wiring and component

No - Checking the cable and component

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

Checking the wiring and component

Check the cable between transmission control module (TCM) terminal #A37 (#A37) and transmission connector terminal #D7 (control module side). Check for a short-circuit to ground. See Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault.
Remedy as necessary.

Resetting Transmission fluid change counter

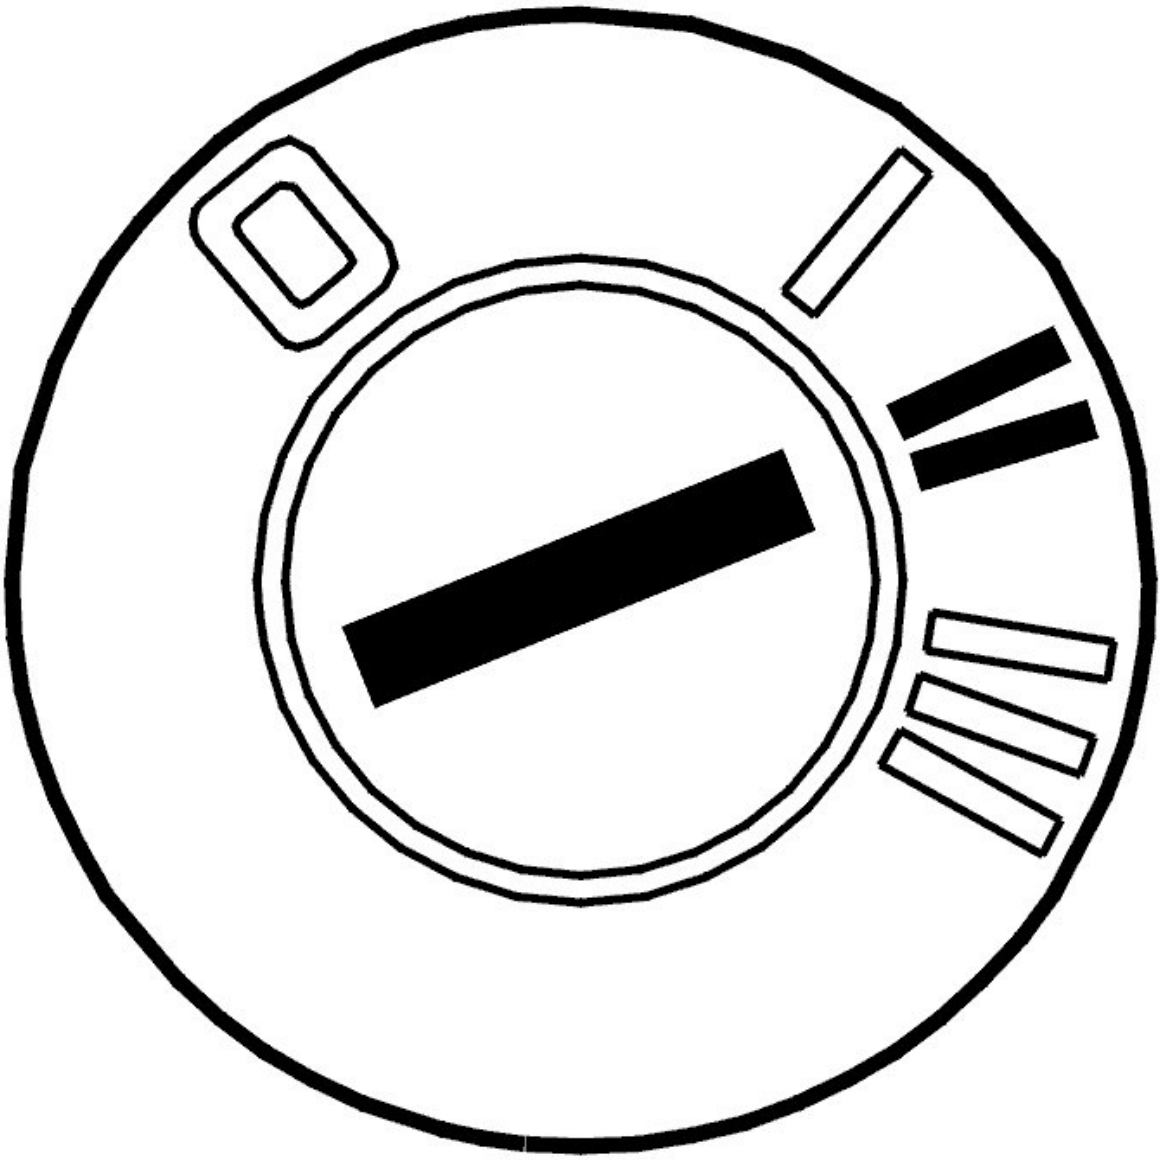
Hint: The transmission control module (TCM) has a counter for the oil quality. The counter counts up if the transmission is exposed to too high a load or an ambient temperature that is too high. If the counter is not reset when the oil is drained or changed, there is a risk that a diagnostic trouble code (DTC) will be stored in faulty circumstances. Therefore it is important that the "Transmission oil change" counter is reset.

Note! This applies only when the transmission fluid is changed and when the fluid is changed when repairs are carried out to the transmission temperature sensor.



- Ignition on.

Reset the counter by clicking on the VCT 2000 symbol.

Continue - **DONE**

DONE - Verification

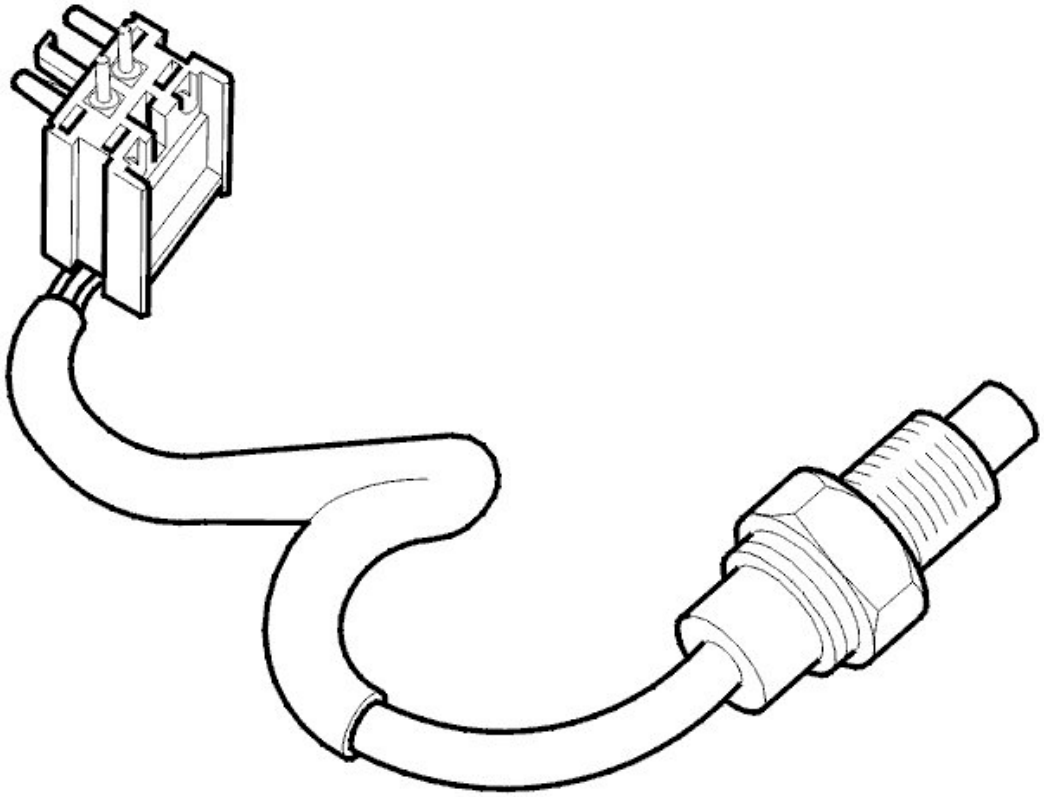
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

Condition



The oil temperature sensor transmits a signal to the control module. This signal is used for functions such as temperature controlled lock-up and the engagement of high-temperature programs. The sensor has an NTC (negative temperature coefficient) resistor. The signal (voltage) decreases with increasing oil temperature. Diagnostic trouble code (DTC) TCM-0044 is stored if the control module receives a signal from the oil temperature sensor corresponding to a temperature below approximately -10°C when the engine is started, and the signal has not changed after the engine has been running for approximately 10 minutes.

Substitute value
- No substitute values.

Possible source
- Contact resistance in the terminals.
- Open-circuit in the signal cable or in the ground lead.
- Short-circuit to supply voltage in the signal cable.
- Defective oil temperature sensor.

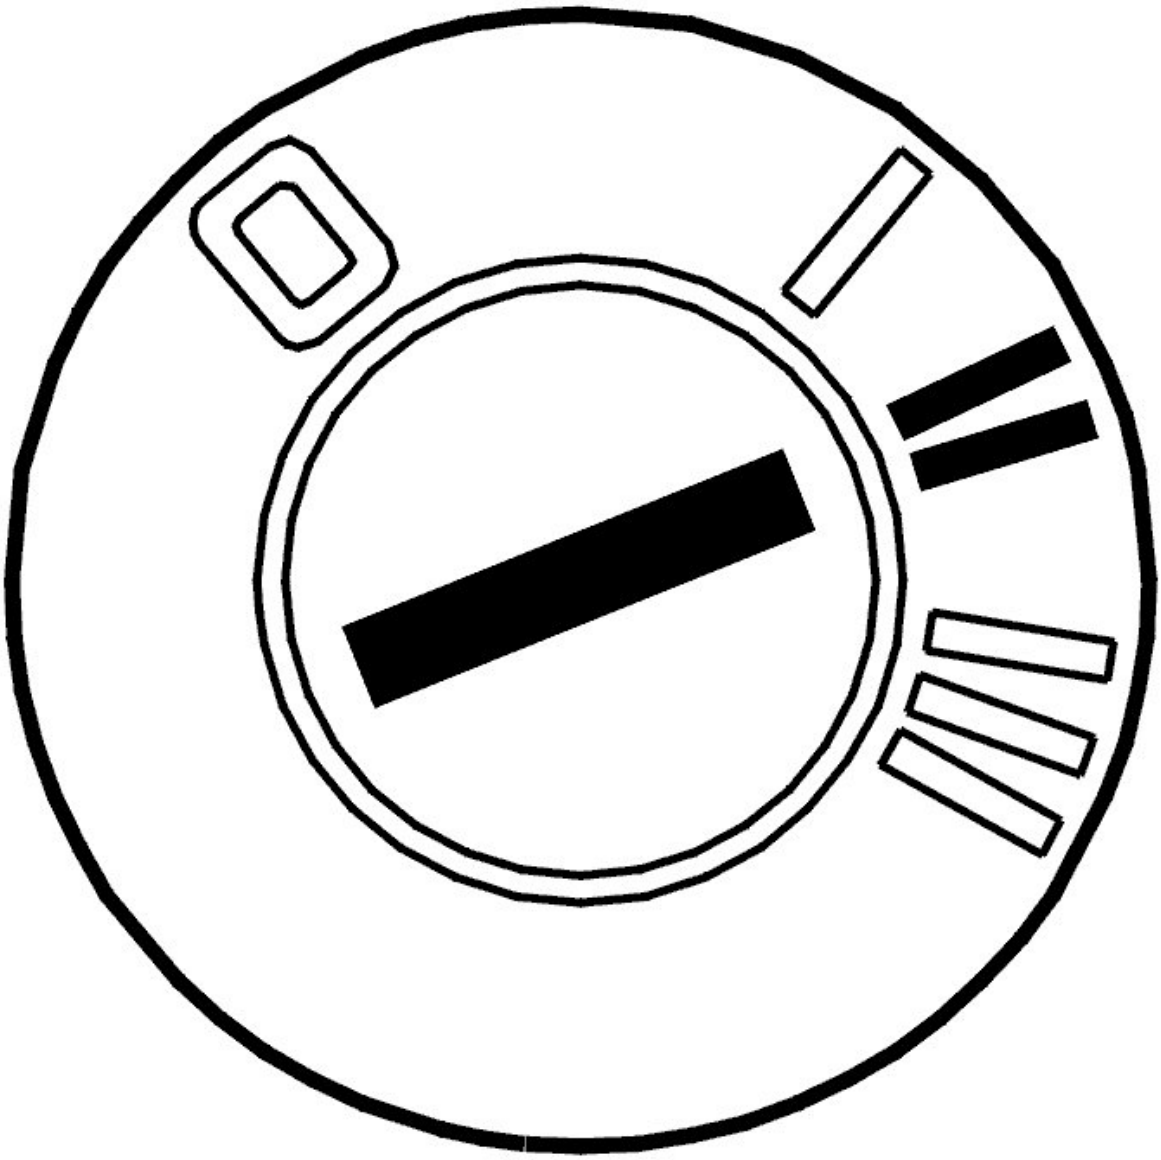
Fault symptom[s]
- General orange warning lamp lit.
- Harsh gear shifting.

Hint: Harsh gear shifting can be caused by:
- No reduction of the line pressure when shifting.
- No reduction of the line pressure when moving the gear selector between positions P-R, N-R and N-D.
- No request for torque limiting to the engine control module (ECM) when shifting.

Signal Too High

Signal too high

Checking transmission fluid temperature sensor



- Ignition off
- Check the control module connector and transmission connector D. Check for contact resistance and oxidation according to Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault. Remedy if necessary
- Reconnect the control module and transmission connectors
- Ignition on
- Read off the oil temperature.

Check that the temperature is within its permitted range.
Compare with the transmission temperature.
If the transmission temperature is within its permitted range, the cause of the fault was contact resistance or oxidation in the control module or transmission connector.

Other information:

- To disconnect the control module, see Transmission control module (TCM), replacing, B5244T5, AW55-50/51SN, B5254T2, AW55-50/51SN, B5254T2, AW50/51 AWD See: Transmission Control Systems/Relays and Modules - Transmission and Drivetrain/Relays and Modules - A/T/Control Module/Service and Repair

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition

The solenoids are controlled by power stages in the transmission control module (TCM). The transmission control module (TCM) opens the power stages to activate the solenoids and sends a voltage through the circuit. Diagnostic trouble code (DTC) TCM-0060 is stored if the control module registers an internal fault in the power stage circuit for solenoids S1, S2, S3, S4 or S5.

Substitute value
- The transmission control module (TCM) Emergency mode III program has been initiated.

Possible source
- Internal fault in the control module.

Fault symptom[s]
- General orange warning lamp lit.
- Malfunction indicator lamp (MIL) lit.
- No lock-up function.
- Harsh gear shifting.
- No shifting.

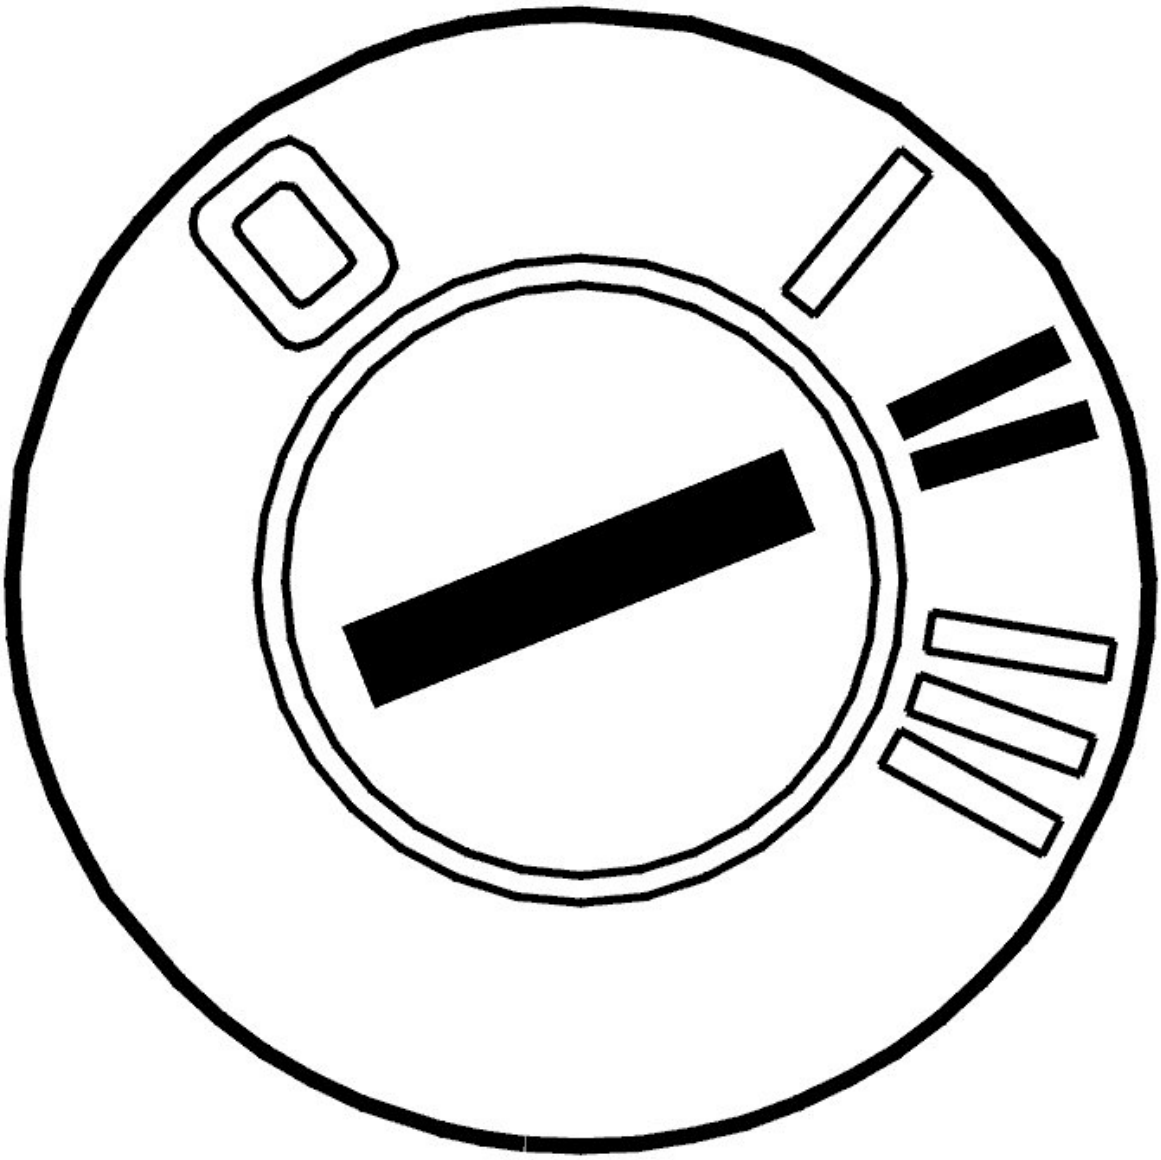
Hint: Harsh gear shifting can be caused by:
- no reduction of line pressure when shifting
- no reduction of line pressure when moving the gear selector between positions P-R, N-R and N-D
- no torque limiting request to engine control module (ECM) when shifting

No shifting - because the transmission control module (TCM) prevents activation of the solenoids. This stops gear-shifting.

Internal Fault

Internal fault

Checking shift solenoids



- Ignition on
- Gear selector in position P.
- Activate shift solenoids S1, S2, S3, S4 and S5 individually.

The status should switch between OFF and ON.
If the status does not change, it indicates that there is an internal fault in the transmission control module (TCM).

Does solenoid status switch?

Yes - No Fault Found

No - Transmission control module (TCM) replacement and programming

---

Transmission control module (TCM) replacement and programming

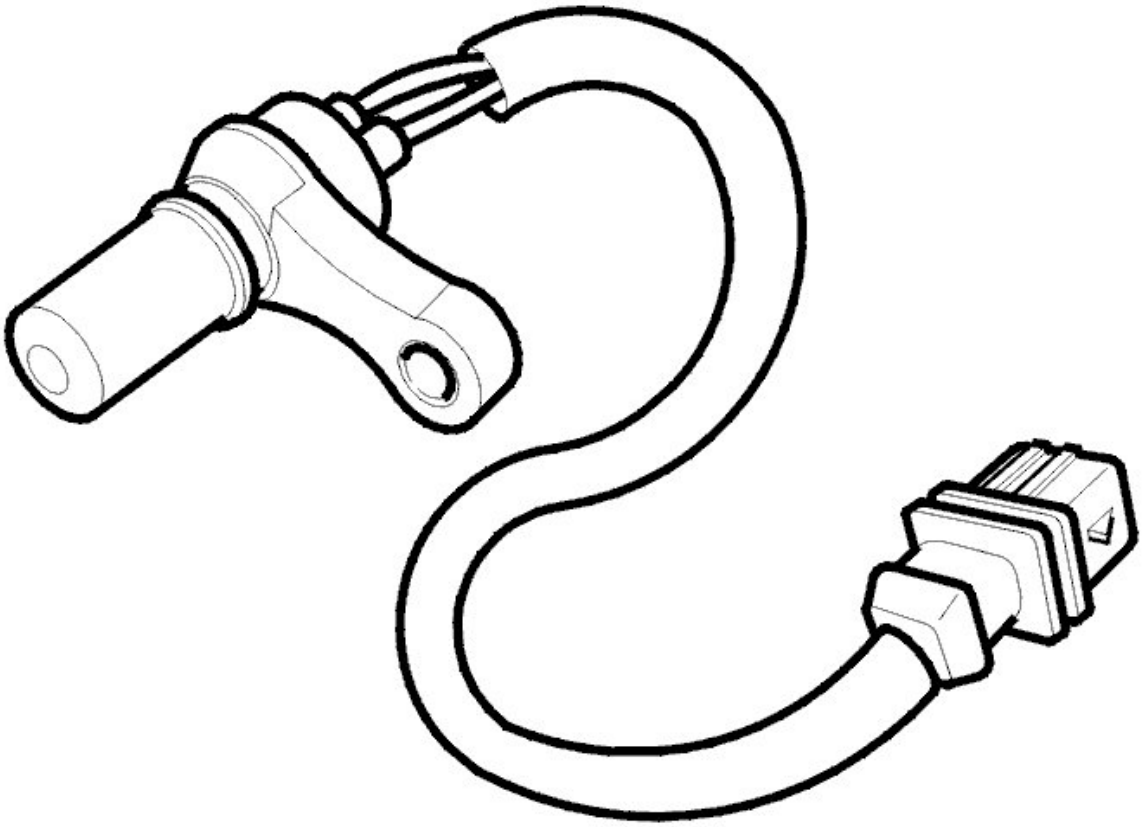
Condition



The automatic transmission control module (TCM) receives speed signals from the transmission speed sensor on the transmission. The transmission control module (TCM) uses the signals to select the correct gear. The control module derives and compares the transmission speed with engine speed (RPM) at the transmission. Diagnostic trouble code (DTC) TCM-0081 is stored if the control module registers that transmission speed signal is too high.

Substitute value
- None.

Possible source
- Short-circuit to supply voltage in the power supply or signal cable.
- Defective transmission speed sensor.

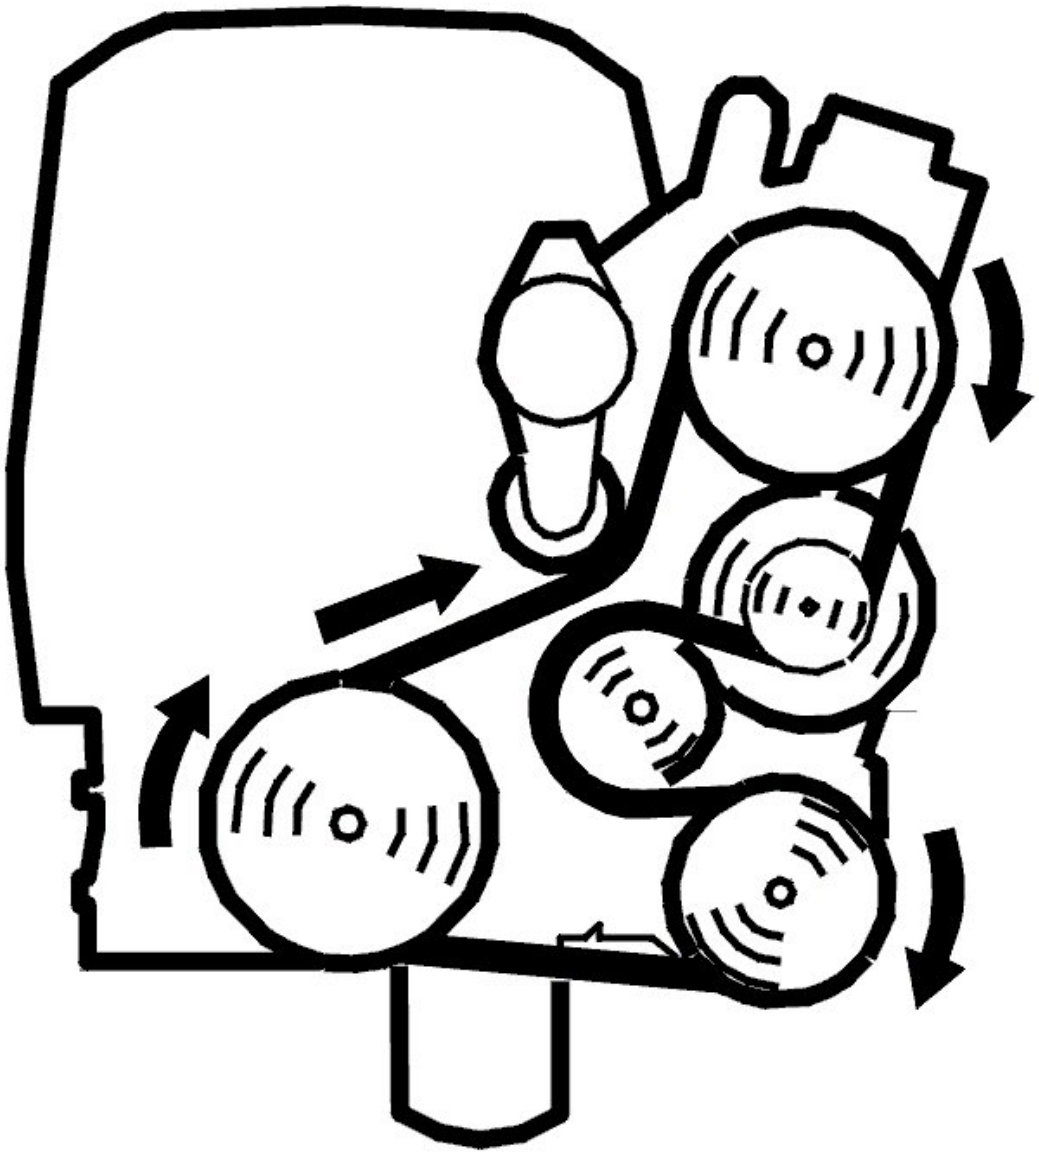
Fault symptom[s]
- General orange warning lamp lit.
- No lock-up function.
- Harsh gear shifting.

Hint: Harsh gear shifting can be caused by:
- No reduction of line pressure when shifting.
- No reduction of line pressure when moving the gear selector between positions P-R, N-R and N-D.
- No torque limiting request to engine control module (ECM) when shifting.

Signal Too High

Signal too high

Checking the transmission output speed sensor signal



- Ignition off
- Raise the car so that the drive wheels are clear of the ground
- Start the engine. Allow the engine to idle
- Shift gear selector to position D so that the drive wheels begin to rotate
- Read off the transmission speed.

Depress the accelerator pedal (AP) and check that the speed is updated.

Note! Ensure that the wheels are not rotating when the gear selector is moved.

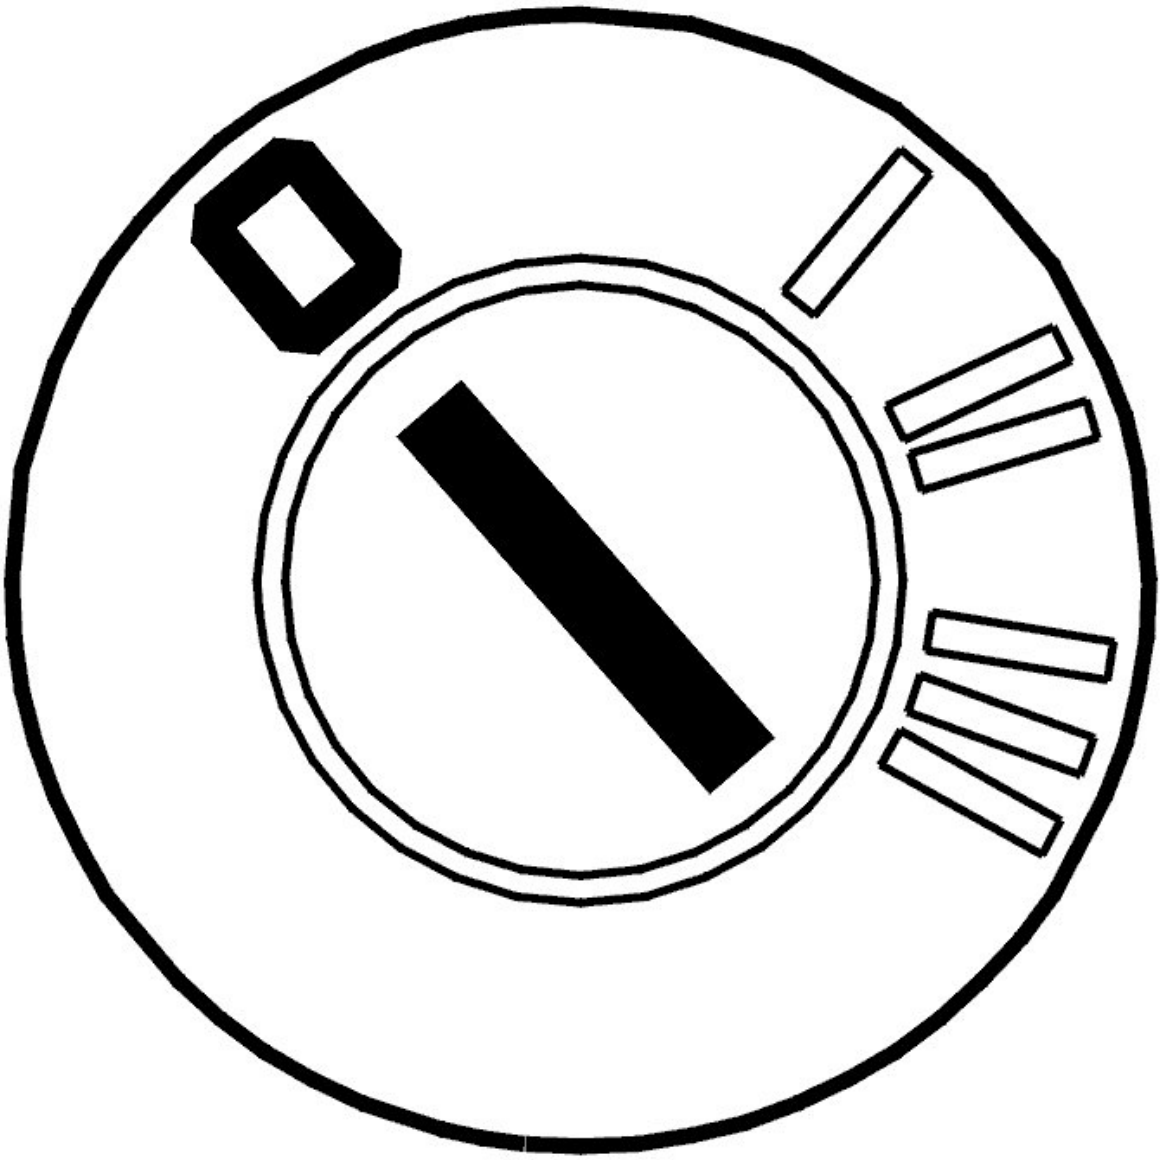
Note! Diagnostic trouble codes (DTCs) may be stored in the ABS system when the rear wheels are stationary and the front wheels rotate. Erase any diagnostic trouble codes (DTCs) stored in the ABS system after fault-tracing.

Was the speed updated?

Yes - Intermittent fault

No - Checking wiring and sensors

Checking wiring and sensors



- Ignition off
- Connect the breakout box.

Check the cables between control module terminals #A57 (#A57) and #A39 (#A39) and transmission output speed sensor terminals #A3 and #A4. Check for a short-circuit to each other.
Check the power supply cable between control module terminal #A57 (#A57) and transmission output speed sensor terminal #A4. Check for a short-circuit to supply voltage according to Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault.
Check the signal cable between control module terminal #A39 (#A39) and transmission output speed sensor terminal #A3. Check for a short-circuit to supply voltage according to Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault.

Hint: With the control module connected, the ignition on and a voltmeter connected between transmission connector terminals #A4 and #A3 (control module side), the voltage must be 1-3 V below Ubat.

Remedy as necessary.

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition

The transmission speed signal is transmitted by a sensor on the transmission. The transmission control module (TCM) uses the signal to determine the input shaft speed after the torque converter. This signal is used to compare the transmission speed with vehicle speed. The transmission control module (TCM) uses this comparison to calculate the gear-shift timing. Engine speed and vehicle speed data affects the adjustment of the system pressure, lock-up function control and engine torque reduction. The result is smooth gear-shifting. Diagnostic trouble code (DTC) TCM-0087 is stored if the control module registers, when comparing with the transmission speed signal, that the engine speed (RPM) signal is too high when the vehicle speed is above approximately 25 km/h.

Substitute value
- The transmission control module (TCM) "Emergency mode I" program has been initiated.

Possible source
- Power supply (-) short-circuited to supply voltage.
- Defectiveengine speed (RPM) sensor.

Fault symptom[s]
- General orange warning lamp lit.
- No lock-up function.

- Harsh gear shifting.

Hint: Harsh gear shifting can be caused by:
- No reduction of the line pressure when shifting.
- No reduction of the line pressure when moving the gear selector between positions P-R, N-R and N-D.
- No request for torque limiting to the engine control module (ECM) when shifting.

Signal Too High

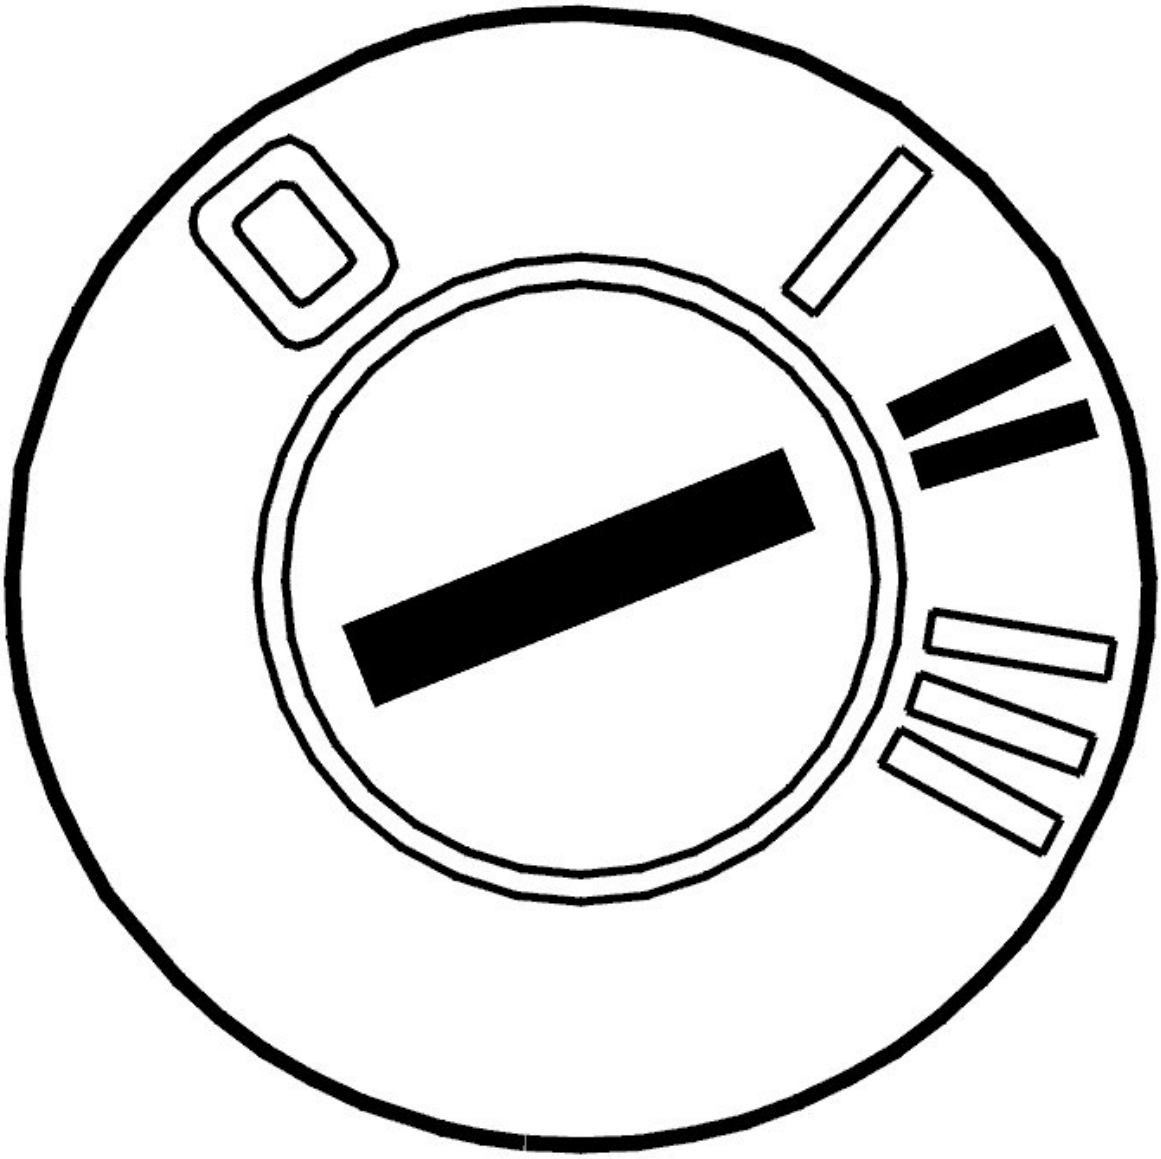
- Solenoid defective.

Fault symptom[s]
- Orange general warning lamp is on.
- Malfunction indicator light (MIL) is on.
- Gear selector movable with ignition off.

Signal Too High

Signal too high

Checking the P-shift lock solenoid



- Ignition on
- Gear selector in position P
- Try moving the gear selector to another position without depressing the brake pedal. It should not be possible to move the gear selector
- Depress the brake pedal and try moving the gear selector to another position. It should now be possible to move the gear selector.

Was the function OK?

Yes - Intermittent fault

No - Checking the wiring and component

Checking the wiring and component

Check the cable between the control module for the gear selector and the solenoid connector. Check for a short-circuit to supply voltage according to Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault.
Check the voltage between terminals #1 and #2 on the solenoid connector (female half).
When the ignition is on and the brake pedal is not depressed the voltage should be 0 V. When the brake pedal is depressed the voltage should be Ubat.
Replace the solenoid if the voltage is OK.

Other information

- To check or replace the shift lock solenoid, see Solenoid back-up (reverse) inhibitor, replacing See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Shifter A/T/Service and Repair/Solenoid Back-Up (Reverse) Inhibitor, Replacing.

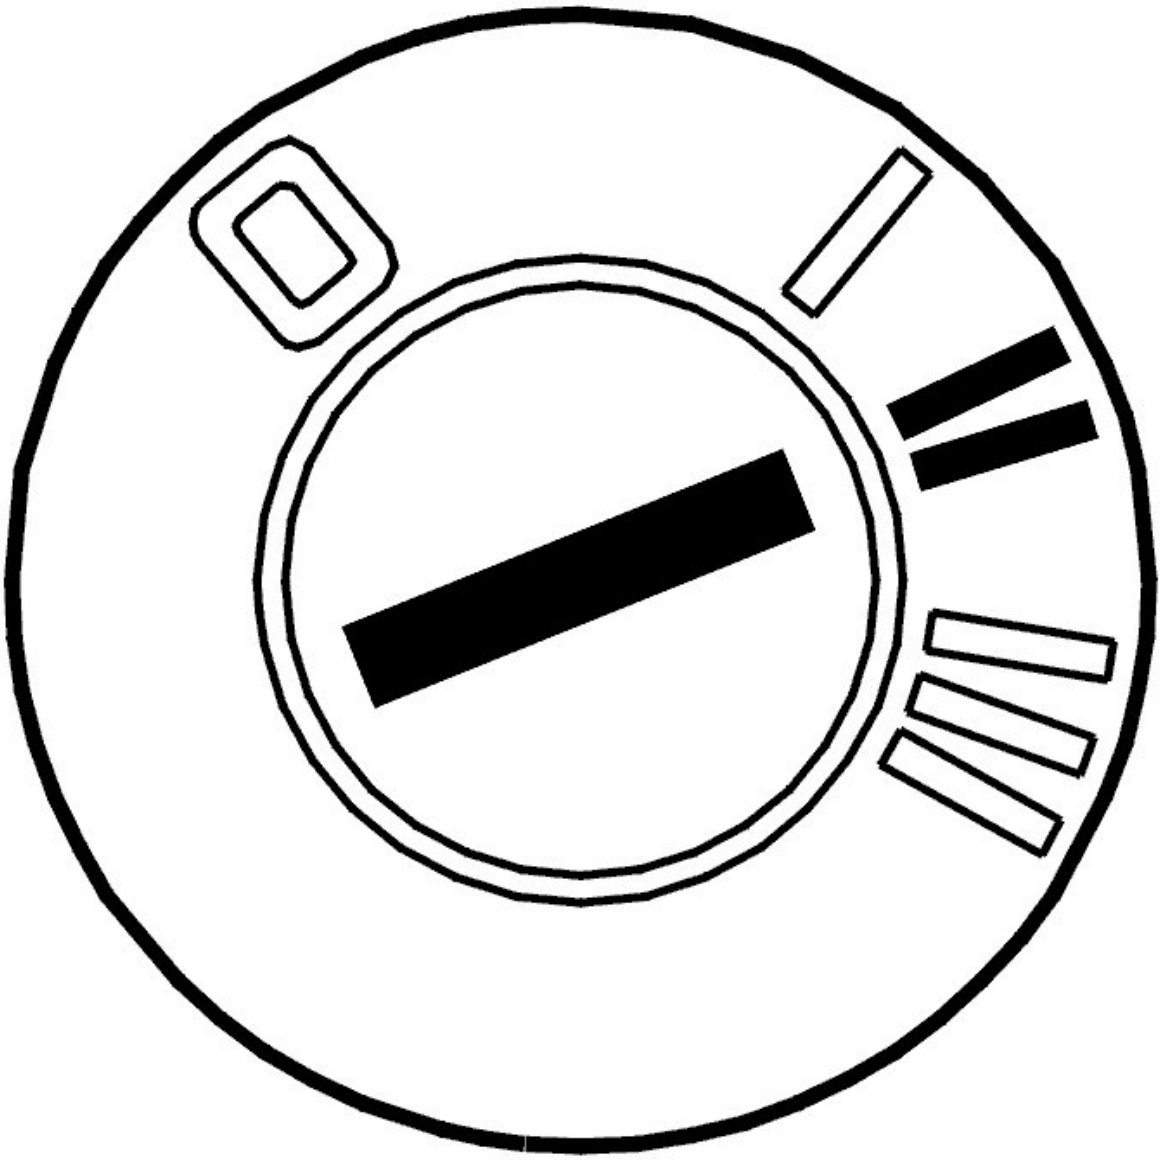
Programming can be carried out when the software has been delivered.
Program the control module according to the table below.

S60	8645432
V70 2000-, V70 XC 2001-/XC70	9494721
S80	9438291
XC90	8691289

Continue - Test driving and reading off diagnostic trouble codes (DTCs)

Test driving and reading off diagnostic trouble codes (DTCs)

Hint: To check that the fault is remedied, test drive the car and then read off the diagnostic trouble codes (DTCs).

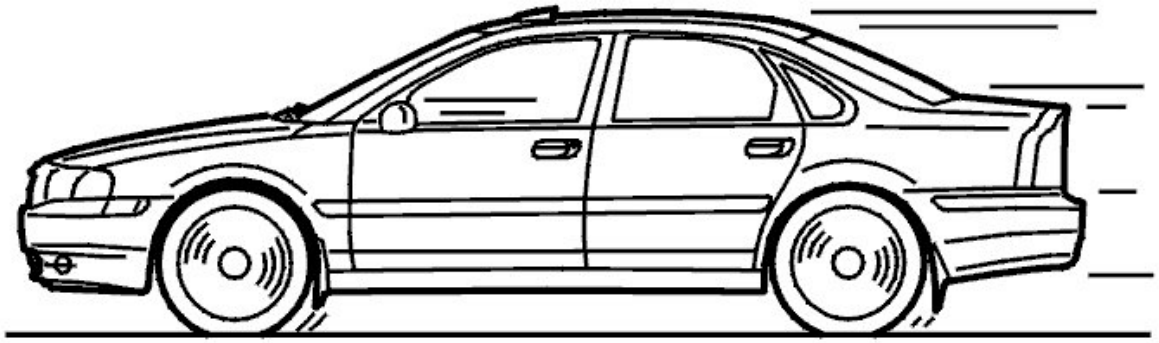


- Ignition on
- Read off diagnostic trouble codes (DTCs).

Other information

- For the test driving schedule, see Test drive schedule, description, B5244T5, AW55-50/51SN, B5254T2, AW55-50/51SN, B5254T2, AW50/51 AWD See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Service and Repair/Procedures/Test Drive Schedule, Description.

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

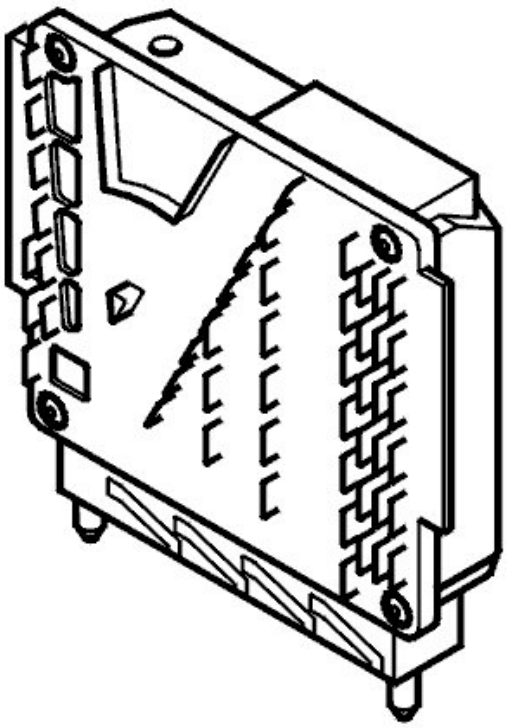


Does diagnostic trouble code (DTC) TCM-0097 or TCM-0098 recur?

Yes - Replacing the transmission control module (TCM)

No - Fault Found

Replacing the transmission control module (TCM)



Replace the transmission control module (TCM). See Transmission control module (TCM), replacing, B5244T5, AW55-50/51SN, B5254T2, AW55-50/51SN, B5254T2, AW50/51 AWD See: Transmission Control Systems/Relays and Modules - Transmission and Drivetrain/Relays and Modules - A/T/Control Module/Service and Repair.

Continue - DONE

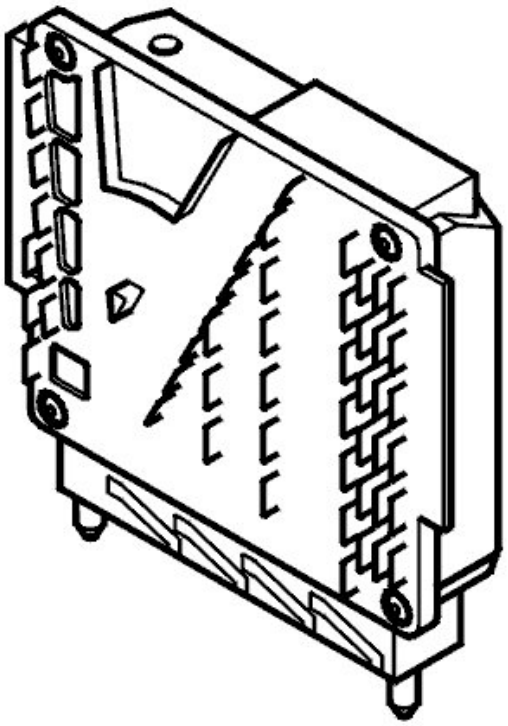
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition



Diagnostic trouble code (DTC) TCM-0099 is stored if the transmission control module (TCM) registers that the storage of data to the control module EEPROM memory is not correctly completed.

Substitute value
- None.

Possible source
- Faulty software in the control module
- Defective EEPROM memory.

Fault symptom[s]
- None.

Internal Fault

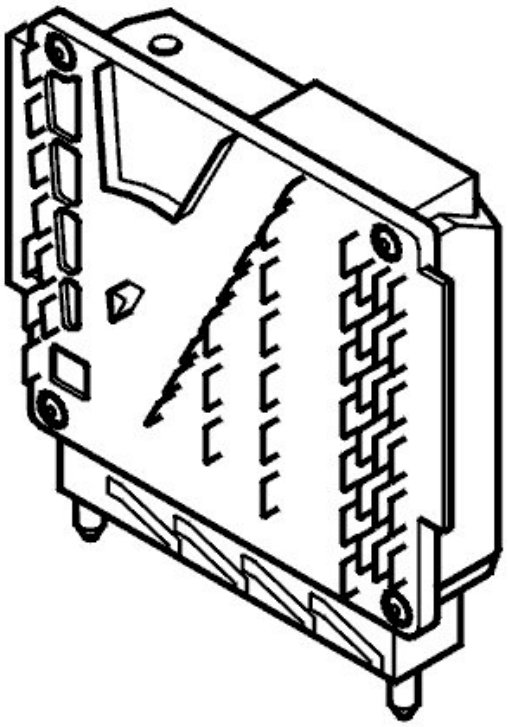
Internal fault

Replacing the control module and programming

The control module has registered an internal fault.

Caution! A new control module is delivered without software. The control module must be programmed in order to function after replacement.

For further information about programming and replacing the control module, see Transmission control module (TCM), replacing, B5244T5, AW55-50/51SN, B5254T2, AW55-50/51SN, B5254T2, AW50/51 AWD See: Transmission Control Systems/Relays and Modules - Transmission and Drivetrain/Relays and Modules - A/T/Control Module/Service and Repair.



Continue - Fault Found

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition

Diagnostic trouble code (DTC) TCM-009A is stored if the control module registers that the power supply is too low in comparison with the supply to the central electronic module (CEM).

Substitute value
- None.

Possible source
- Contact resistance or oxidation in the control module or transmission connectors.

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

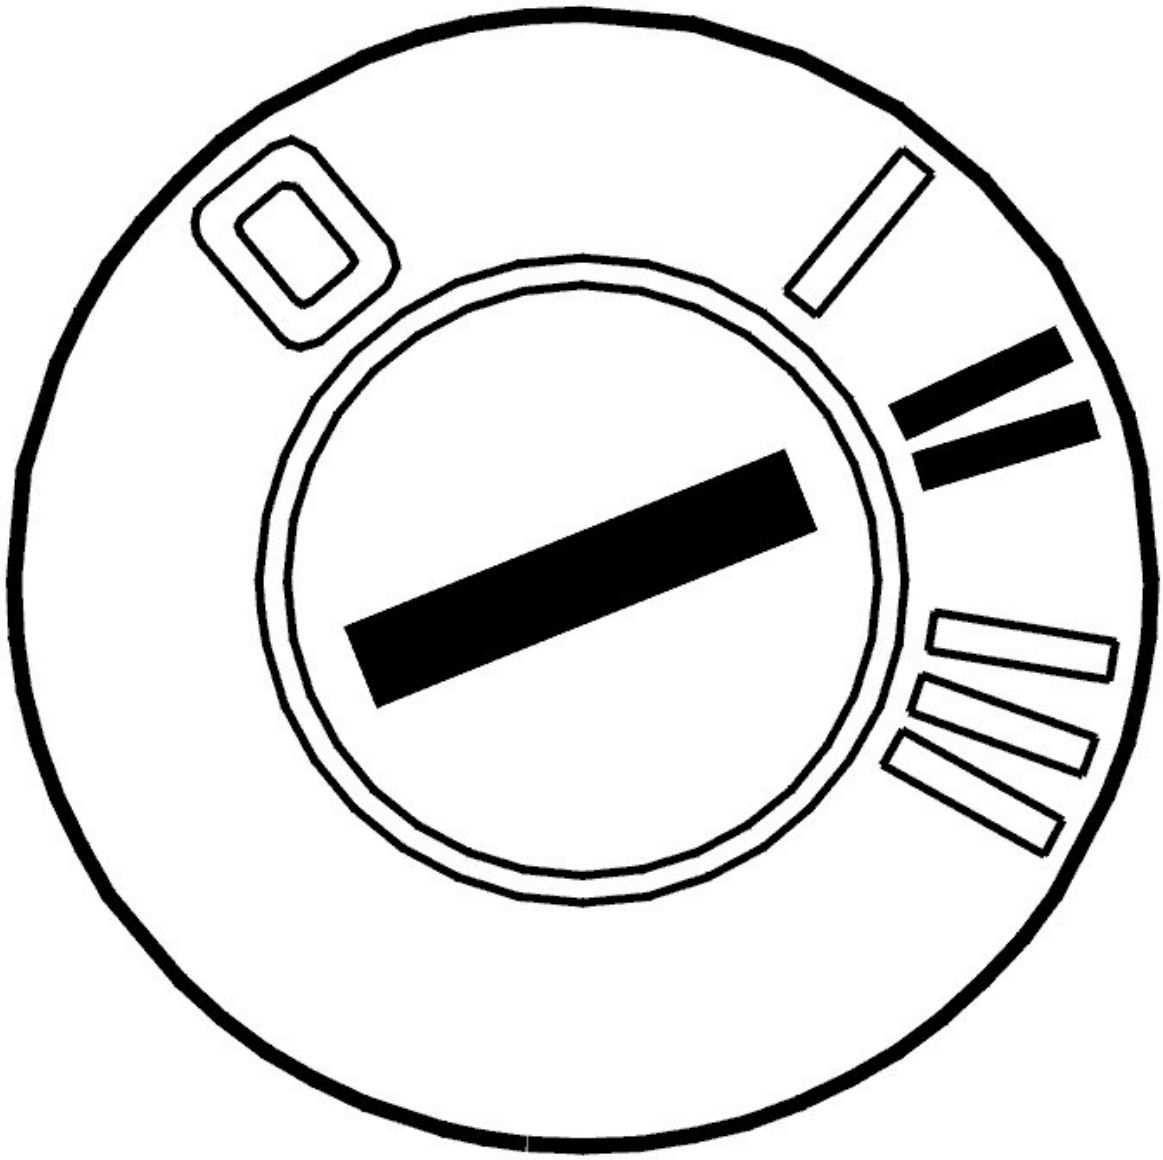
Fault symptom[s]

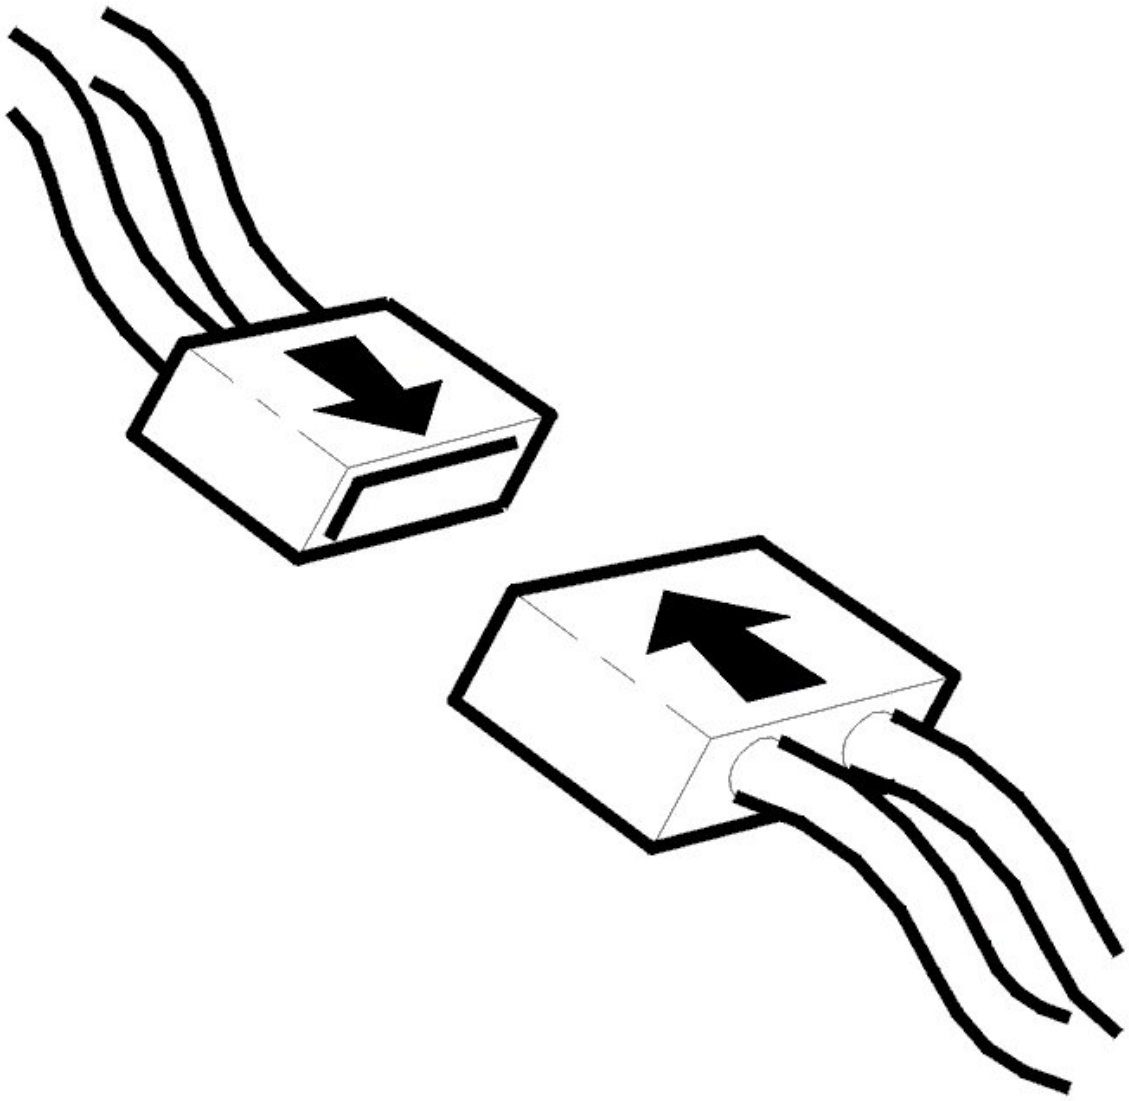
- General orange warning lamp lit.

Signal Too Low

Signal too low

Checking the battery voltage





- Ignition on
- Read off the voltage for the transmission control module (TCM) and the central electronic module (CEM).

The voltage must be battery voltage for both the control modules.

Other information:

- To disconnect the control module, see Transmission control module (TCM), replacing, B5244T5, AW55-50/51SN, B5254T2, AW55-50/51SN, B5254T2, AW50/51 AWD See: Transmission Control Systems/Relays and Modules - Transmission and Drivetrain/Relays and Modules - A/T/Control Module/Service and Repair.

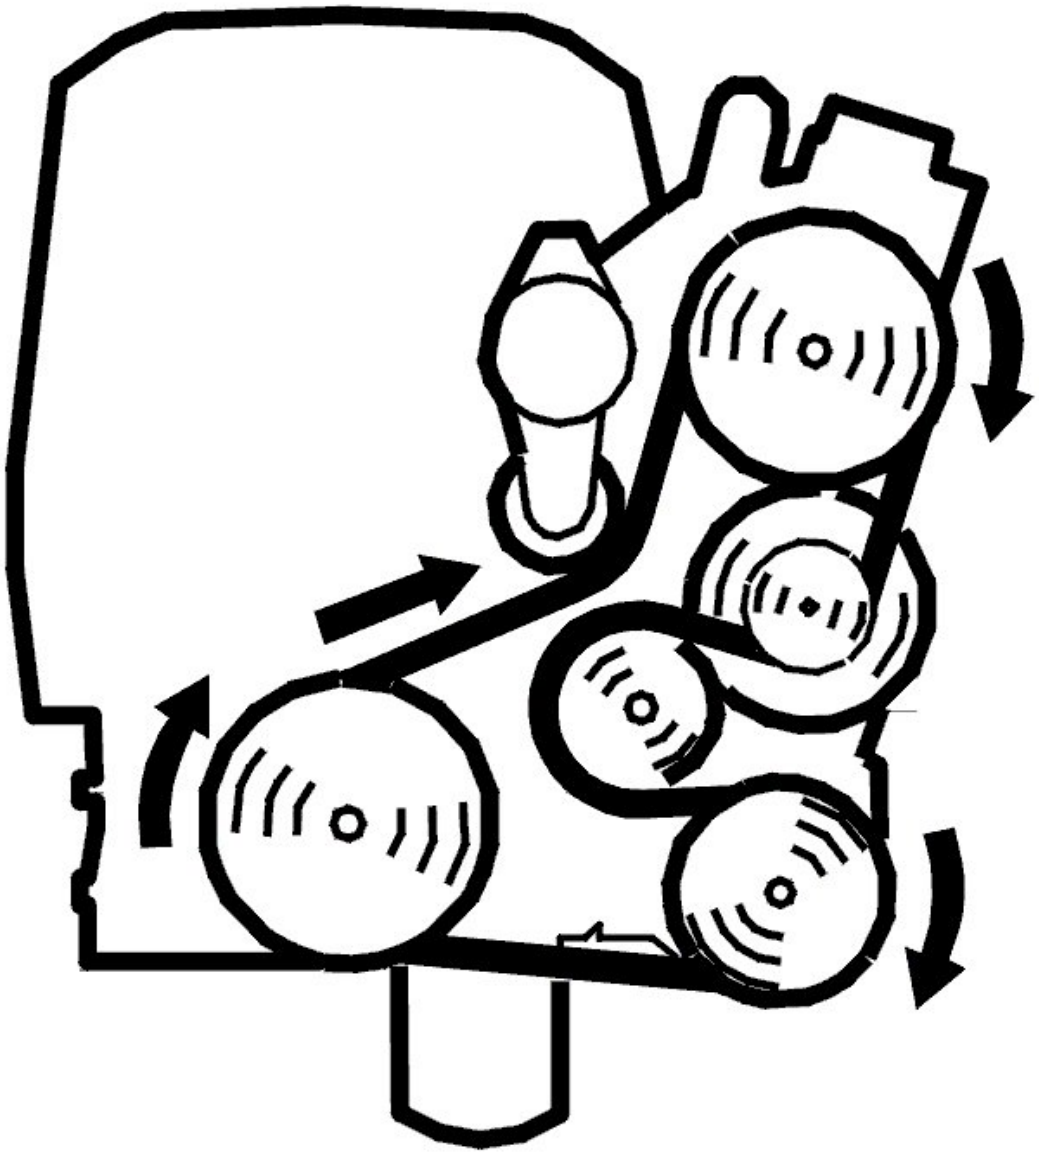
Select an option:

1. Voltage too low for both control modules
2. Voltage too low for the transmission control module (TCM).

1 - Checking the battery voltage

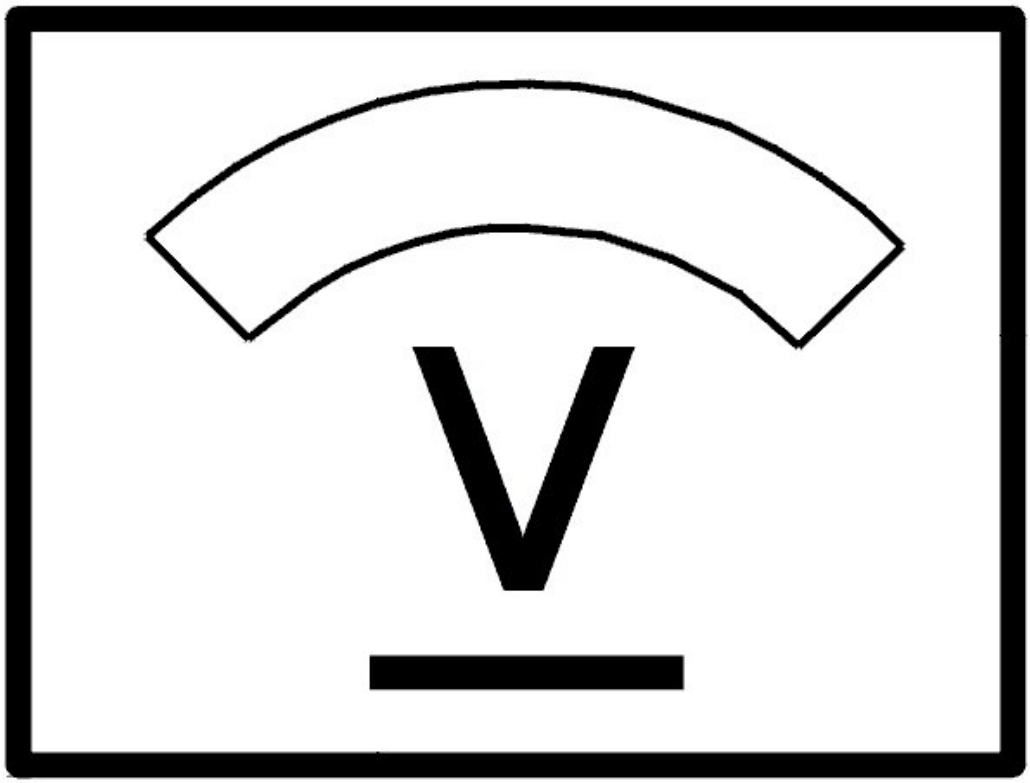
2 - Checking the power supply

Checking the battery voltage



- Start the engine and let it run at idle speed
- Connect a voltmeter between the battery positive and negative terminals.

The voltmeter should read 12-15 V. If the voltage is lower, check the charging system for low charge voltage.



Was a fault detected?

Yes - Verification

No - Checking the battery terminals

Checking the battery terminals

Check the battery positive and negative terminals and the front terminals in the engine compartment. Check for contact resistance and oxidation. Remedy as necessary.

Continue - Fault-tracing information

Fault-tracing information

Information

Fault-tracing information

The fault should be diagnosed and remedied. Since this is not the case the fault-tracing process has failed.
Complete the fault-tracing for those fault or try again.

Do you want to terminate fault-tracing at this time?

Yes - FAULT-TRACING FAILED

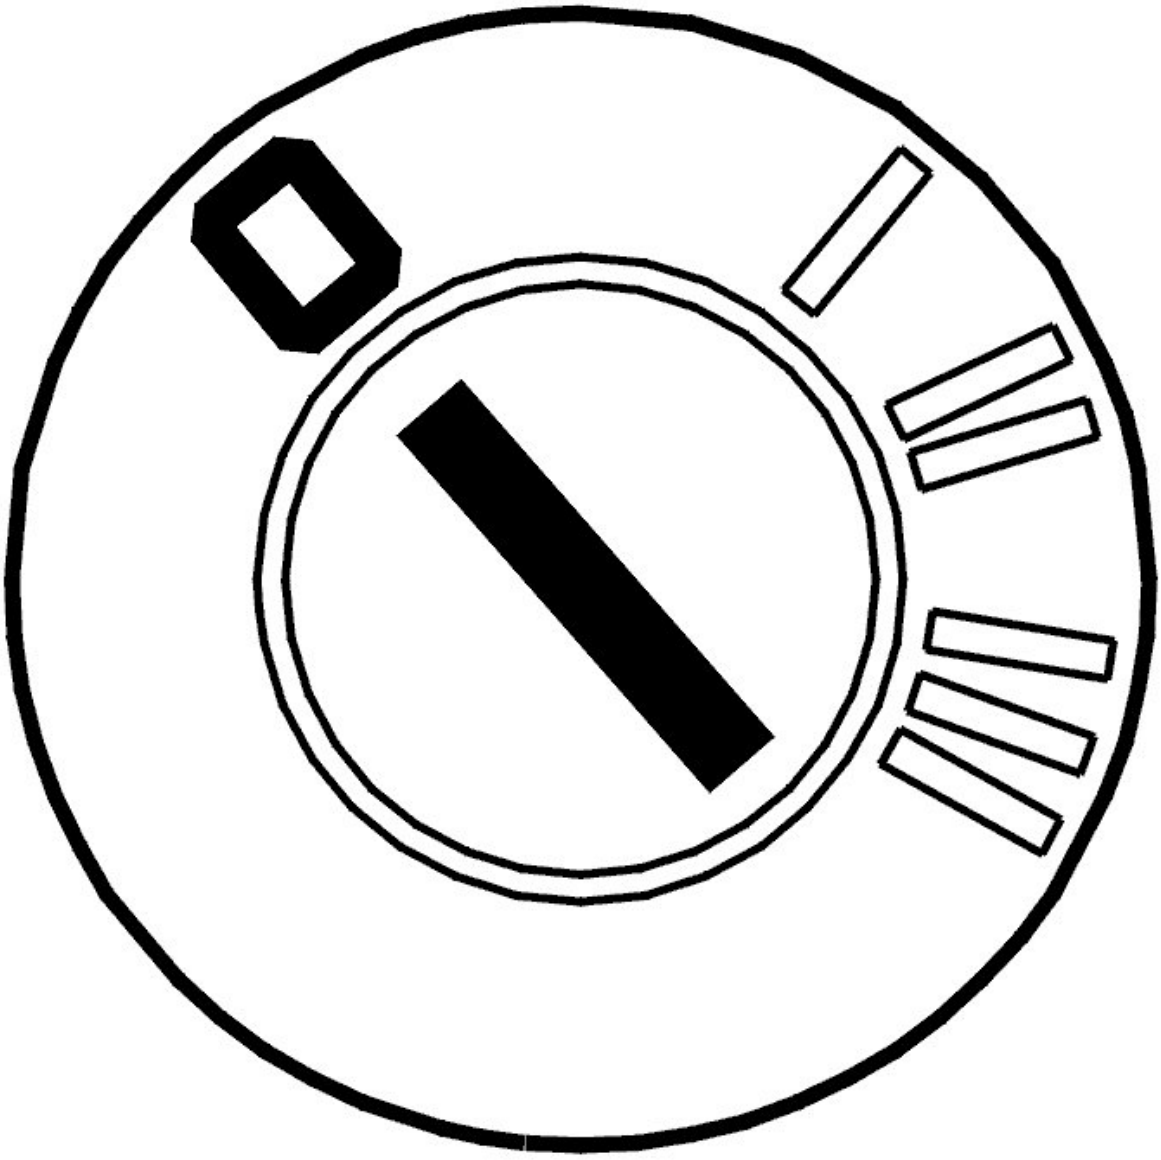
Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

No - Attempt New Test

FAULT-TRACING FAILED - No Fault Found

Attempt New Test - Checking the battery voltage

Checking the power supply



- Ignition off.

Check the transmission control module (TCM) connector and the relay for extended X supply 2/101 (located in the central electronic module (CEM)). Check for contact resistance and oxidation according to Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault. Check the power supply cable between fuse 20 in the integrated relay / fusebox in the engine compartment and the relay for extended X supply 2/101 (terminal #3 on the central electronic module CEM). Check the power supply cable between relay terminal #1 and transmission control module (TCM) terminal #A35 (#A35). Check for an open-circuit according to Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault. For information about the cable routing, see the relevant Wiring Diagram.

Hint: With the ignition on and voltmeter connected between transmission control module (TCM) terminals #A35 (#A35) and #A53 (#A53) the voltmeter should read battery voltage.

Other information:

- To connect the breakout box, see Connecting the breakout box, B5244T5, B5254T2 See: Pinout Values and Diagnostic Parameters/Connecting the Breakout Box
- To disconnect the control module, see Transmission control module (TCM), replacing, B5244T5, AW55-50/51SN, B5254T2,

AW55-50/51SN, B5254T2, AW50/51 AWD See: Transmission Control Systems/Relays and Modules - Transmission and Drivetrain/Relays and Modules - A/T/Control Module/Service and Repair

- To disconnect relay 2/101 for extended X-supply, see Central electronic module (CEM), replacing See: Body Control Module/Service and Repair/Central Electronic Module (CEM), Replacing
- For information about signals, see Signal description. Transmission control module (TCM), AW50/51 AWD, AW55-50/51SN See: Transmission Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Description. Transmission Control Module (TCM).

Is the transmission operating correctly?

Yes - Fault Found

No - Replacing the control system

Replacing the control system

Fault-tracing indicates an internal fault in the transmission.
Replace the control system. See Solenoid control system, replacing See: Transmission Control Systems/Actuators and Solenoids - Transmission and Drivetrain/Actuators and Solenoids - A/T/Shift Solenoid/Service and Repair/Solenoid Control System, Replacing.

Continue - Resetting the adaptation and oil quality counter

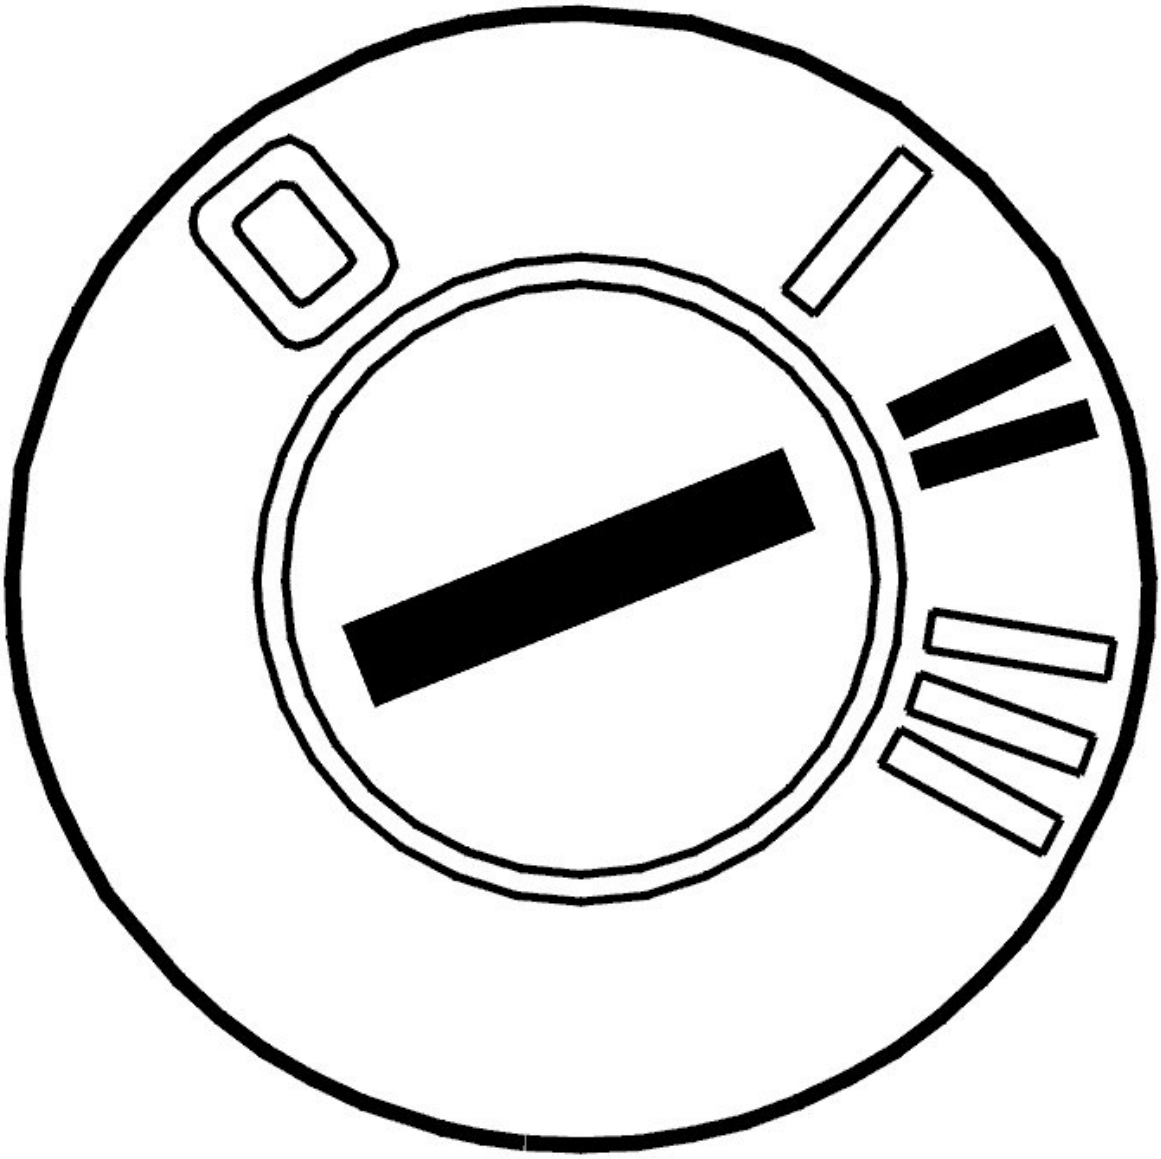
Resetting the adaptation and oil quality counter

Resetting the adaptation

Resetting adaptation and the counter for "Transmission oil change"

Hint: The transmission has torque controlled adaptive pressure control. Pressure control means that the transmission regulates the pressure itself during each gear shift. This avoids harsh gear shifting. Each gear shift is evaluated by the control module and stored in the memory. This allows for compensation for wear and tear in the transmission and clutch. It is important that the adaptation in the memory is reset after the transmission has been repaired. This is to ensure normal operation. The oil is replaced during repair; the "Transmission oil change" counter must be reset. If the counter is not reset when the fluid is drained and replaced, there is a risk that a diagnostic trouble code (DTC) will be stored in incorrect circumstances.

Note! This applies only if the transmission or one of the components in the transmission have been replaced.



- Ignition on.

Click on the VCT2000 symbol to reset the adaptation and counter.

Continue - DONE

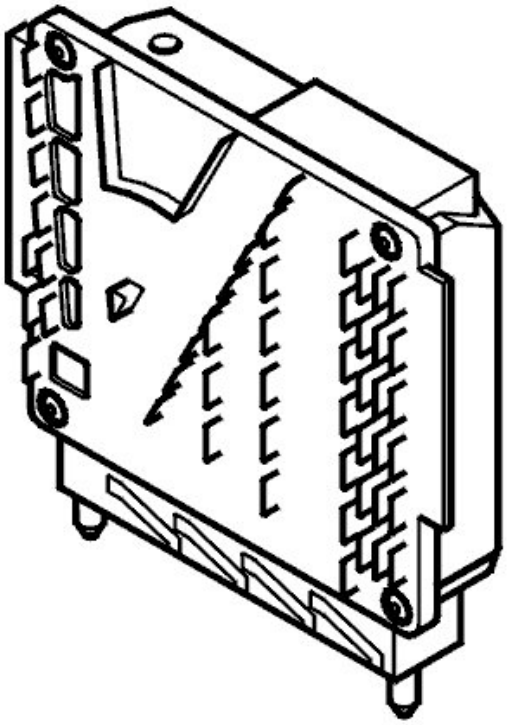
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition



Shift solenoids S1, S2, S3, S4 and S5 operate in tandem to control gear-shifting. The solenoids are controlled by power stages in the transmission control module (TCM). The transmission control module (TCM) opens the power stages to activate the solenoids and sends a voltage through the circuit. Diagnostic trouble codes (DTCs) TCM-0001, TCM-0007, TCM-0101 TCM-0107 or TCM-010A are stored (depending on the solenoid)if the transmission control module (TCM) registers that the signal in circuits S1, S2, S3, S4 or S5 is too high when the solenoid should not be activated.

Substitute value
- The transmission control module (TCM) "Emergency mode I" program has been initiated.

Possible source
- Short-circuit to supply voltage in the signal cable.
- Internal fault in the control module.

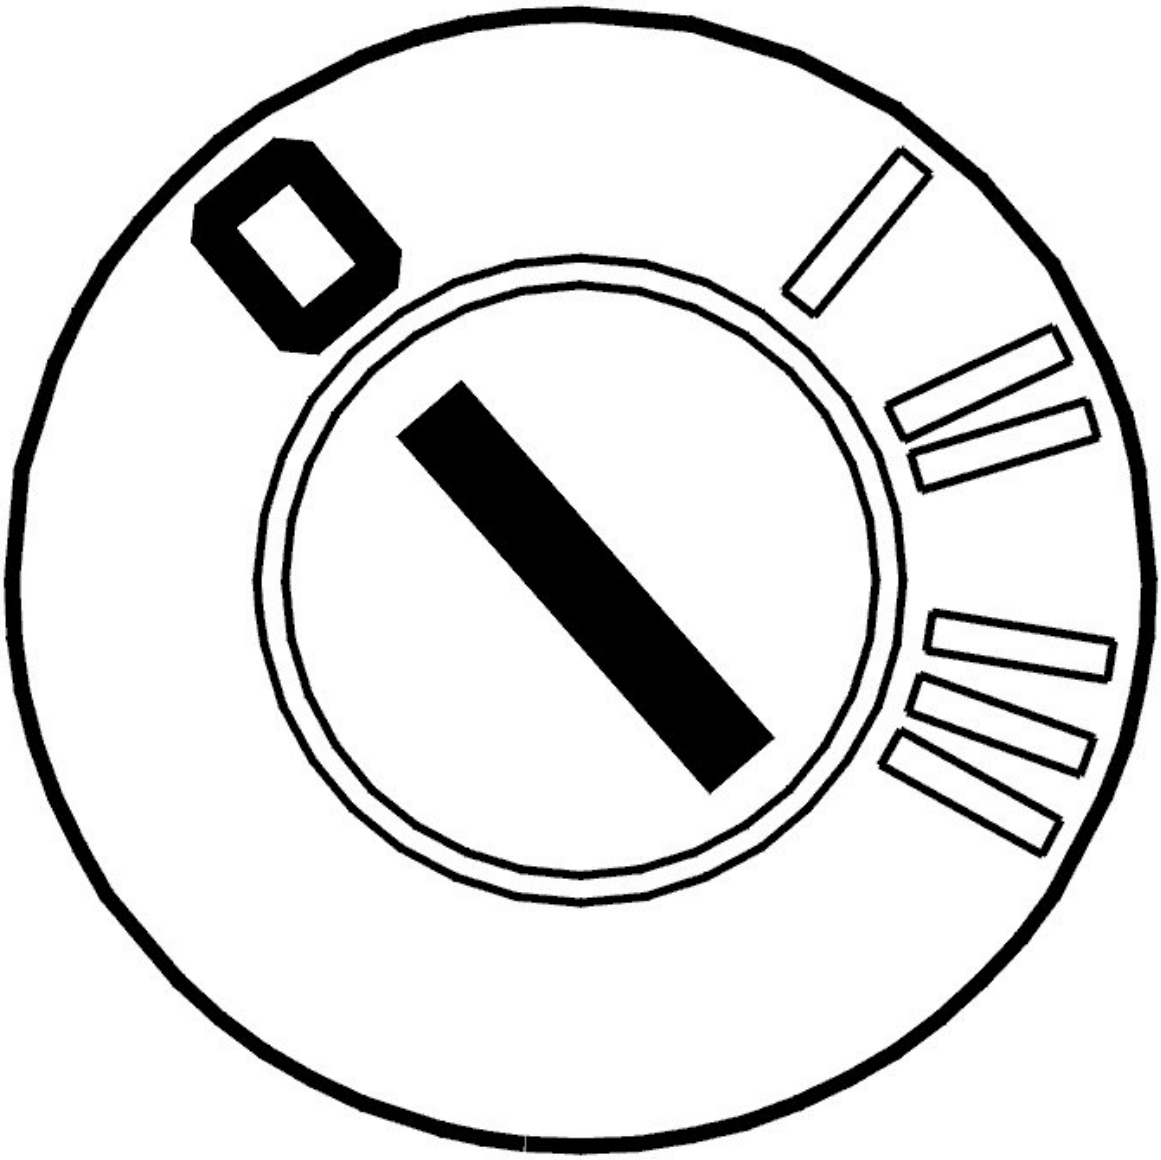
Fault symptom[s]
- General orange warning lamp lit.
- Malfunction indicator lamp (MIL) lit.
- Harsh gear shifting.
- No shifting.
- No lock-up function.

Signal Too High

Signal too high

Checking the temperature sensor

Hint: In some cases, the diagnostic trouble code (DTC) may be caused by a defective oil temperature sensor. Check the function of the oil temperature sensor first.



- Ignition off
- Read off the oil temperature.

Check that the function of the temperature sensor is OK. Test drive the car to increase the temperature of the transmission fluid. Read off the temperature again. Check that the temperature has increased.

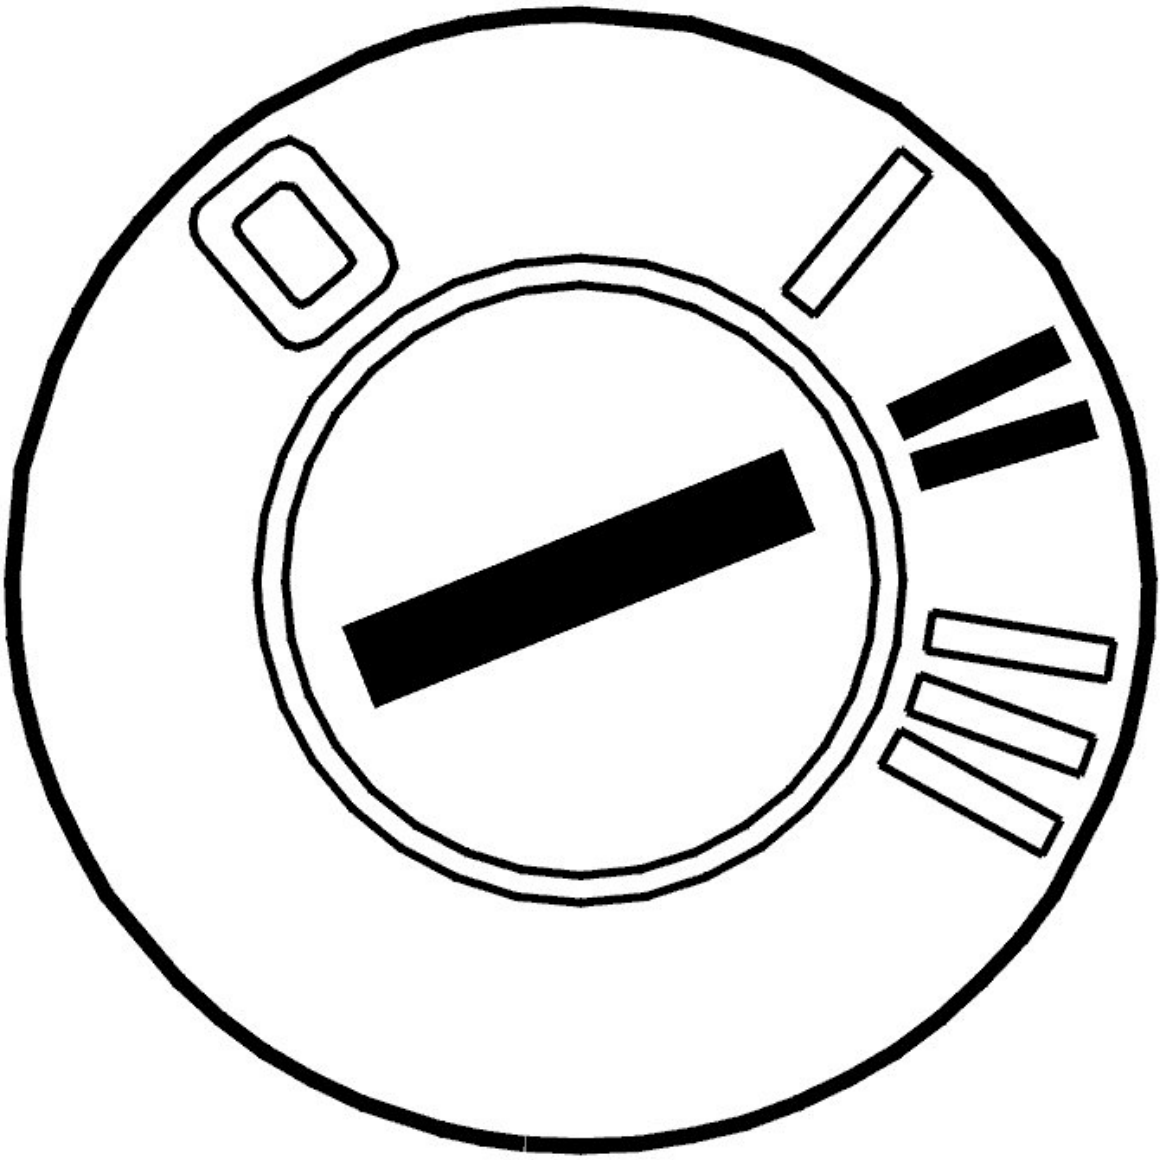
Note! If the temperature is outside its permitted range, fault-trace the temperature sensor.

Is the oil temperature within its permitted range?

Yes - Checking shift solenoid S3

No - Checking transmission fluid temperature sensor

Checking shift solenoid S3



- Ignition on
- Gear selector in position P
- Activate solenoid S3.

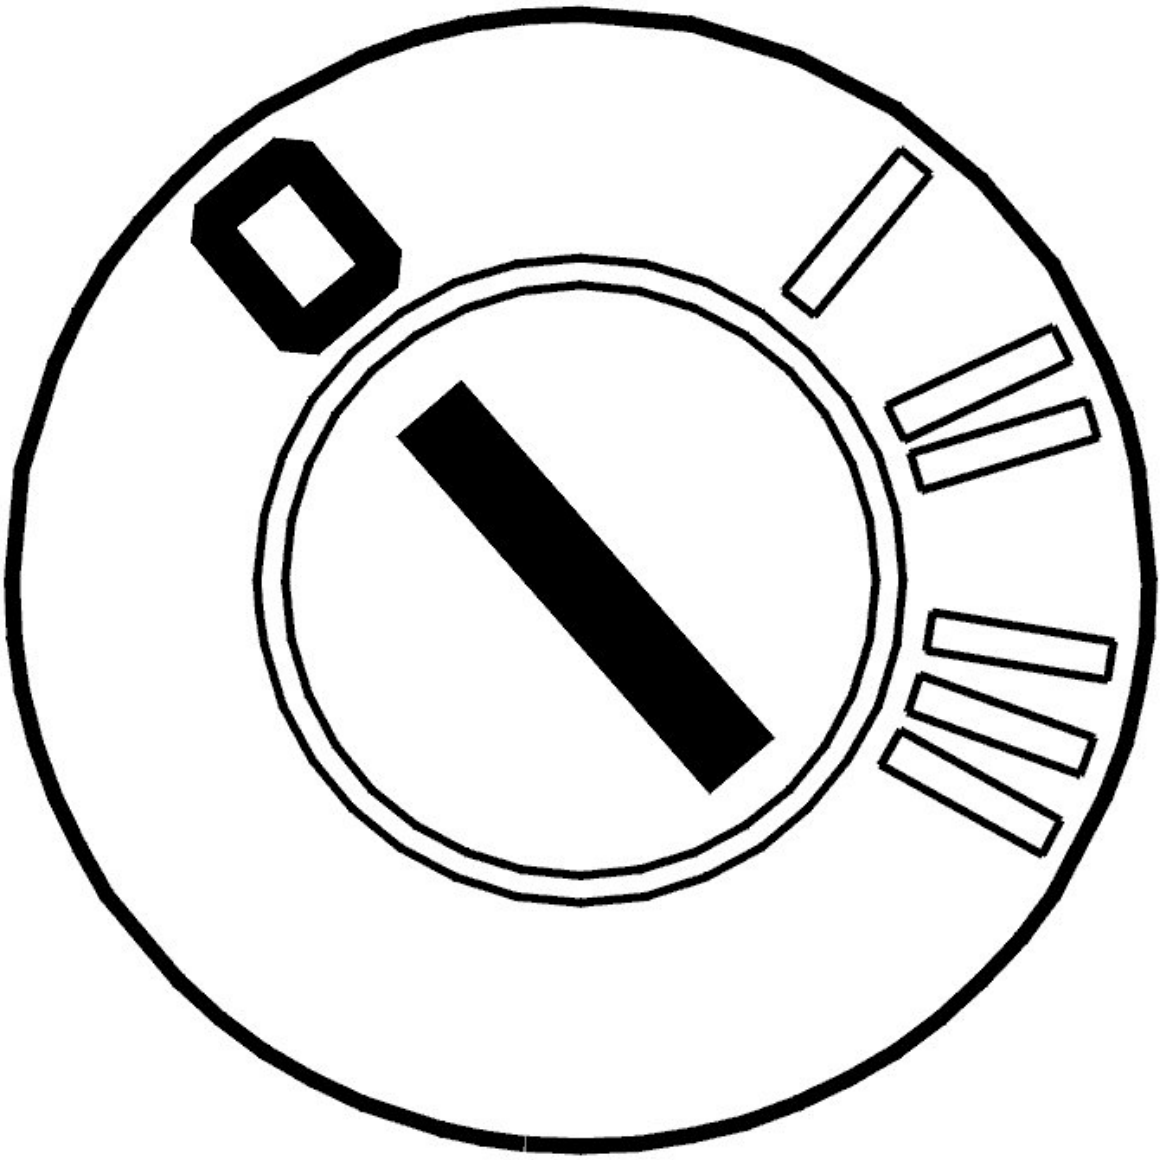
The value must change between OFF and ON.

Does the value change?

Yes - Intermittent fault

No - Checking the wiring

Checking the wiring



- Ignition off.

Check the cable between control module terminal #A48 (#A48) and transmission connector terminal #C3 (control module side). Check for a short-circuit to supply voltage according to Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault. Also check against the other cables in the circuit. Use the relevant wiring diagram.

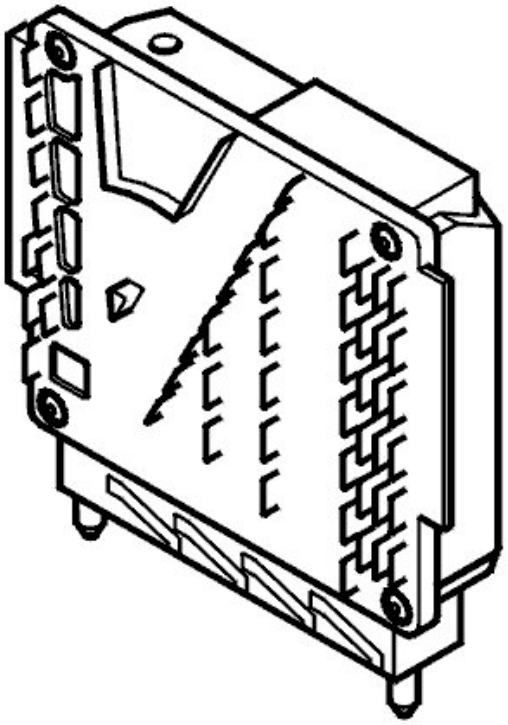
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition



Shift solenoids S1, S2, S3, S4 and S5 operate in tandem to control gear-shifting. The solenoids are controlled by power stages in the transmission control module (TCM). The transmission control module (TCM) opens the power stages to activate the solenoids and sends a voltage through the circuit. Diagnostic trouble codes (DTCs) TCM-0002, TCM-0008, TCM-0102, TCM-0108 or TCM-010B are stored (depending on the solenoid) if the transmission control module (TCM) registers that the signal in circuits S1, S2, S3, S4 or S5 is missing when the solenoid is activated.

Substitute value
- The transmission control module (TCM) "Emergency mode I" program has been initiated.

Possible source
- Contact resistance in terminals.
- Open-circuit in the signal cable.
- Defective solenoid.
- Internal fault in the control module.

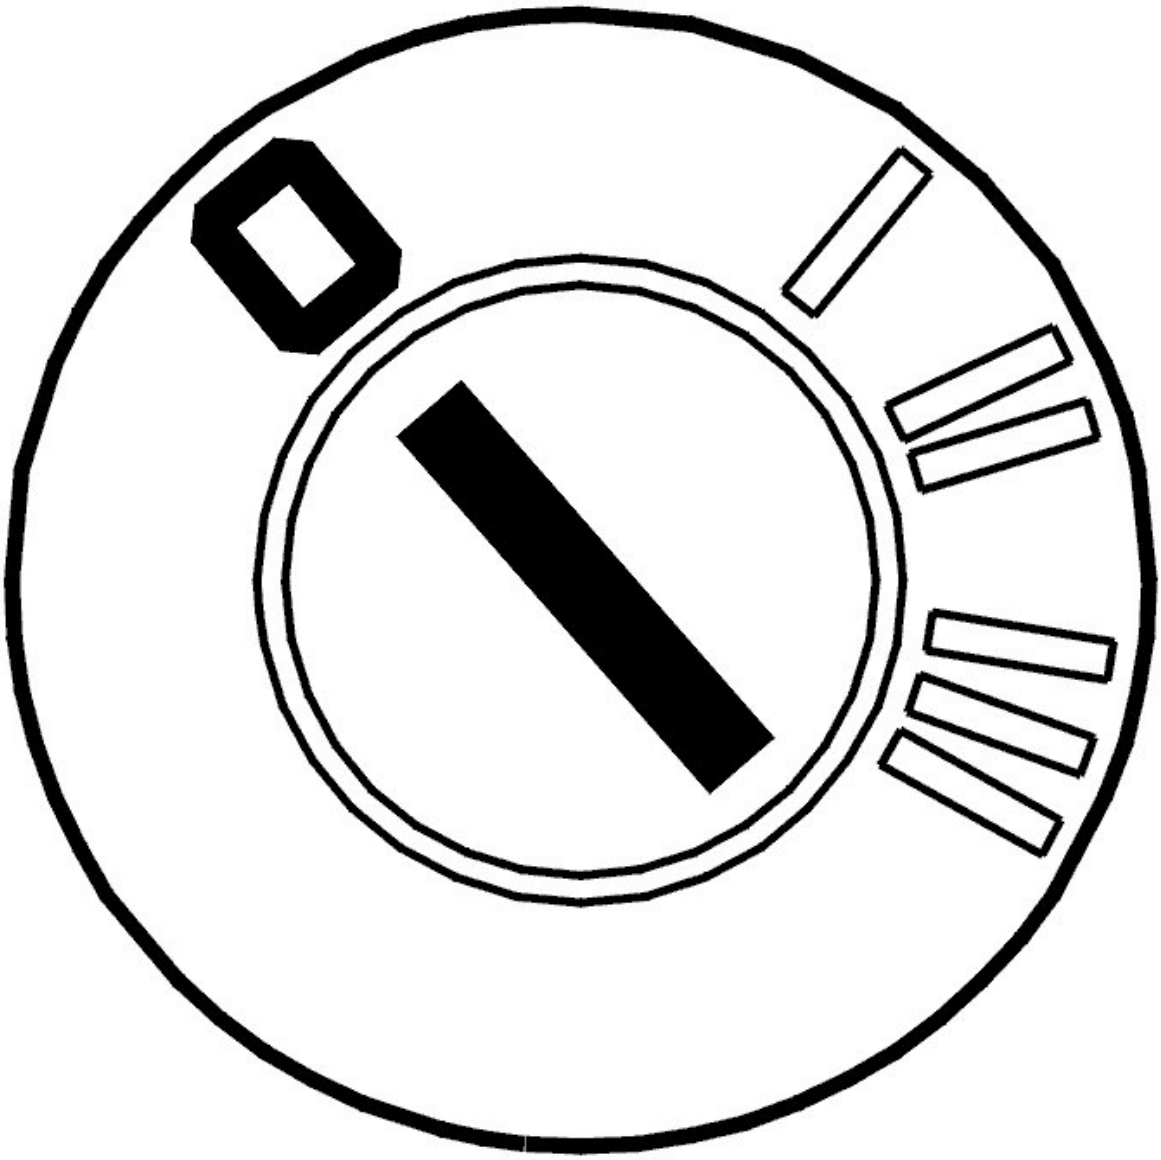
Fault symptom[s]
- General orange warning lamp lit.
- Malfunction indicator lamp (MIL) lit.
- Harsh gear shifting.
- No shifting.
- No lock-up function.

Signal Missing

Signal missing

Checking the temperature sensor

Hint: In some cases, the diagnostic trouble code (DTC) may be caused by a defective oil temperature sensor. Check the function of the oil temperature sensor first.



- Ignition off
- Read off the oil temperature.

Check that the function of the temperature sensor is OK. Test drive the car to increase the temperature of the transmission fluid. Read off the temperature again. Check that the temperature has increased.

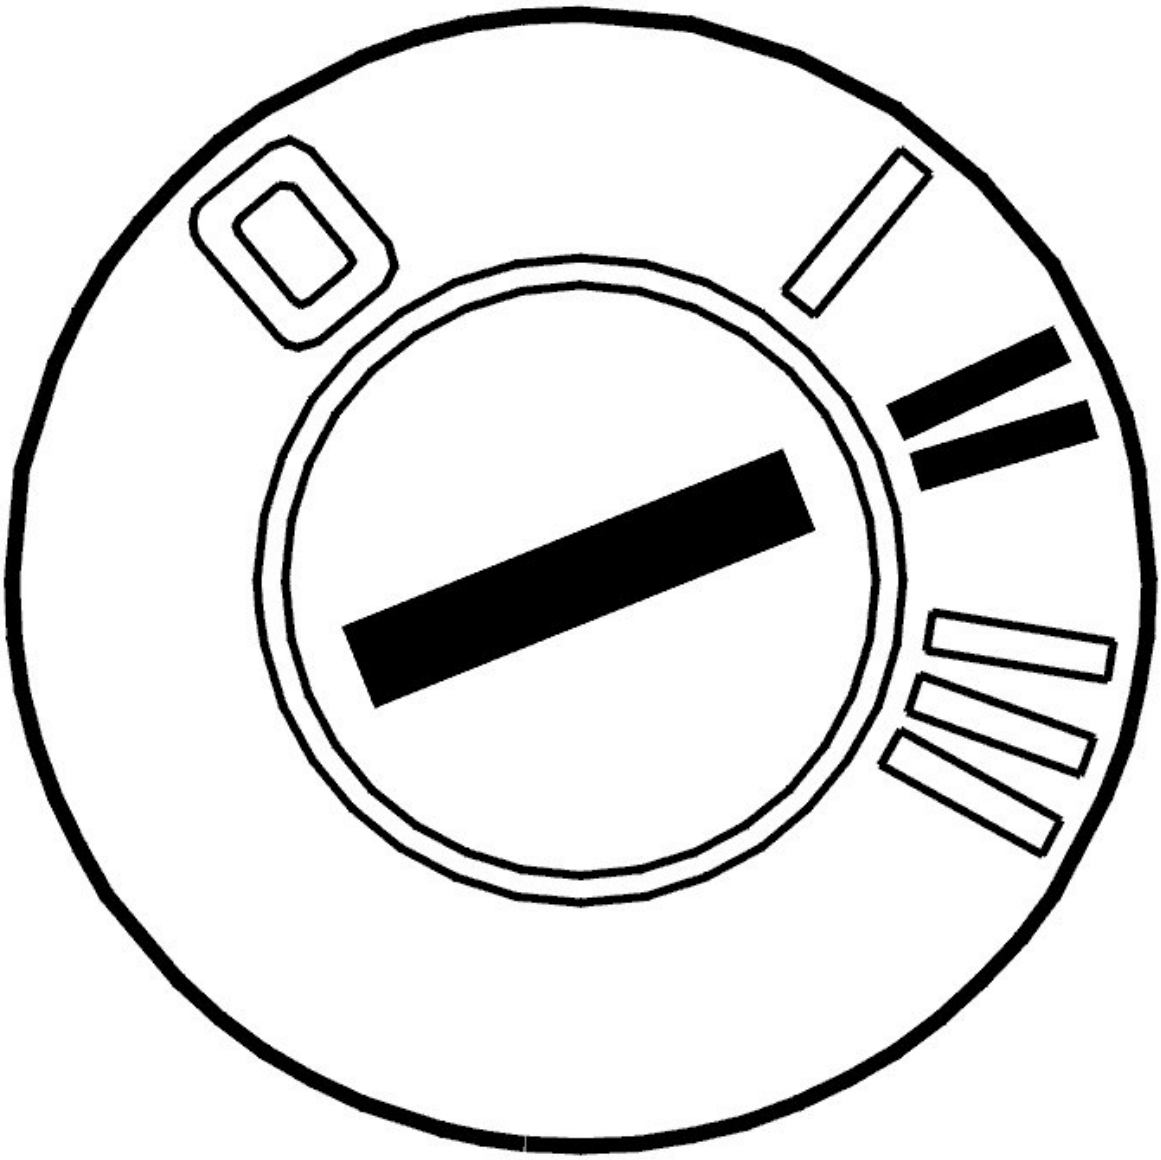
Hint: If the temperature is outside its permitted range, fault-trace the temperature sensor.

Is the oil temperature within its permitted range?

Yes - Checking shift solenoid S3

No - Checking transmission fluid temperature sensor

Checking shift solenoid S3



- Ignition on
- Gear selector in position P
- Activate solenoid S3.

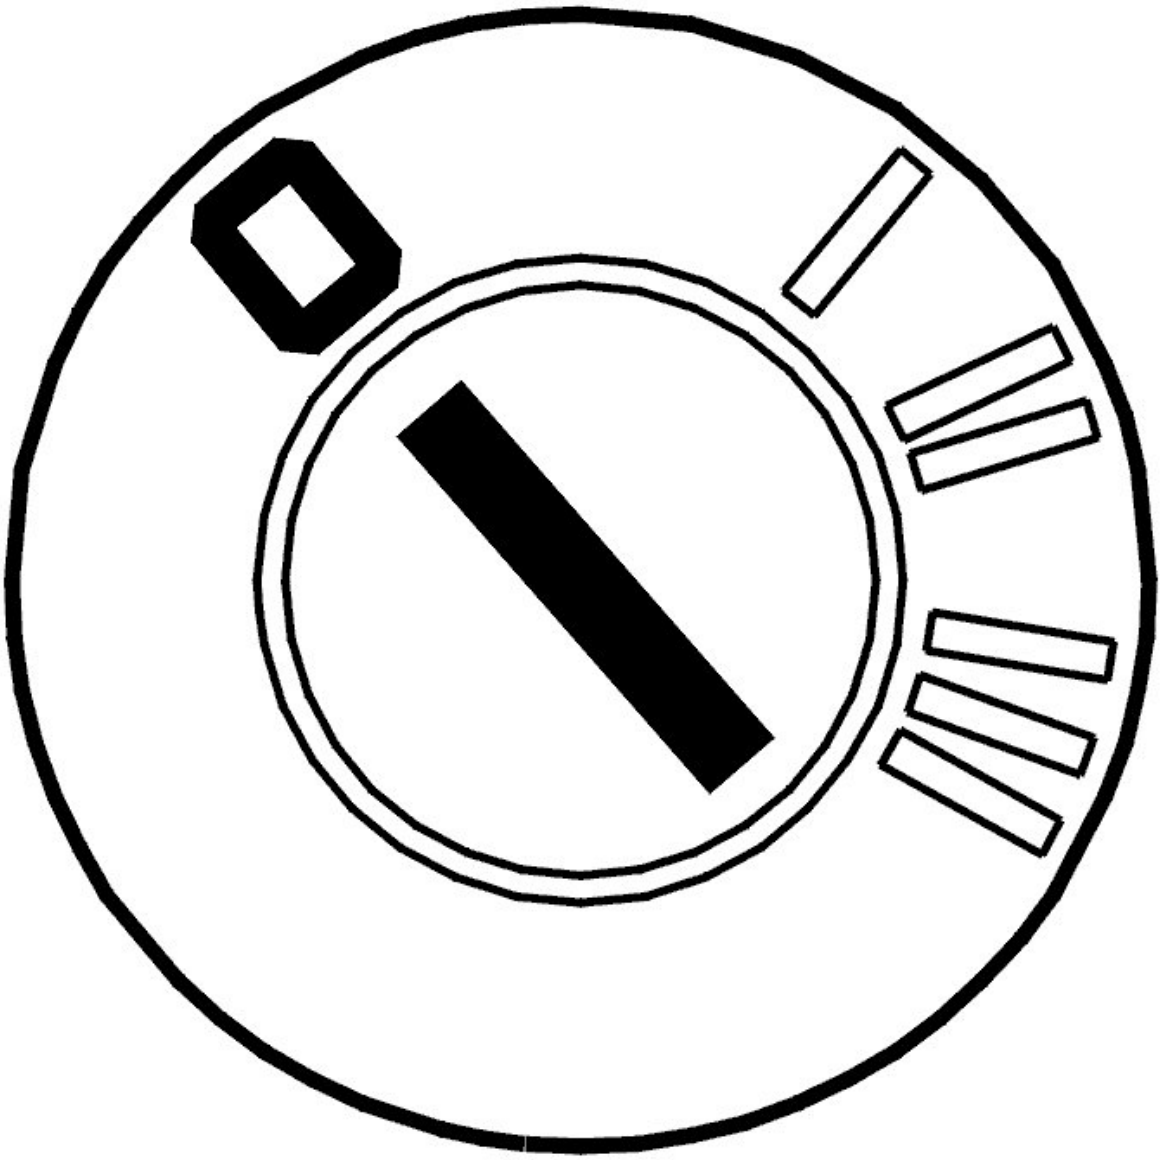
The current should oscillate between 0 and approximately 1.5 A.

Does the current oscillate?

Yes - Intermittent fault

No - Checking resistance

Checking resistance

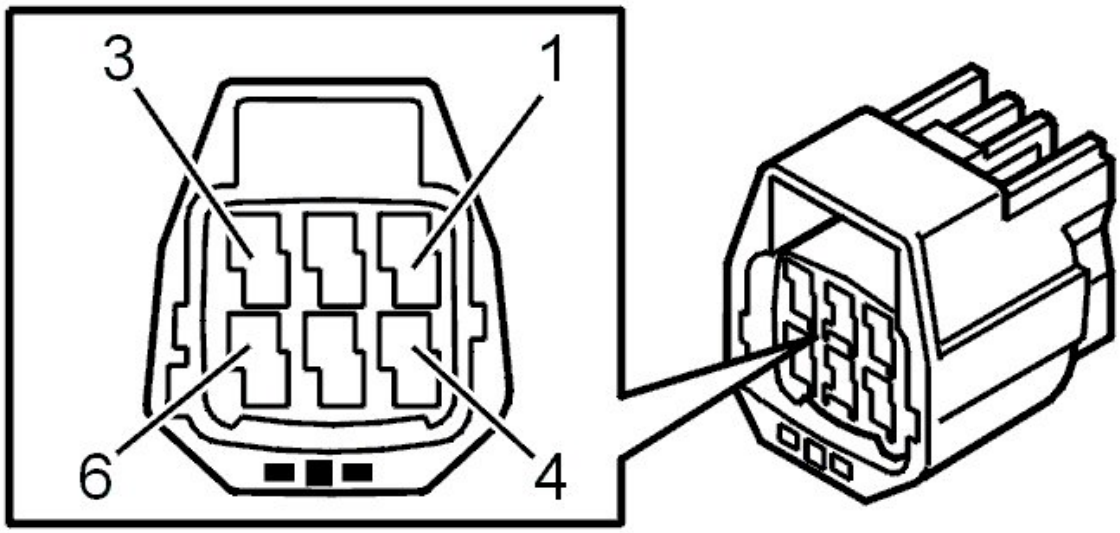


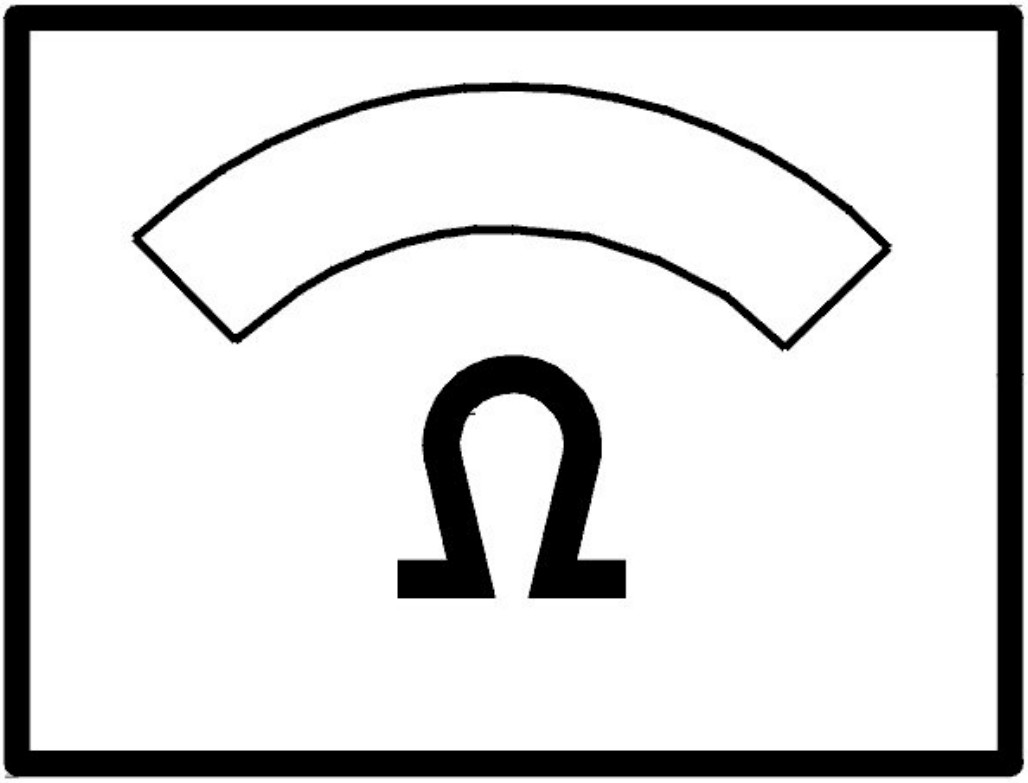
- Ignition off
- Disconnect the transmission connector.

Check solenoid S3 by measuring the resistance between transmission connector terminal #C3 and the transmission housing. The resistance must be 11-15 ohms.

Other information:

- To disconnect the transmission connectors, see Connectors transmission, disconnecting / connecting See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Wiring Harness/Service and Repair/Procedures
- For information about signals, see Signal description. Transmission control module (TCM), AW50/51 AWD, AW55-50/51SN See: Transmission Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Description. Transmission Control Module (TCM).





Was the resistance OK

Yes - Checking the wiring

No - Checking the wiring and component

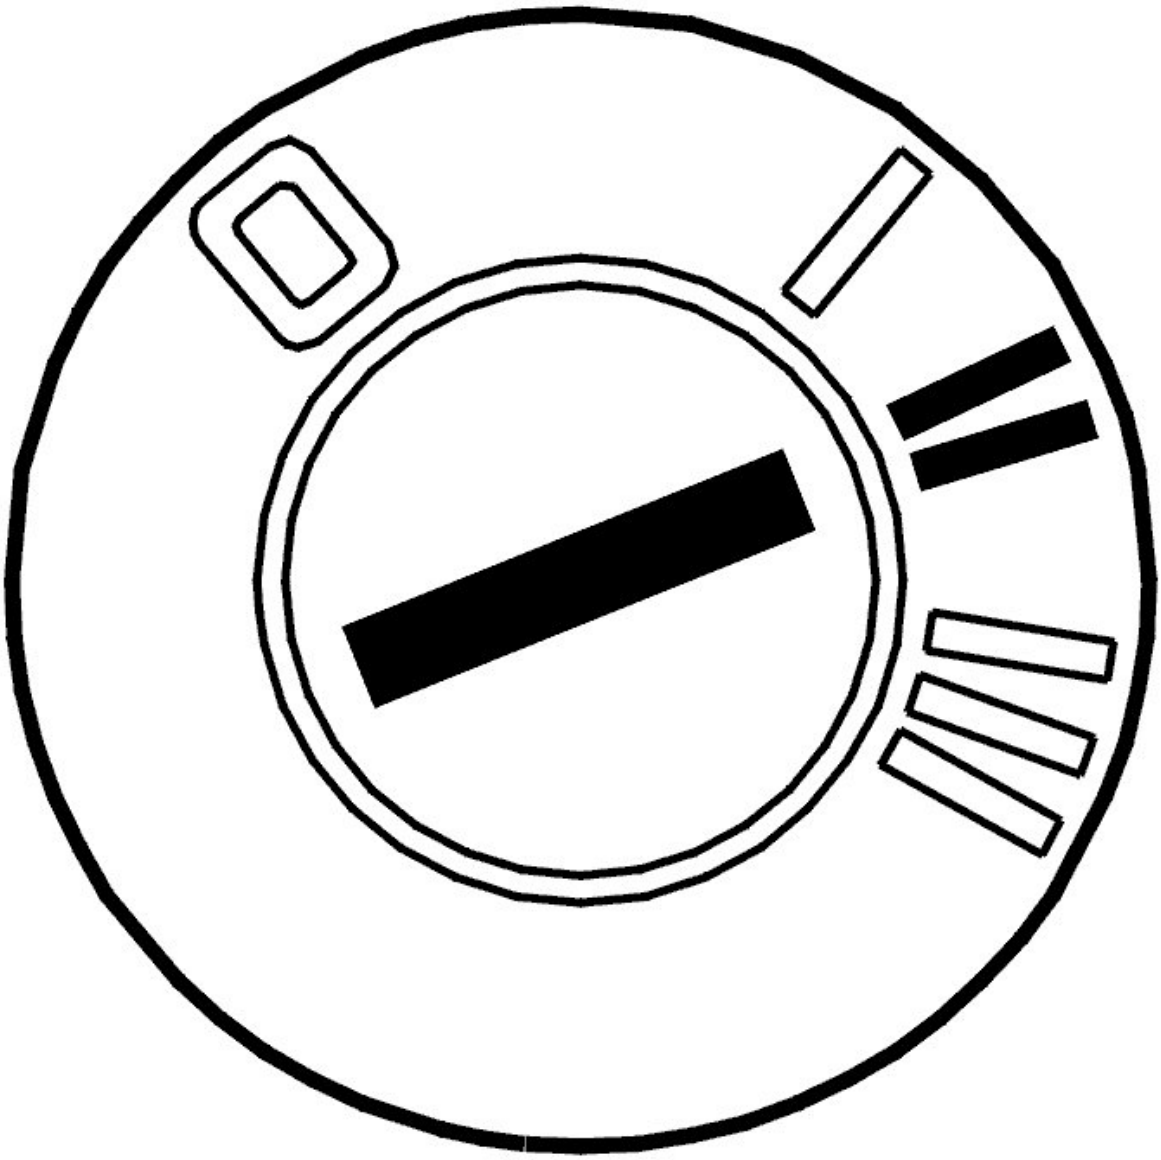
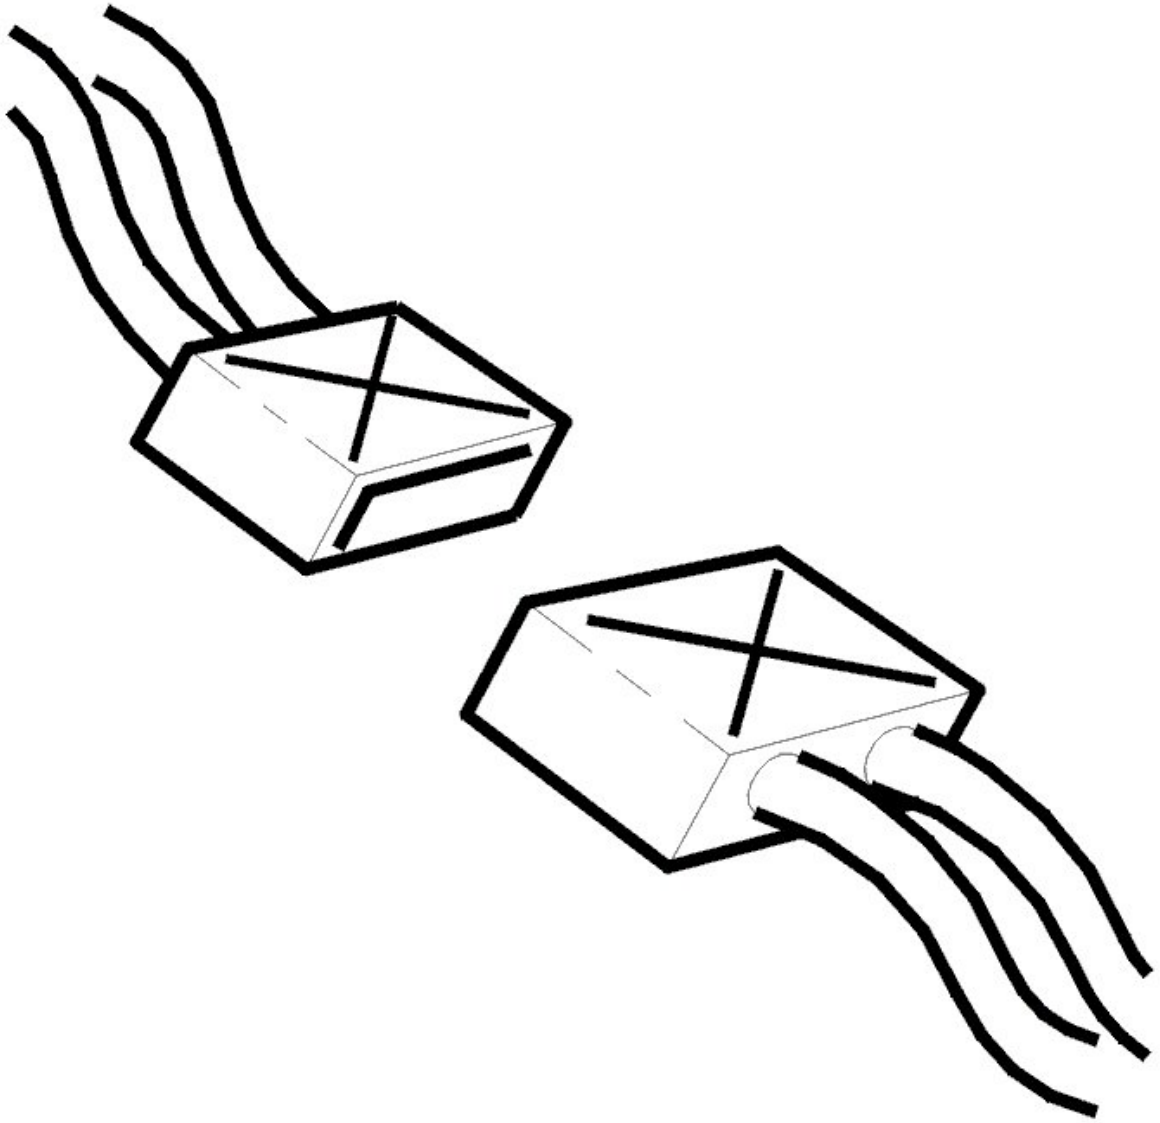
Was a fault detected?

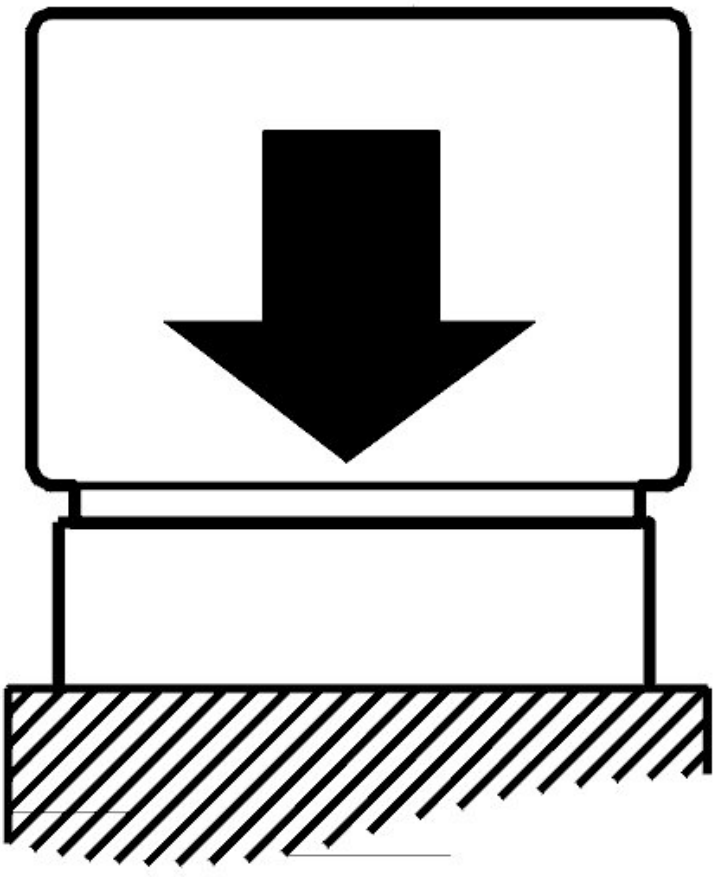
Yes - Verification

No - Checking the control module

Checking the control module







- Ignition off
- The breakout box connected
- Connect the control module.
- Transmission connector C disconnected
- Ignition on
- Gear selector in position P.

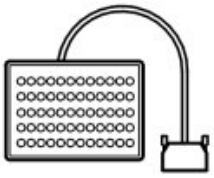
Check the transmission control module (TCM) by measuring the resistance between terminals #A48 (#A48) and #A53 (#A53) on the breakout box. The resistance must be approximately 9 kohms.

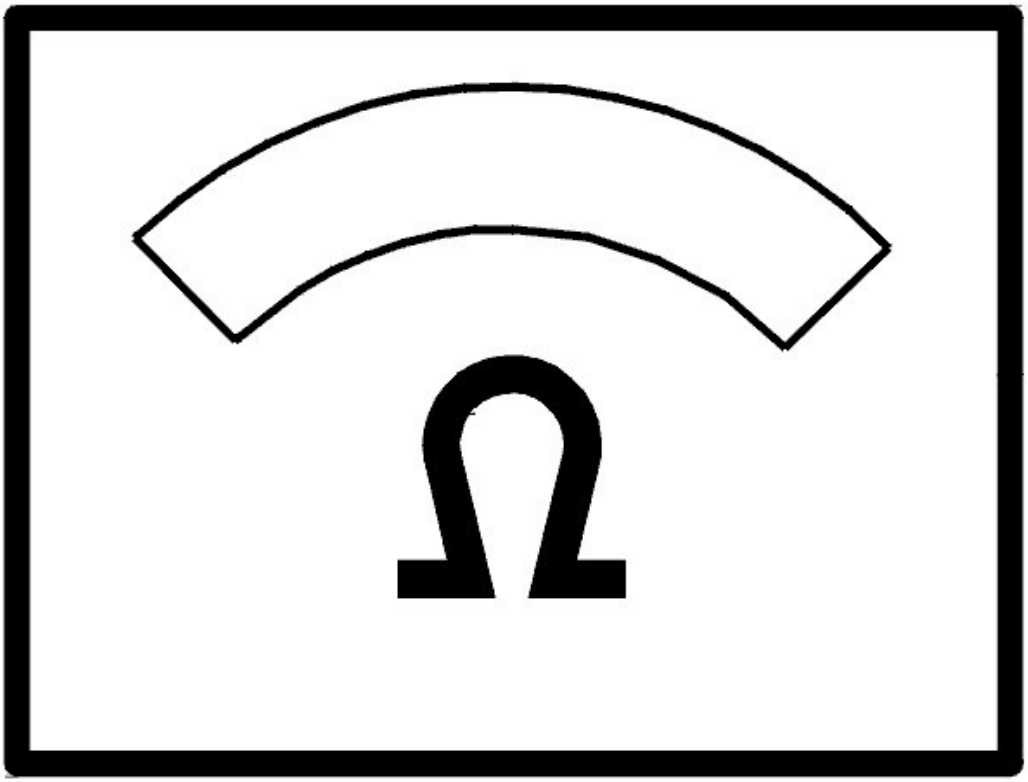
Note! When removing the transmission connector, the control module may store diagnostic trouble codes (DTCs) for the gear-shift position sensor, the shift solenoids, the temperature sensor etc.

Try a new control module if the resistance is infinite.

Other information:

- To disconnect the transmission connectors, see Connectors transmission, disconnecting / connecting See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Wiring Harness/Service and Repair/Procedures
- To replace the control module, see Transmission control module (TCM), replacing, B5244T5, AW55-50/51SN, B5254T2, AW55-50/51SN, B5254T2, AW50/51 AWD See: Transmission Control Systems/Relays and Modules - Transmission and Drivetrain/Relays and Modules - A/T/Control Module/Service and Repair
- For information about signals, see Signal description. Transmission control module (TCM), AW50/51 AWD, AW55-50/51SN See: Transmission Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Description. Transmission Control Module (TCM).



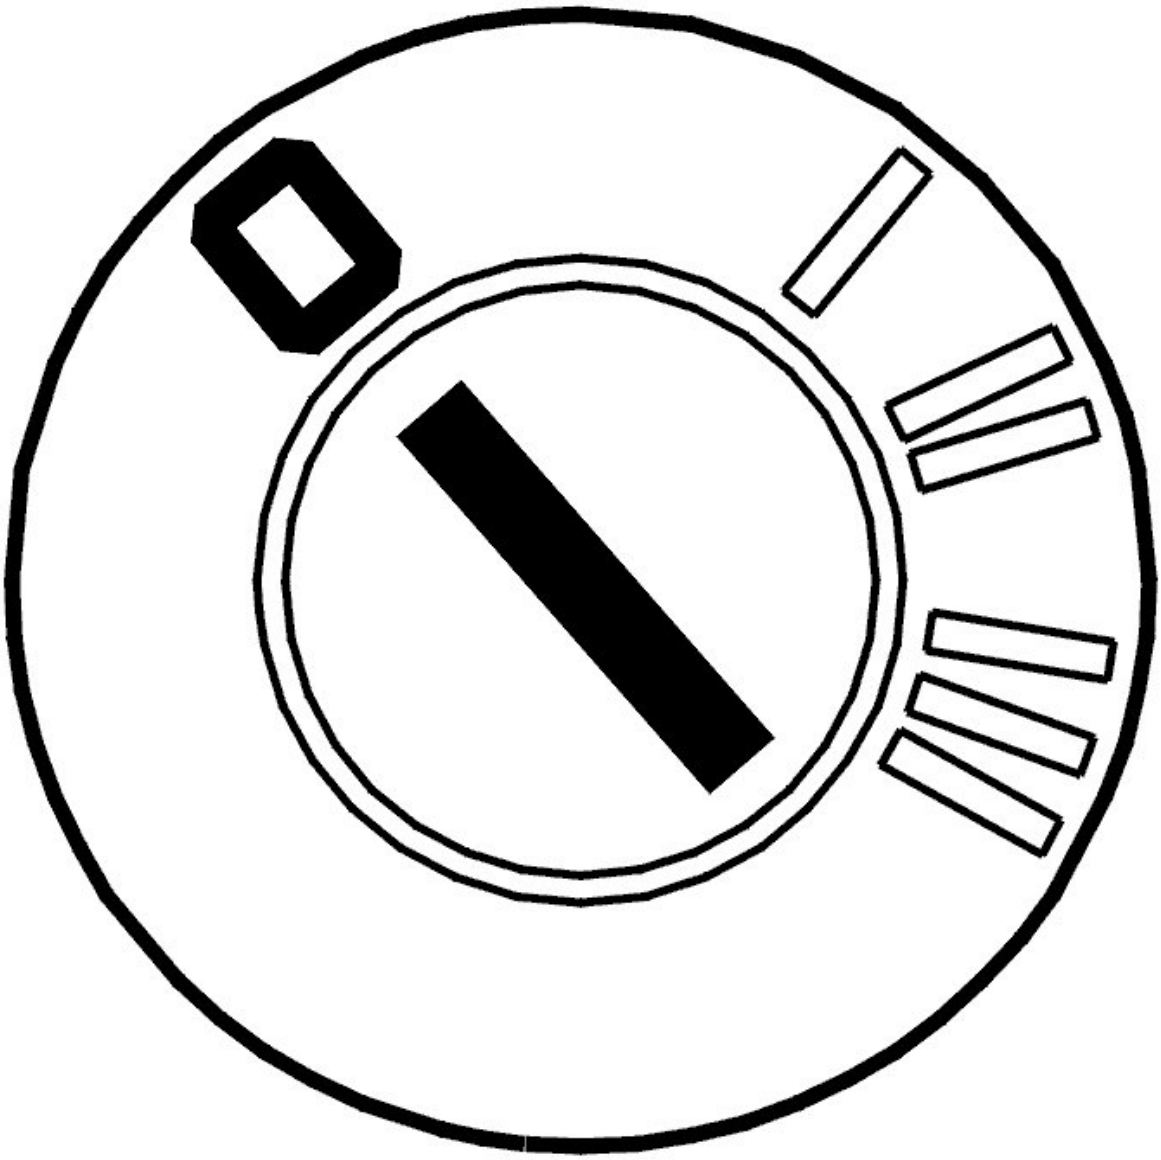


Was the resistance OK?

Yes - No Fault Found

No - Verification

Checking the wiring and component



- Ignition off
- Open the control system.

Check the cable between transmission connector terminal #C3 (transmission side) and the connector for solenoid S3. Check for an open-circuit according to Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault.

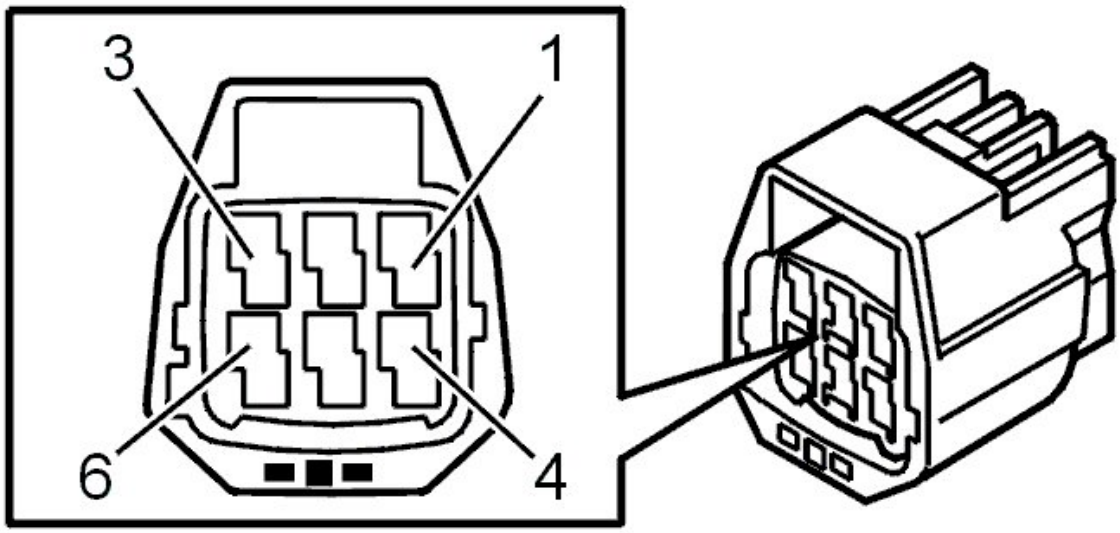
Hint:

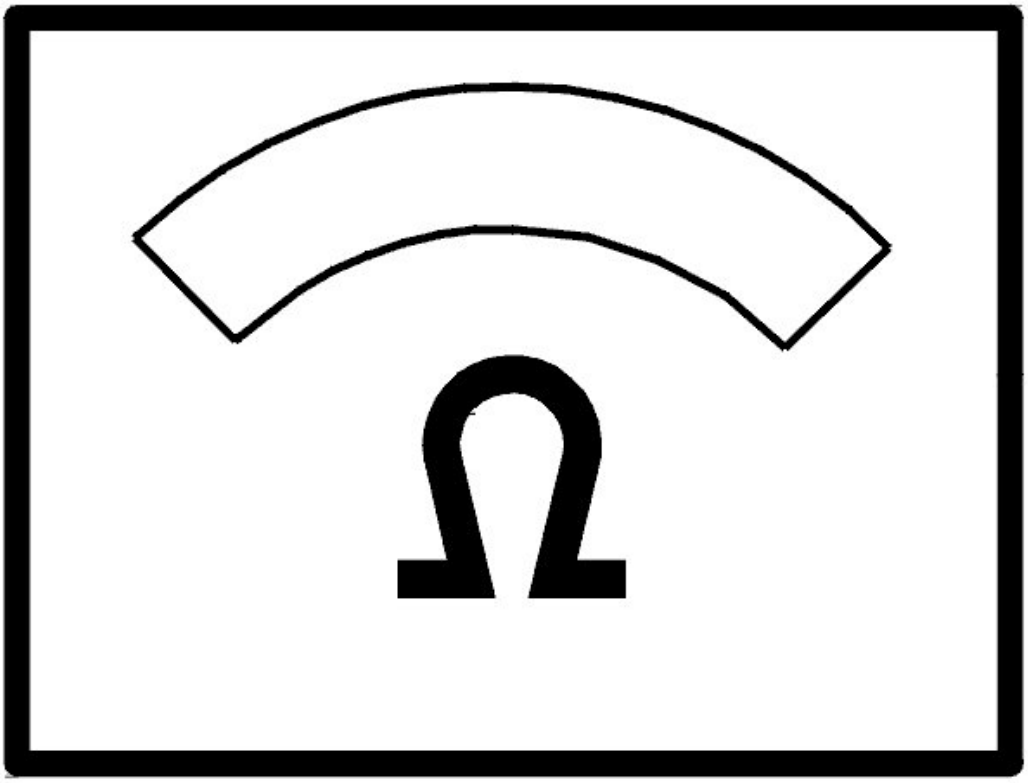
- Check solenoid S3 by measuring the resistance between the terminal pin on solenoid S3 and the transmission housing. The resistance must be 11-15 ohms.

Remedy as necessary.

Other information:

- To disconnect the transmission connectors, see Connectors transmission, disconnecting / connecting See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Wiring Harness/Service and Repair/Procedures
- To open the control system and to check or replace solenoid S3, see Solenoid control system, replacing See: Transmission Control Systems/Actuators and Solenoids - Transmission and Drivetrain/Actuators and Solenoids - A/T/Shift Solenoid/Service and Repair/Solenoid Control System, Replacing
- To replace the cable harness for the control system, see Wiring harness / oil temperature sensor, replacing See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Wiring Harness/Service and Repair/Removal and Replacement
- For information about signals, see Signal description. Transmission control module (TCM), AW50/51 AWD, AW55-50/51SN See: Transmission Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Description. Transmission Control Module (TCM).





Select Continue when the fault has been remedied.

Continue - Resetting the adaptation and oil quality counter

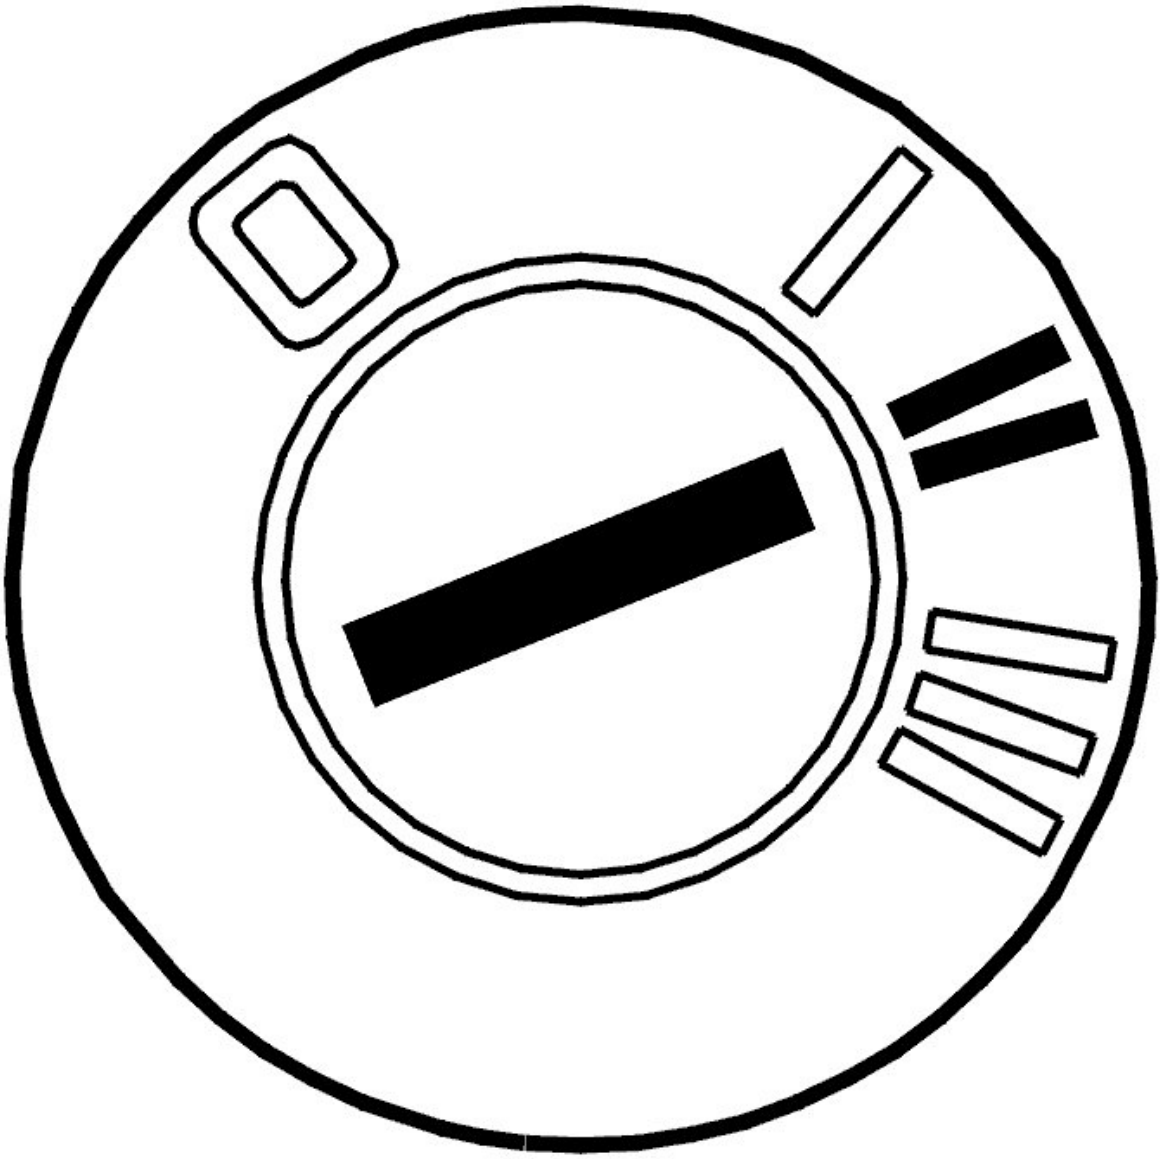
Resetting the adaptation and oil quality counter

Resetting the adaptation

Resetting adaptation and the counter for "Transmission oil change"

Hint: The transmission has torque controlled adaptive pressure control. Pressure control means that the transmission regulates the pressure itself during each gear shift. This avoids harsh gear shifting. Each gear shift is evaluated by the control module and stored in the memory. This allows for compensation for wear and tear in the transmission and clutch. It is important that the adaptation in the memory is reset after the transmission has been repaired. This is to ensure normal operation. The oil is replaced during repair; the "Transmission oil change" counter must be reset. If the counter is not reset when the fluid is drained and replaced, there is a risk that a diagnostic trouble code (DTC) will be stored in incorrect circumstances.

Note! This applies only if the transmission or one of the components in the transmission have been replaced.



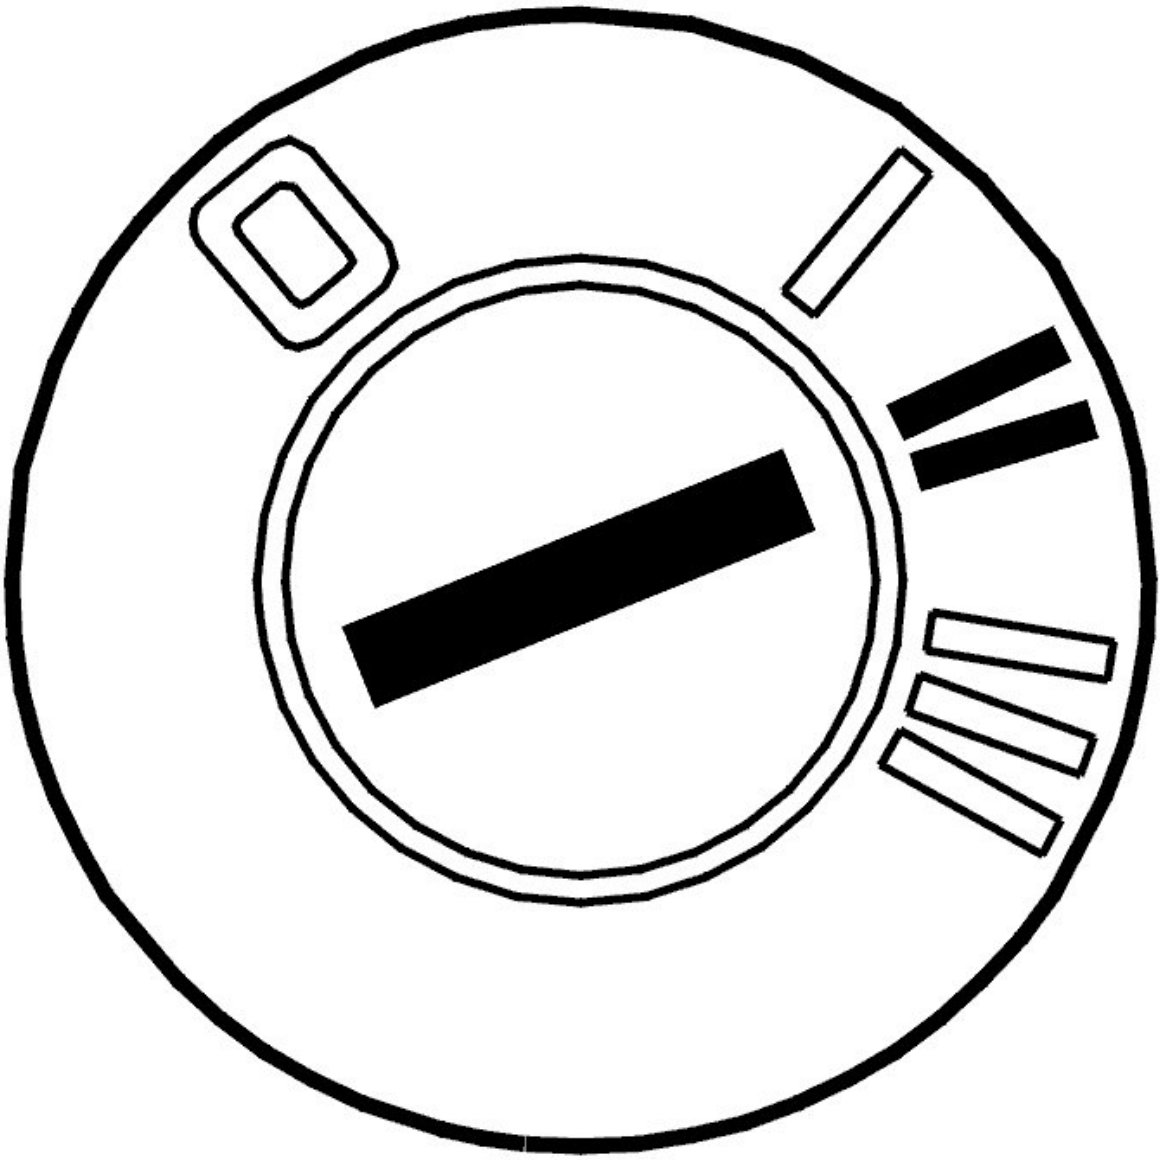
- Ignition on.

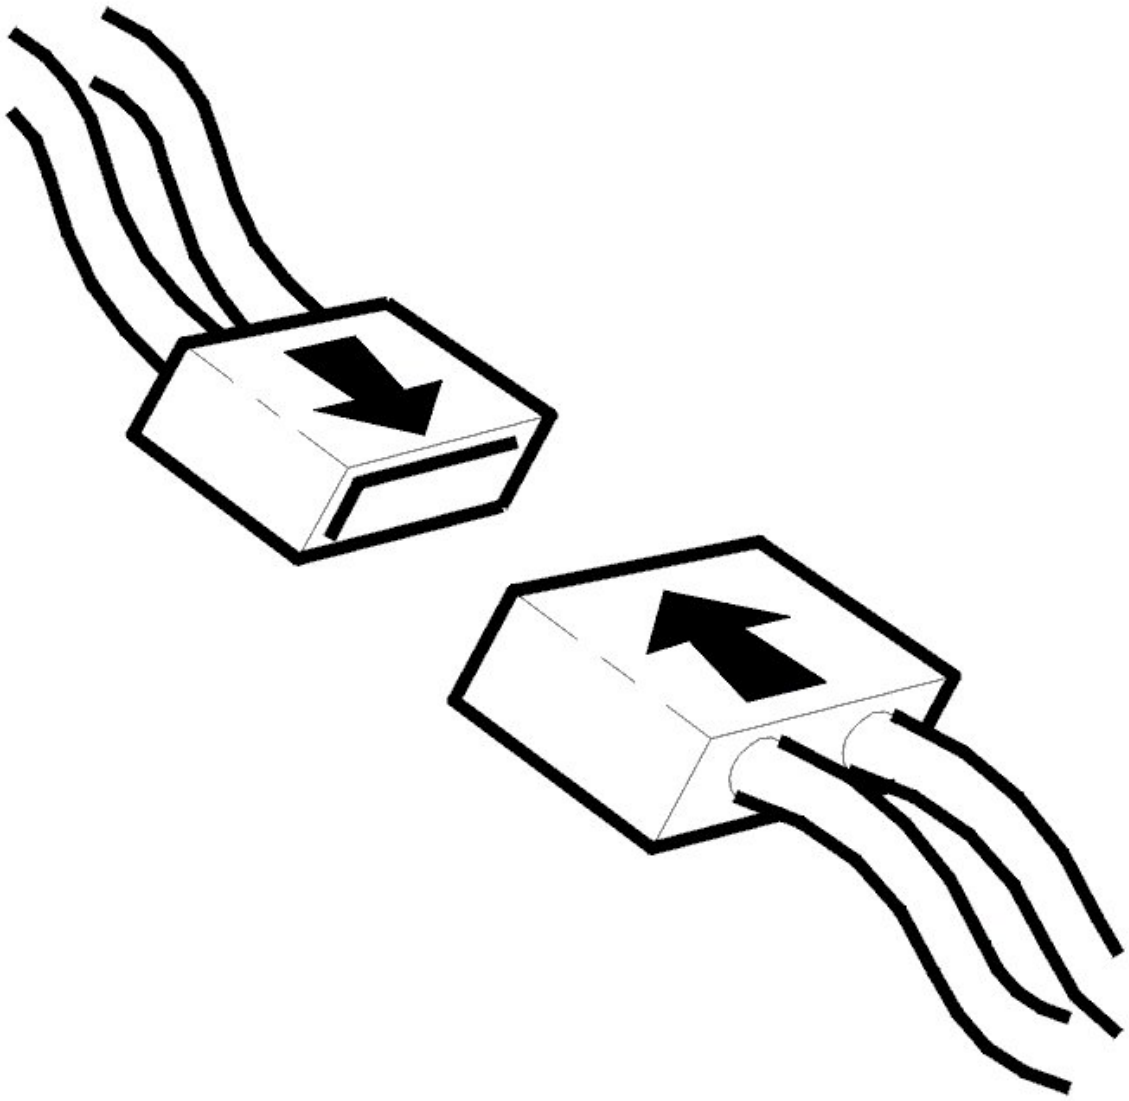
Click on the VCT2000 symbol to reset the adaptation and counter.

Continue - Verification

Verification

Hint: After carrying out the repair, check that the fault has been remedied.





- Ignition off.
- Reinstall the components, reconnect the connectors etc.
- Ignition on.
- Gear selector in position P.
- Activate solenoid S3.

The current should oscillate between 0 and 1.5 A.

Does the current oscillate?

Yes - VERIFIED

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition
Shift solenoids S1, S2, S3, S4 and S5 operate in tandem to control gear-shifting. Diagnostic trouble codes (DTCs) TCM-0003, TCM-0009, TCM-0103, TCM-0109 or TCM-010C are stored if the transmission control module (TCM) registers that there is a short-circuit to ground in circuits S1, S2, S3, S4 or S5 when the solenoid should be activated.

Substitute value
- The transmission control module (TCM) "Emergency mode I" program has been initiated.

Possible source
- Short-circuit to ground in the signal cable.
- Defective solenoid.
- Internal fault in the control module.

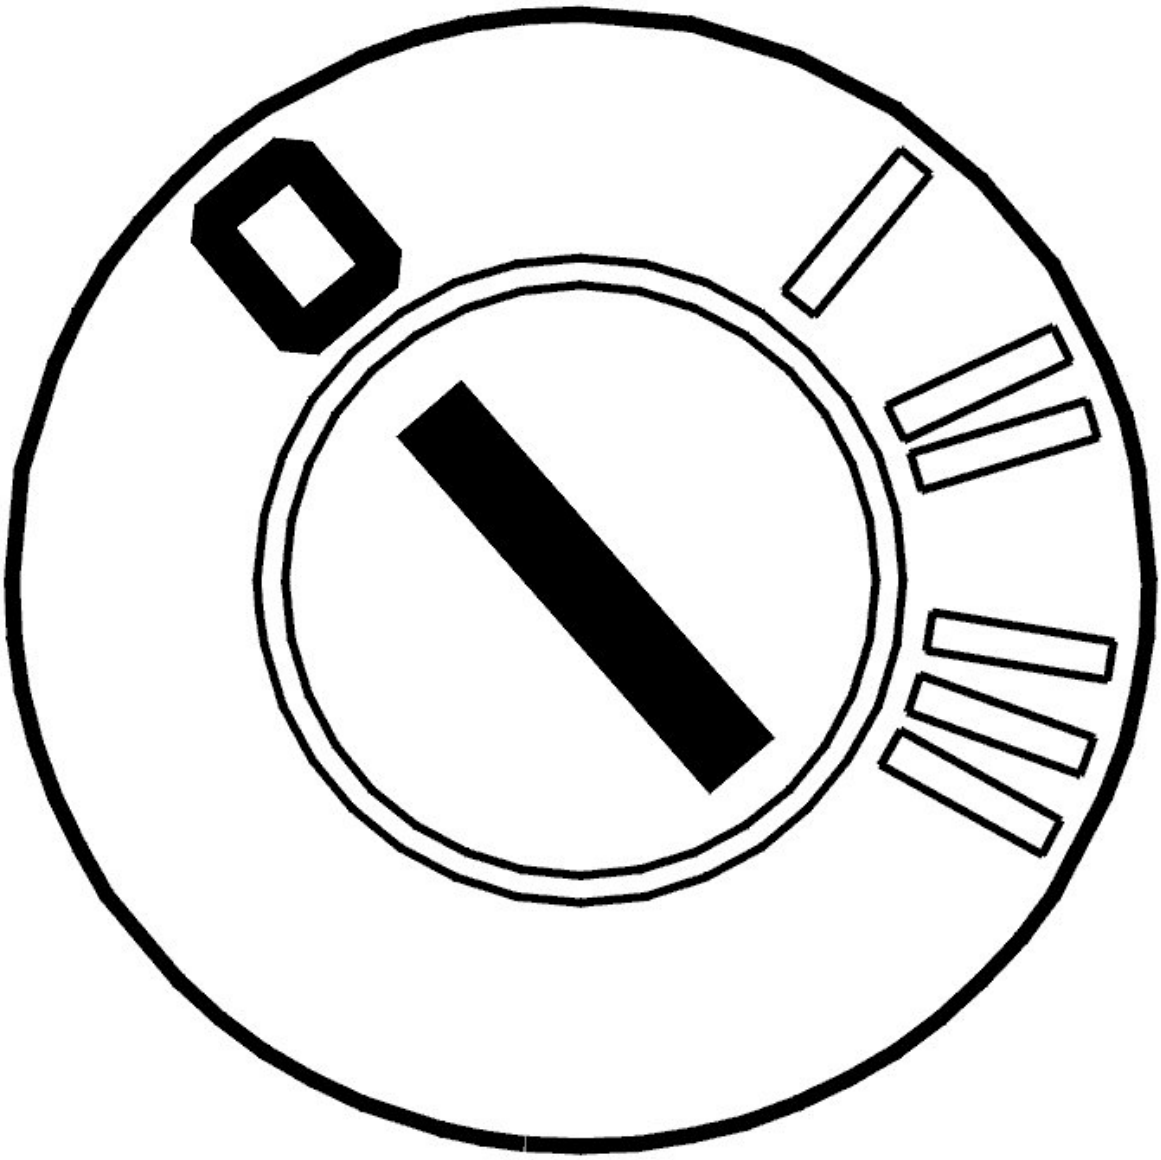
Fault symptom[s]
- General orange warning lamp lit.
- No lock-up function.
- Harsh gear shifting.
- No shifting.

Signal Too Low

Signal too low

Checking the temperature sensor

Hint: In some cases, the diagnostic trouble code (DTC) may be caused by a defective oil temperature sensor. Check the function of the oil temperature sensor first.



- Ignition off
- Read off the oil temperature.

Check that the function of the temperature sensor is OK. Test drive the car to increase the temperature of the transmission fluid. Read off the temperature again. Check that the temperature has increased.

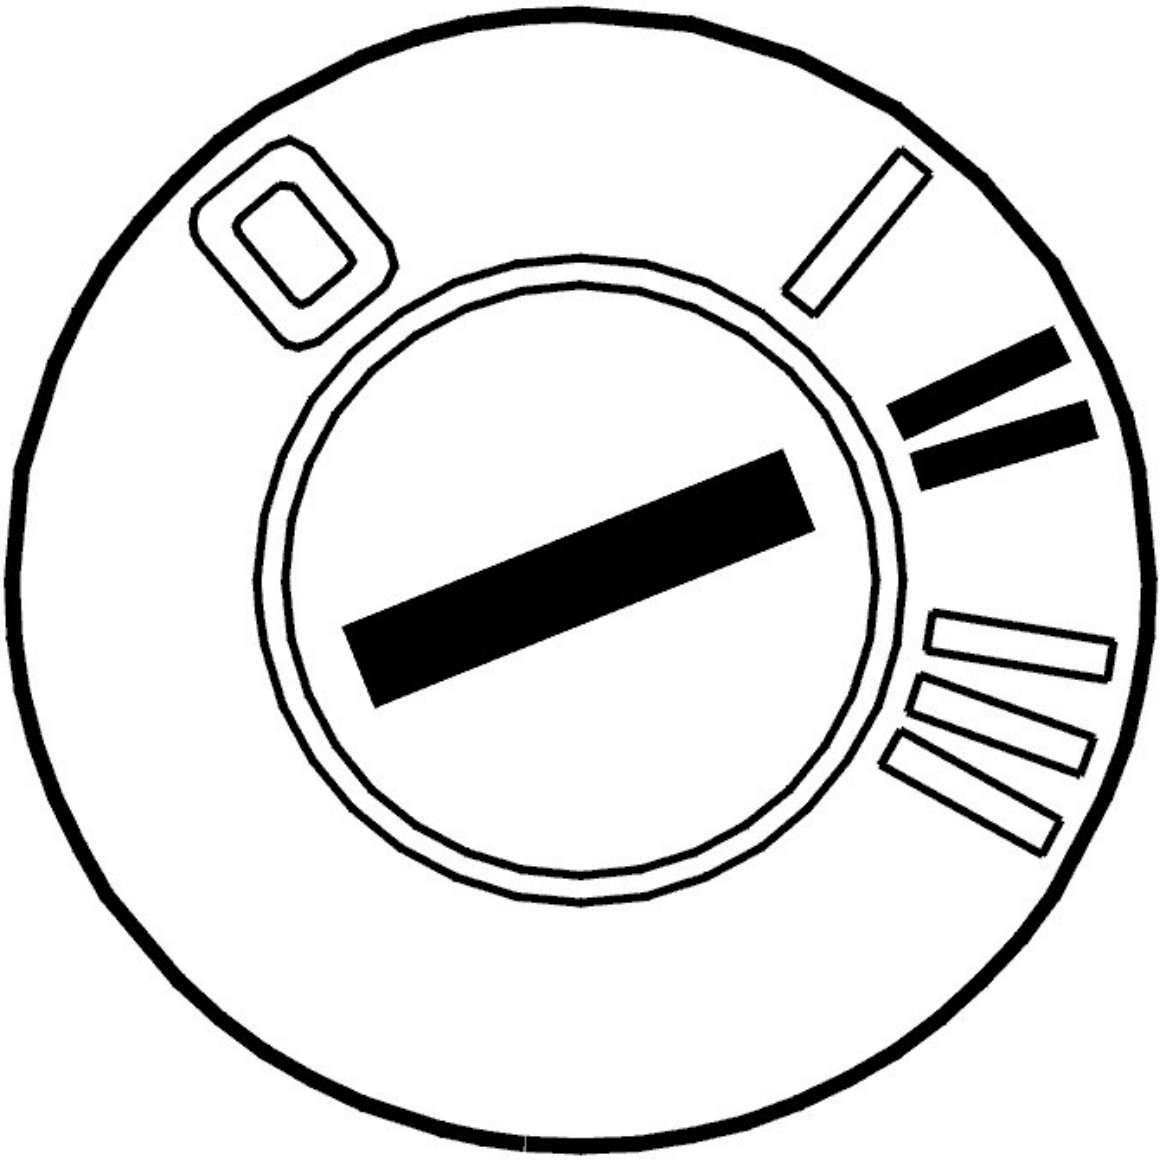
Hint: If the temperature is outside its permitted range, fault-trace the temperature sensor.

Is the oil temperature within its permitted range?

Yes - Checking shift solenoid S3

No - Checking transmission fluid temperature sensor

Checking shift solenoid S3



- Ignition on
- Gear selector in position P
- Activate solenoid S3.

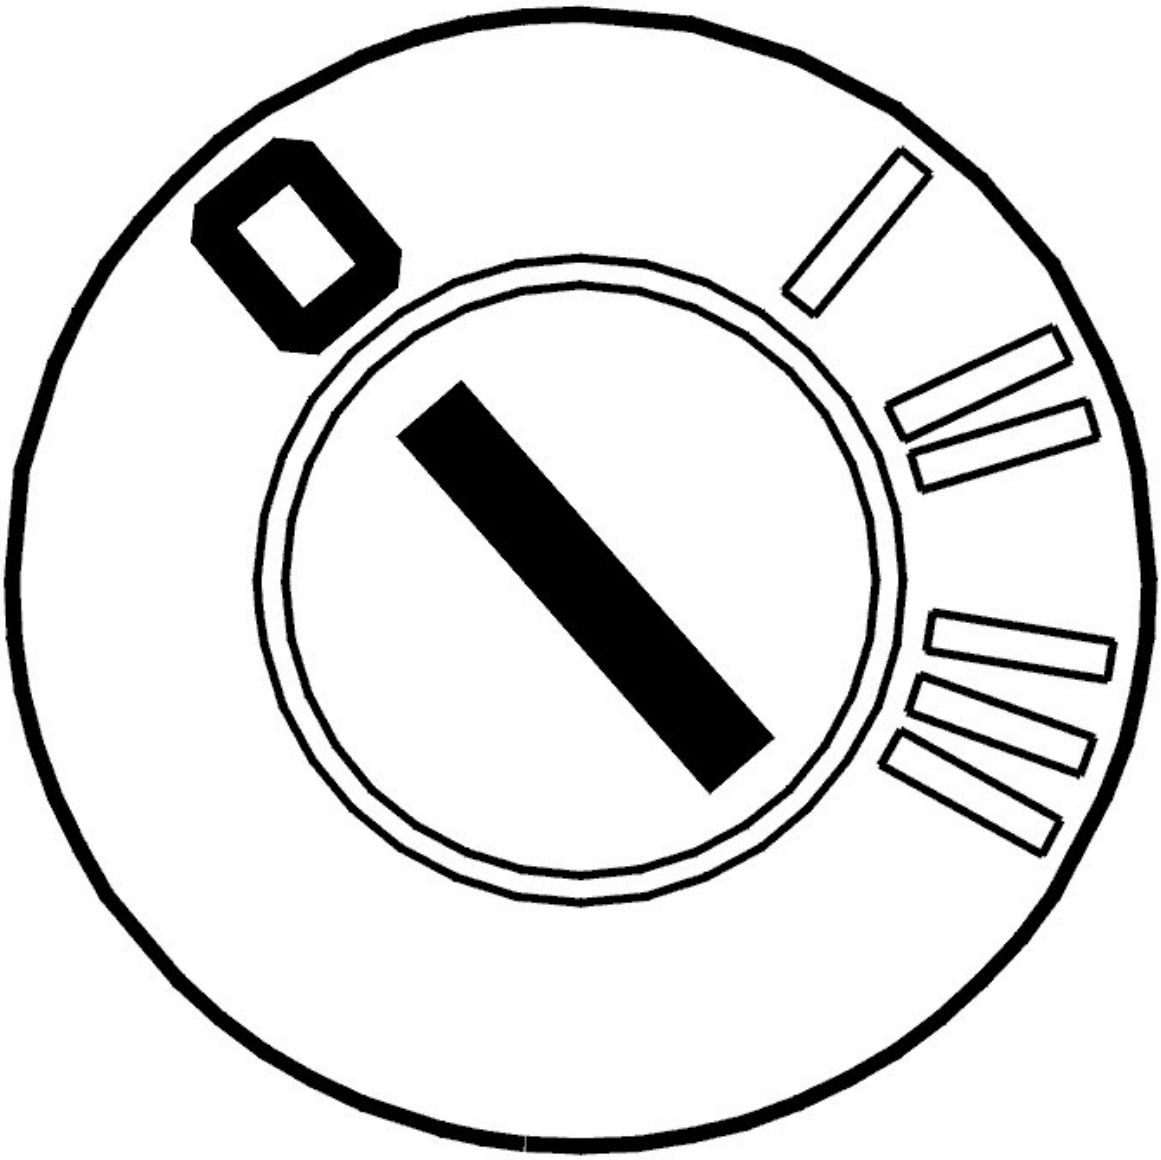
The value must change between OFF and ON.

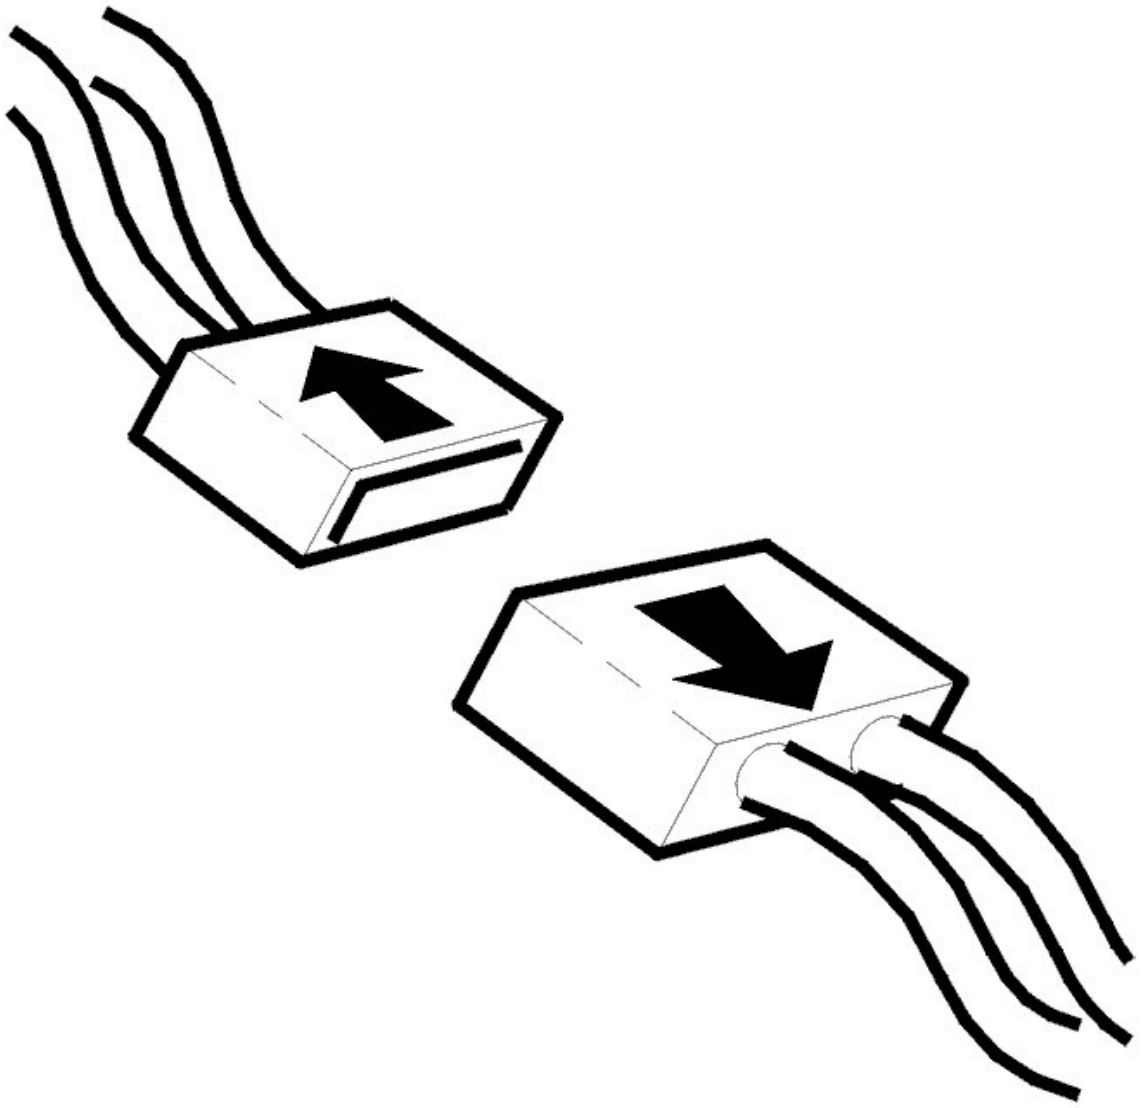
Does the value change?

Yes - Intermittent fault

No - Checking resistance

Checking resistance





- Ignition off
- Disconnect transmission connector C.

Check solenoid S3 by measuring the resistance between transmission connector terminal #C3 and the transmission housing. The resistance must be 11-15 ohms.

Other information:

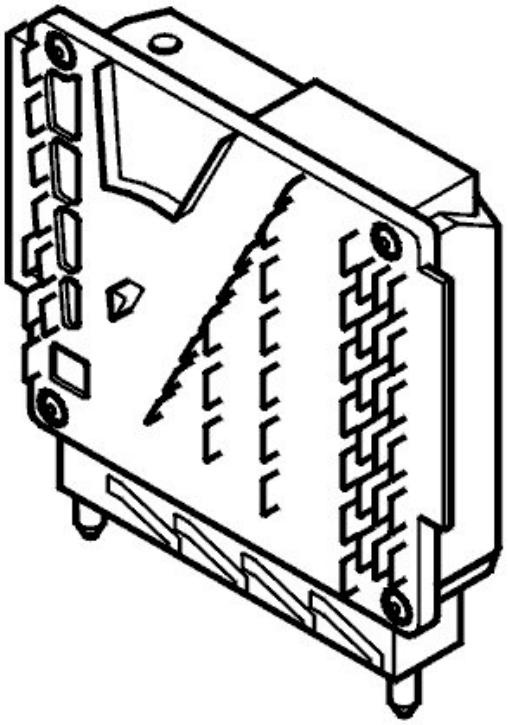
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition



Shift solenoids S1, S2, S3, S4 and S5 operate in tandem to control gear-shifting. The solenoids are controlled by power stages in the transmission control module (TCM). The transmission control module (TCM) opens the power stages to activate the solenoids and sends a voltage through the circuit. Diagnostic trouble codes (DTCs) TCM-0001, TCM-0007, TCM-0101 TCM-0107 or TCM-010A are stored (depending on the solenoid)if the transmission control module (TCM) registers that the signal in circuits S1, S2, S3, S4 or S5 is too high when the solenoid should not be activated.

Substitute value
- The transmission control module (TCM) "Emergency mode I" program has been initiated.

Possible source
- Short-circuit to supply voltage in the signal cable.
- Internal fault in the control module.

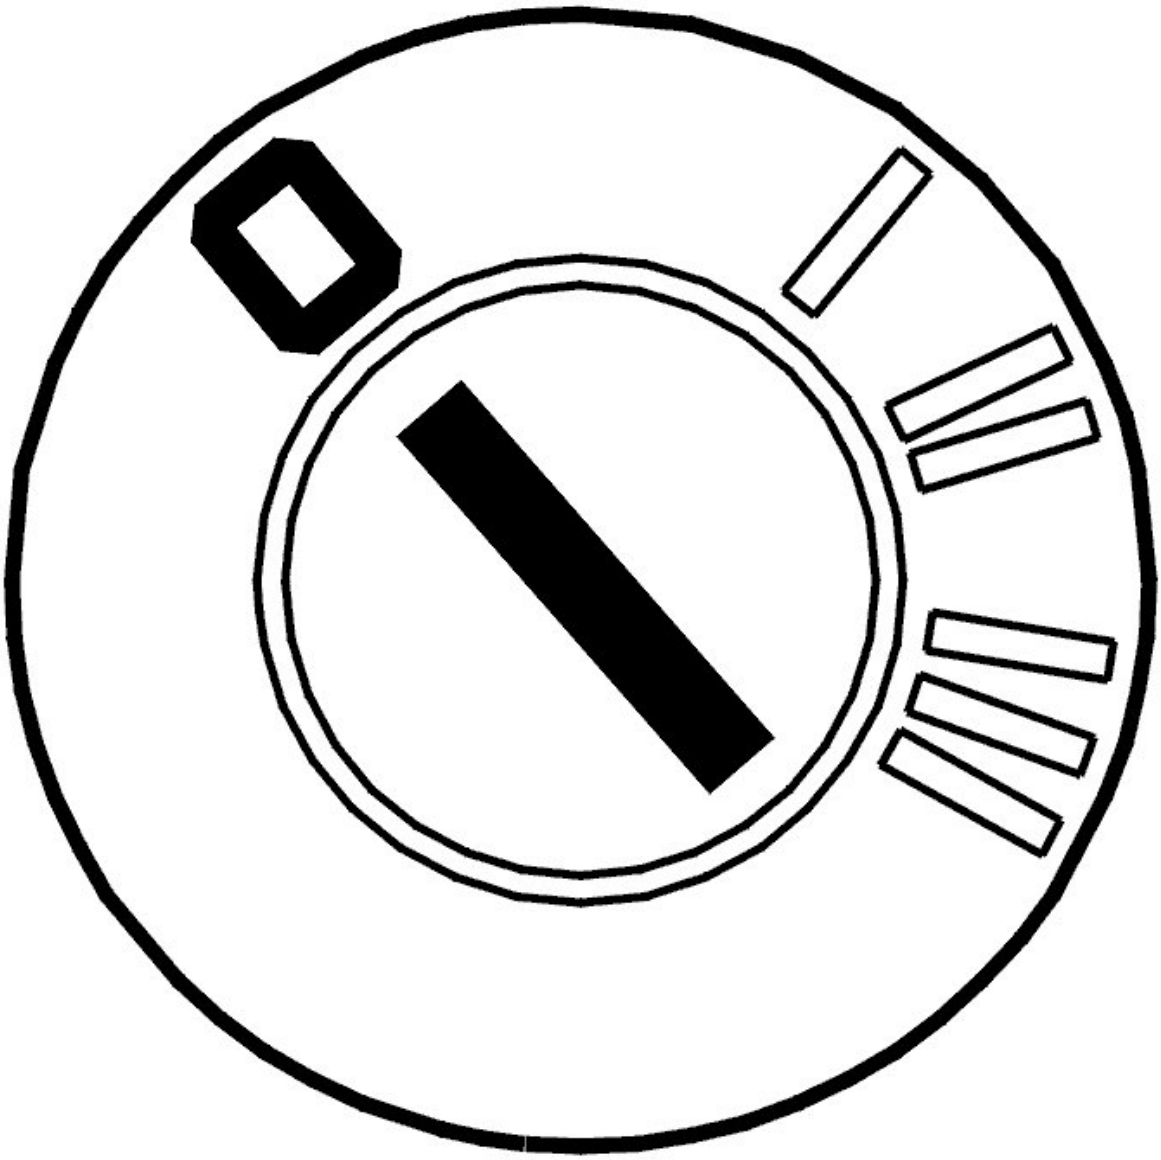
Fault symptom[s]
- General orange warning lamp lit.
- Malfunction indicator lamp (MIL) lit.
- Harsh gear shifting.
- No shifting.
- No lock-up function.

Signal Too High

Signal too high

Checking the temperature sensor

Hint: In some cases, the diagnostic trouble code (DTC) may be caused by a defective oil temperature sensor. Check the function of the oil temperature sensor first.



- Ignition off
- Read off the oil temperature.

Check that the function of the temperature sensor is OK. Test drive the car to increase the temperature of the transmission fluid. Read off the temperature again. Check that the temperature has increased.

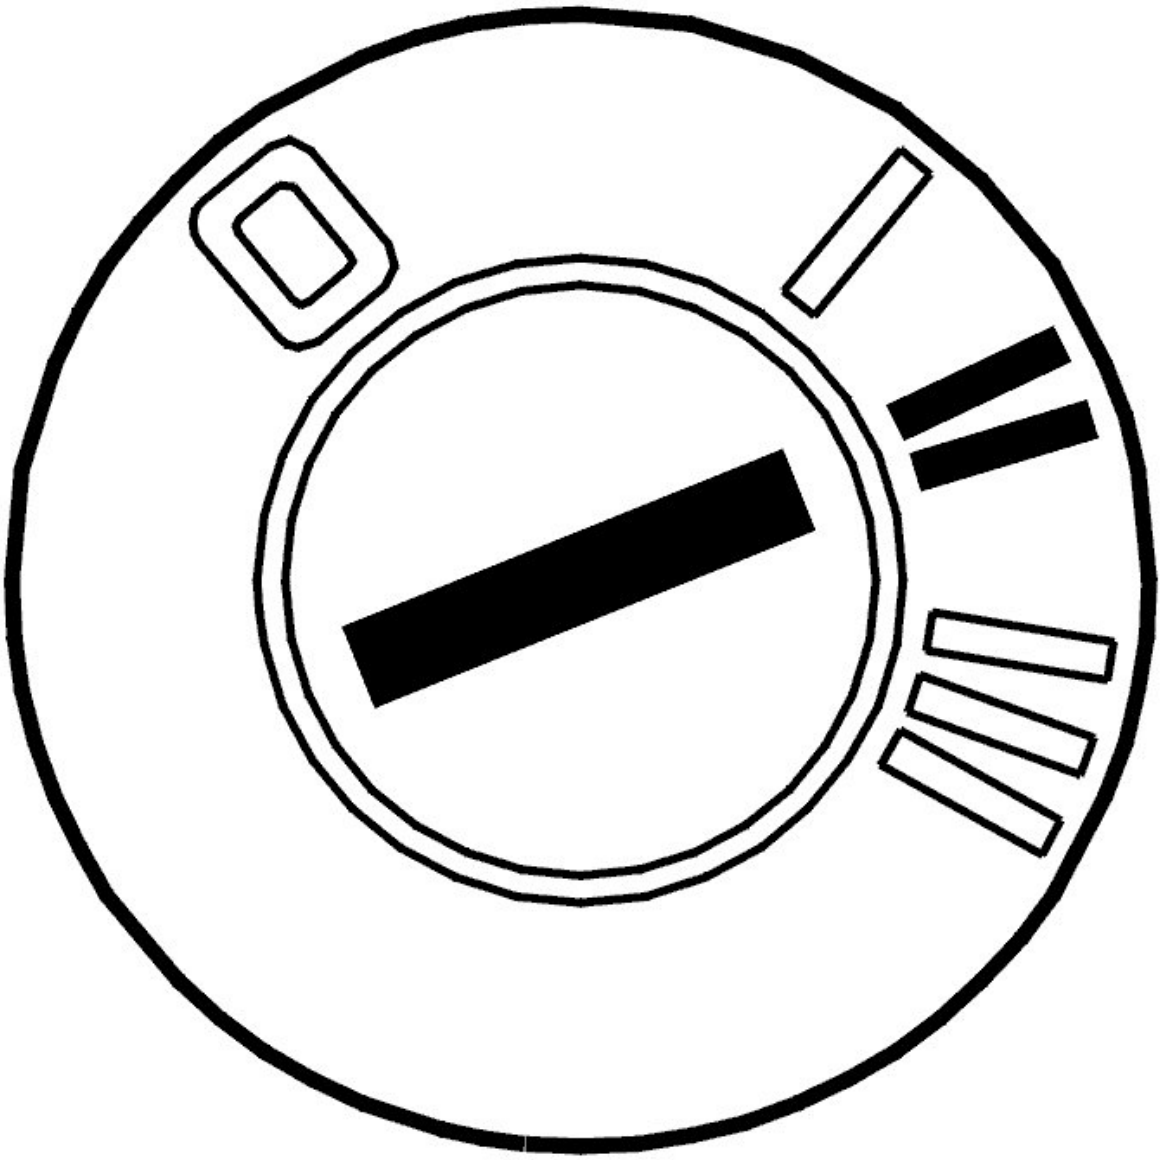
Note! If the temperature is outside its permitted range, fault-trace the temperature sensor.

Is the oil temperature within its permitted range?

Yes - Checking shift solenoid S4

No - Checking transmission fluid temperature sensor

Checking shift solenoid S4



- Ignition on
- Gear selector in position P
- Activate solenoid S4.

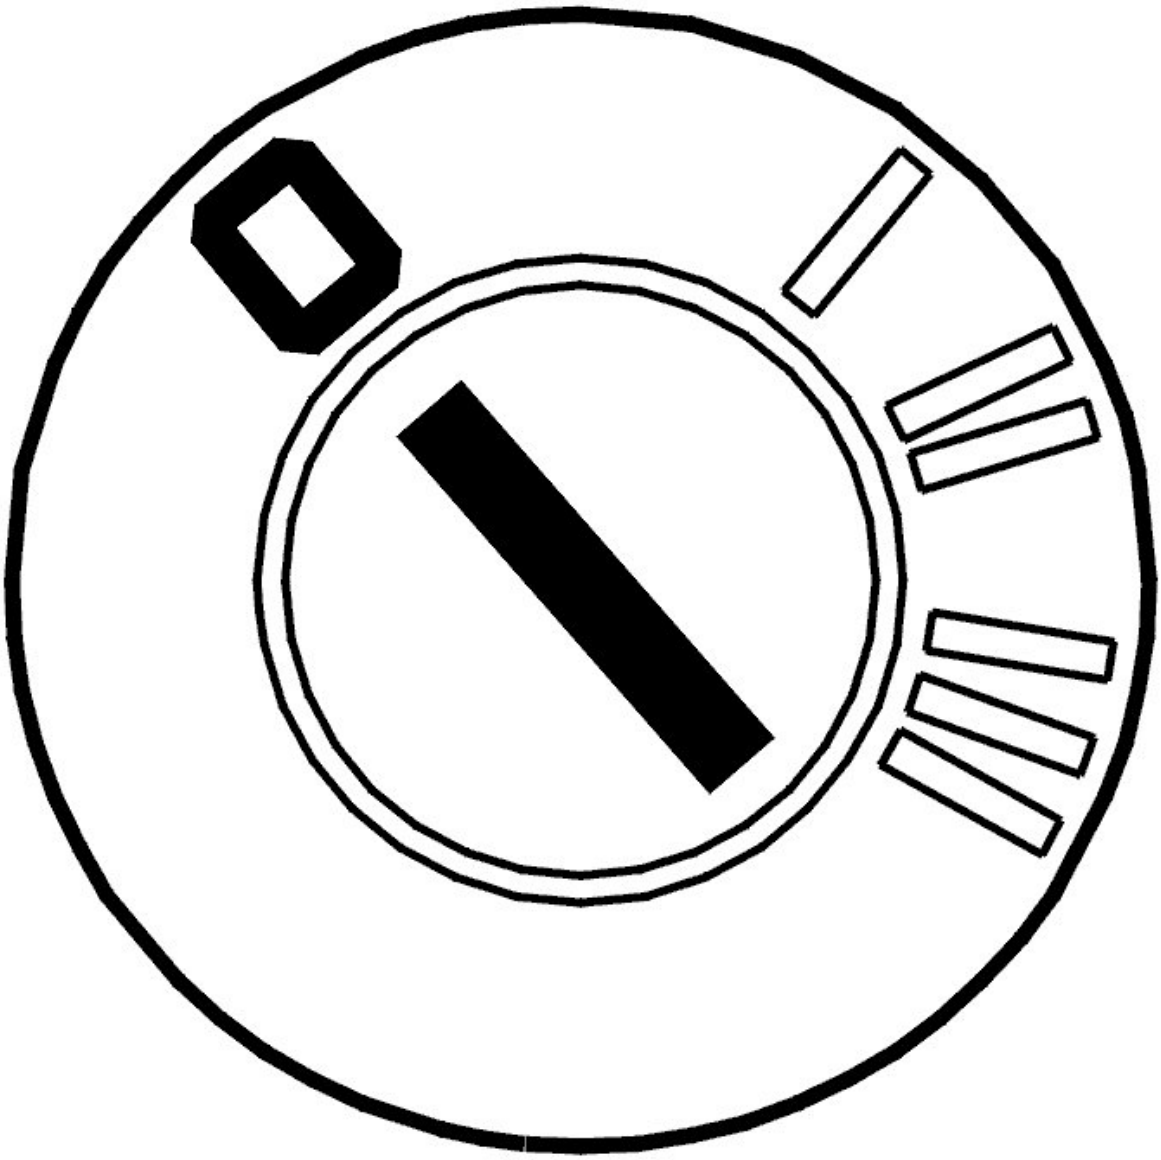
The value must change between OFF and ON.

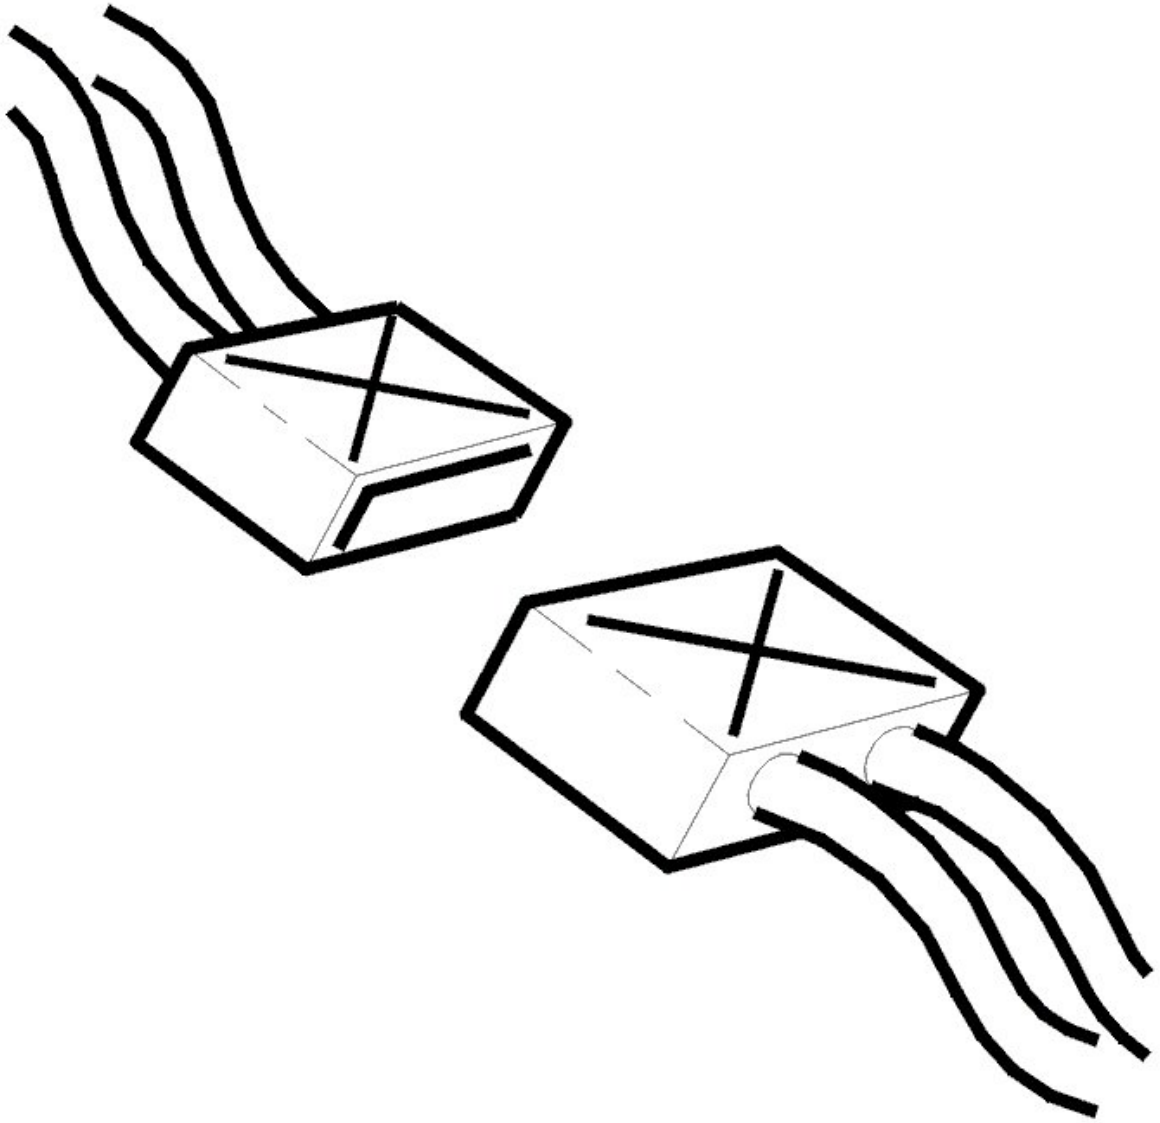
Does the value change?

Yes - Intermittent fault

No - Checking solenoid S4

Checking solenoid S4



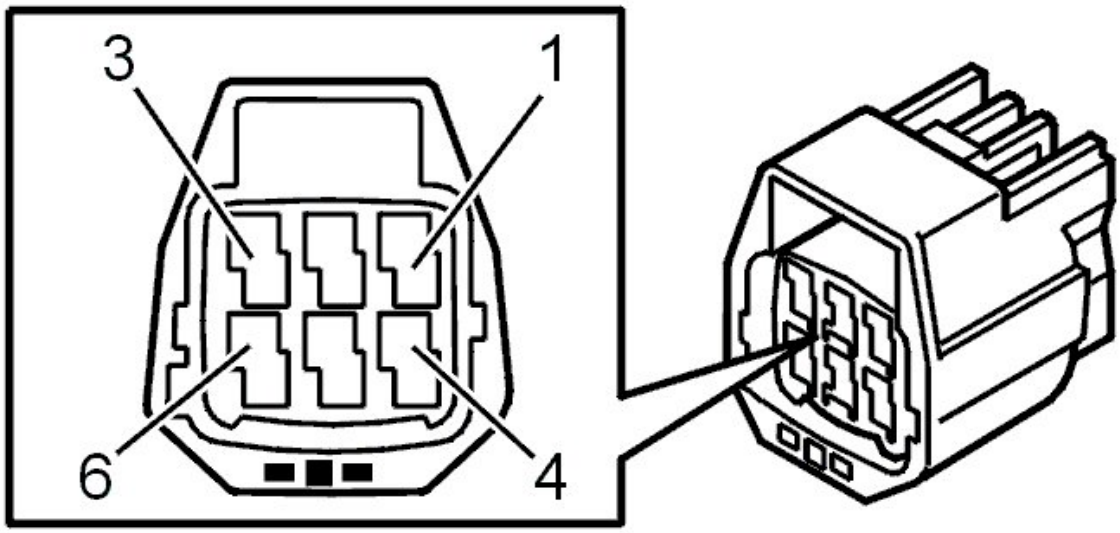


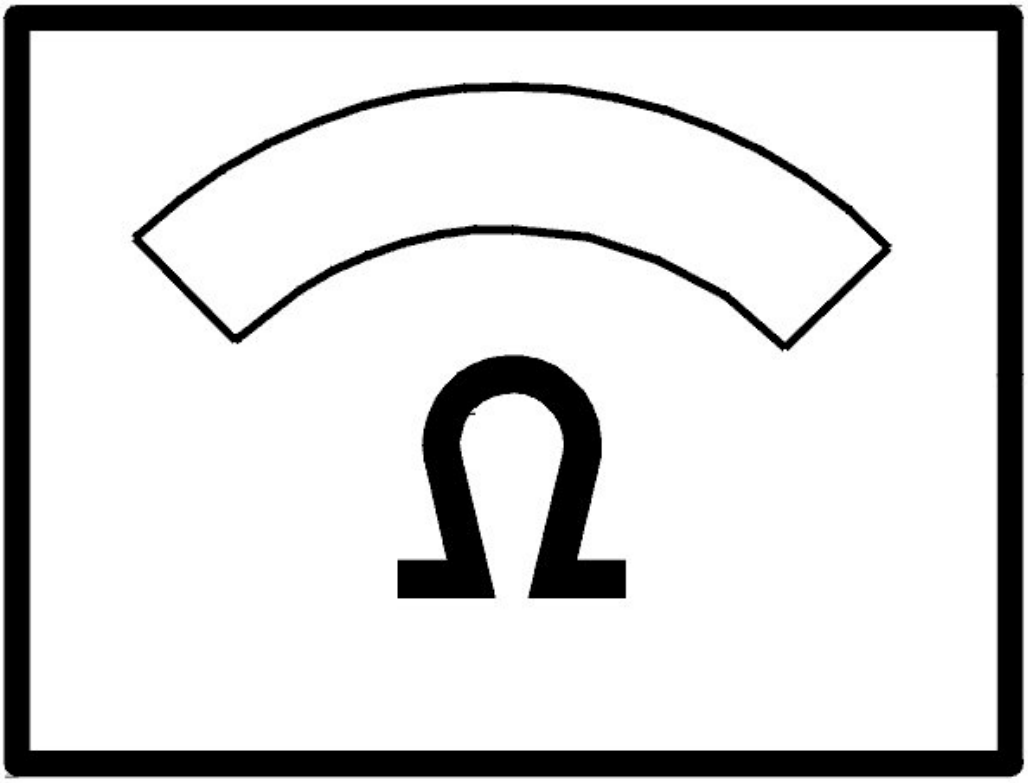
- Ignition off
- Disconnect transmission connector C.

Check solenoid S4 by measuring the resistance between transmission connector terminal #C4 and the transmission housing. The ohmmeter should read 11-15 ohms at 20°C.

Other information:

- To disconnect the transmission connectors, see Connectors transmission, disconnecting / connecting See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Wiring Harness/Service and Repair/Procedures
- For information about signals, see Signal description. Transmission control module (TCM), AW50/51 AWD, AW55-50/51SN See: Transmission Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Description. Transmission Control Module (TCM).



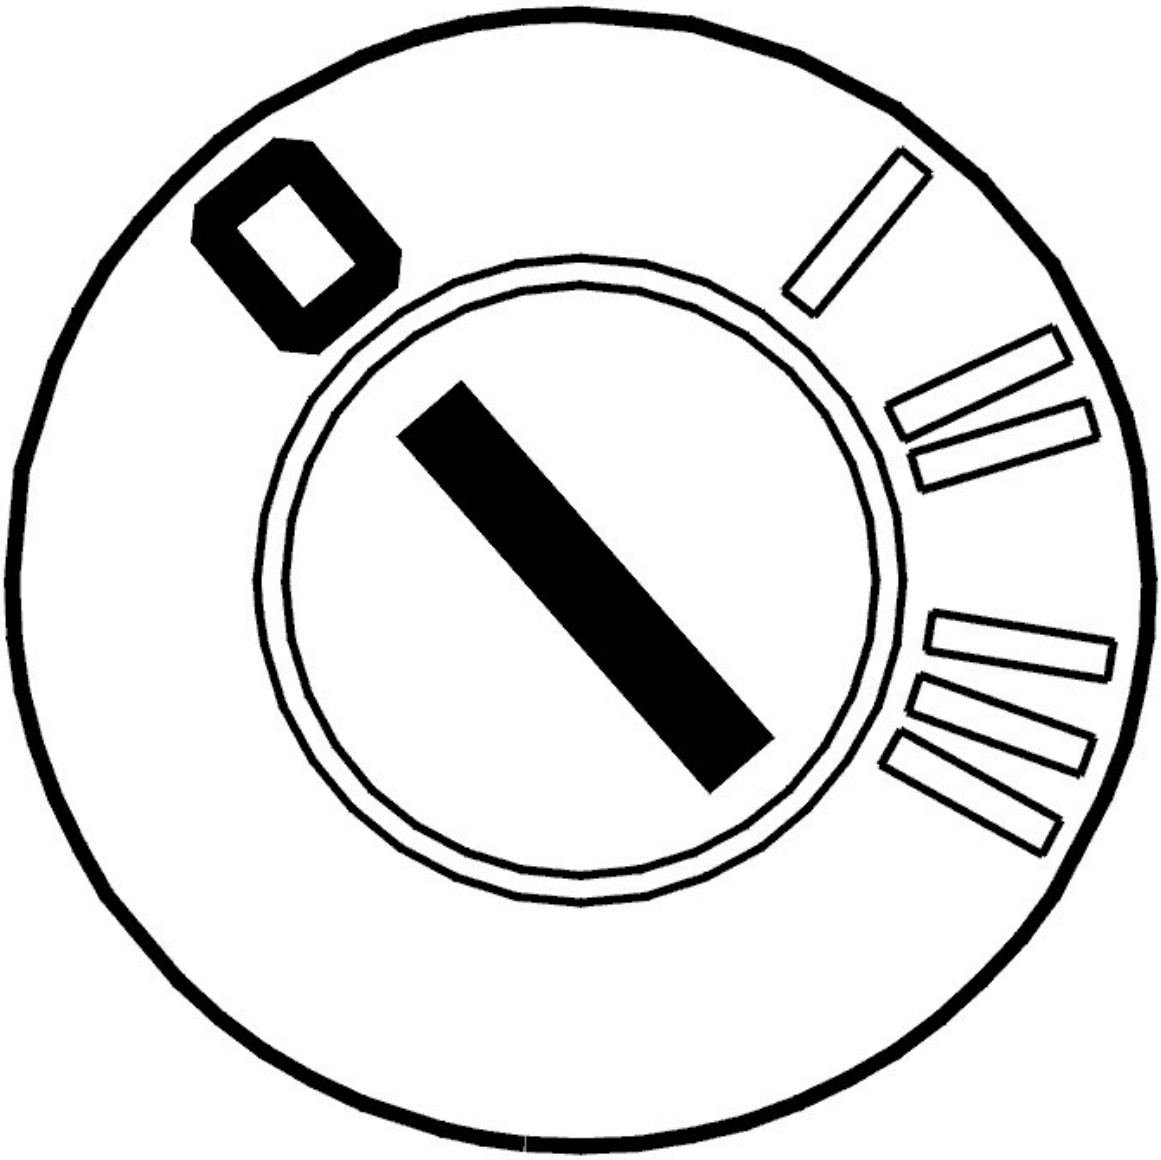


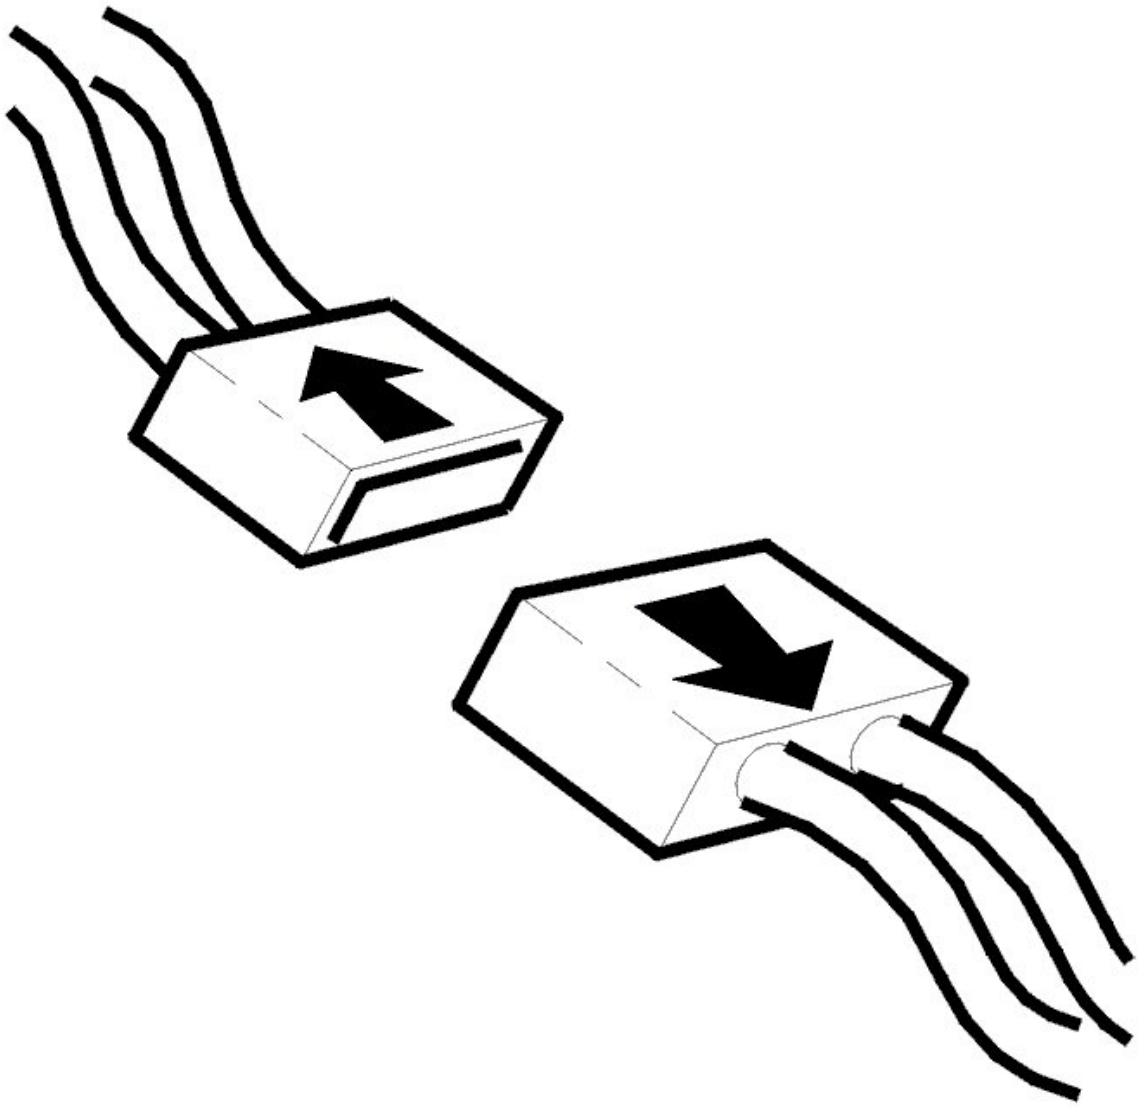
Was the resistance OK?

OK - Checking the wiring

Not OK - Checking the wiring and component

Checking the wiring



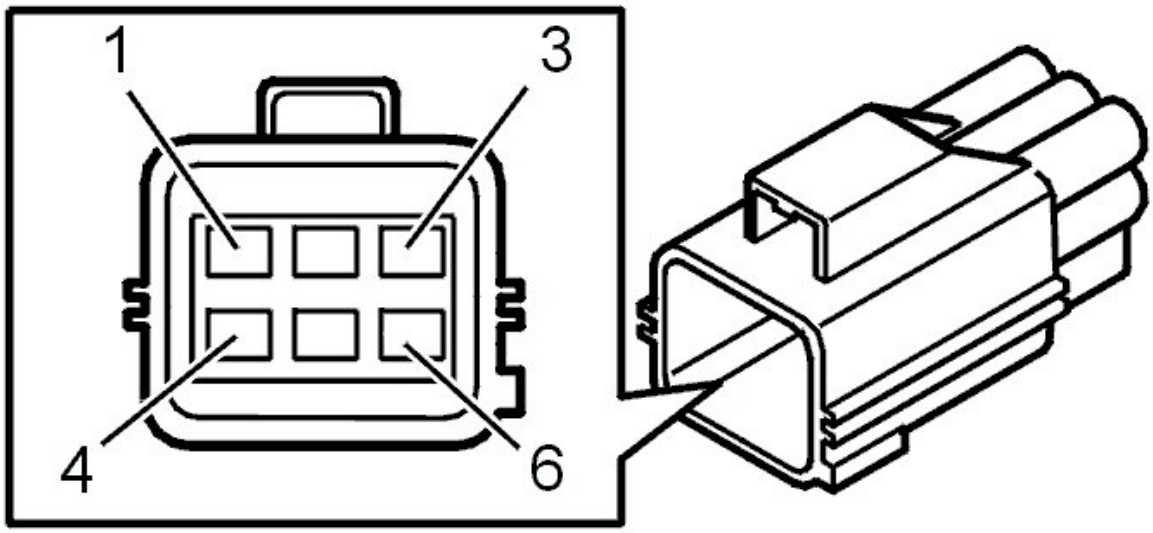


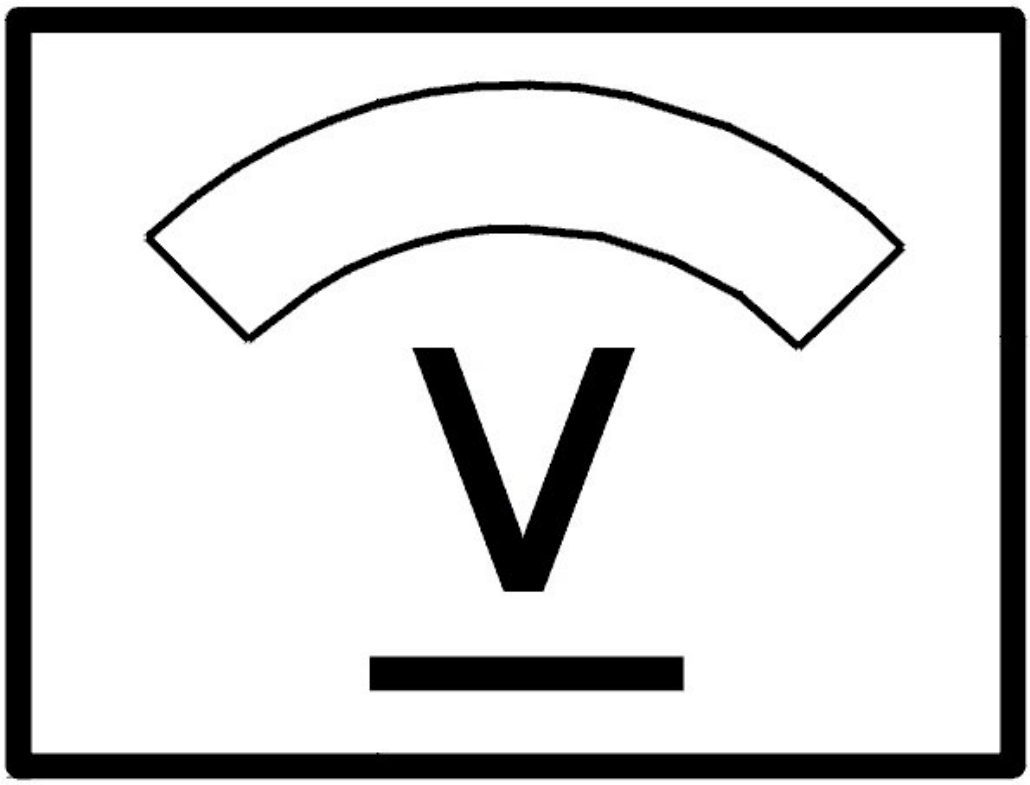
- Ignition off
- The breakout box connected
- Transmission connector C disconnected.

Check the cable between control module terminal #A47 (#A47) and transmission connector terminal #C4 (control module side). Check for a short-circuit to supply voltage according to Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault. Also check against the other cables in the circuit. Use the relevant wiring diagram.

Other information:

- To connect the breakout box, see Connecting the breakout box, B5244T5, B5254T2 See: Pinout Values and Diagnostic Parameters/Connecting the Breakout Box
- To disconnect the transmission connectors, see Connectors transmission, disconnecting / connecting See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Wiring Harness/Service and Repair/Procedures
- For information about signals, see Signal description. Transmission control module (TCM), AW50/51 AWD, AW55-50/51SN See: Transmission Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Description. Transmission Control Module (TCM).



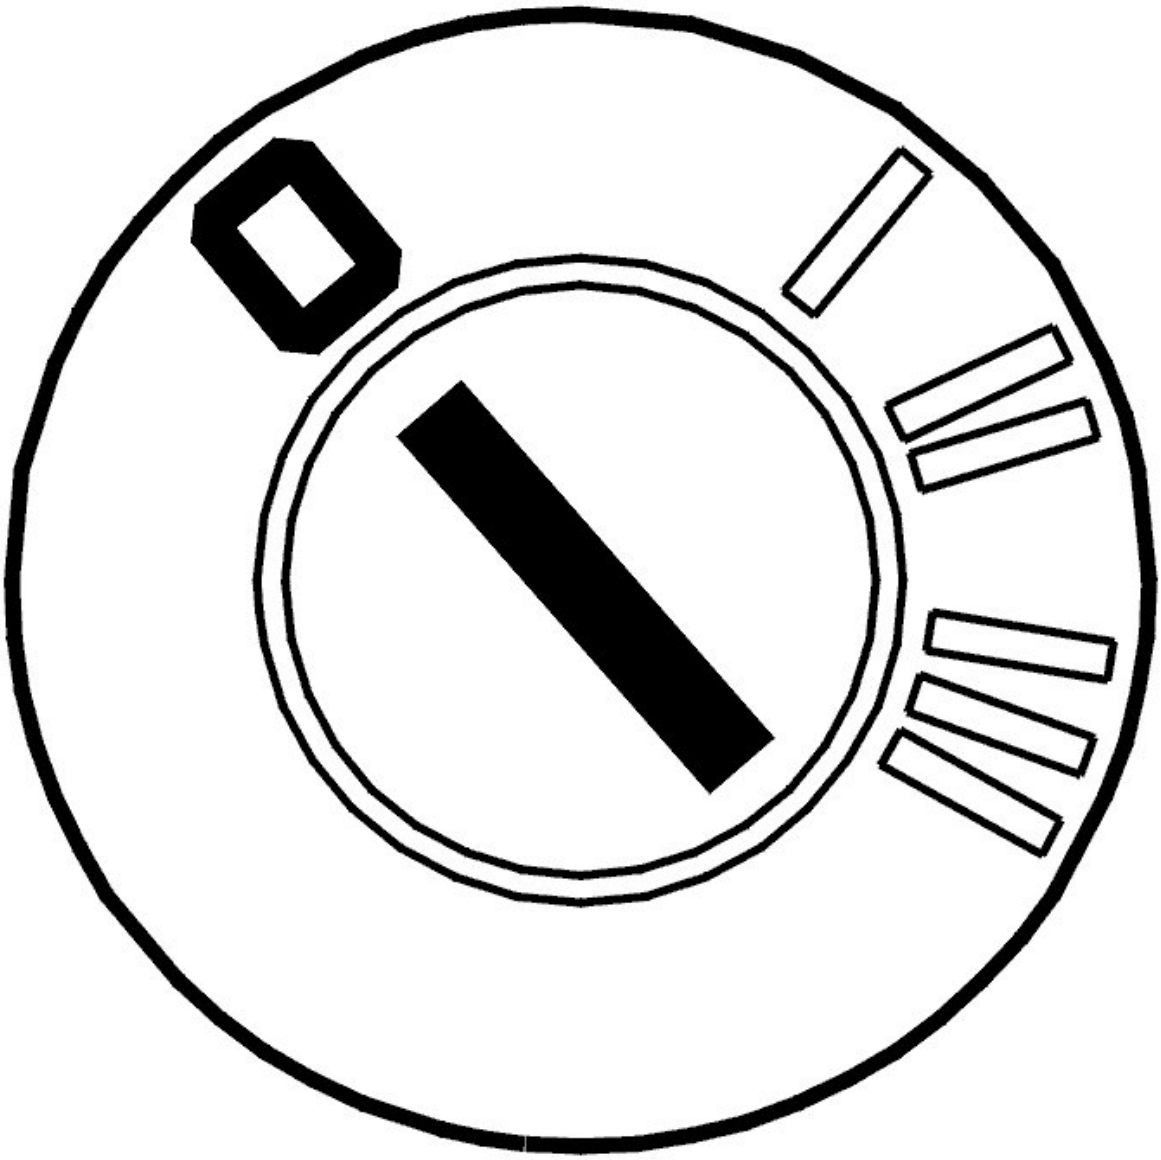


Was a fault detected?

Yes - Verification

No - Checking the wiring and component

Checking the wiring and component

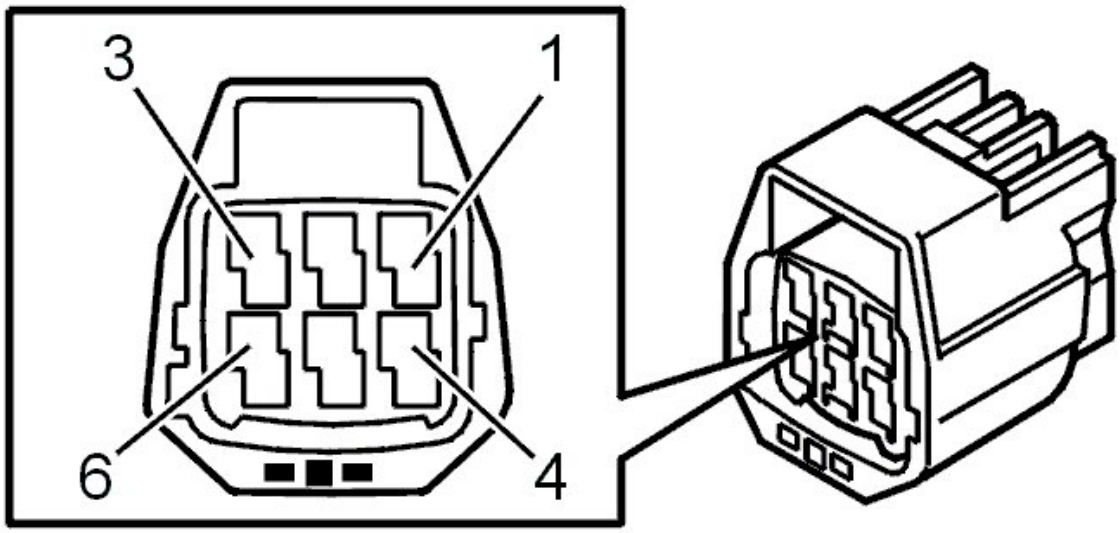


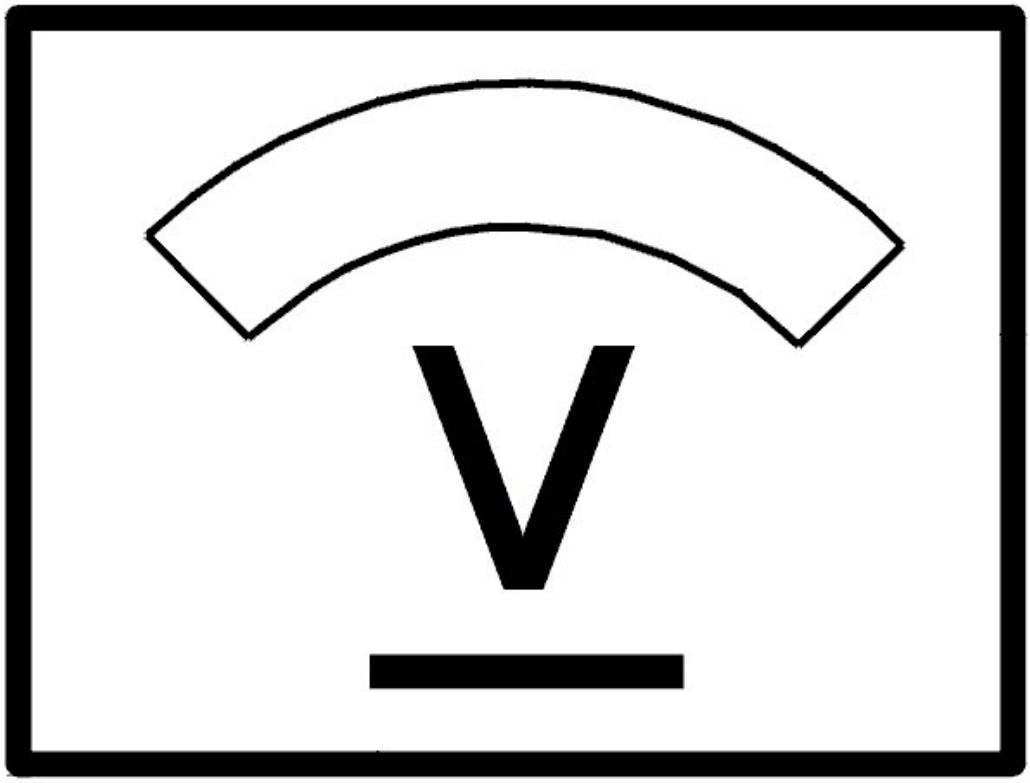
- Ignition off
- Open the transmission control system.

Check the cable between transmission connector terminal #C4 (transmission side) and the connector for solenoid S4. Check for a short-circuit to supply voltage according to Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault. Also check against the other cables in the circuit. Use the relevant wiring diagram.
Replace solenoid S4 if no faults are found in the cable-.
Remedy as necessary.

Other information:

- To connect the breakout box, see Connecting the breakout box, B5244T5, B5254T2 See: Pinout Values and Diagnostic Parameters/Connecting the Breakout Box
- To disconnect the transmission connectors, see Connectors transmission, disconnecting / connecting See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Wiring Harness/Service and Repair/Procedures
- To open the control system and to check or replace solenoid S4, see Solenoid control system, replacing See: Transmission Control Systems/Actuators and Solenoids - Transmission and Drivetrain/Actuators and Solenoids - A/T/Shift Solenoid/Service and Repair/Solenoid Control System, Replacing
- To replace the cable harness for the control system, see Wiring harness / oil temperature sensor, replacing See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Wiring Harness/Service and Repair/Removal and Replacement
- For information about signals, see Signal description. Transmission control module (TCM), AW50/51 AWD, AW55-50/51SN See: Transmission Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Description. Transmission Control Module (TCM).





Continue - Resetting the adaptation and oil quality counter

Resetting the adaptation and oil quality counter

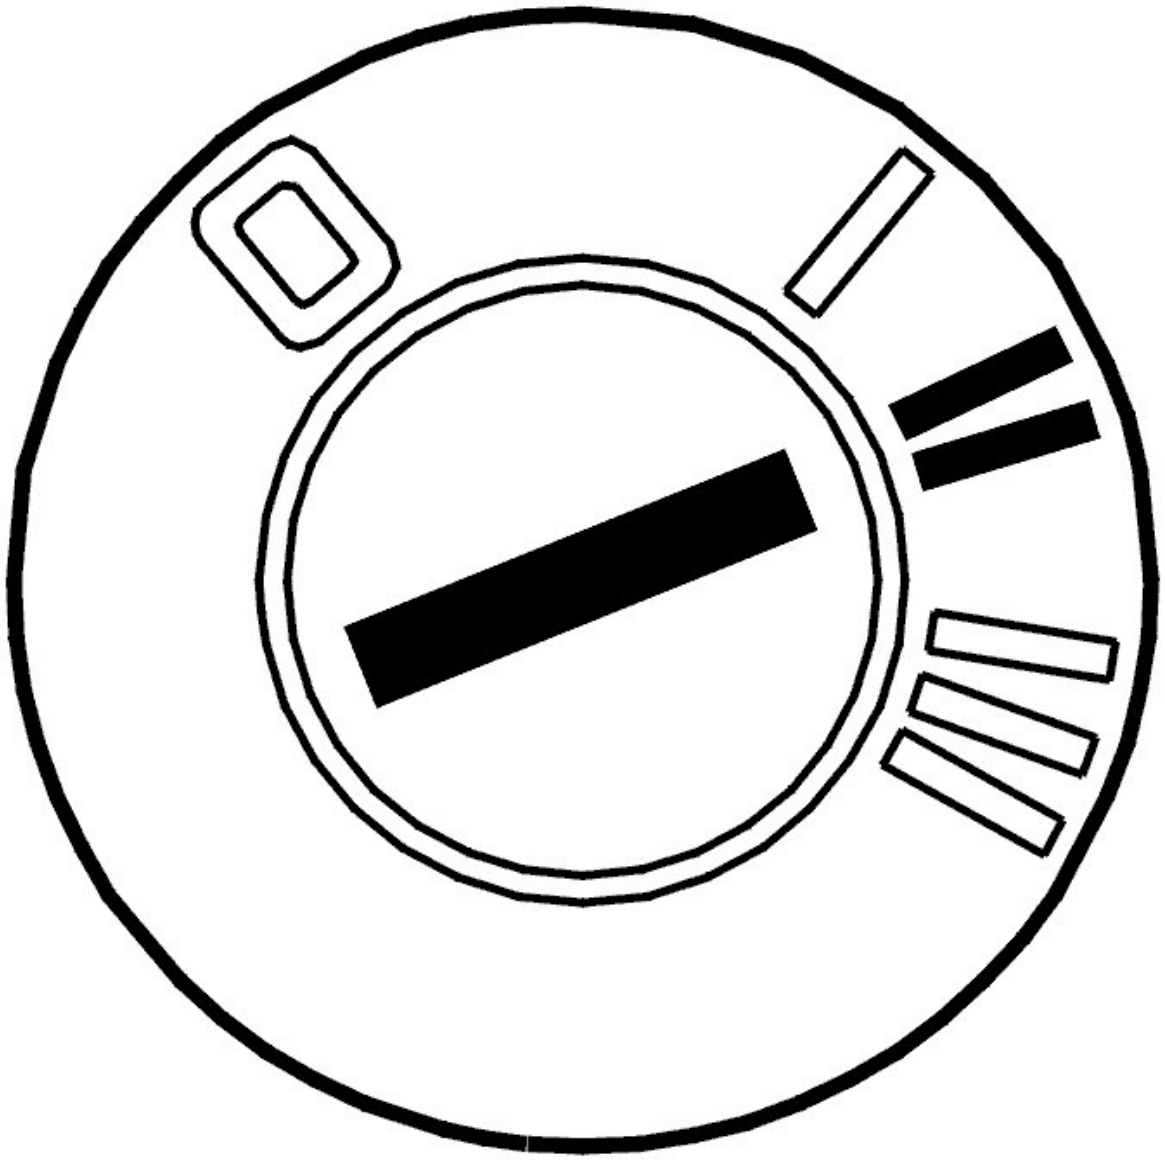
Resetting the adaptation

Resetting adaptation and the counter for "Transmission oil change"

Hint: The transmission has torque controlled adaptive pressure control. Pressure control means that the transmission regulates the pressure itself

during each gear shift. This avoids harsh gear shifting. Each gear shift is evaluated by the control module and stored in the memory. This allows for compensation for wear and tear in the transmission and clutch. It is important that the adaptation in the memory is reset after the transmission has been repaired. This is to ensure normal operation. The oil is replaced during repair; the "Transmission oil change" counter must be reset. If the counter is not reset when the fluid is drained and replaced, there is a risk that a diagnostic trouble code (DTC) will be stored in incorrect circumstances.

Note! This applies only if the transmission or one of the components in the transmission have been replaced.



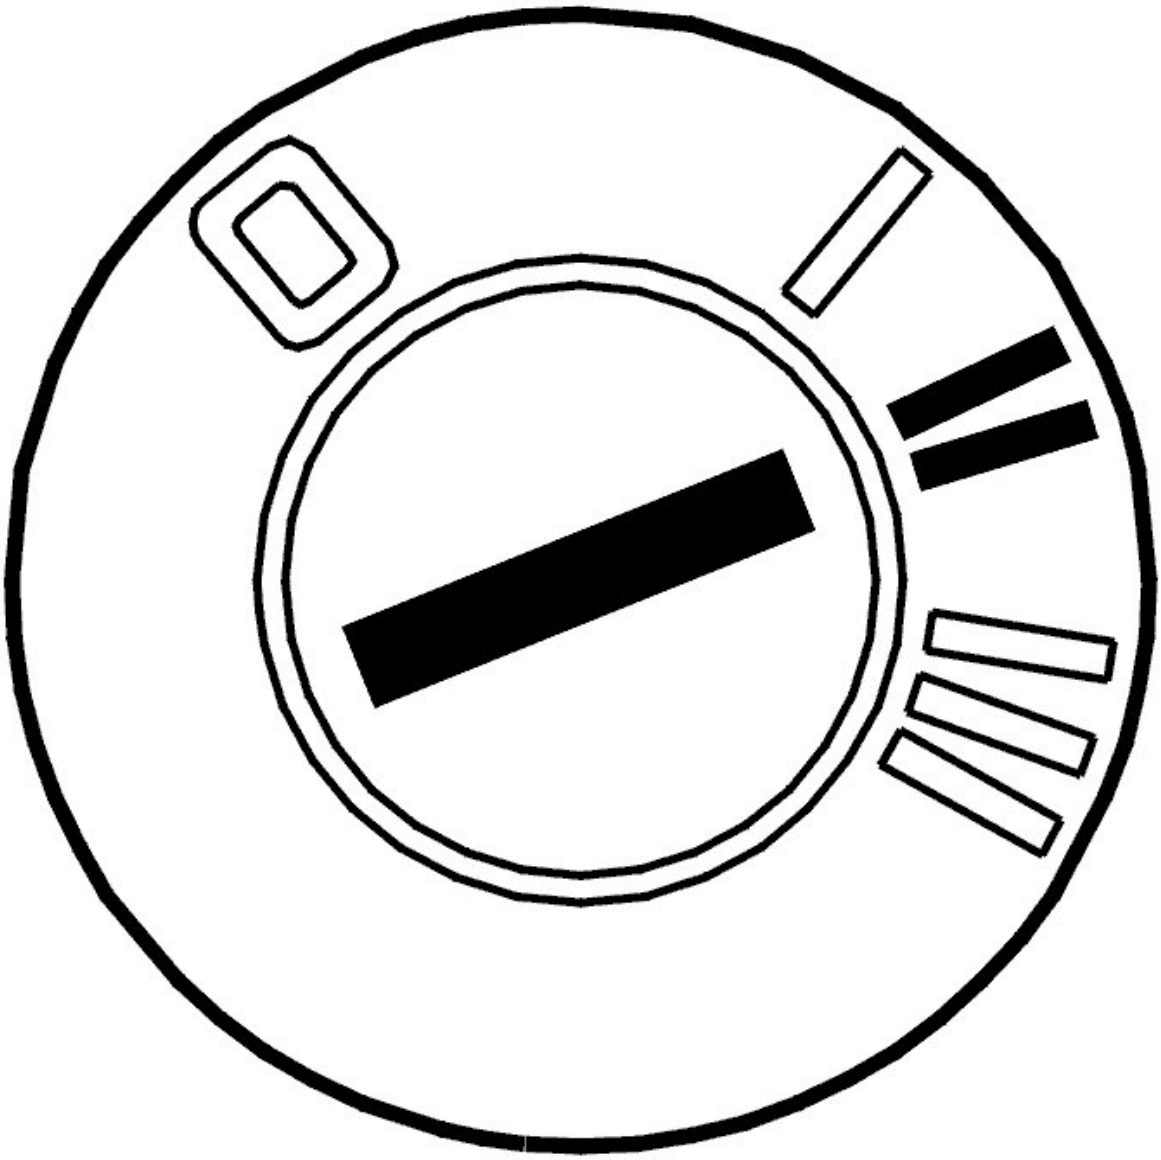
- Ignition on.

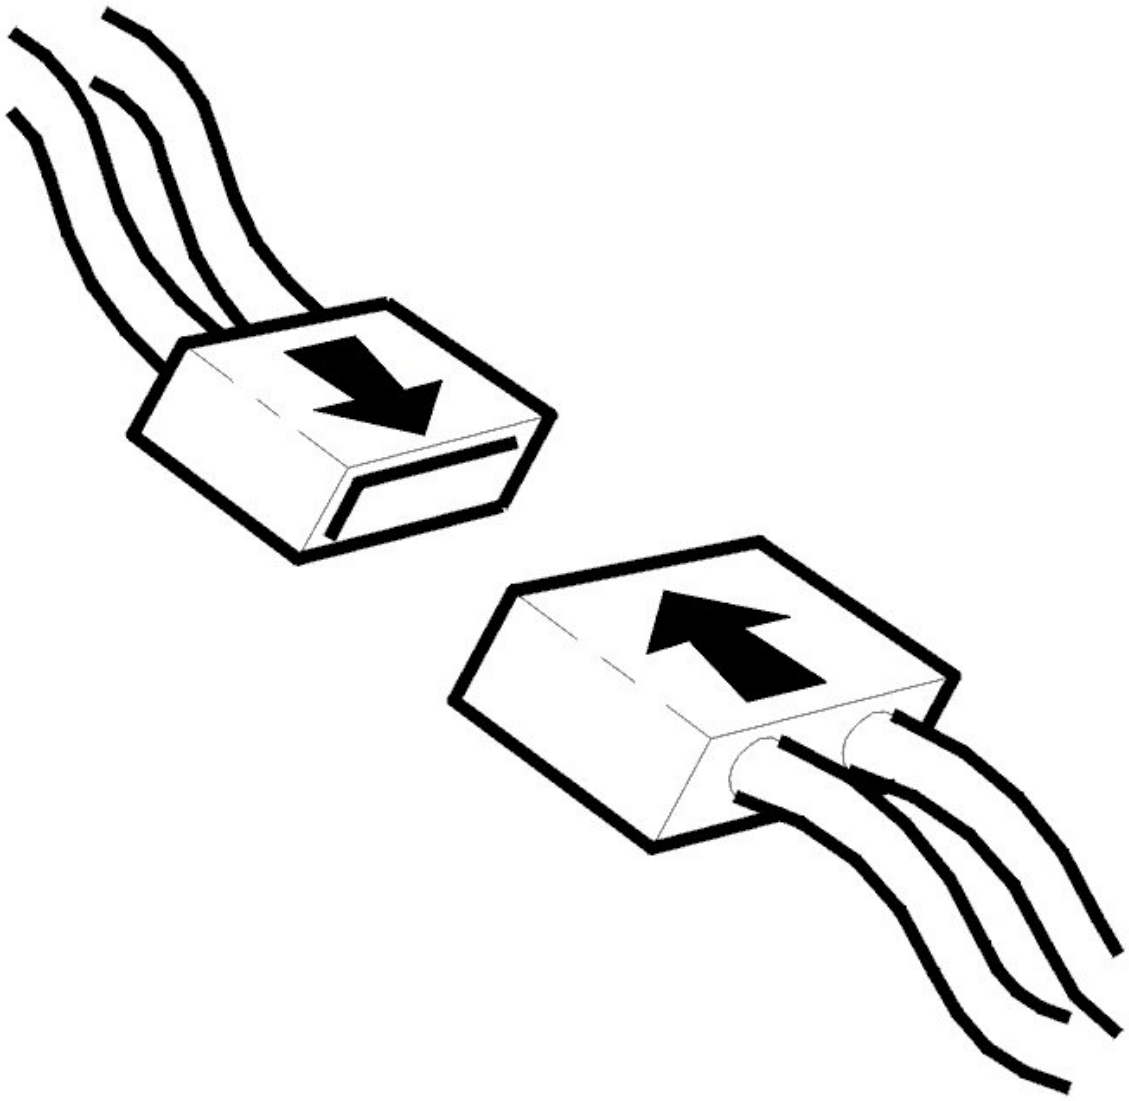
Click on the VCT2000 symbol to reset the adaptation and counter.

Continue - Verification

Verification

Hint: After carrying out the repair, check that the fault has been remedied.





- Ignition off.
- Reinstall the components, reconnect the connectors etc.
- Ignition on.
- Gear selector in position P.
- Activate solenoid S4.

The value should change between OFF and ON.

Does the value change between OFF and ON?

Yes - VERIFIED

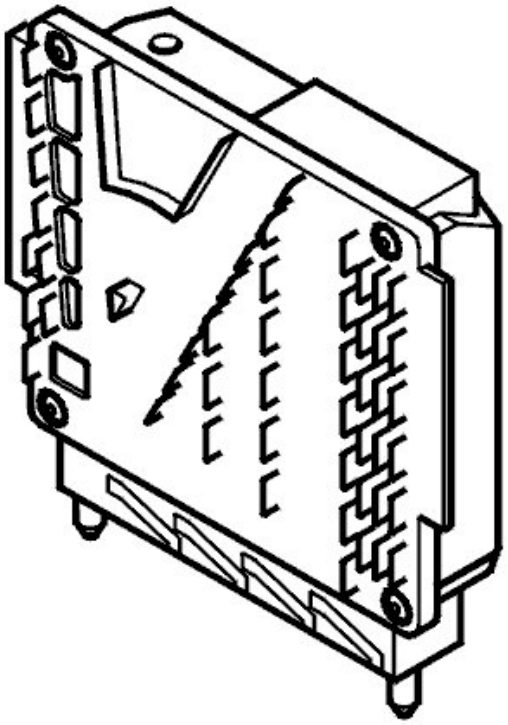
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition



Shift solenoids S1, S2, S3, S4 and S5 operate in tandem to control gear-shifting. The solenoids are controlled by power stages in the transmission control module (TCM). The transmission control module (TCM) opens the power stages to activate the solenoids and sends a voltage through the circuit. Diagnostic trouble codes (DTCs) TCM-0002, TCM-0008, TCM-0102, TCM-0108 or TCM-010B are stored (depending on the solenoid) if the transmission control module (TCM) registers that the signal in circuits S1, S2, S3, S4 or S5 is missing when the solenoid is activated.

Substitute value
- The transmission control module (TCM) "Emergency mode I" program has been initiated.

Possible source
- Contact resistance in terminals.
- Open-circuit in the signal cable.
- Defective solenoid.
- Internal fault in the control module.

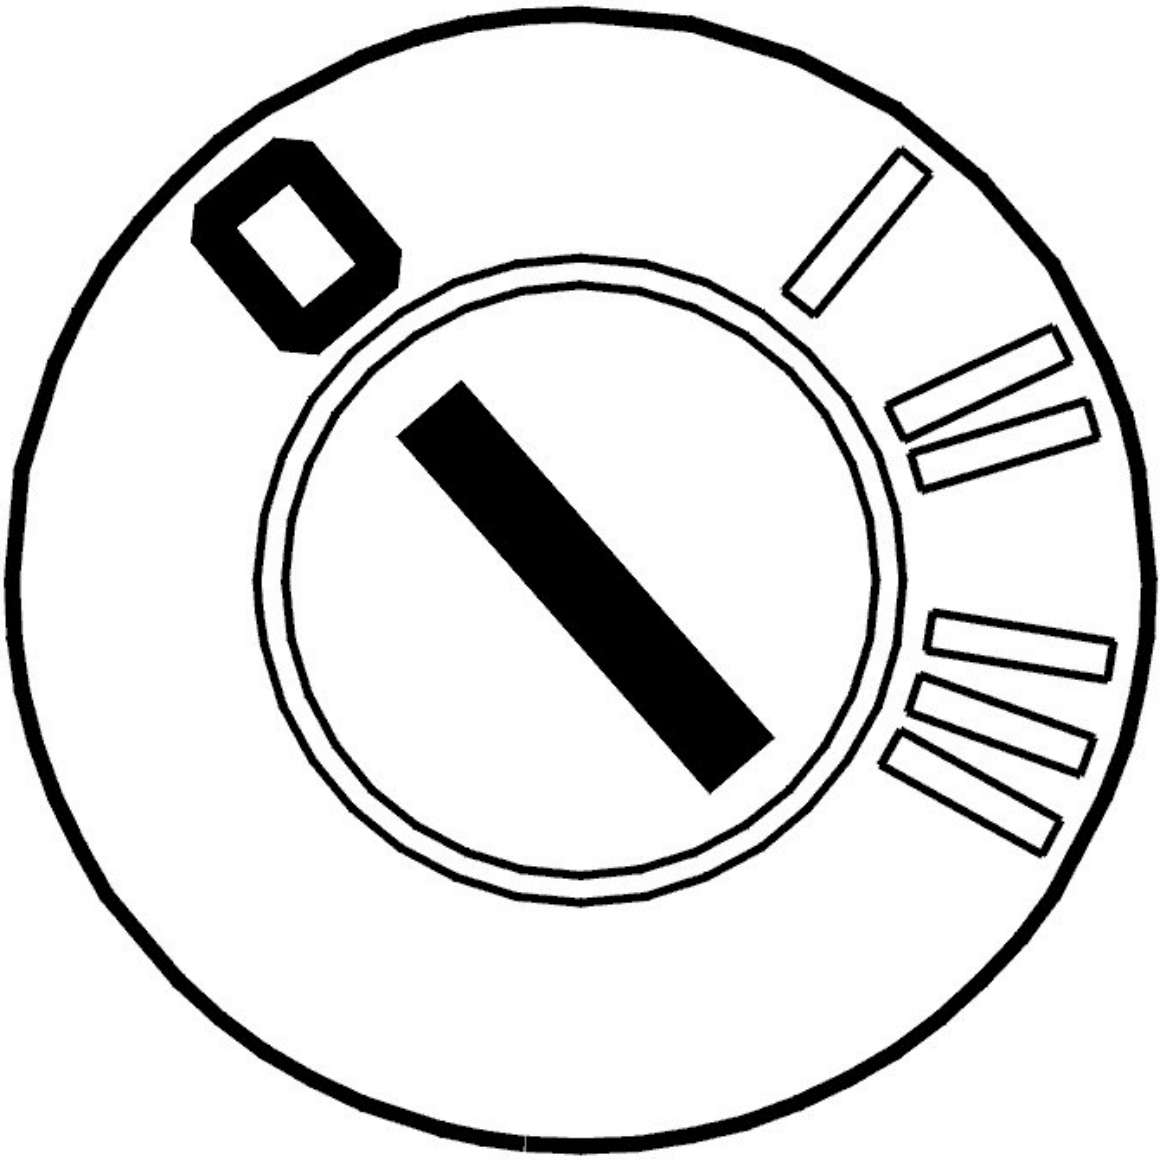
Fault symptom[s]
- General orange warning lamp lit.
- Malfunction indicator lamp (MIL) lit.
- Harsh gear shifting.
- No shifting.
- No lock-up function.

Signal Missing

Signal missing

Checking the temperature sensor

Hint: In some cases, the diagnostic trouble code (DTC) may be caused by a defective oil temperature sensor. Check the function of the oil temperature sensor first.



- Ignition off
- Read off the oil temperature.

Check that the function of the temperature sensor is OK. Test drive the car to increase the temperature of the transmission fluid. Read off the temperature again. Check that the temperature has increased.

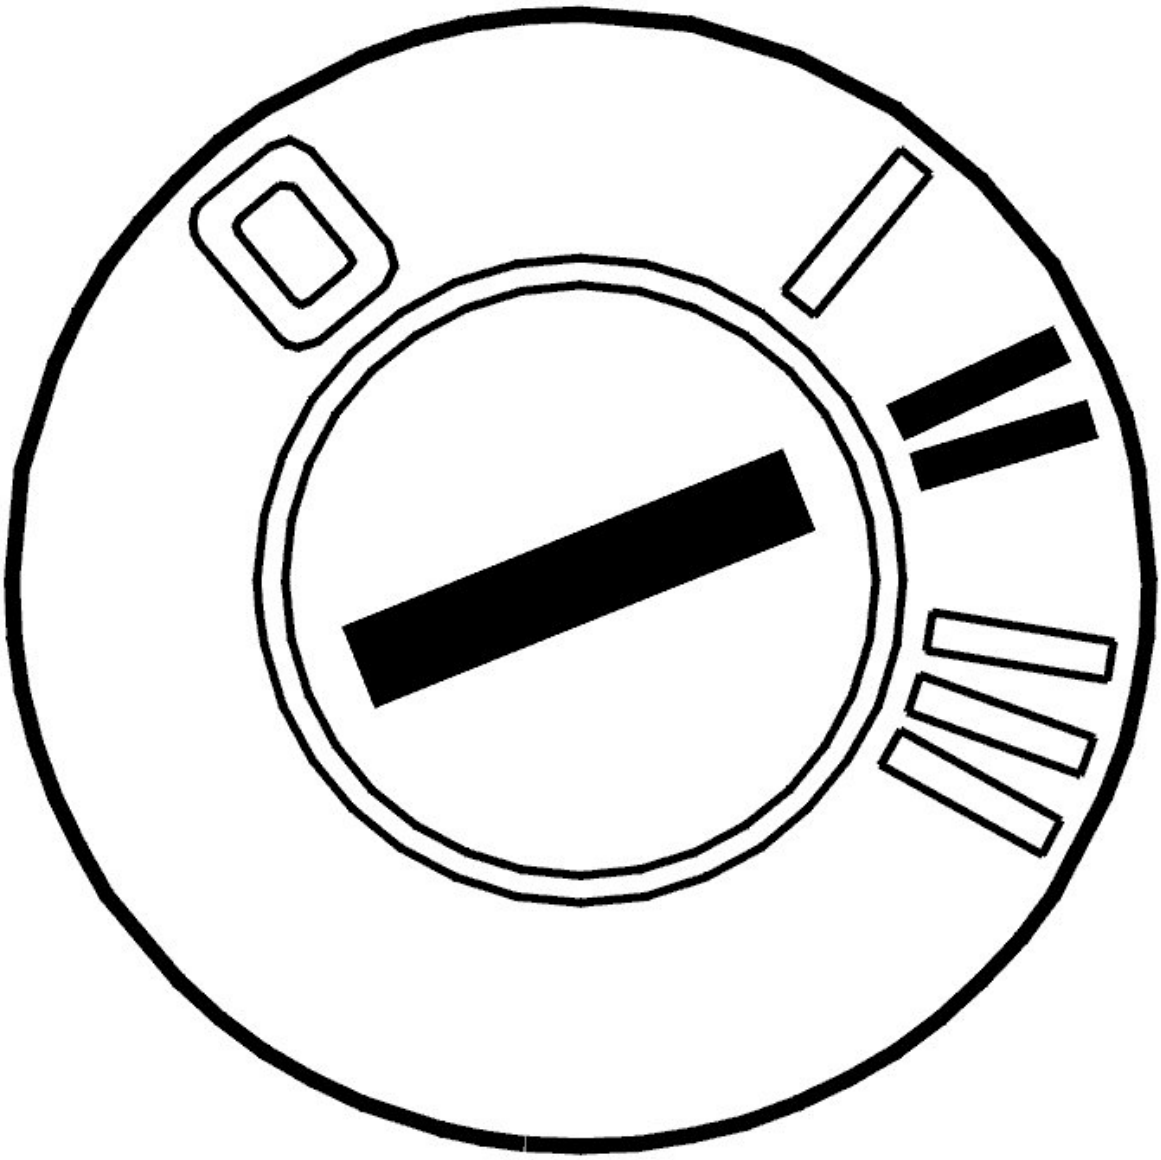
Hint: If the temperature is outside its permitted range, fault-trace the temperature sensor.

Is the oil temperature within its permitted range?

Yes - Checking shift solenoid S4

No - Checking transmission fluid temperature sensor

Checking shift solenoid S4



- Ignition on
- Gear selector in position P
- Activate solenoid S4.

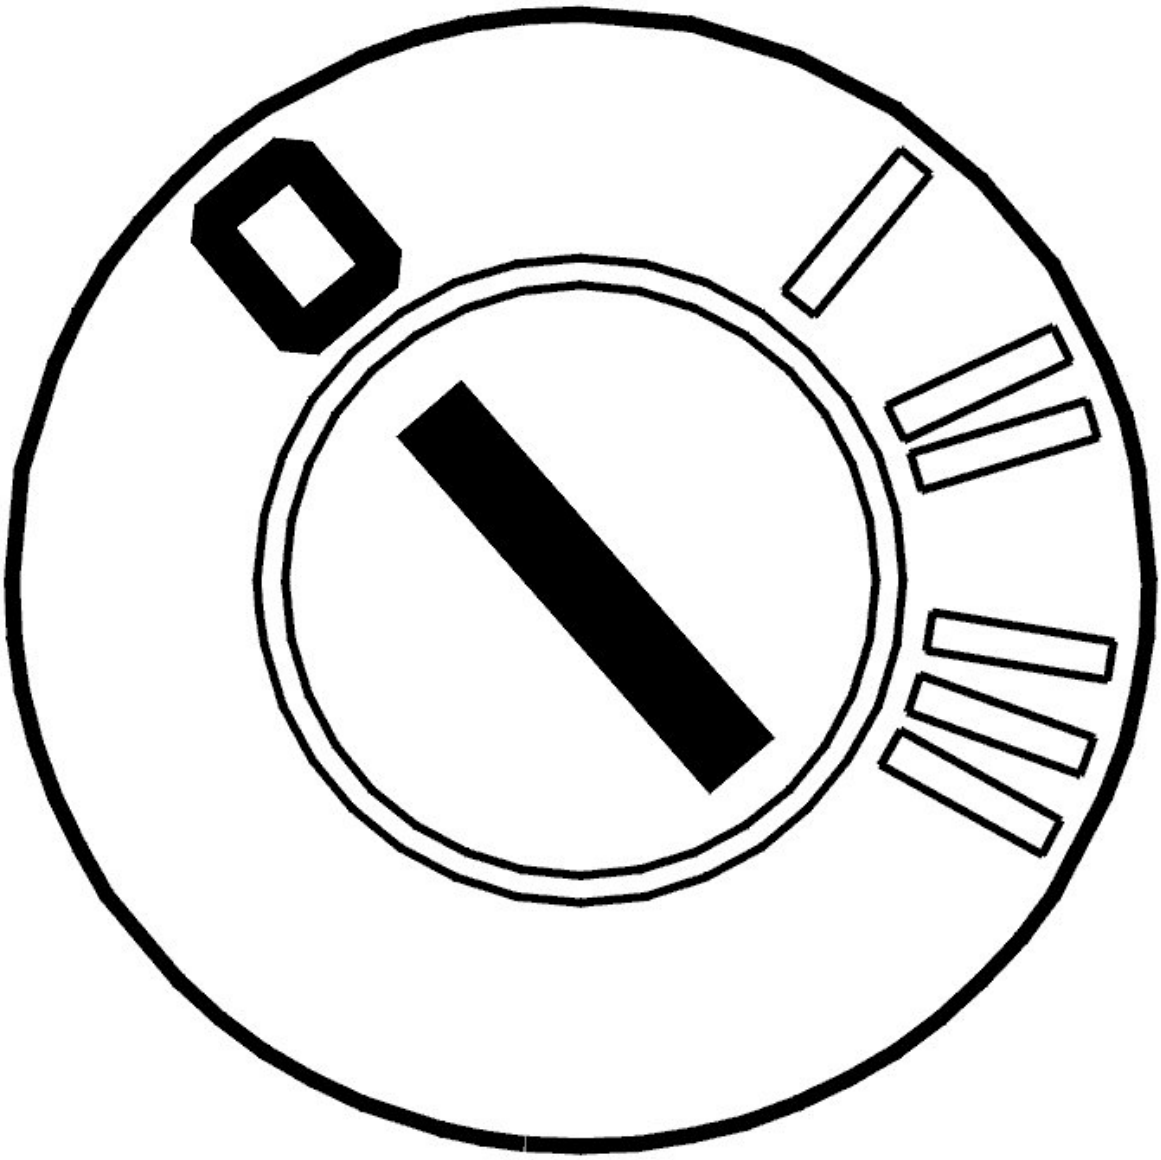
The current should oscillate between 0 and approximately 1.5 A.

Does the current oscillate?

Yes - Intermittent fault

No - Checking resistance

Checking resistance

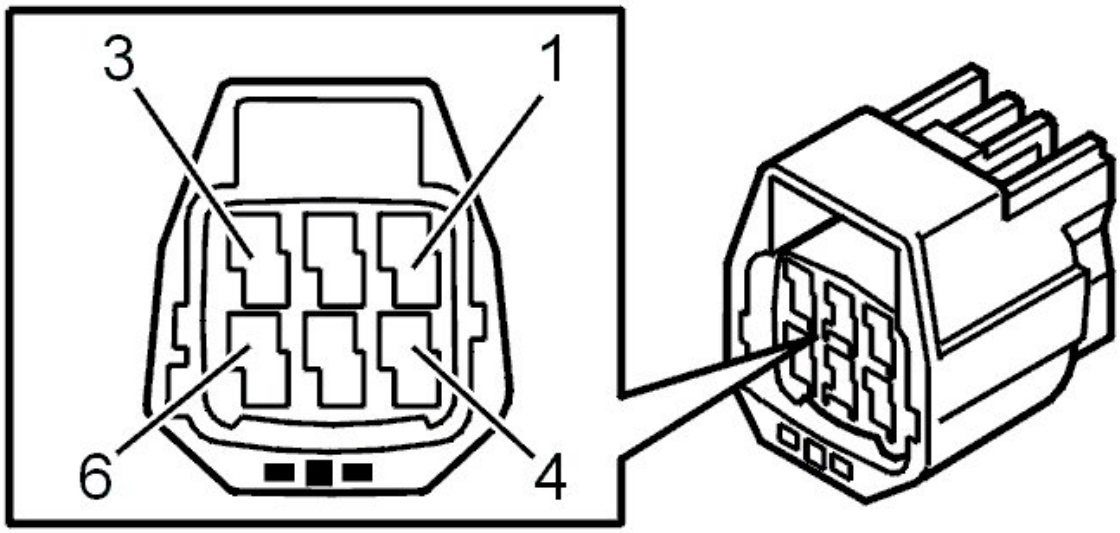


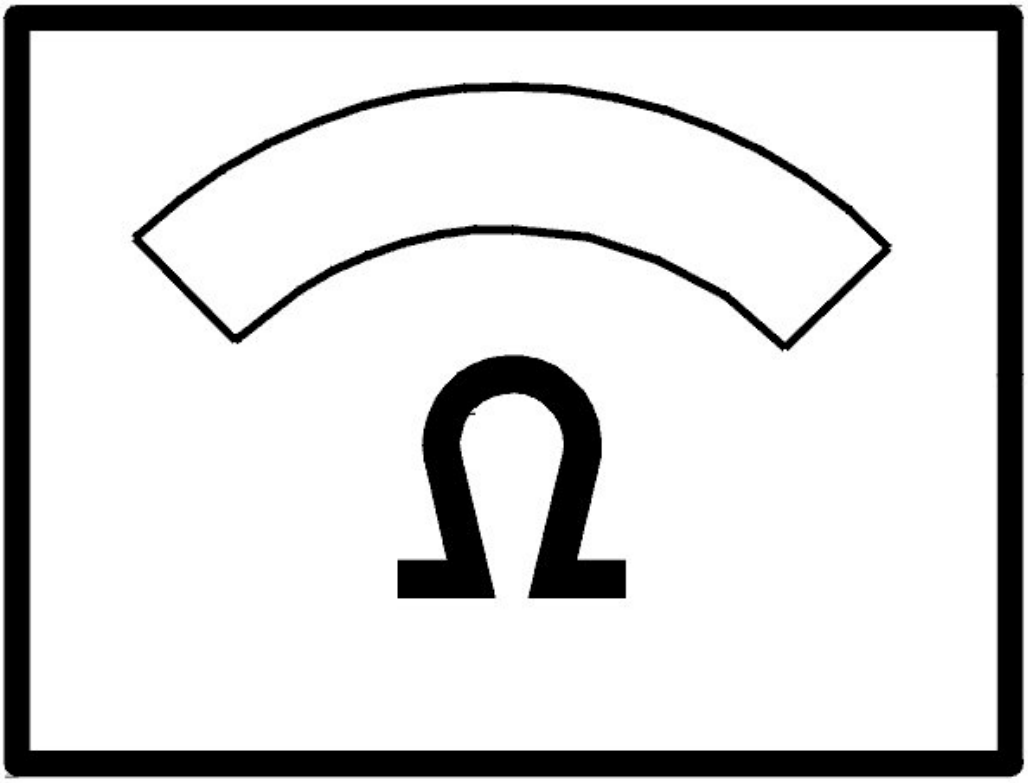
- Ignition off
- Disconnect transmission connector C.

Check solenoid S4 by measuring the resistance between transmission connector terminal #C4 and the transmission housing. The resistance must be 11-15 ohms.

Other information:

- To disconnect the transmission connectors, see Connectors transmission, disconnecting / connecting See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Wiring Harness/Service and Repair/Procedures
- For information about signals, see Signal description. Transmission control module (TCM), AW50/51 AWD, AW55-50/51SN See: Transmission Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Description. Transmission Control Module (TCM).



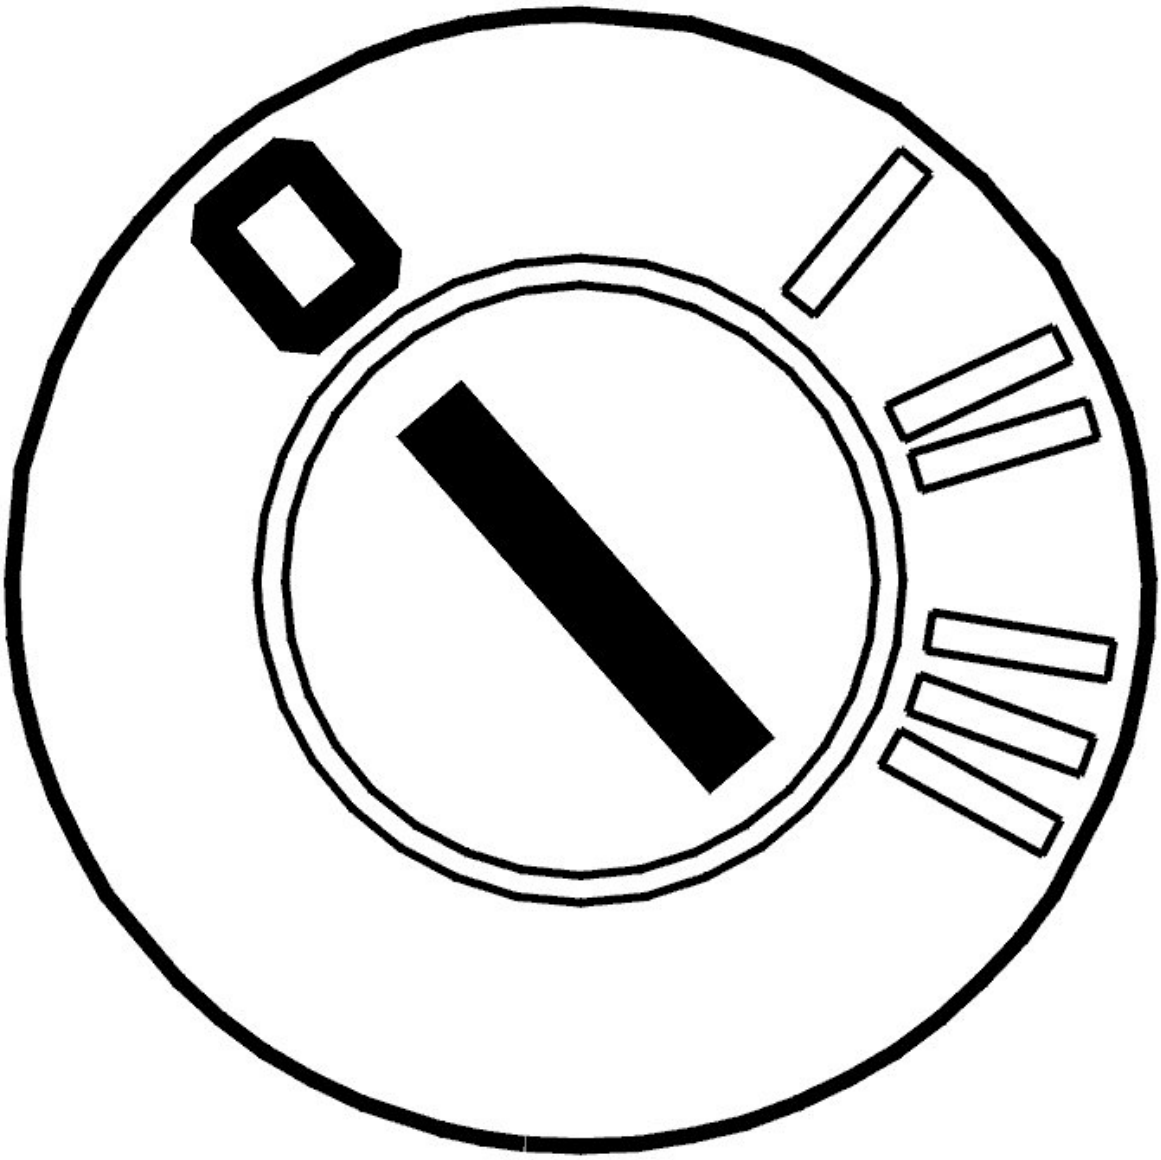


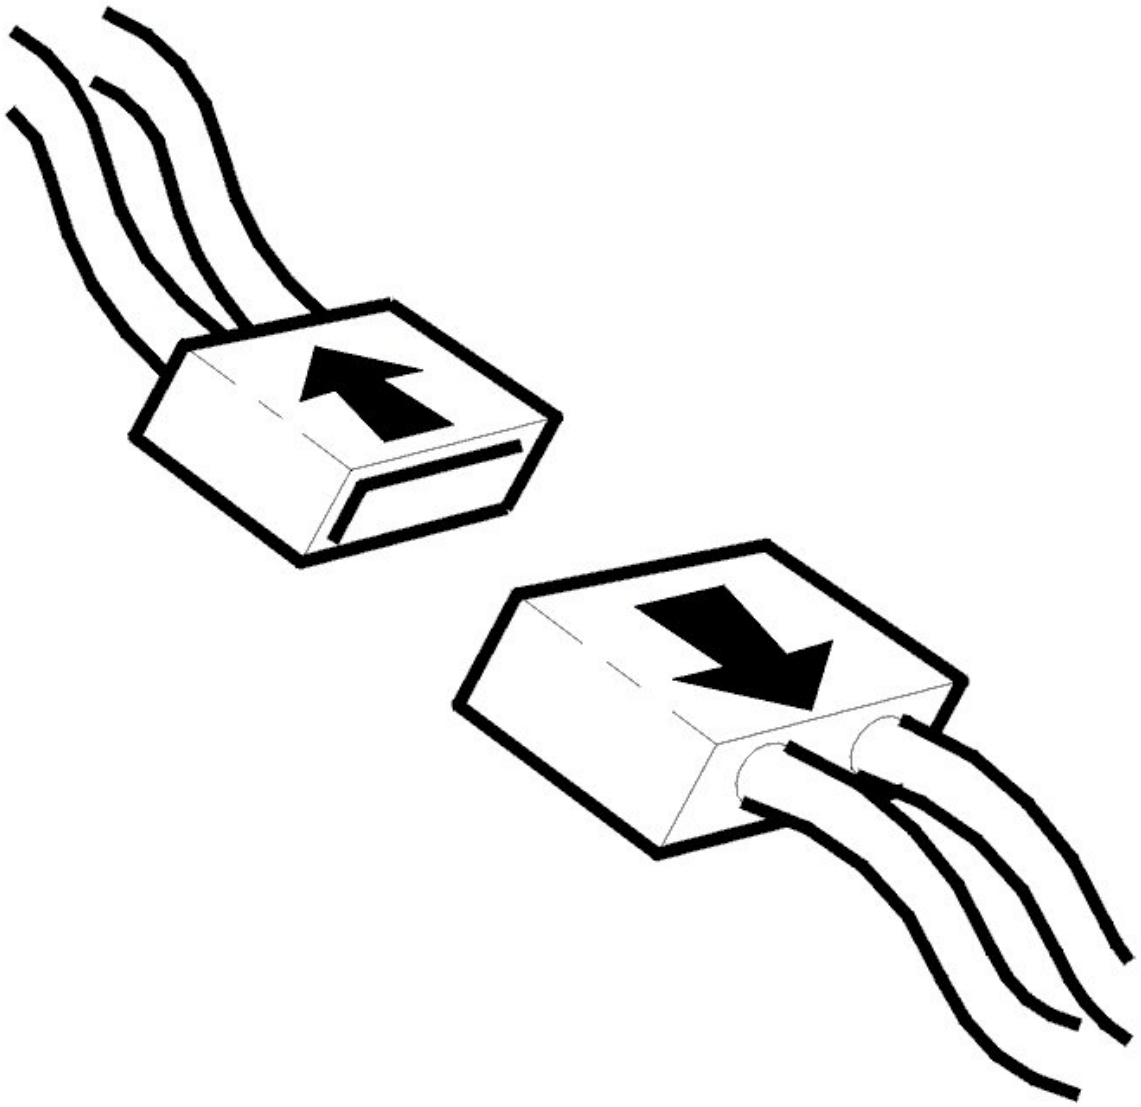
Was the resistance OK?

Yes - Checking the wiring

No - Checking the wiring and component

Checking the wiring



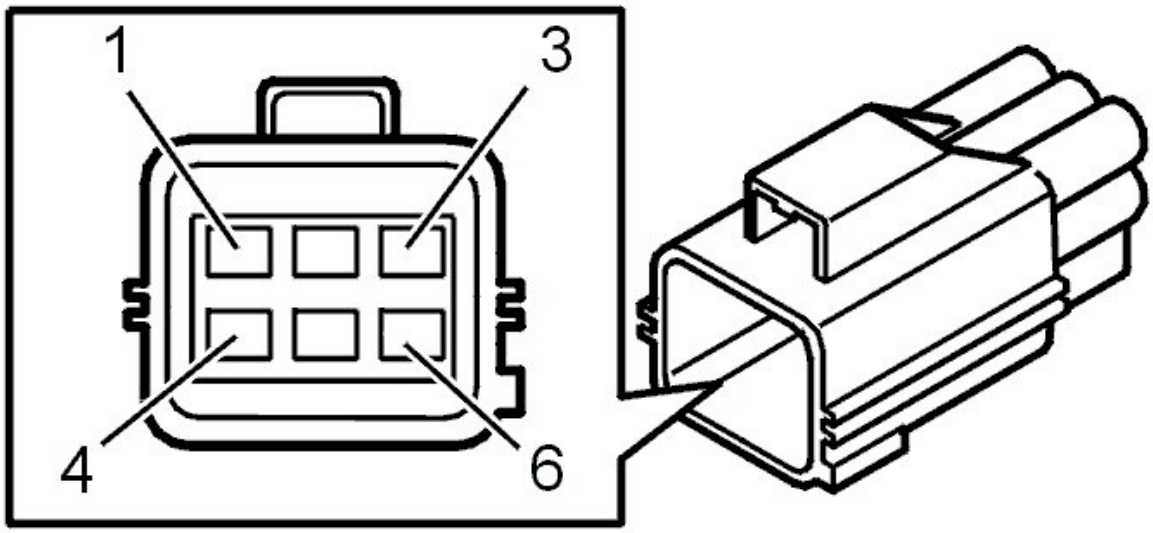


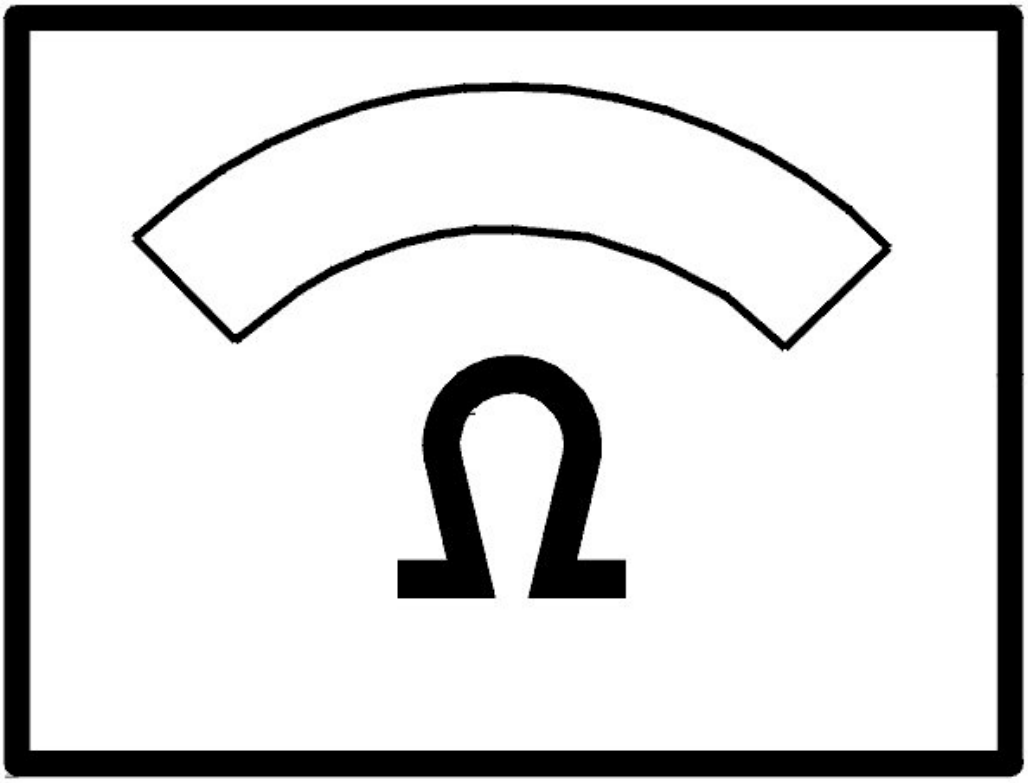
- Ignition off
- The breakout box connected
- Transmission connector C disconnected.

Check the cable between control module terminal #A47 (#A47) and transmission connector terminal #C4 (control module side). Check for an open-circuit according to Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault.
Remedy as necessary.

Other information:

- To connect the breakout box, see Connecting the breakout box, B5244T5, B5254T2 See: Pinout Values and Diagnostic Parameters/Connecting the Breakout Box
- To disconnect the transmission connectors, see Connectors transmission, disconnecting / connecting See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Wiring Harness/Service and Repair/Procedures
- For information about signals, see Signal description. Transmission control module (TCM), AW50/51 AWD, AW55-50/51SN See: Transmission Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Description. Transmission Control Module (TCM).



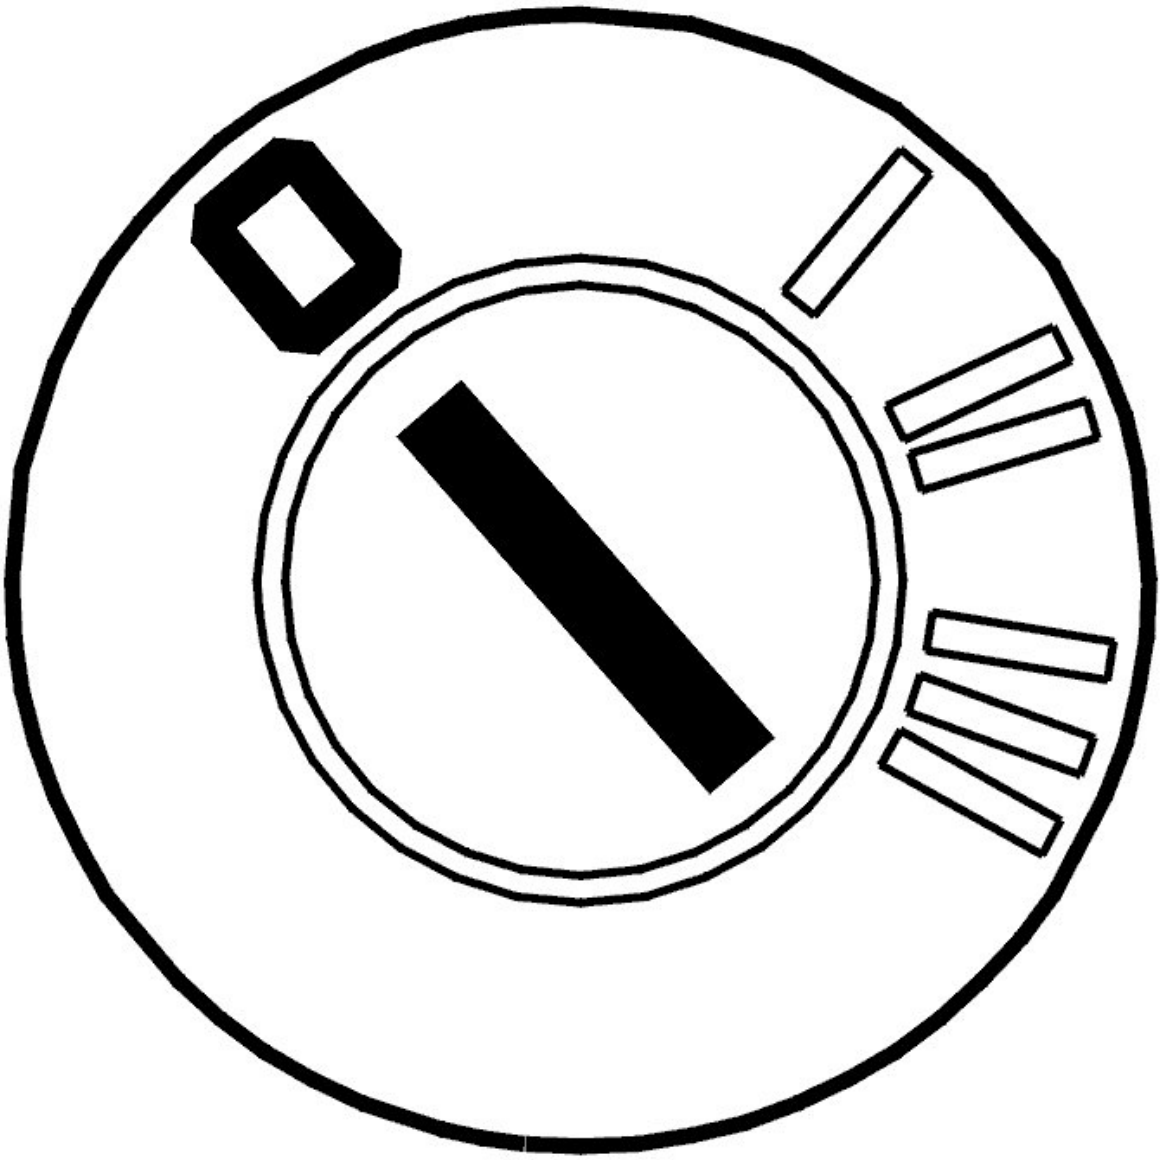


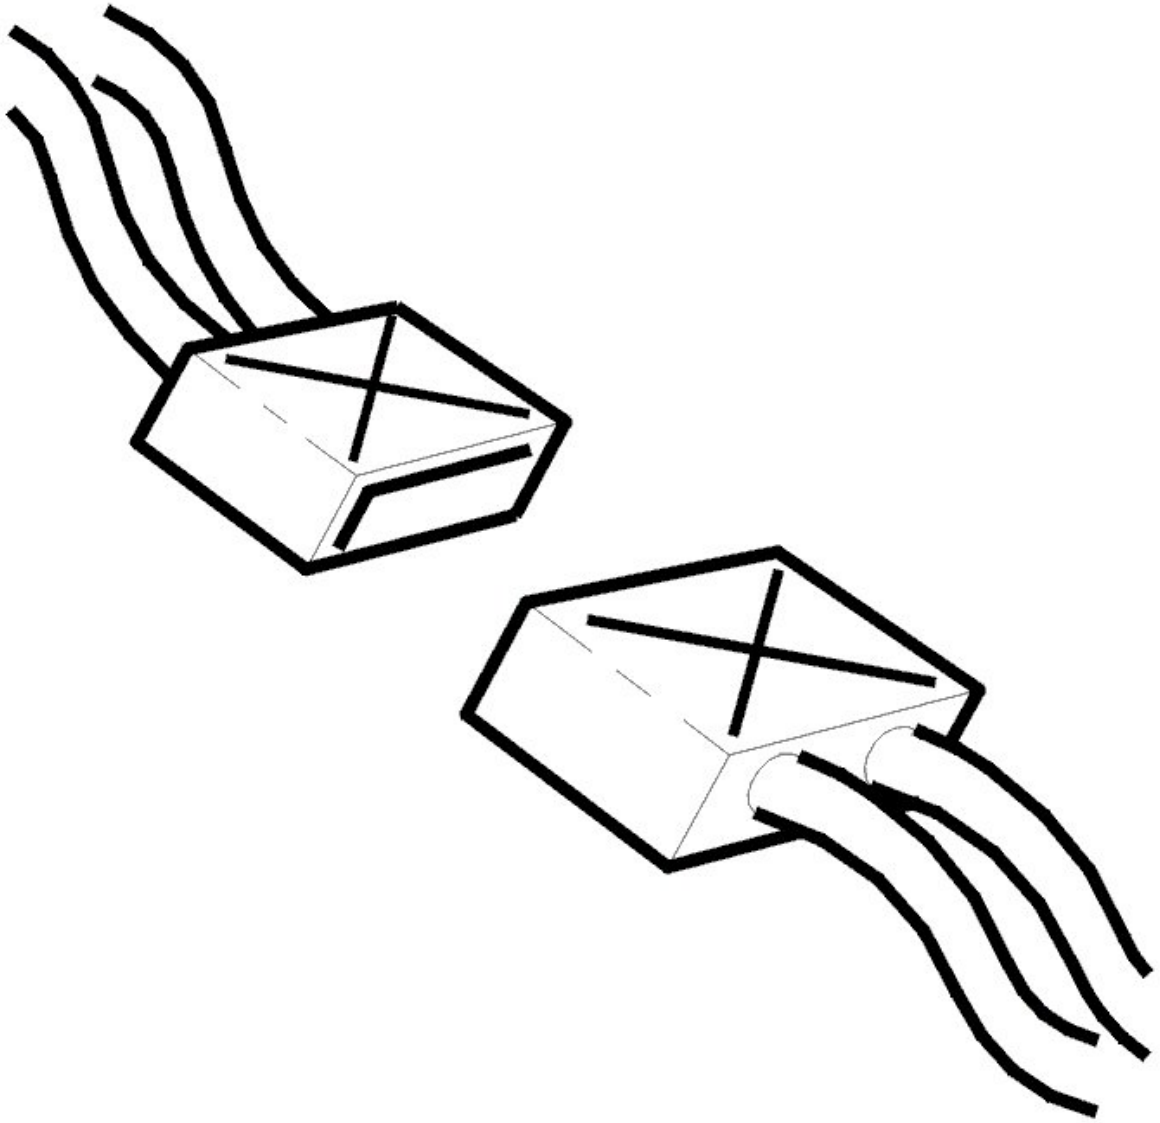
Was a fault detected?

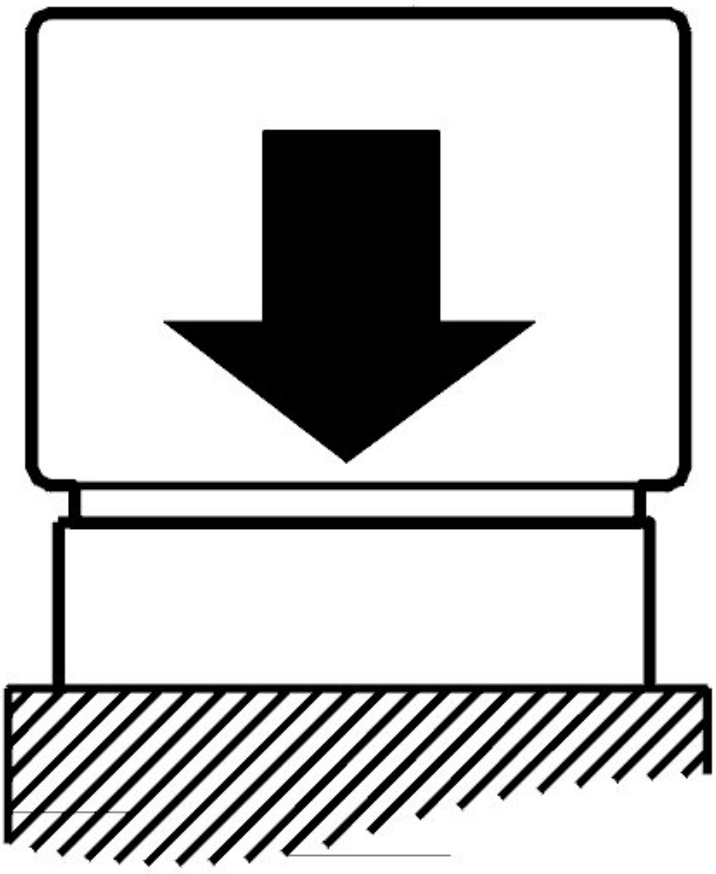
Yes - Verification

No - Checking the control module

Checking the control module







- Ignition off
- The breakout box connected
- Connect the control module.
- Transmission connector C disconnected
- Gear selector in position P.

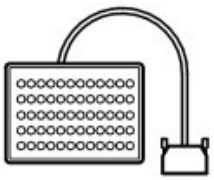
Check the transmission control module (TCM) by measuring the resistance between terminals #A47 (#A47) and #A53 (#A53) on the breakout box. The resistance must be approximately 9 kohms.

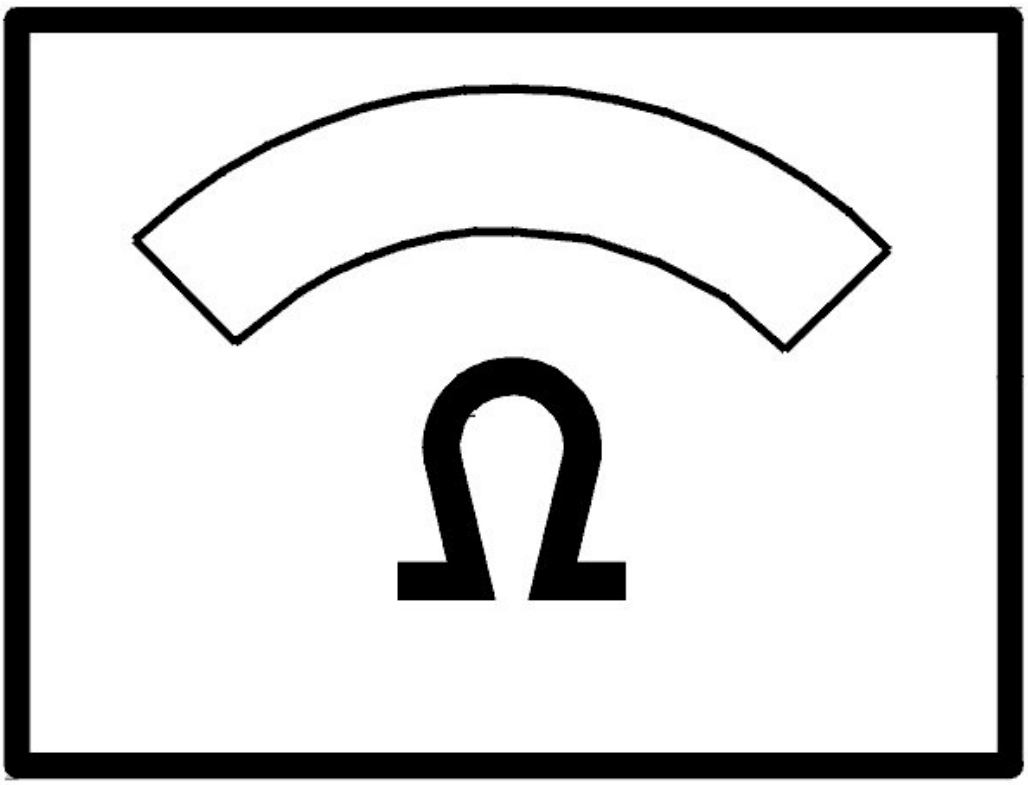
Note! When removing the transmission connector, the control module may store diagnostic trouble codes (DTCs) for the gear-shift position sensor, the shift solenoids, the temperature sensor etc.

Try a new control module if the resistance is infinite.

Other information:

- To disconnect the transmission connectors, see Connectors transmission, disconnecting / connecting See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Wiring Harness/Service and Repair/Procedures
- To replace the control module, see Transmission control module (TCM), replacing, B5244T5, AW55-50/51SN, B5254T2, AW55-50/51SN, B5254T2, AW50/51 AWD See: Transmission Control Systems/Relays and Modules - Transmission and Drivetrain/Relays and Modules - A/T/Control Module/Service and Repair
- For information about signals, see Signal description. Transmission control module (TCM), AW50/51 AWD, AW55-50/51SN See: Transmission Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Description. Transmission Control Module (TCM).



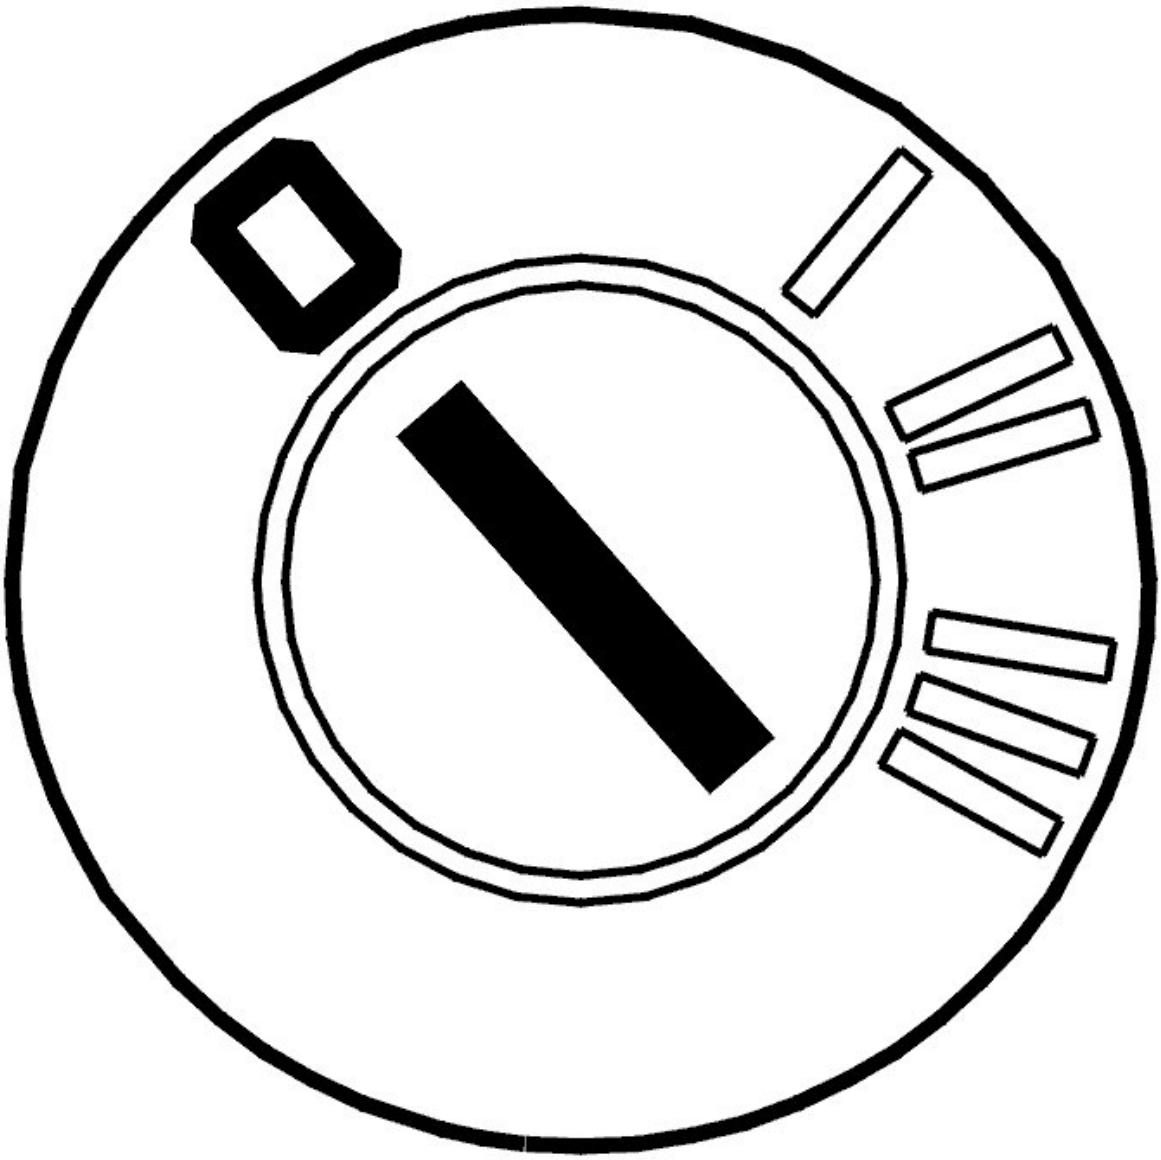


Was the resistance OK?

Yes - No Fault Found

No - Verification

Checking the wiring and component



- Ignition off
- Open the transmission control system.

Check the cable between transmission connector terminal #C4 (transmission side) and the connector for solenoid S4. Check for an open-circuit according to Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault.
Check solenoid S4 by measuring the resistance between the terminal pin on solenoid S4 and the transmission housing. The resistance must be 11-15 ohms. Replace solenoid S4 if the resistance is incorrect.
Remedy as necessary.

Other information:

- To disconnect the transmission connectors, see Connectors transmission, disconnecting / connecting See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Wiring Harness/Service and Repair/Procedures
- To open the control system and to check or replace solenoid S4, see Solenoid control system, replacing See: Transmission Control Systems/Actuators and Solenoids - Transmission and Drivetrain/Actuators and Solenoids - A/T/Shift Solenoid/Service and Repair/Solenoid Control System, Replacing

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition
Shift solenoids S1, S2, S3, S4 and S5 operate in tandem to control gear-shifting. Diagnostic trouble codes (DTCs) TCM-0003, TCM-0009, TCM-0103, TCM-0109 or TCM-010C are stored if the transmission control module (TCM) registers that there is a short-circuit to ground in circuits S1, S2, S3, S4 or S5 when the solenoid should be activated.

Substitute value
- The transmission control module (TCM) "Emergency mode I" program has been initiated.

Possible source
- Short-circuit to ground in the signal cable.
- Defective solenoid.
- Internal fault in the control module.

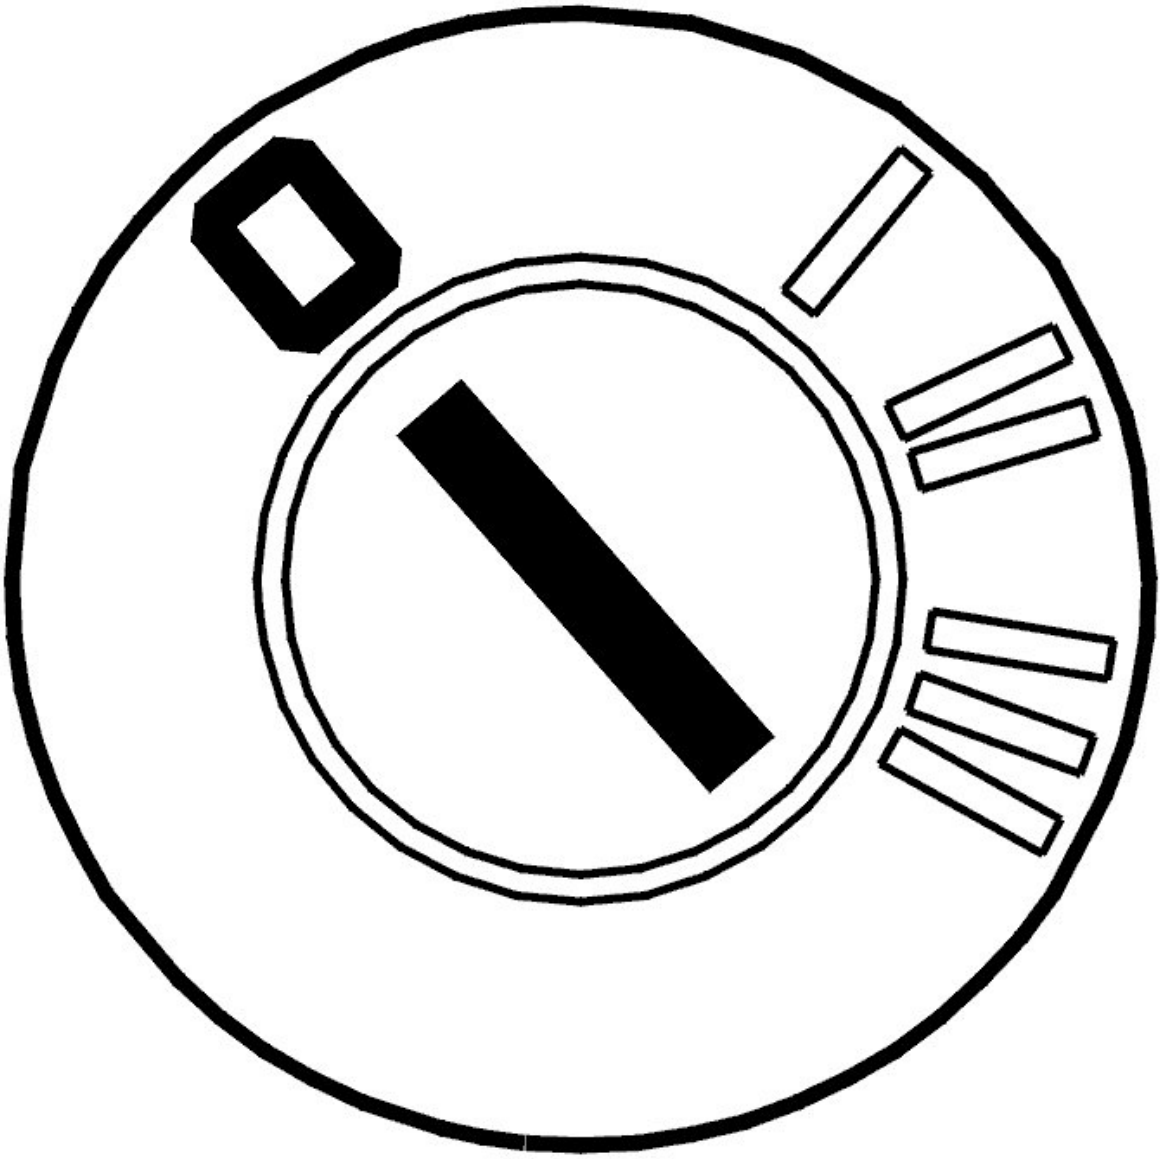
Fault symptom[s]
- General orange warning lamp lit.
- No lock-up function.
- Harsh gear shifting.
- No shifting.

Signal Too Low

Signal too low

Checking the temperature sensor

Hint: In some cases, the diagnostic trouble code (DTC) may be caused by a defective oil temperature sensor. Check the function of the oil temperature sensor first.



- Ignition off

- Read off the oil temperature.

Check that the function of the temperature sensor is OK. Test drive the car to increase the temperature of the transmission fluid. Read off the temperature again. Check that the temperature has increased.

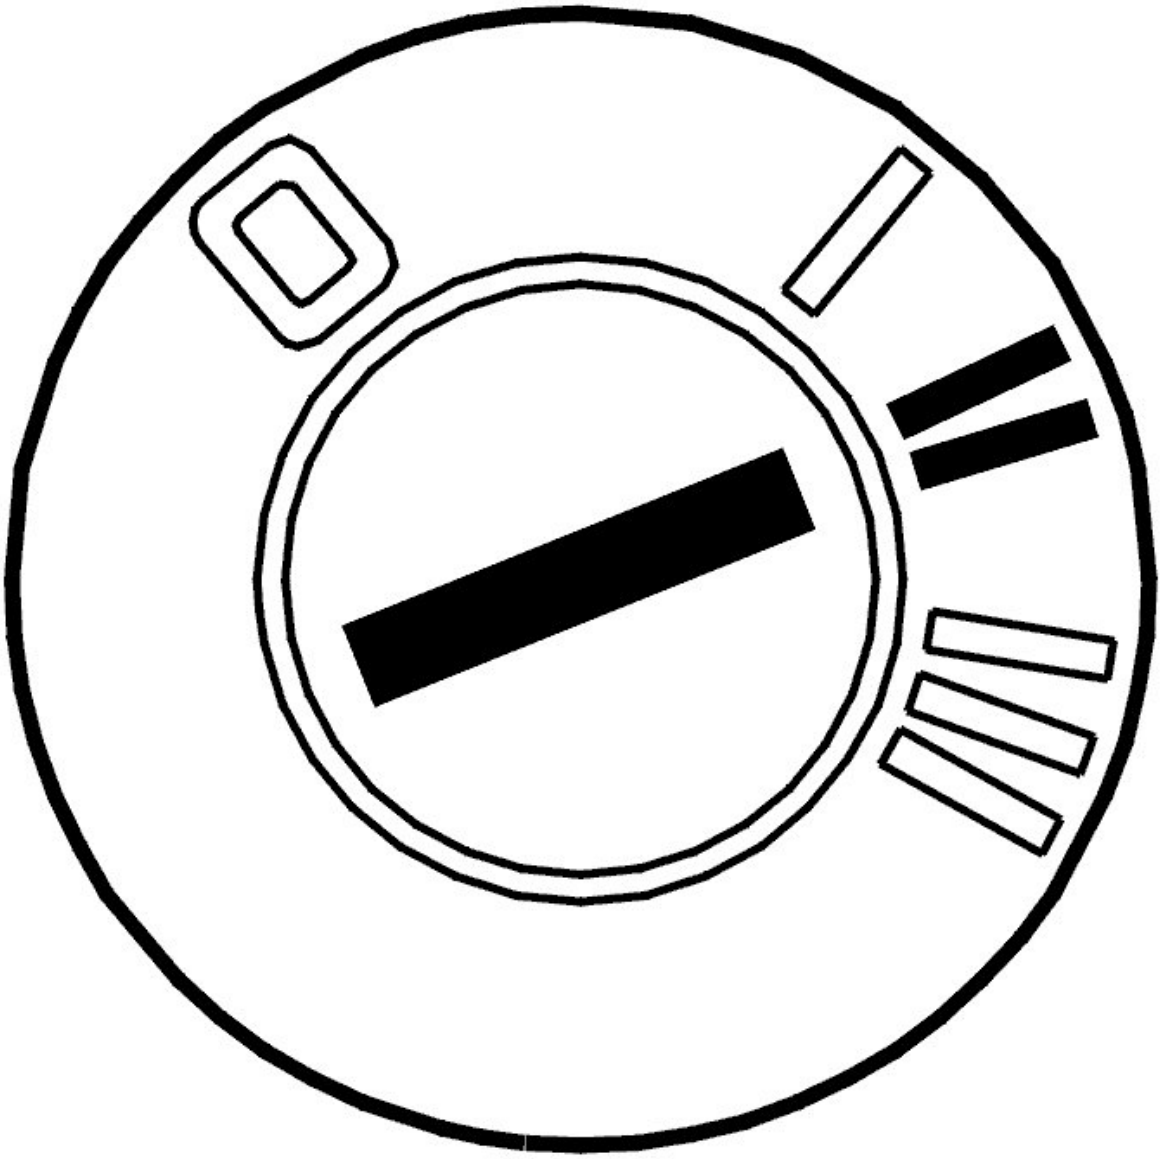
Hint: If the temperature is outside its permitted range, fault-trace the temperature sensor.

Is the oil temperature within its permitted range?

Yes - Checking shift solenoid S4

No - Checking transmission fluid temperature sensor

Checking shift solenoid S4



- Ignition on
- Gear selector in position P
- Activate solenoid S4.

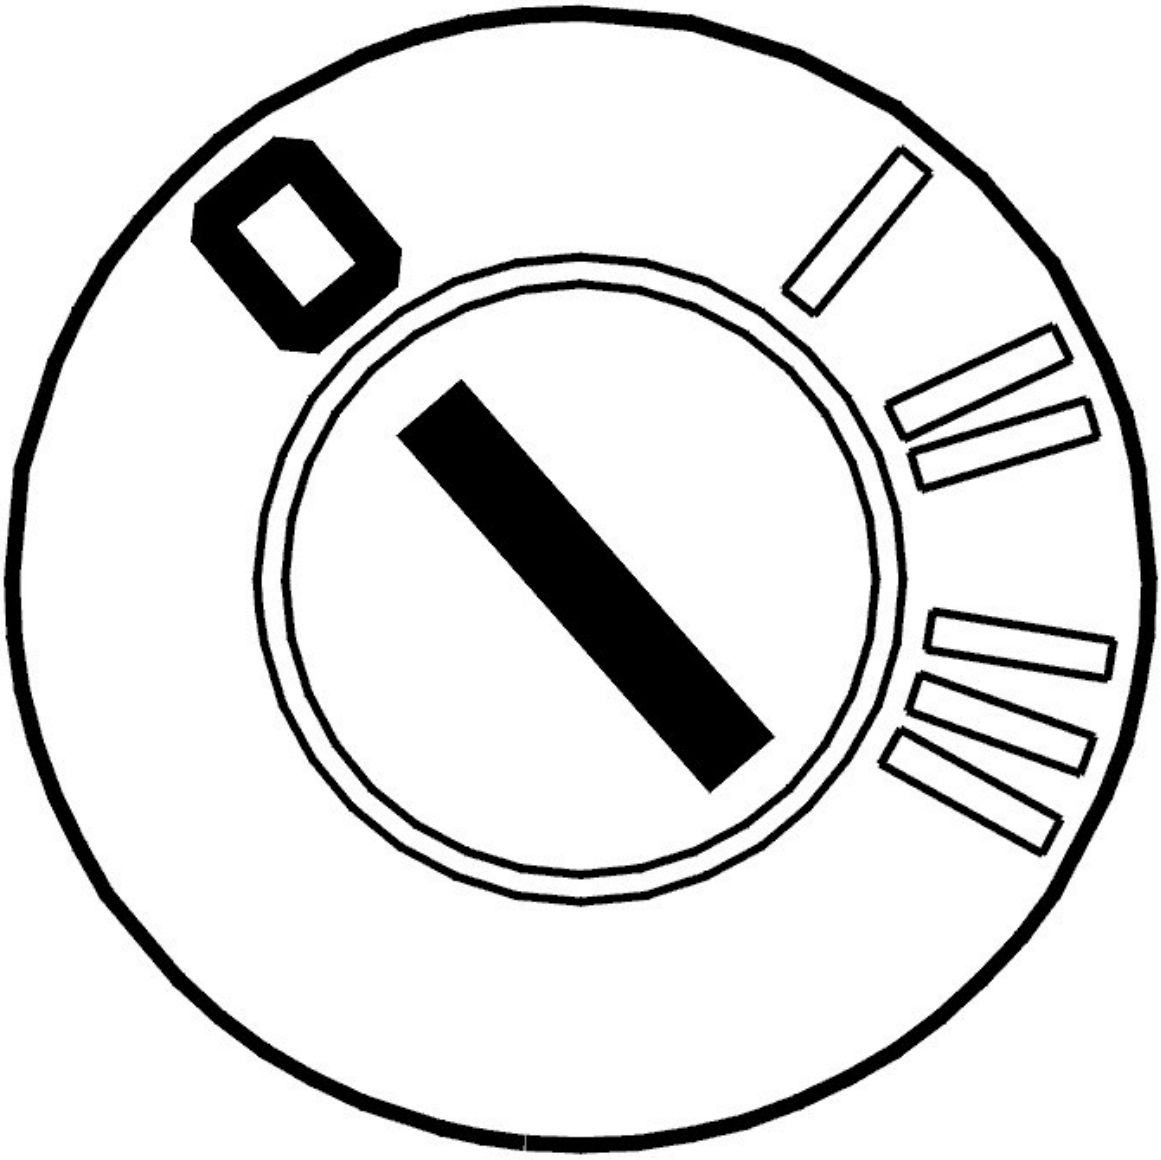
The value must change between OFF and ON.

Does the value change?

Yes - Intermittent fault

No - Checking resistance

Checking resistance

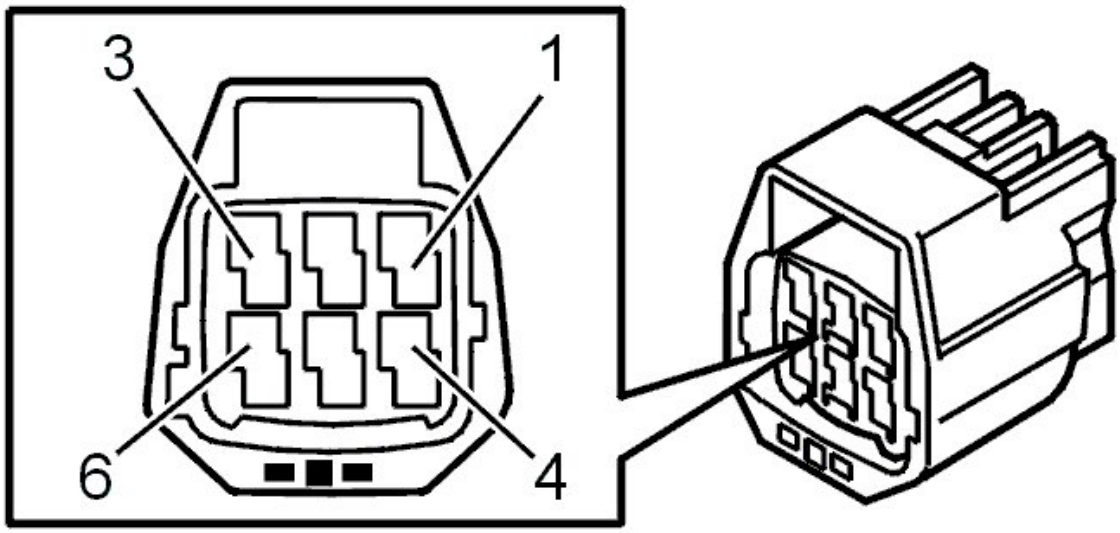


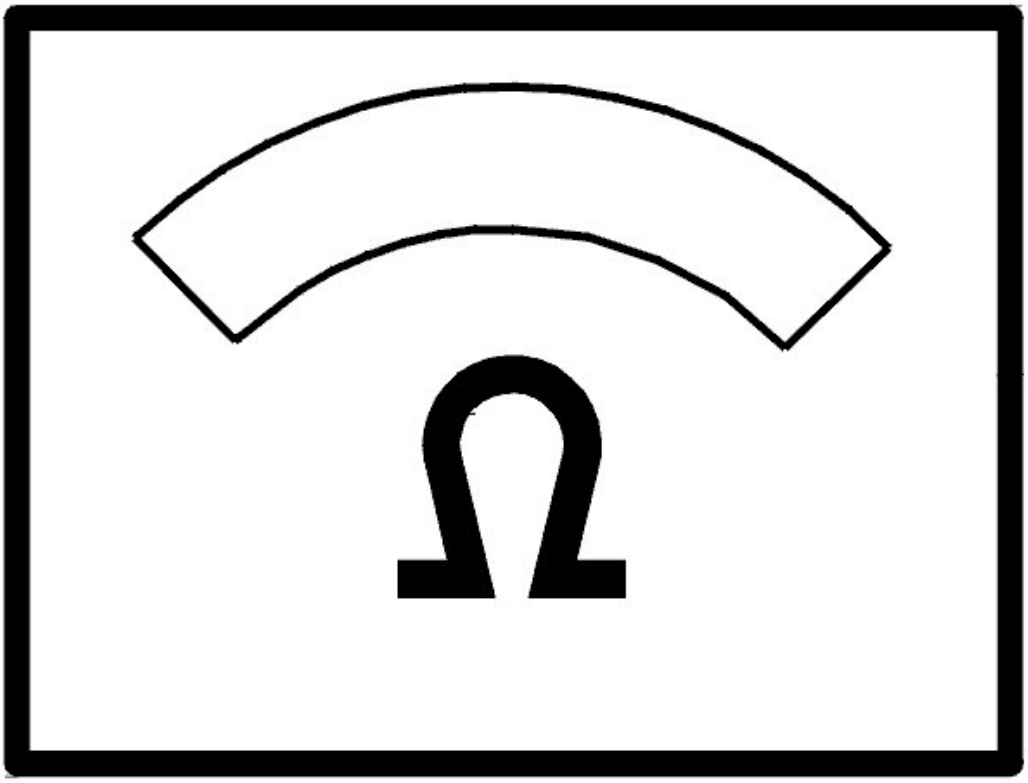
- Ignition off
- Disconnect transmission connector C.

Check solenoid S4 by measuring the resistance between transmission connector terminal #C4 and the transmission housing. The resistance must be 11-15 ohms.

Other information:

- To disconnect the transmission connectors, see Connectors transmission, disconnecting / connecting See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Wiring Harness/Service and Repair/Procedures
- For information about signals, see Signal description. Transmission control module (TCM), AW50/51 AWD, AW55-50/51SN See: Transmission Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Description. Transmission Control Module (TCM).



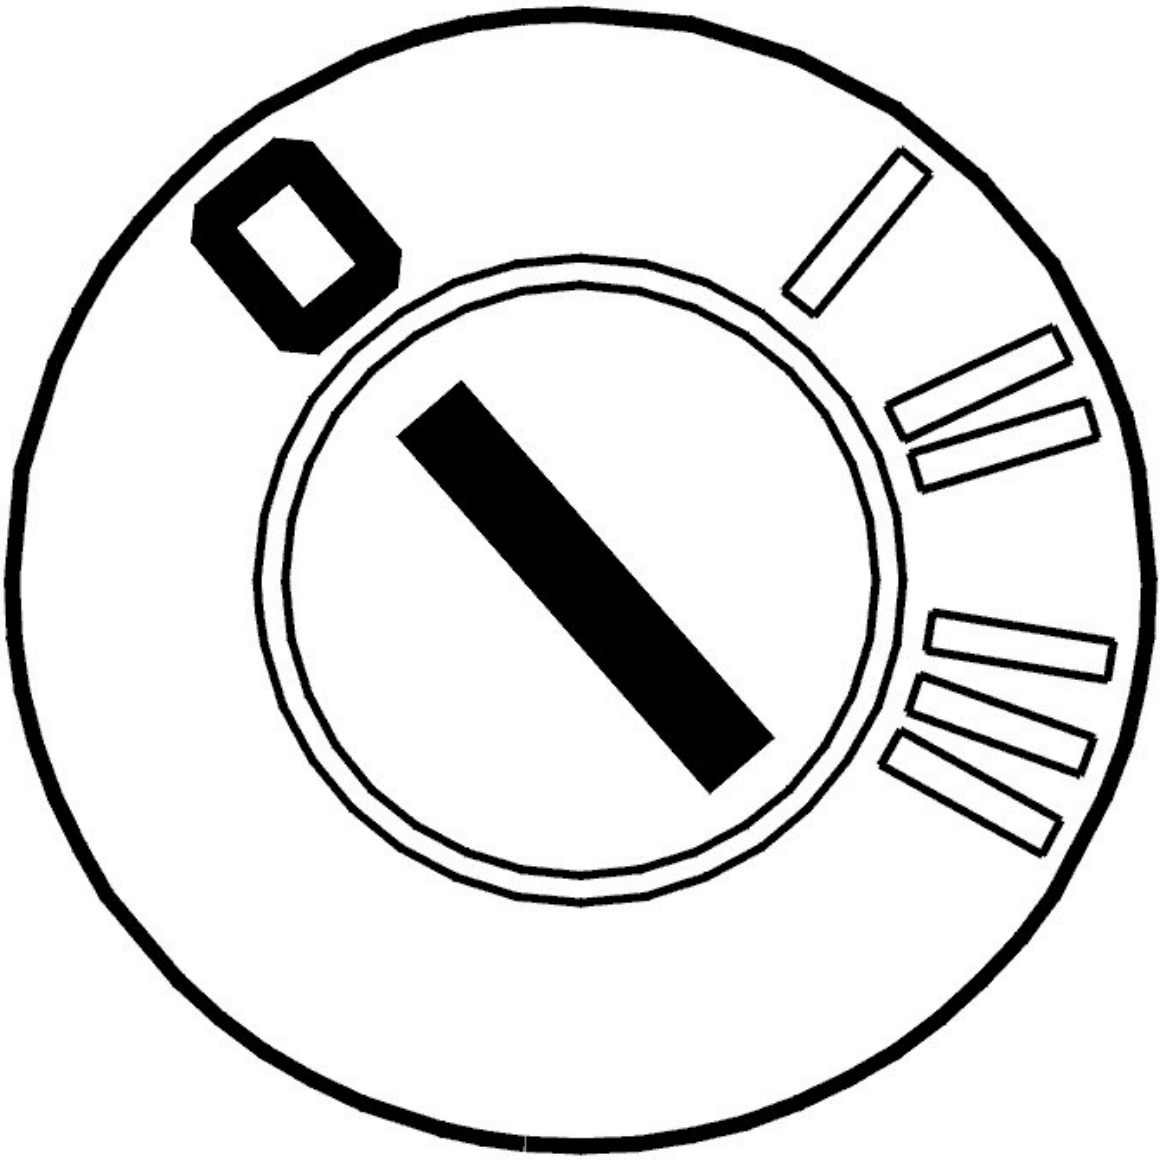


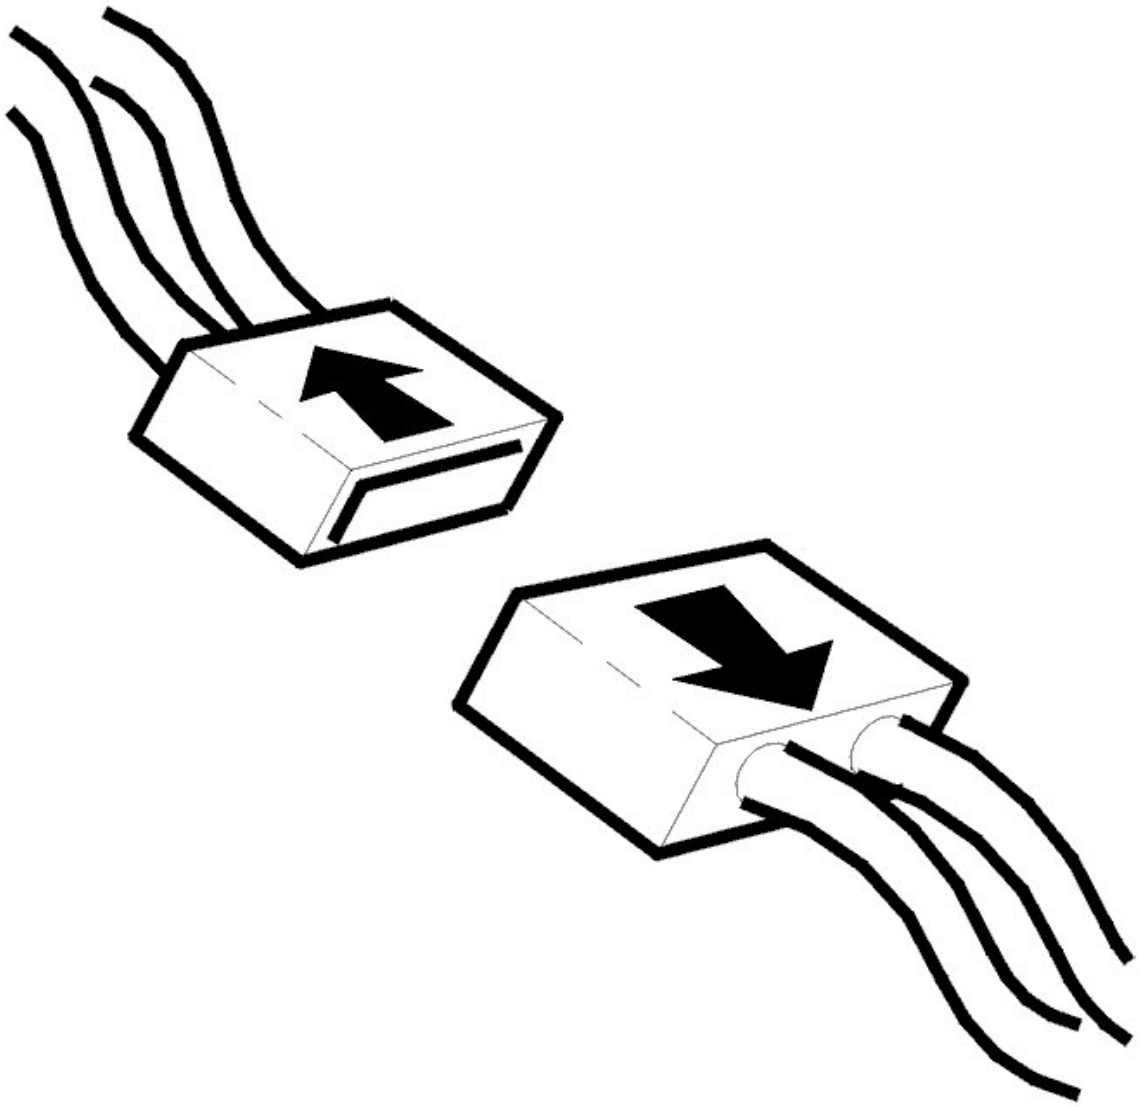
Was the resistance OK

Yes - Checking the wiring

No - Checking the wiring and component

Checking the wiring



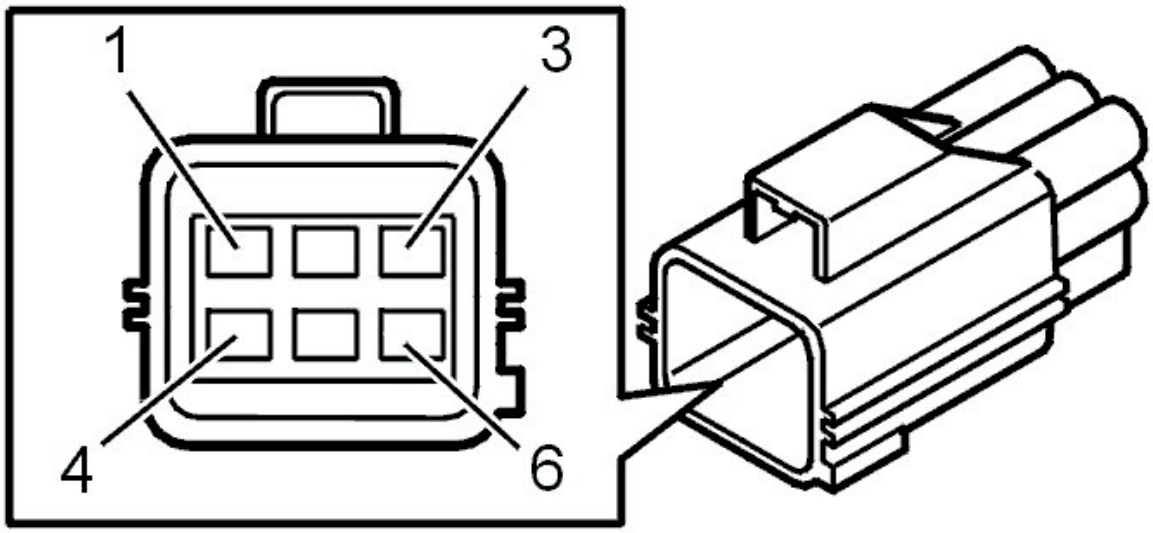


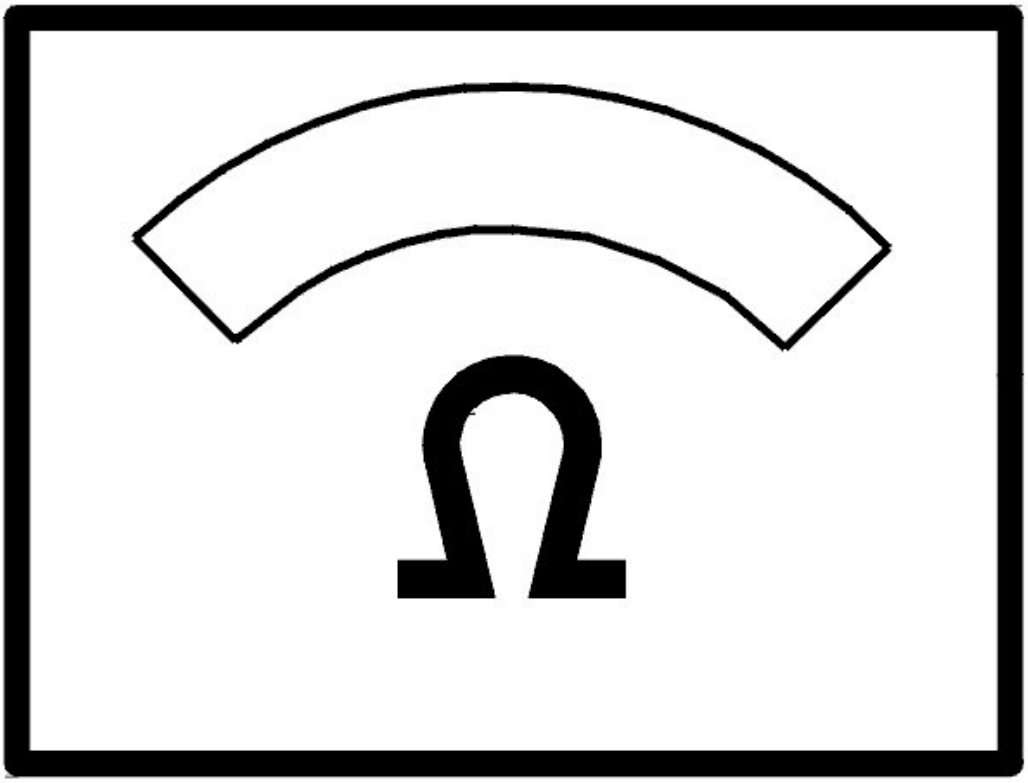
- Ignition off
- The breakout box connected
- Transmission connector C disconnected.

Check the cable between transmission control module (TCM) terminal #A47 (#A47) and transmission connector terminal #C4 (control module side). Check for a short-circuit to ground according to Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault.
Remedy as necessary.

Other information:

- To connect the breakout box, see Connecting the breakout box, B5244T5, B5254T2 See: Pinout Values and Diagnostic Parameters/Connecting the Breakout Box
- To disconnect the transmission connectors, see Connectors transmission, disconnecting / connecting See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Wiring Harness/Service and Repair/Procedures
- For information about signals, see Signal description. Transmission control module (TCM), AW50/51 AWD, AW55-50/51SN See: Transmission Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Description. Transmission Control Module (TCM).



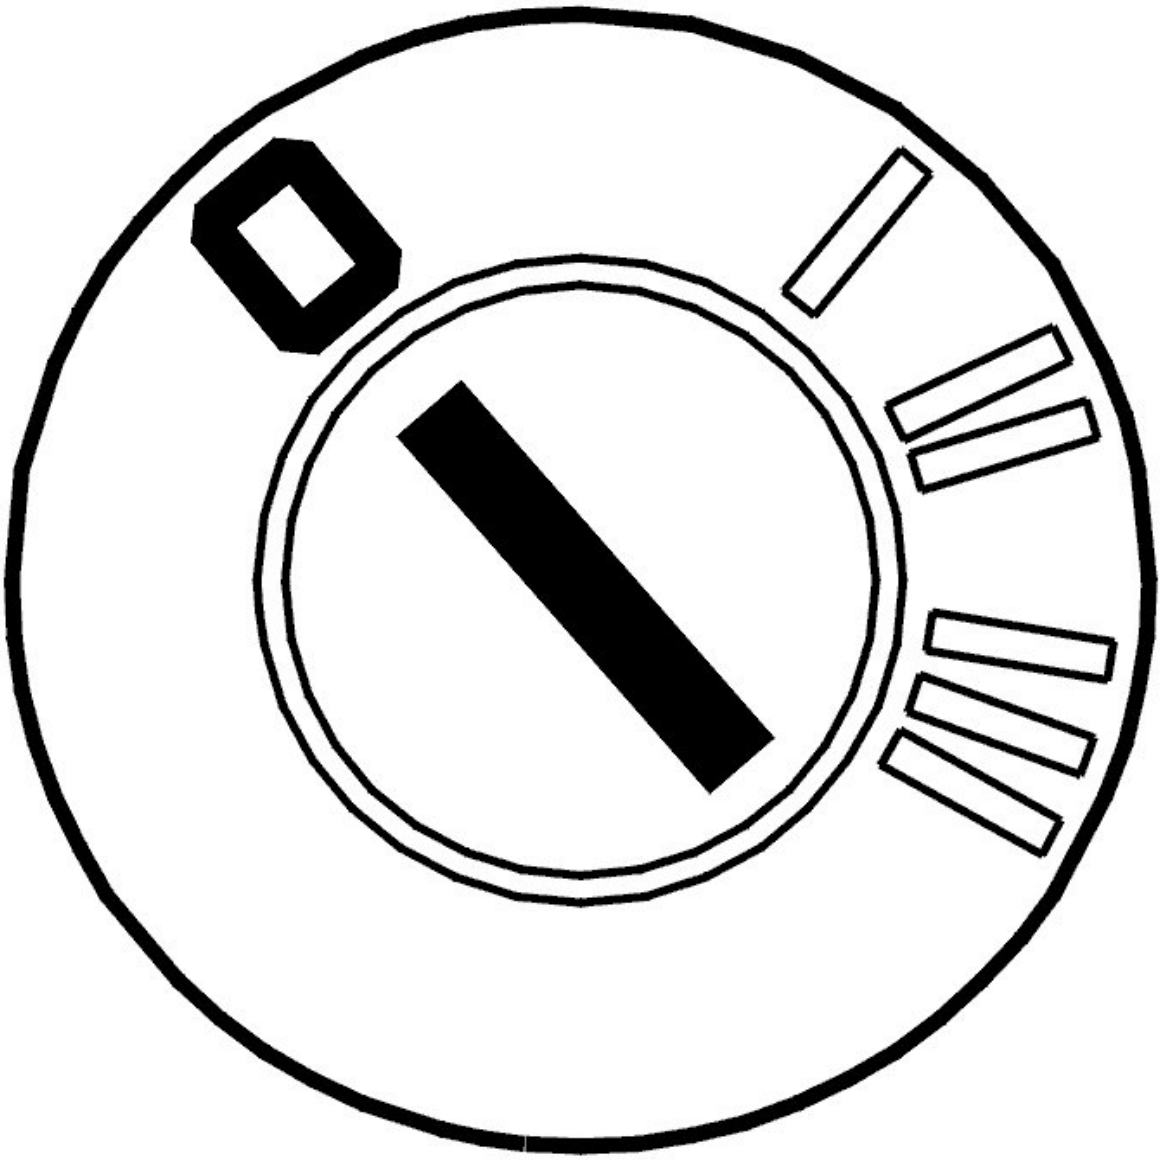


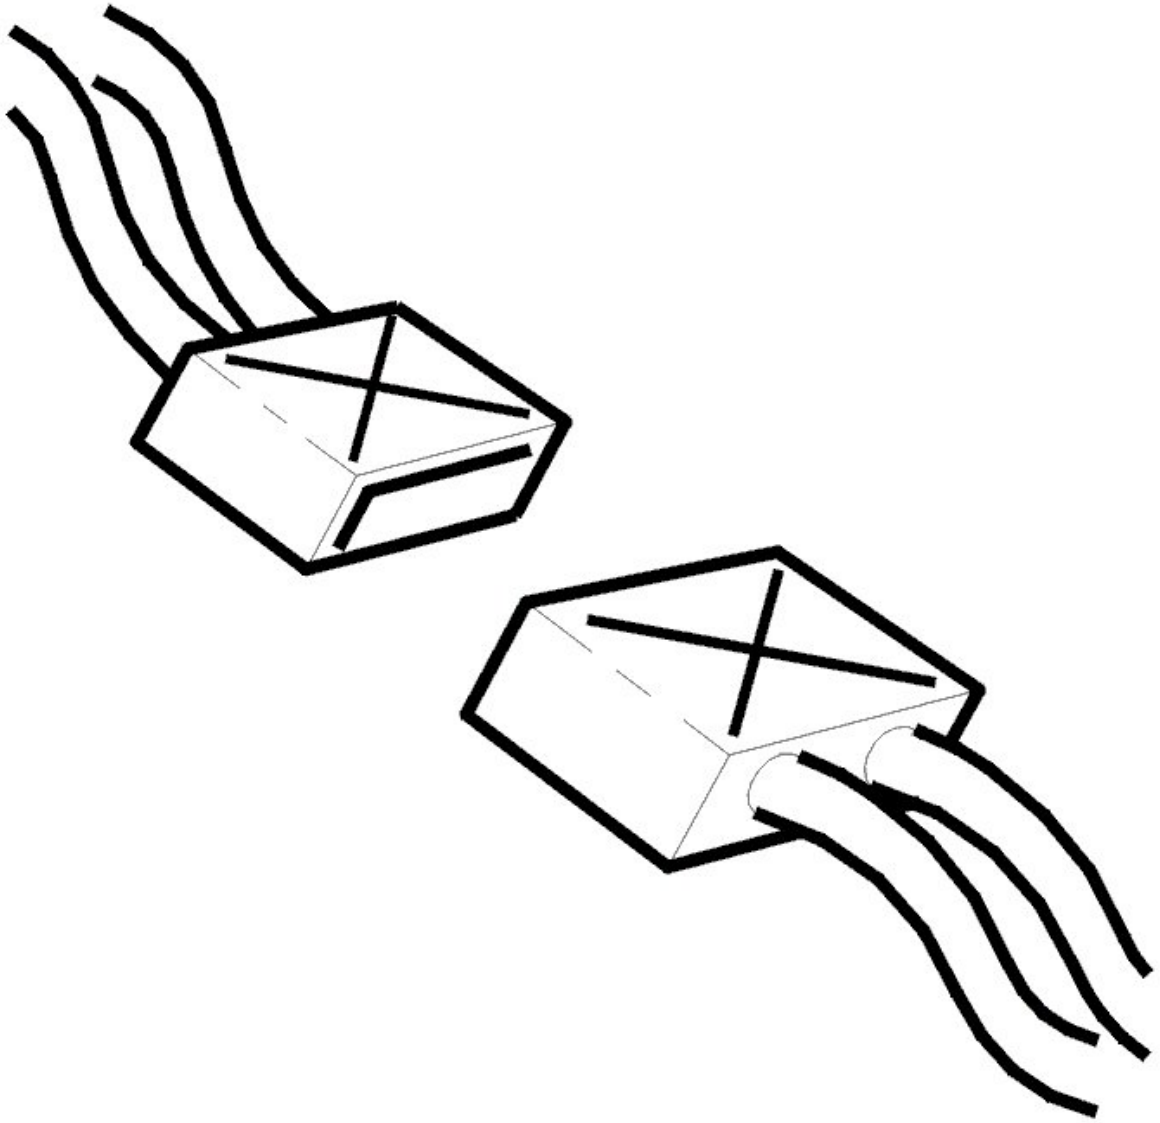
Was a fault detected?

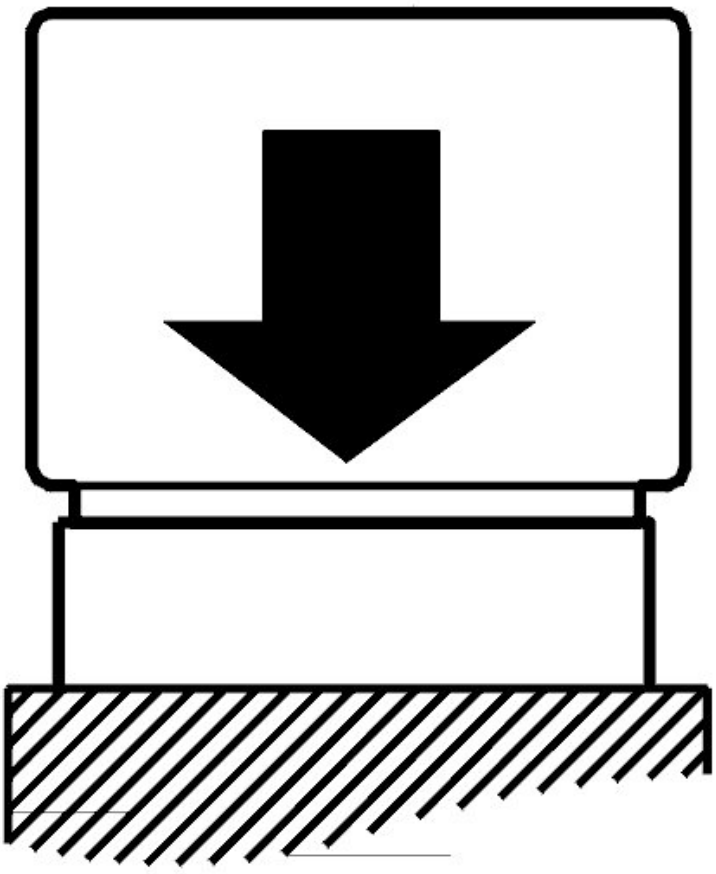
Yes - Verification

No - Checking the control module

Checking the control module







- Ignition off
- The breakout box connected
- Connect the control module.
- Transmission connector disconnected
- Gear selector in position P.

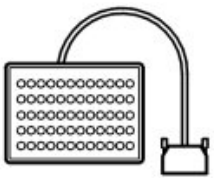
Check the transmission control module (TCM) by measuring the resistance between terminals #A47 (#A47) and #A53 (#A53) on the breakout box. The resistance must be approximately 9 kohms.

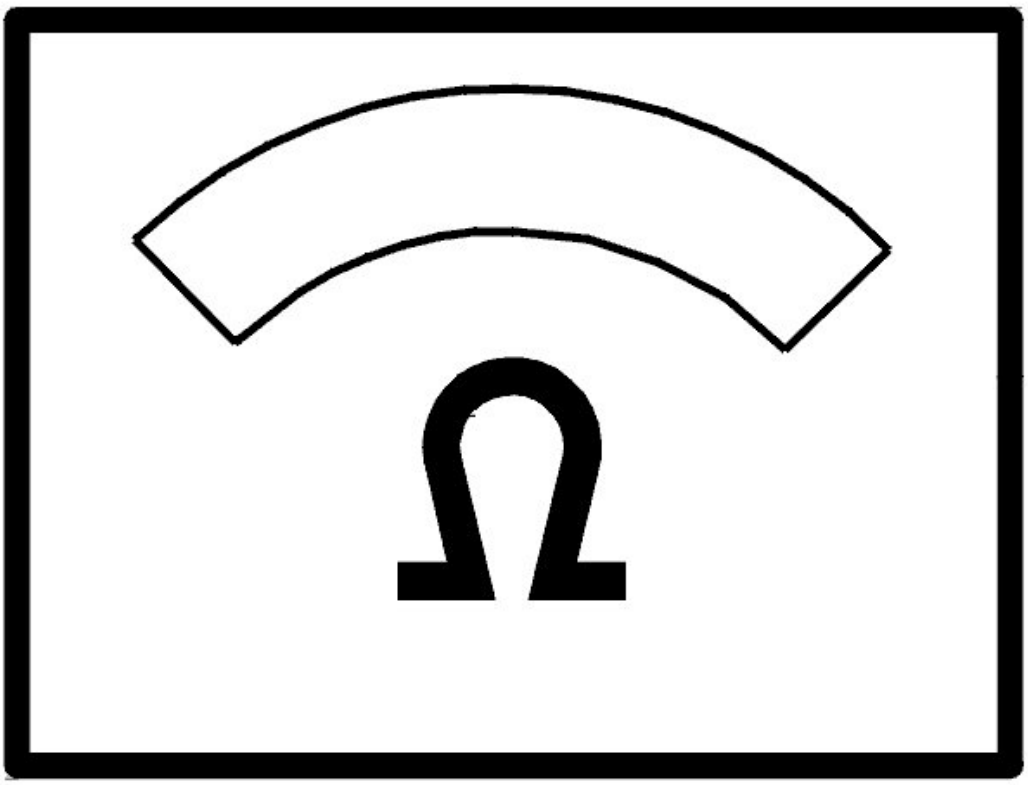
Note! When removing the transmission connector, the control module may store diagnostic trouble codes (DTCs) for the gear-shift position sensor, the shift solenoids, the temperature sensor etc.

Try a new control module if the resistance is infinite.

Other information:

- To disconnect the transmission connectors, see Connectors transmission, disconnecting / connecting See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Wiring Harness/Service and Repair/Procedures
- For information about signals, see Signal description. Transmission control module (TCM), AW50/51 AWD, AW55-50/51SN See: Transmission Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Description. Transmission Control Module (TCM)
- To replace the control module, see Transmission control module (TCM), replacing, B5244T5, AW55-50/51SN, B5254T2, AW55-50/51SN, B5254T2, AW50/51 AWD See: Transmission Control Systems/Relays and Modules - Transmission and Drivetrain/Relays and Modules - A/T/Control Module/Service and Repair.



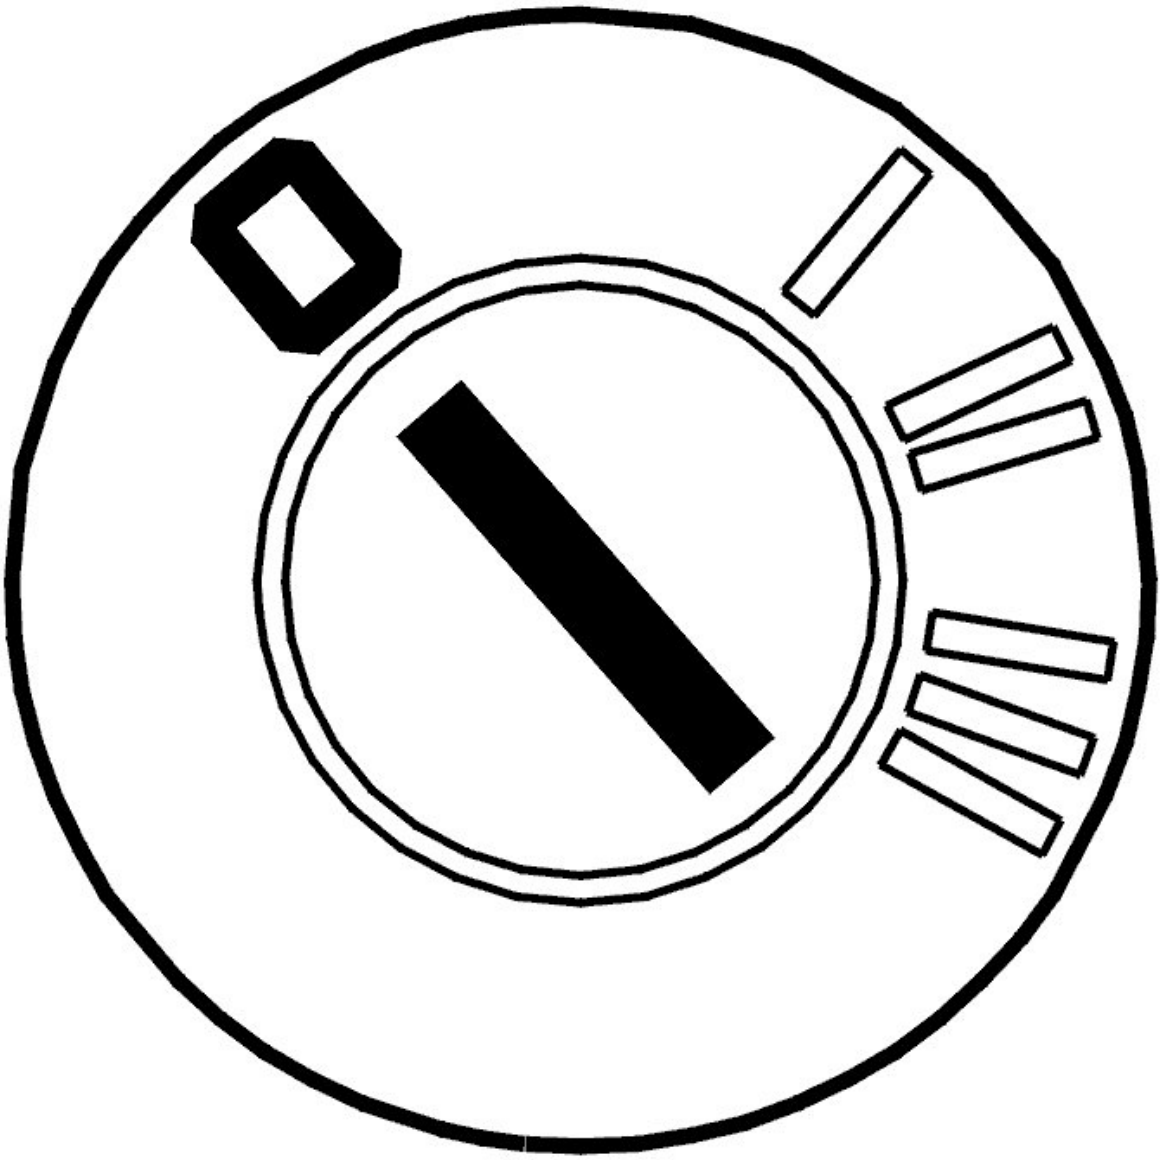


Was the resistance OK?

Yes - No Fault Found

No - Verification

Checking the wiring and component

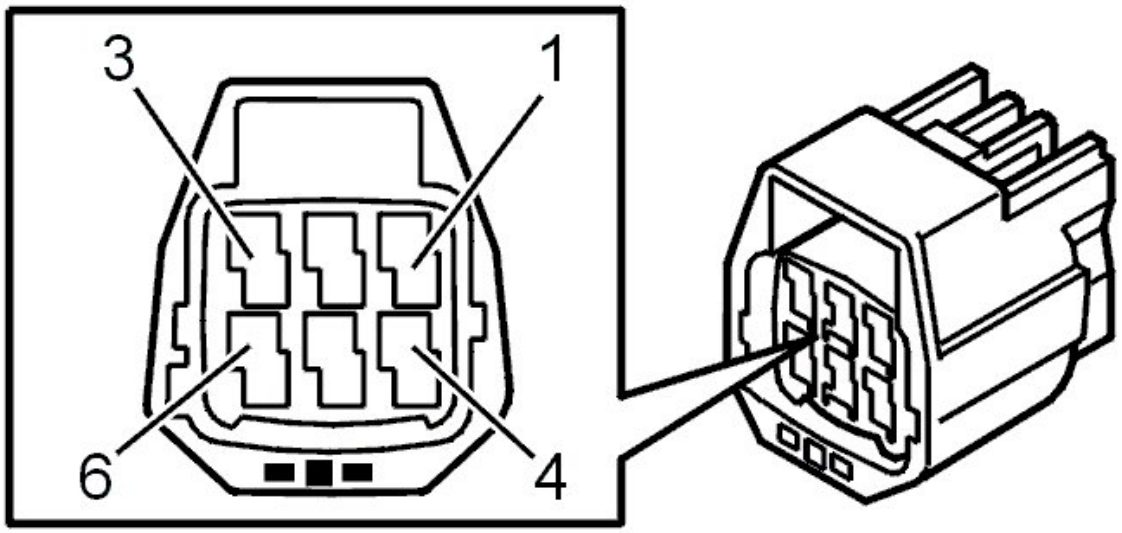


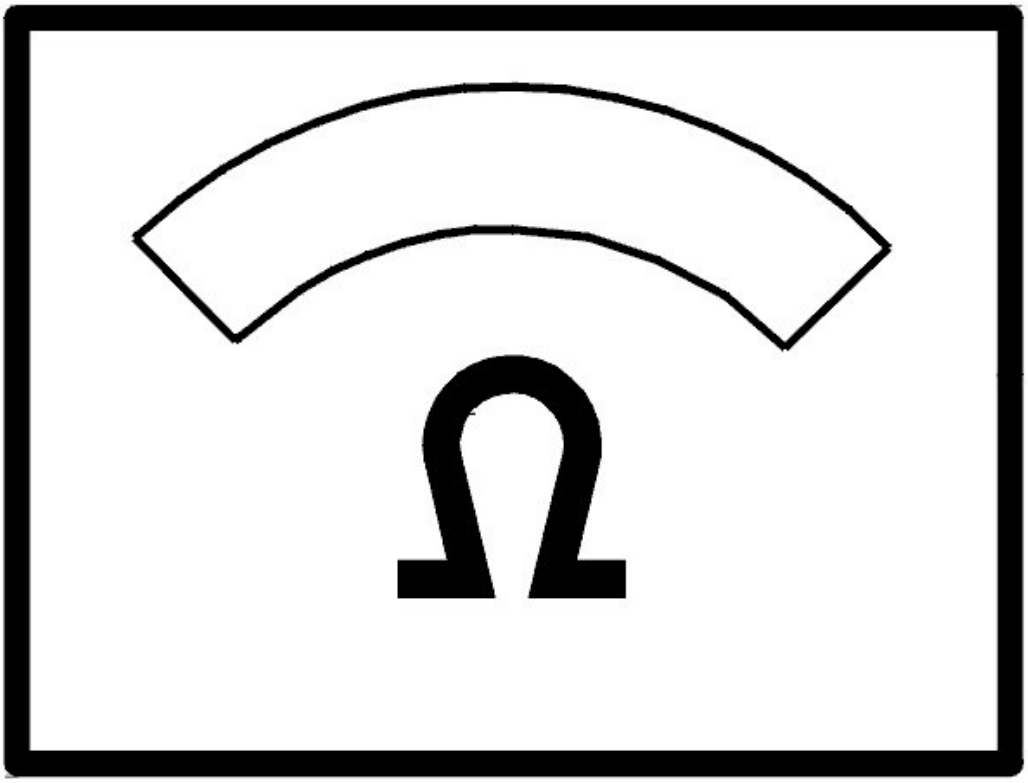
- Ignition off
- Open the transmission control system.

Check the cable between transmission connector terminal #C4 (transmission side) and the connector for solenoid S4. Check for a short-circuit to ground according to Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault.
Check solenoid S4 by measuring the resistance between the terminal pin on solenoid S4 and the transmission housing. The resistance must be 11-15 ohms. Replace solenoid S4 if the resistance is incorrect.
Remedy as necessary.

Other information:

- To disconnect the transmission connectors, see Connectors transmission, disconnecting / connecting See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Wiring Harness/Service and Repair/Procedures
- To open the control system and to check or replace solenoid S4, see Solenoid control system, replacing See: Transmission Control Systems/Actuators and Solenoids - Transmission and Drivetrain/Actuators and Solenoids - A/T/Shift Solenoid/Service and Repair/Solenoid Control System, Replacing
- To replace the cable harness for the control system, see Wiring harness / oil temperature sensor, replacing See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Wiring Harness/Service and Repair/Removal and Replacement
- For information about signals, see Signal description. Transmission control module (TCM), AW50/51 AWD, AW55-50/51SN See: Transmission Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Description. Transmission Control Module (TCM).





Select Continue when the fault has been remedied.

Continue - Resetting the adaptation and oil quality counter

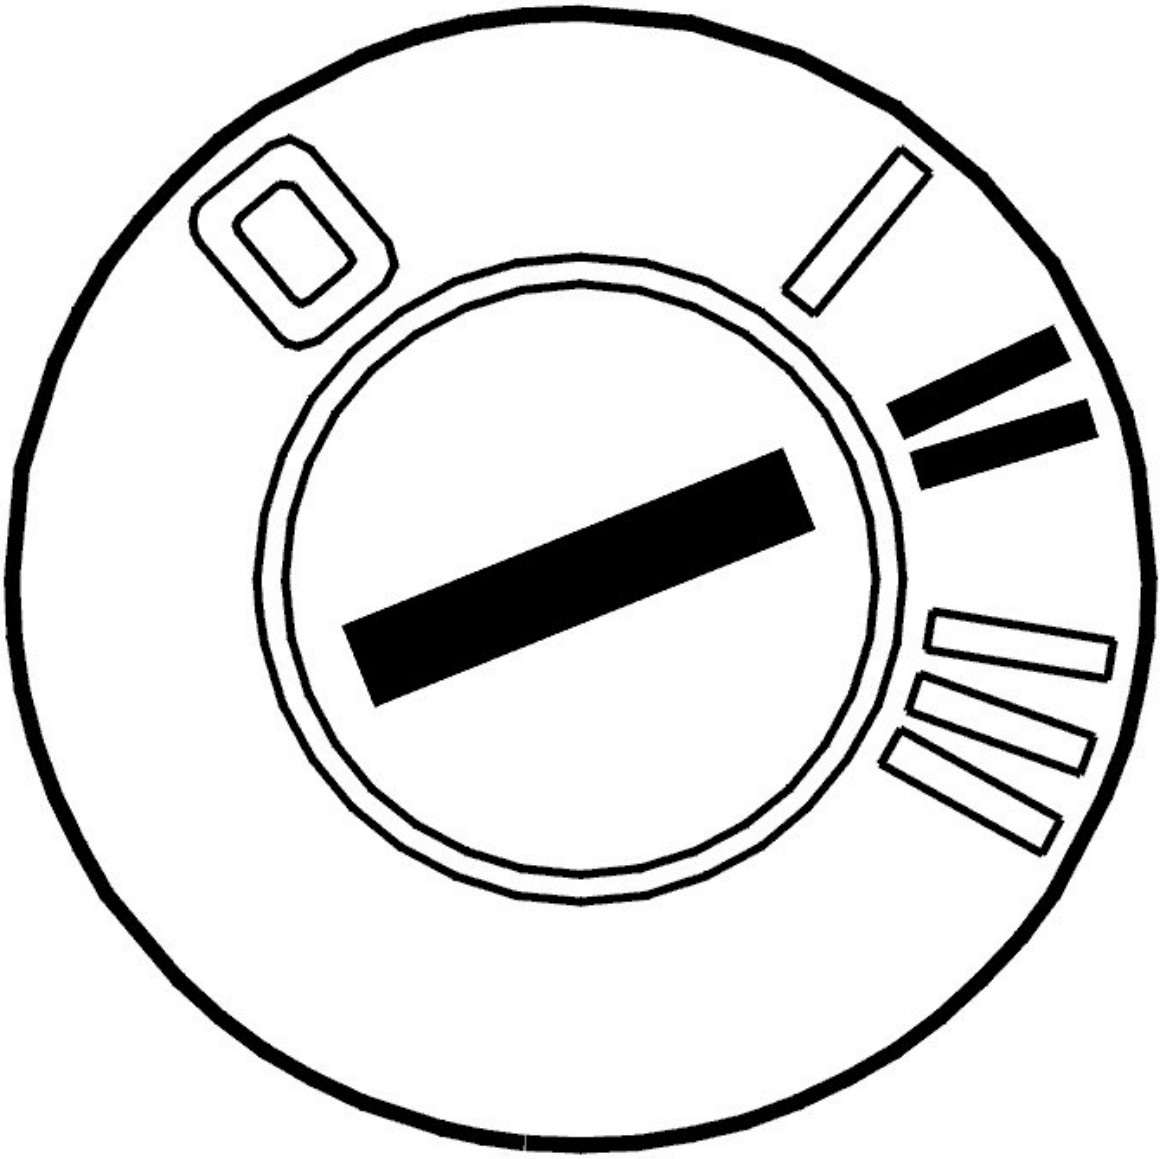
Resetting the adaptation and oil quality counter

Resetting the adaptation

Resetting adaptation and the counter for "Transmission oil change"

Hint: The transmission has torque controlled adaptive pressure control. Pressure control means that the transmission regulates the pressure itself during each gear shift. This avoids harsh gear shifting. Each gear shift is evaluated by the control module and stored in the memory. This allows for compensation for wear and tear in the transmission and clutch. It is important that the adaptation in the memory is reset after the transmission has been repaired. This is to ensure normal operation. The oil is replaced during repair; the "Transmission oil change" counter must be reset. If the counter is not reset when the fluid is drained and replaced, there is a risk that a diagnostic trouble code (DTC) will be stored in incorrect circumstances.

Note! This applies only if the transmission or one of the components in the transmission have been replaced.



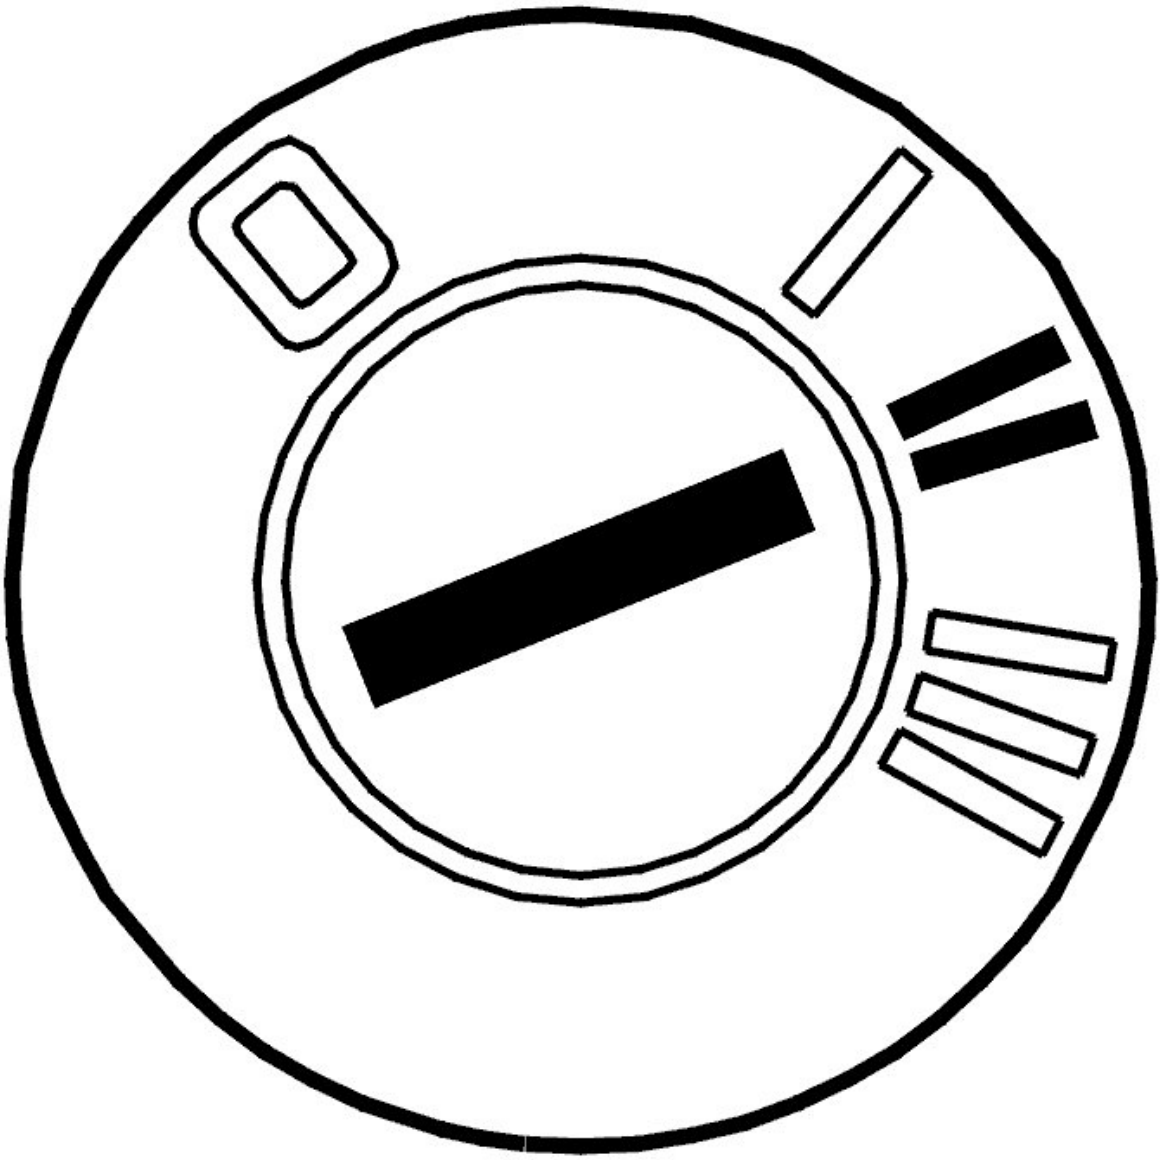
- Ignition on.

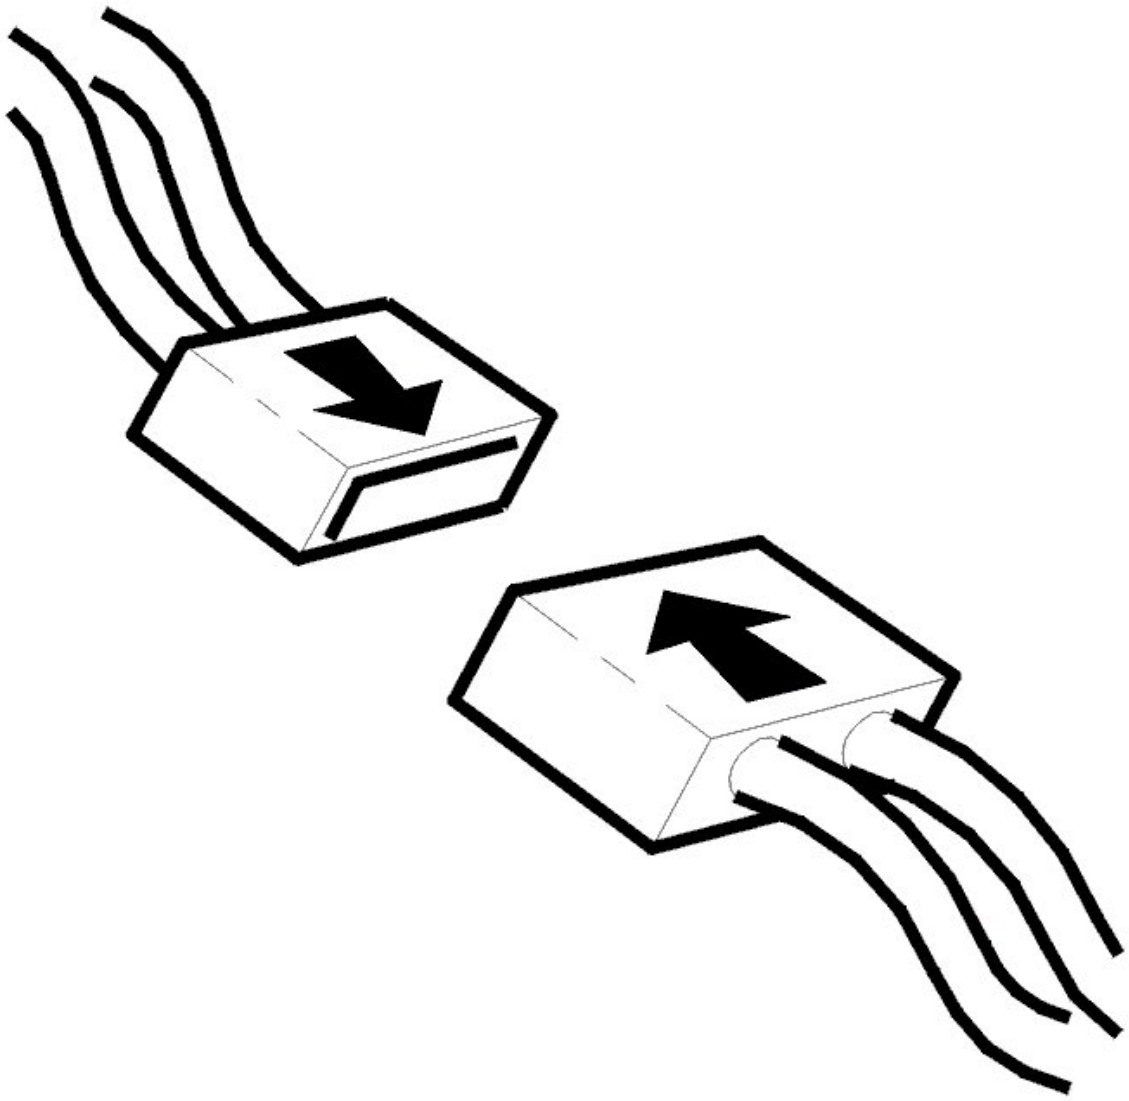
Click on the VCT2000 symbol to reset the adaptation and counter.

Continue - Verification

Verification

Hint: After carrying out the repair, check that the fault has been remedied.





- Ignition off.
- Reinstall the components, reconnect the connectors etc.
- Ignition on.
- Gear selector in position P.
- Activate solenoid S4.

The value should change between OFF and ON.

Does the value change between OFF and ON?

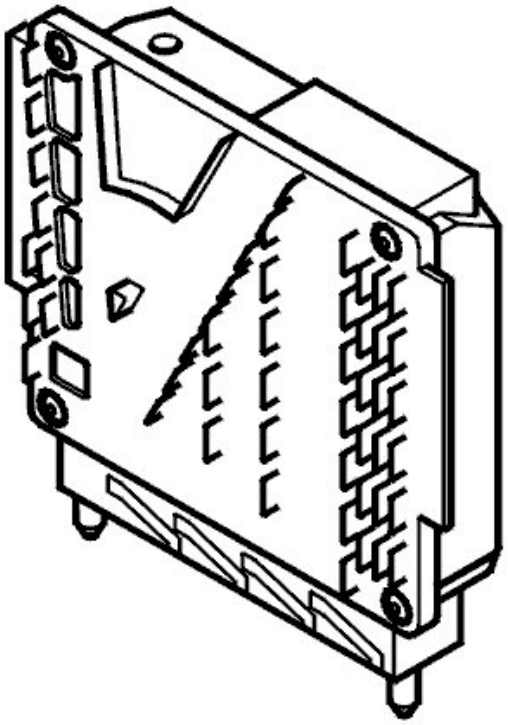
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition



Shift solenoids S1, S2, S3, S4 and S5 operate in tandem to control gear-shifting. The solenoids are controlled by power stages in the transmission control module (TCM). The transmission control module (TCM) opens the power stages to activate the solenoids and sends a voltage through the circuit. Diagnostic trouble codes (DTCs) TCM-0001, TCM-0007, TCM-0101 TCM-0107 or TCM-010A are stored (depending on the solenoid)if the transmission control module (TCM) registers that the signal in circuits S1, S2, S3, S4 or S5 is too high when the solenoid should not be activated.

Substitute value
- The transmission control module (TCM) "Emergency mode I" program has been initiated.

Possible source
- Short-circuit to supply voltage in the signal cable.
- Internal fault in the control module.

Fault symptom[s]
- General orange warning lamp lit.
- Malfunction indicator lamp (MIL) lit.
- Harsh gear shifting.
- No shifting.
- No lock-up function.

Signal Too High

Signal too high

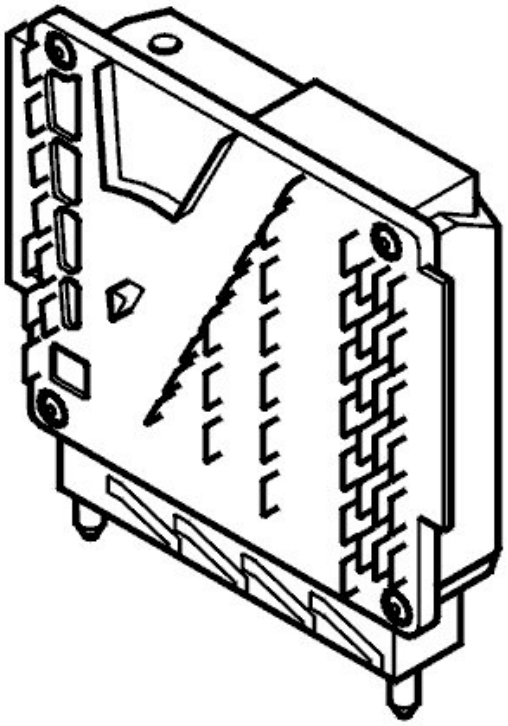
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

Condition



Shift solenoids S1, S2, S3, S4 and S5 operate in tandem to control gear-shifting. The solenoids are controlled by power stages in the transmission control module (TCM). The transmission control module (TCM) opens the power stages to activate the solenoids and sends a voltage through the circuit. Diagnostic trouble codes (DTCs) TCM-0002, TCM-0008, TCM-0102, TCM-0108 or TCM-010B are stored (depending on the solenoid) if the transmission control module (TCM) registers that the signal in circuits S1, S2, S3, S4 or S5 is missing when the solenoid is activated.

Substitute value
- The transmission control module (TCM) "Emergency mode I" program has been initiated.

Possible source
- Contact resistance in terminals.
- Open-circuit in the signal cable.
- Defective solenoid.
- Internal fault in the control module.

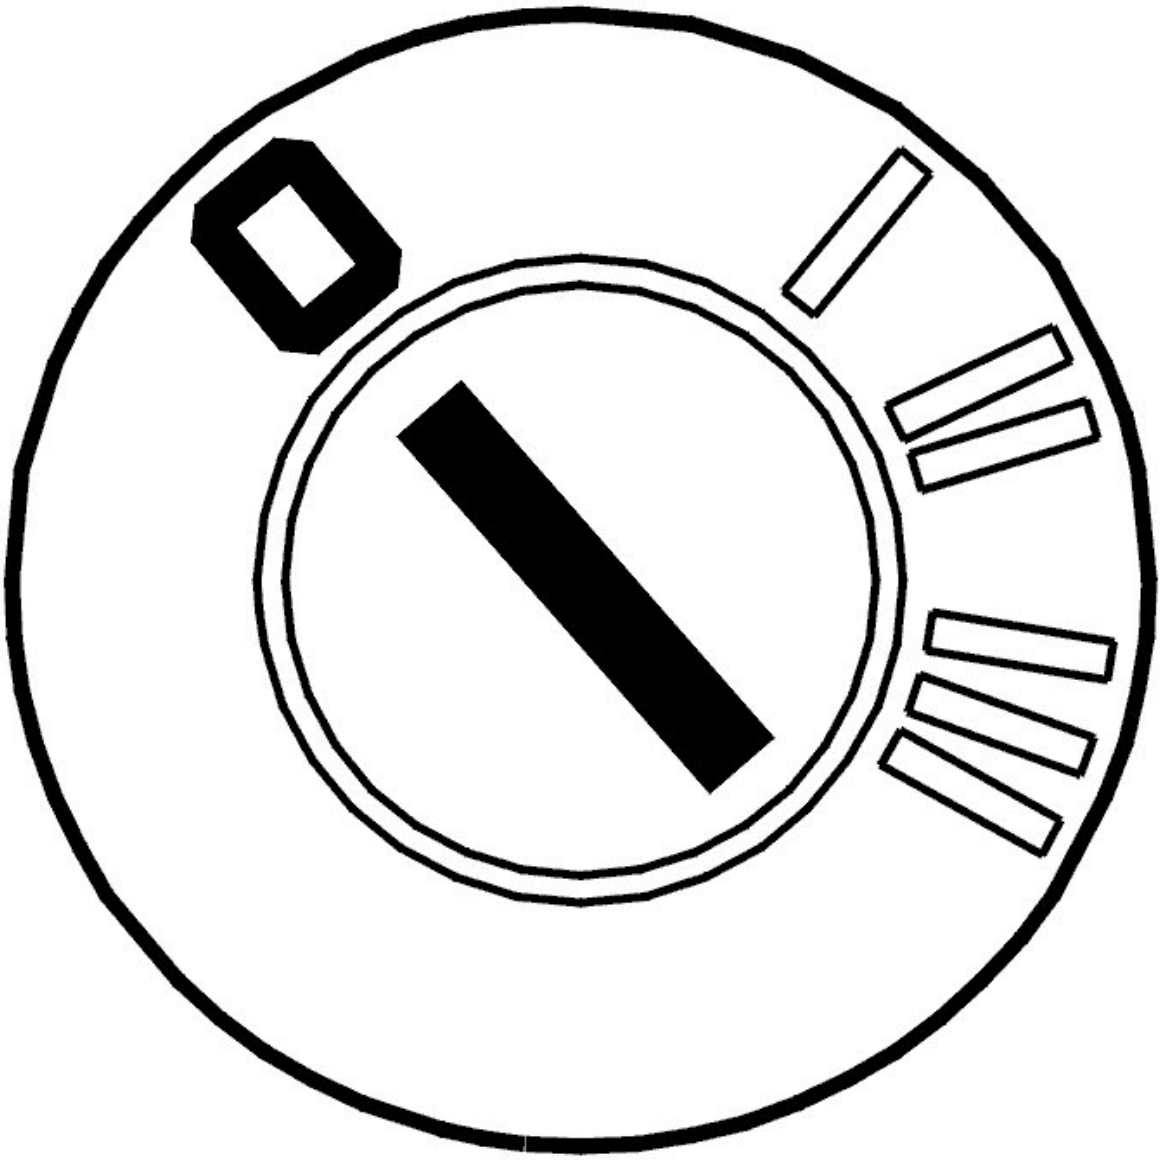
Fault symptom[s]
- General orange warning lamp lit.
- Malfunction indicator lamp (MIL) lit.
- Harsh gear shifting.
- No shifting.
- No lock-up function.

Signal Missing

Signal missing

Checking the temperature sensor

Hint: In some cases, the diagnostic trouble code (DTC) may be caused by a defective oil temperature sensor. Check the function of the oil temperature sensor first.



- Ignition off
- Read off the oil temperature.

Check that the function of the temperature sensor is OK. Test drive the car to increase the temperature of the transmission fluid. Read off the temperature again. Check that the temperature has increased.

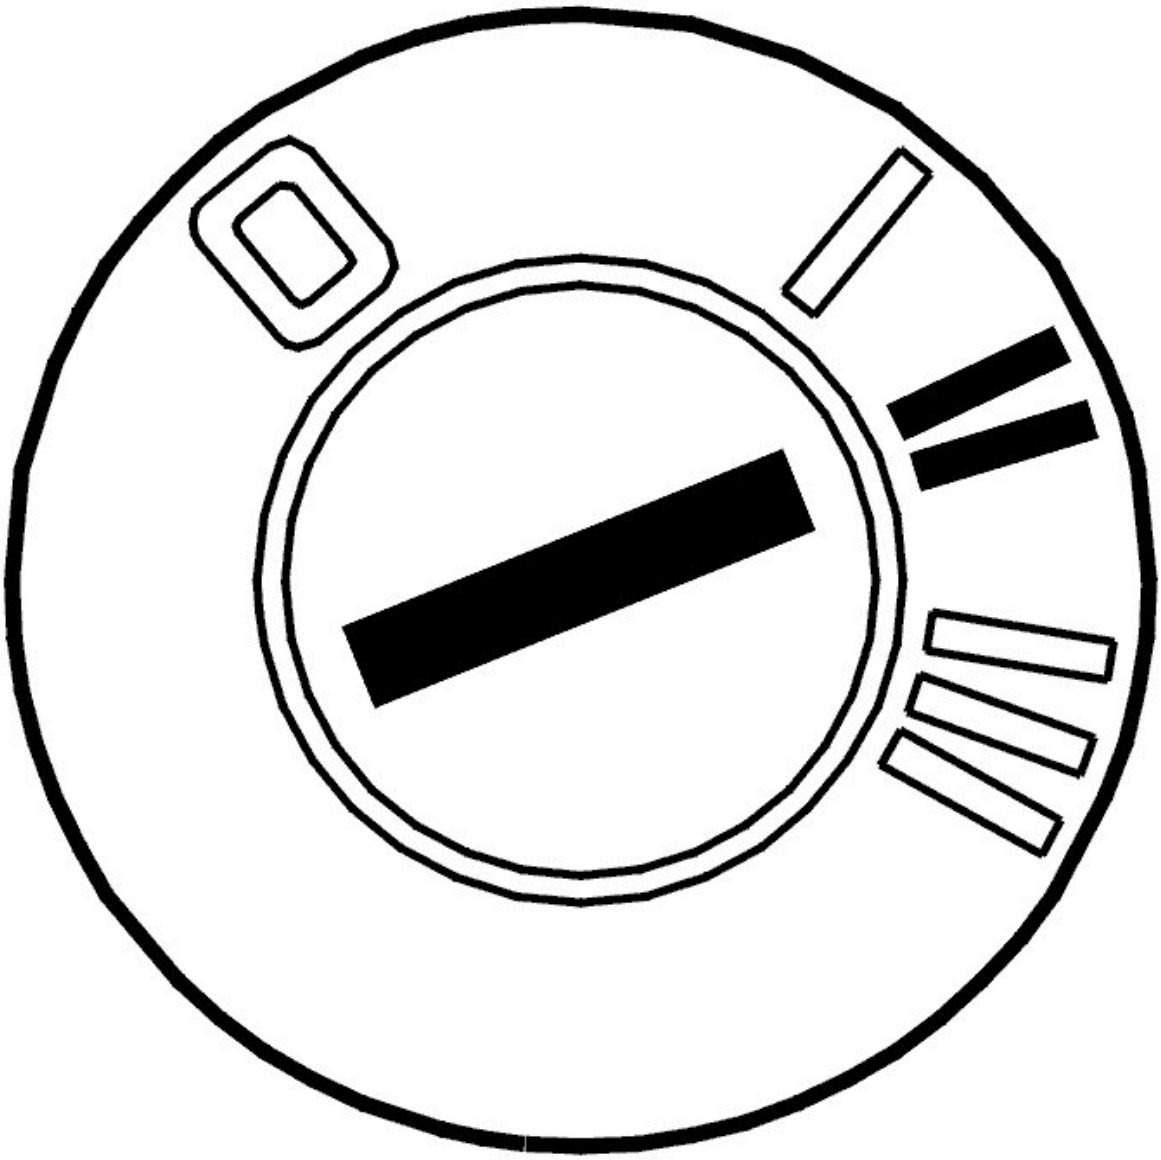
Hint: If the temperature is outside its permitted range, fault-trace the temperature sensor.

Is the oil temperature within its permitted range?

Yes - Checking shift solenoid S5

No - Checking transmission fluid temperature sensor

Checking shift solenoid S5



- Ignition on
- Gear selector in position P
- Activate solenoid S5.

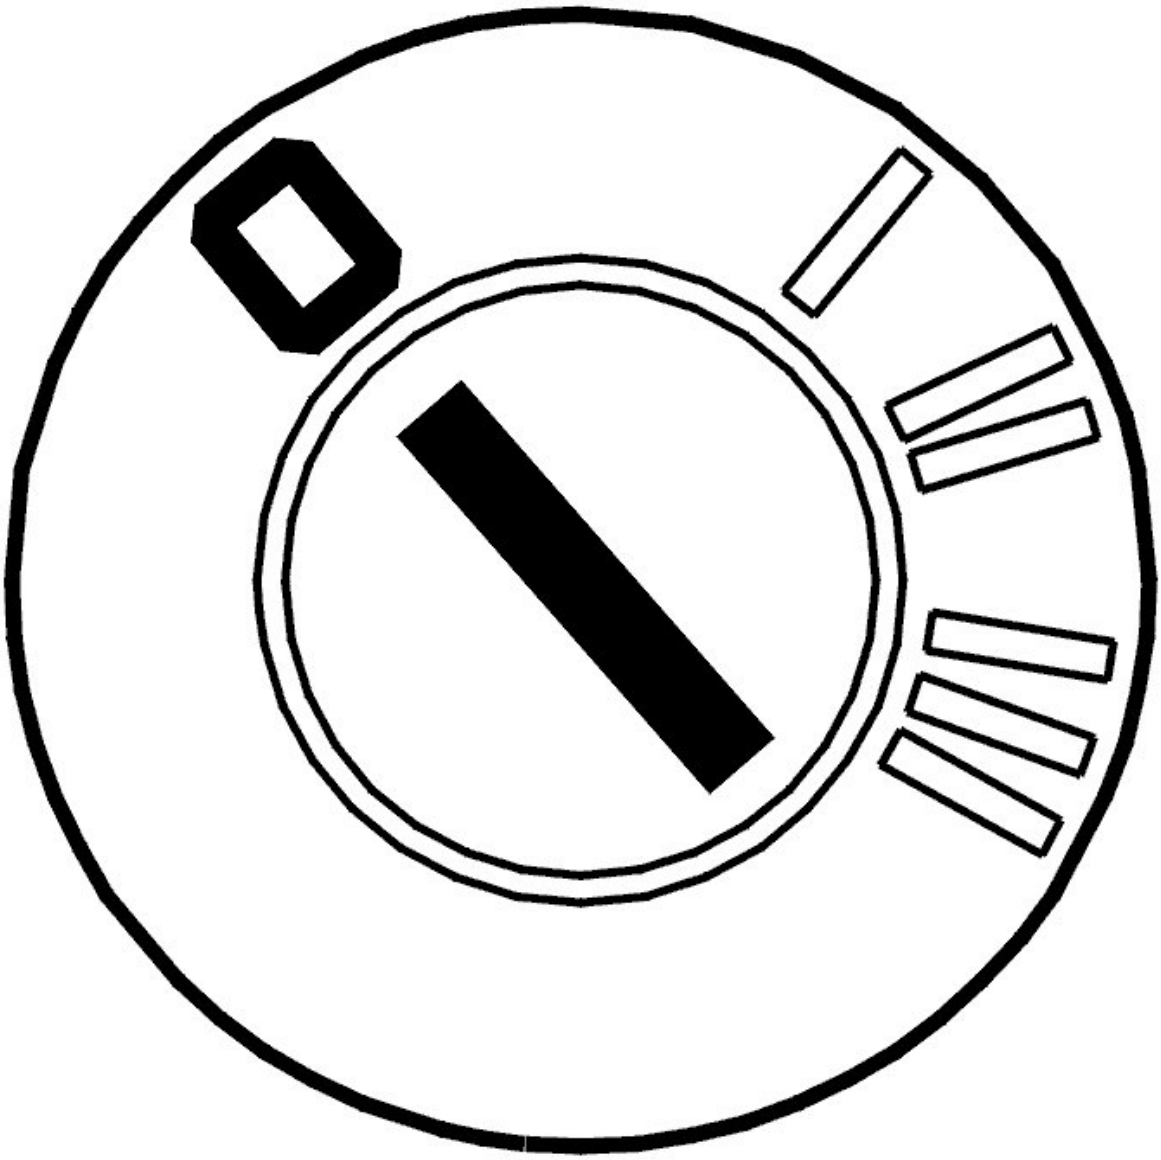
The current should oscillate between 0 and approximately 1.5 A.

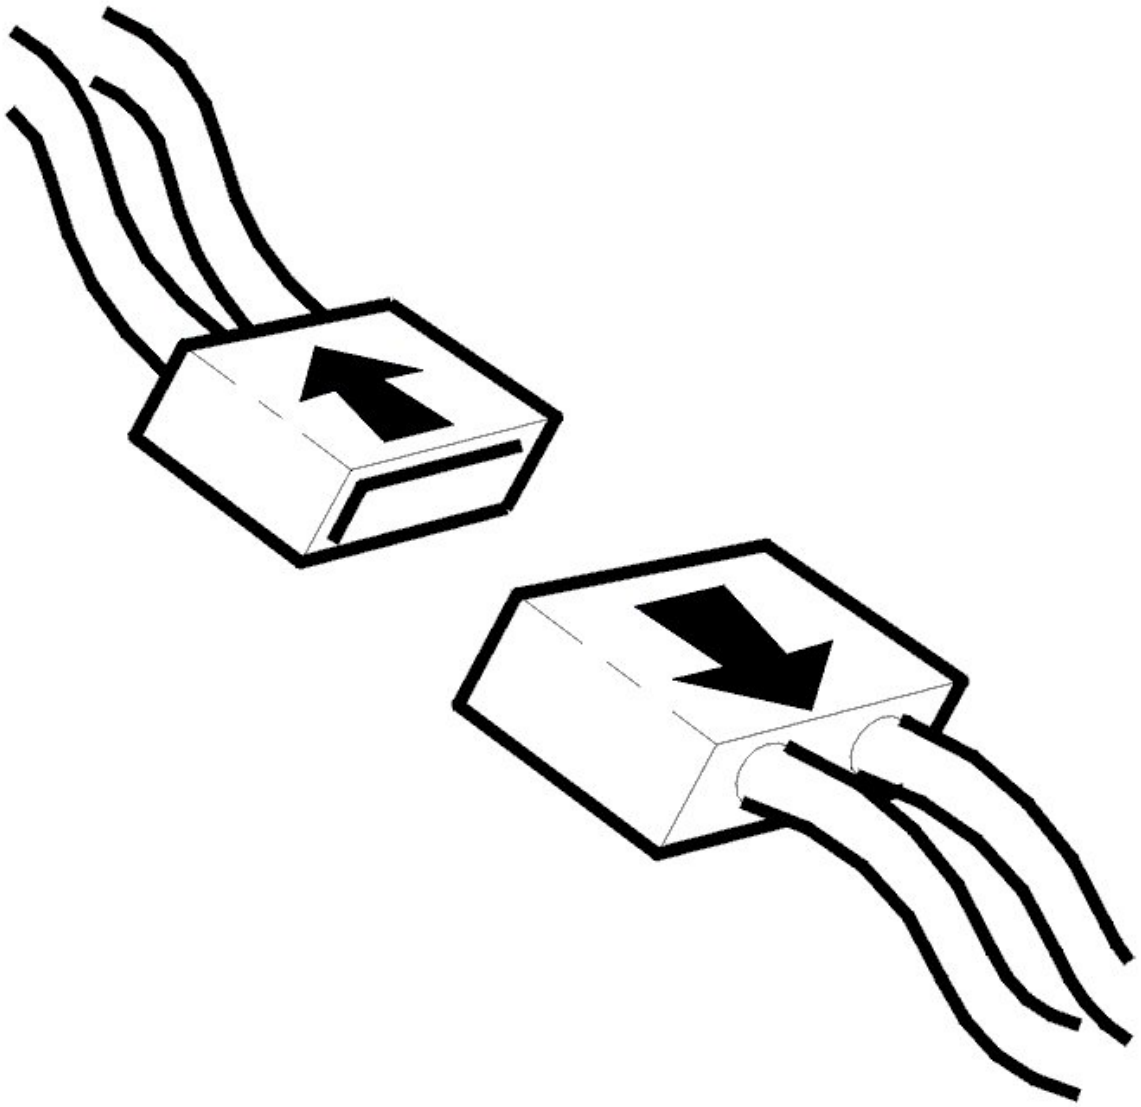
Does the current oscillate?

Yes - Intermittent fault

No - Checking resistance

Checking resistance



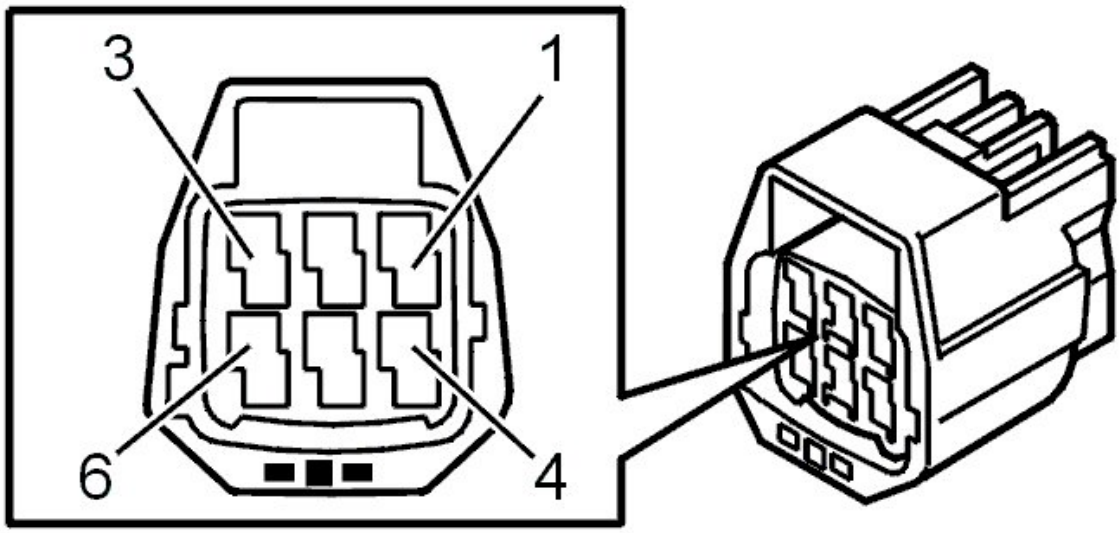


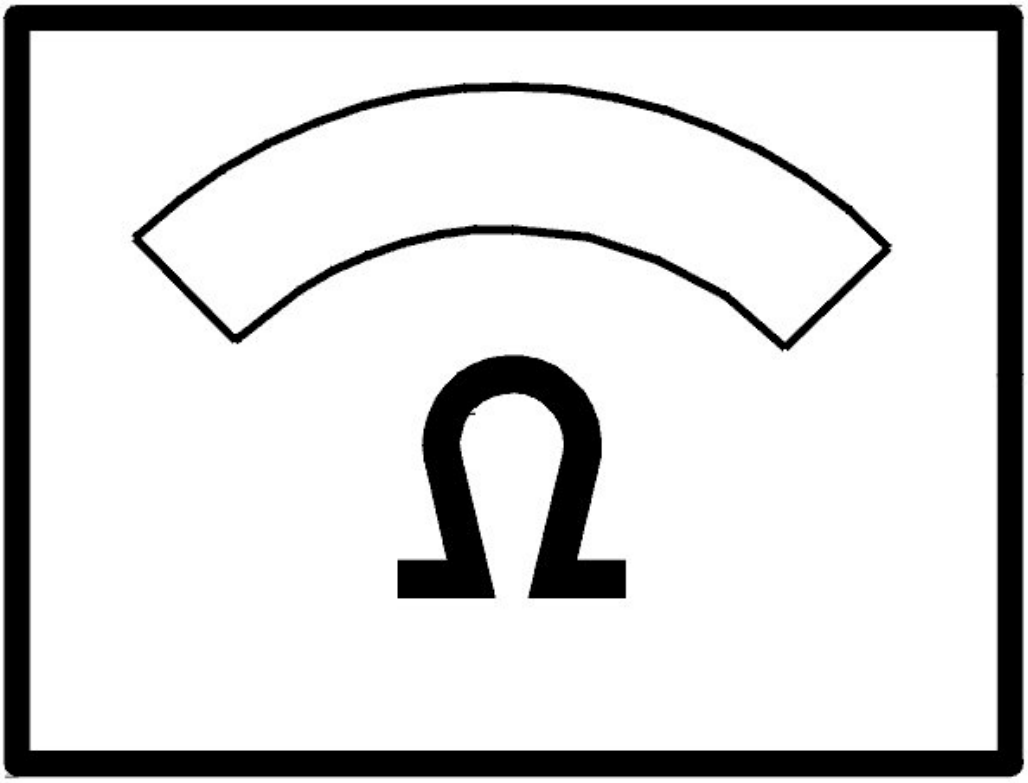
- Ignition off
- Disconnect transmission connector C.

Check solenoid S5. Measure the resistance between transmission connector terminal #C5 (transmission side) and the transmission housing. The resistance must be 11-15 ohms.

Other information:

- To disconnect the transmission connectors, see Connectors transmission, disconnecting / connecting See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Wiring Harness/Service and Repair/Procedures
- For information about signals, see Signal description. Transmission control module (TCM), AW50/51 AWD, AW55-50/51SN See: Transmission Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Description. Transmission Control Module (TCM).



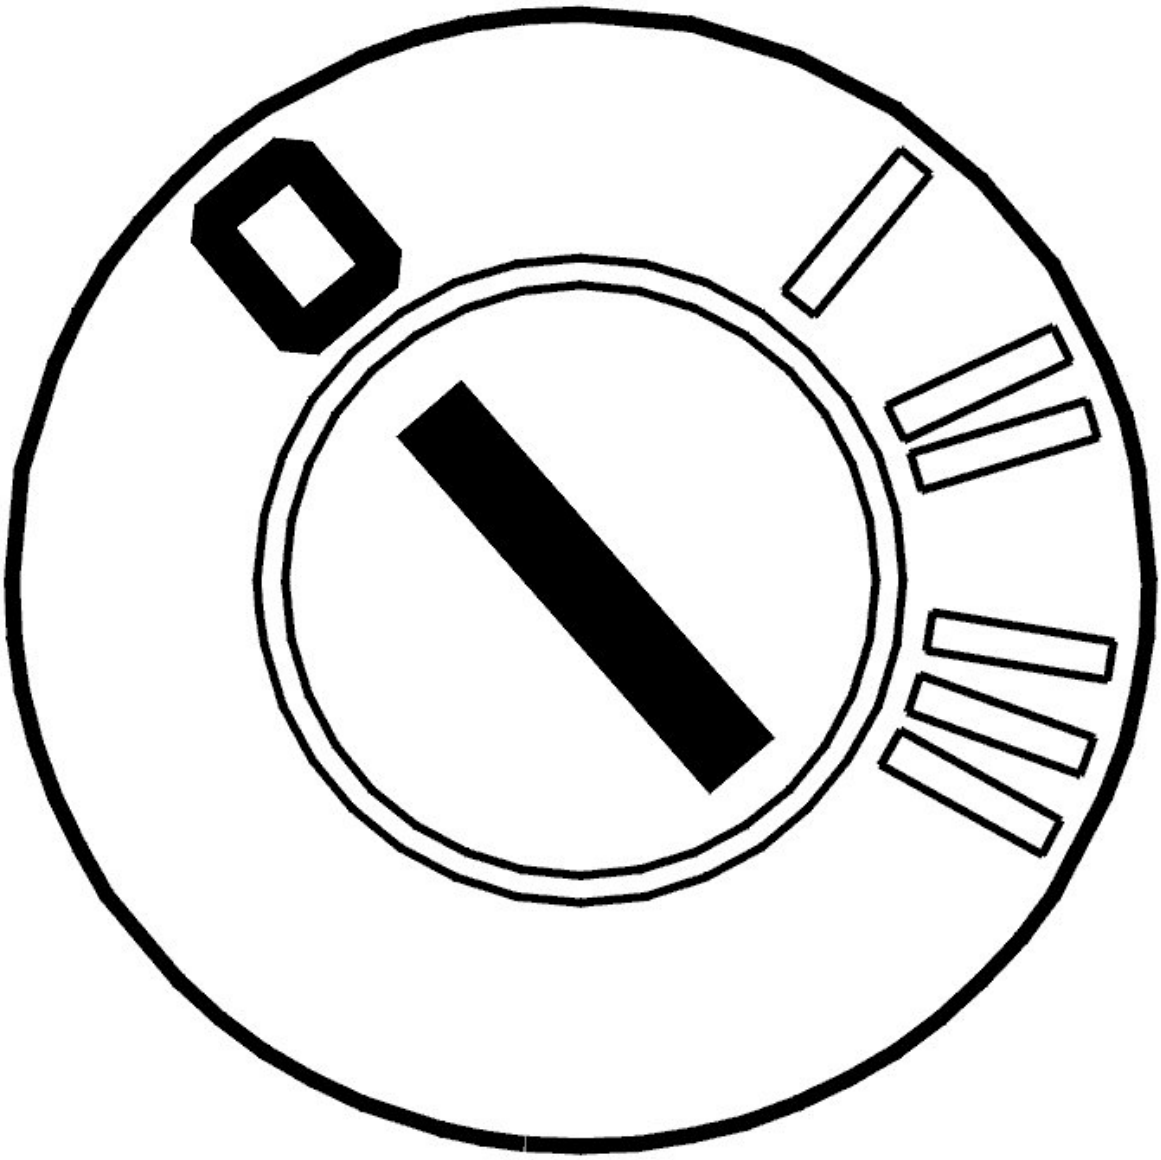


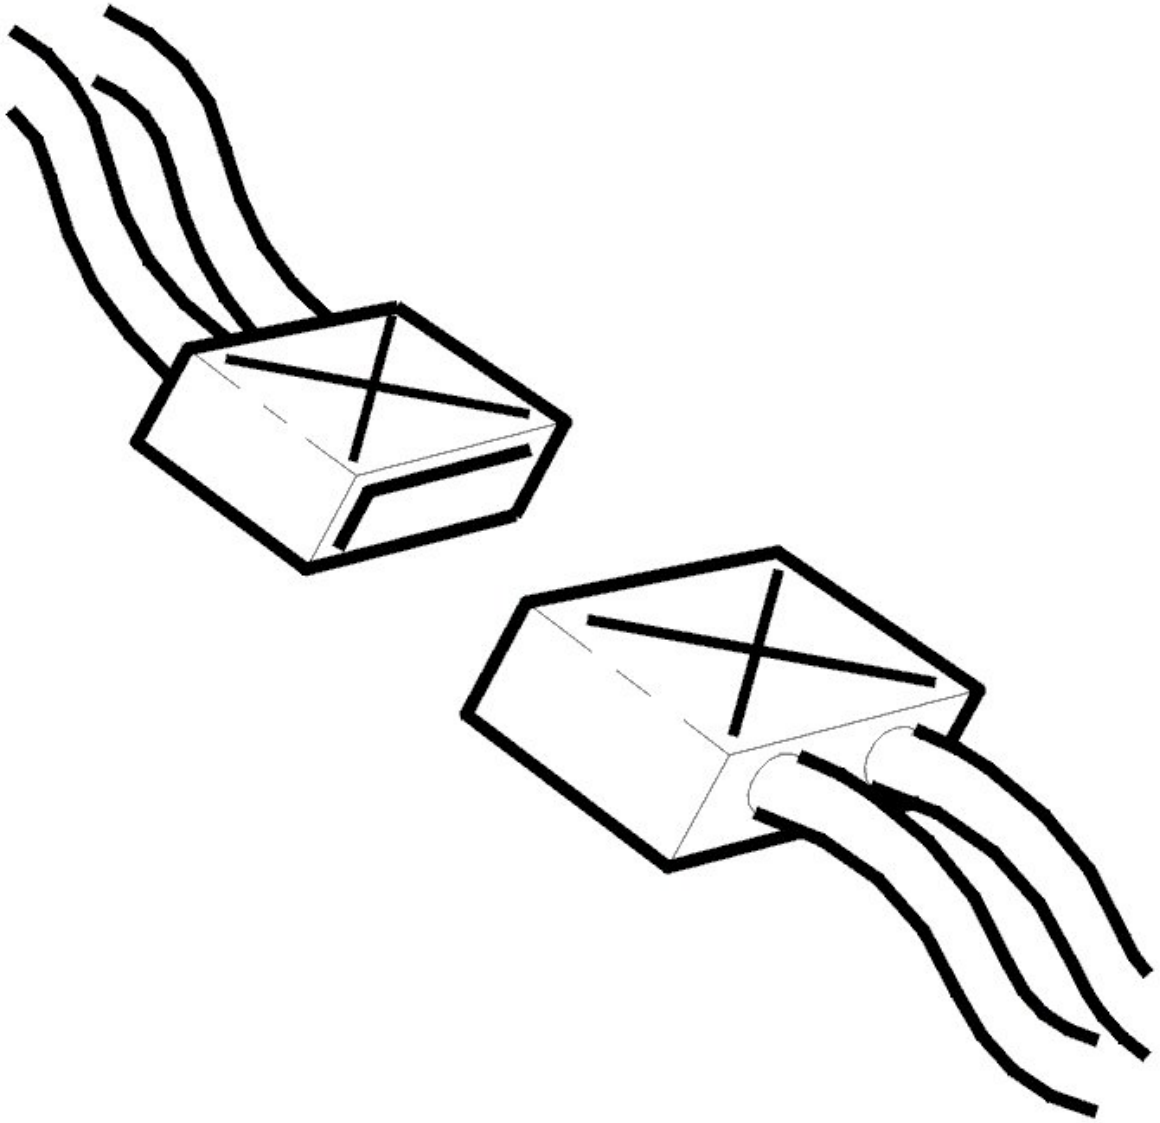
Was the resistance OK?

Yes - Checking the wiring

No - Checking the wiring and component

Checking the wiring



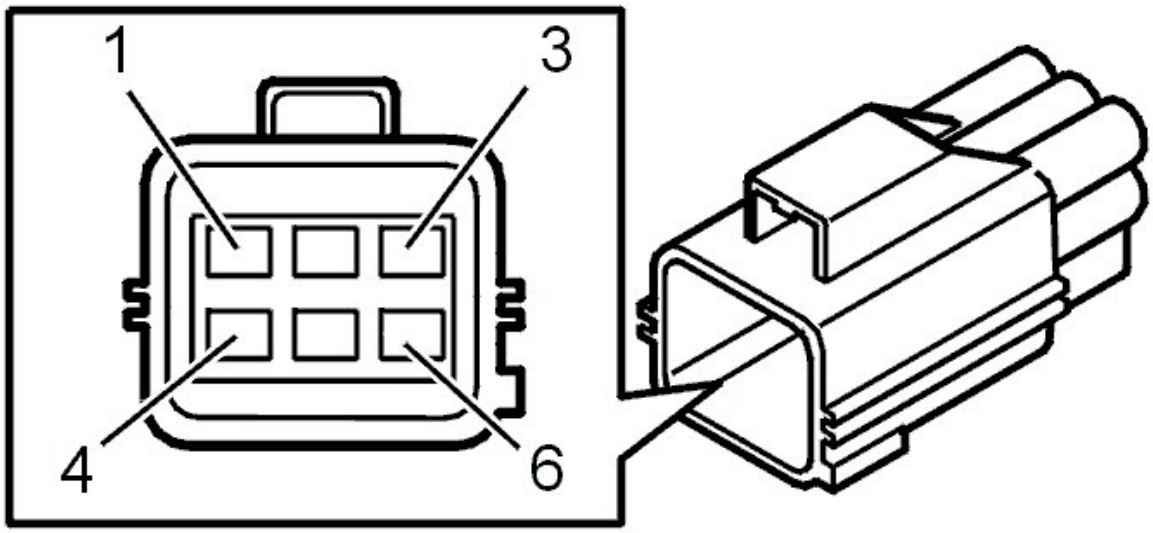


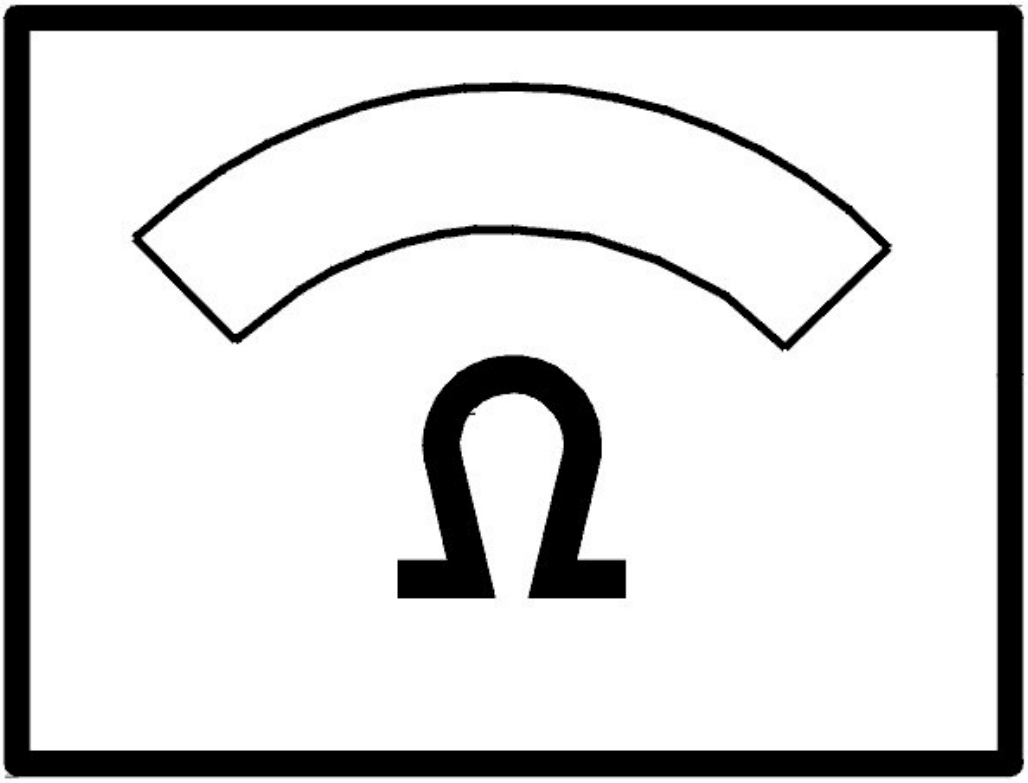
- Ignition off
- The breakout box connected
- Transmission connector C disconnected.

Check the cable between transmission control module (TCM) terminal #B6 (#A66) and transmission connector terminal #C5 (control module side).
Check for an open-circuit according to Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault.
Remedy as necessary.

Other information:

- To connect the breakout box, see Connecting the breakout box, B5244T5, B5254T2 See: Pinout Values and Diagnostic Parameters/Connecting the Breakout Box
- To disconnect the transmission connectors, see Connectors transmission, disconnecting / connecting See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Wiring Harness/Service and Repair/Procedures
- For information about signals, see Signal description. Transmission control module (TCM), AW50/51 AWD, AW55-50/51SN See: Transmission Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Description. Transmission Control Module (TCM).



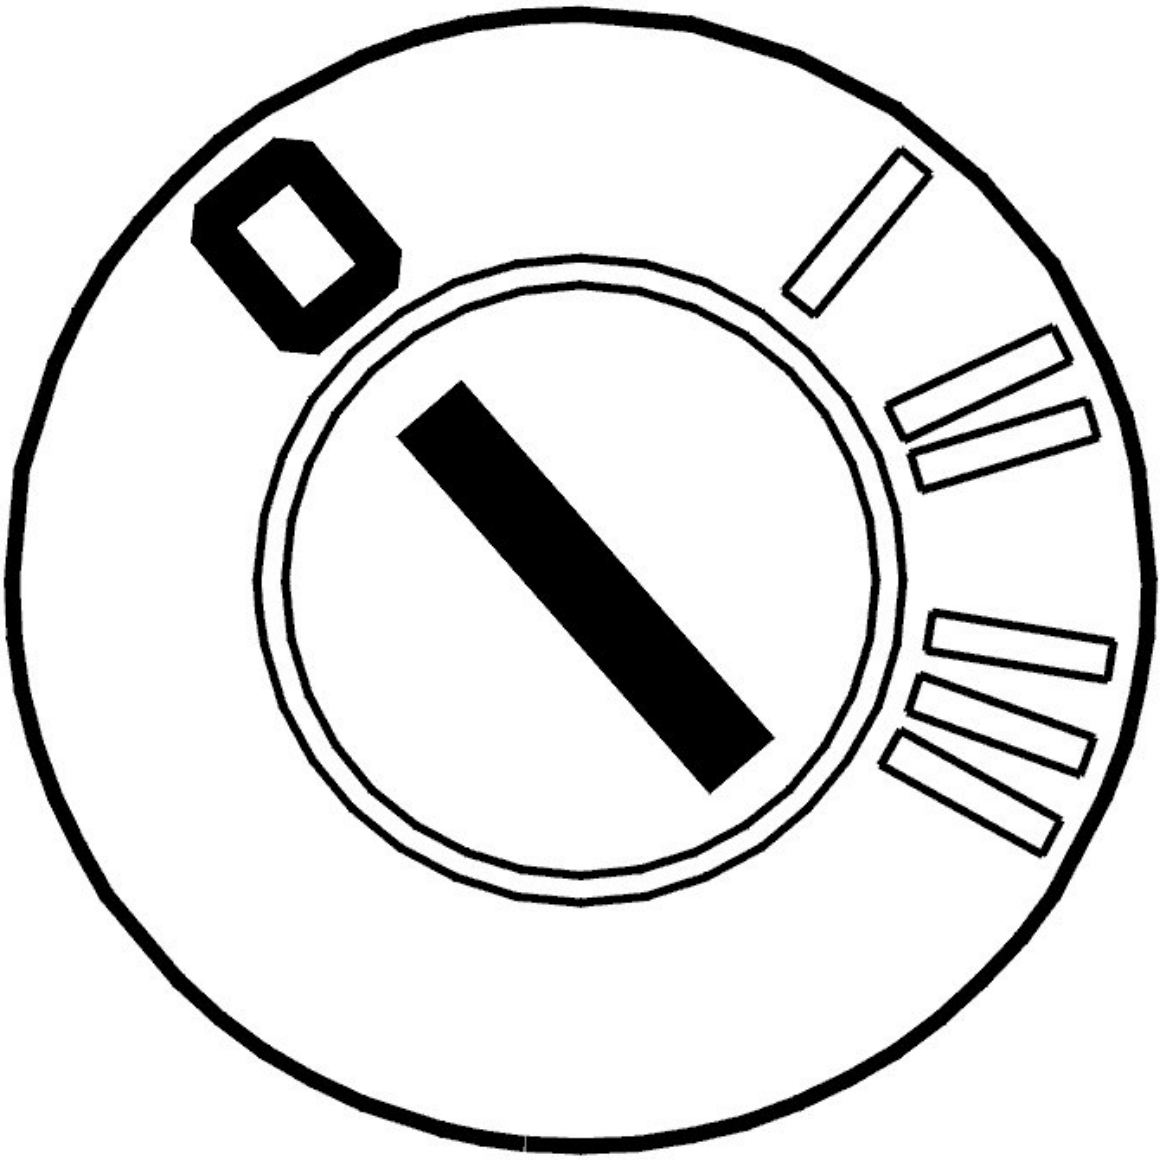


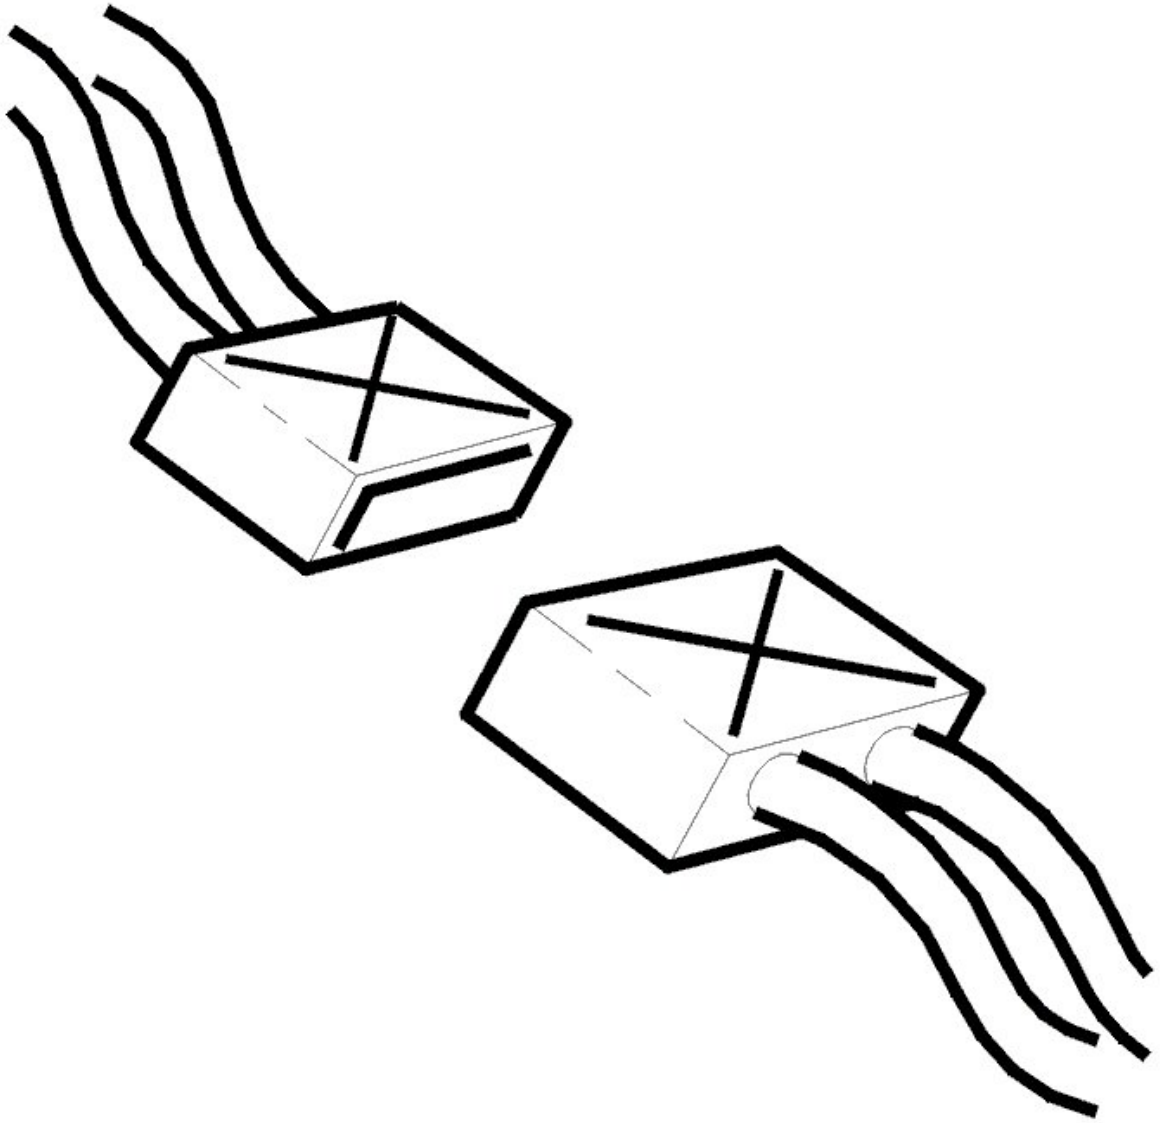
Was a fault detected?

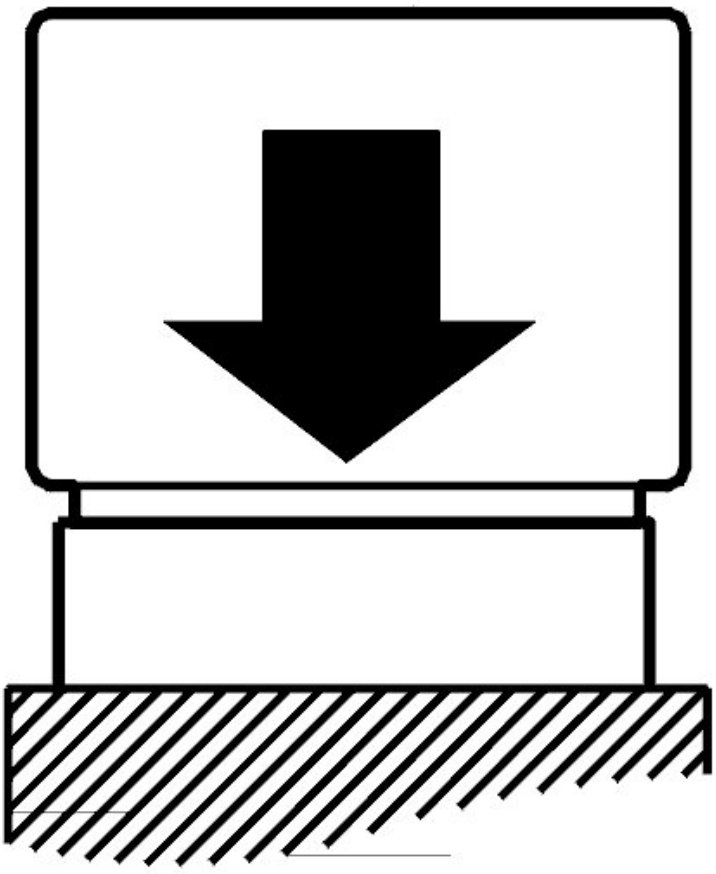
Yes - Verification

No - Checking the control module

Checking the control module







- Ignition off
- The breakout box connected
- Connect the control module.
- Transmission connector C disconnected
- Gear selector in position P.

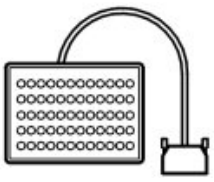
Check the transmission control module (TCM) by measuring the resistance between terminals #B6 (#A66) and #A53 (#A53) on the breakout box. The resistance must be approximately 9 kohms.

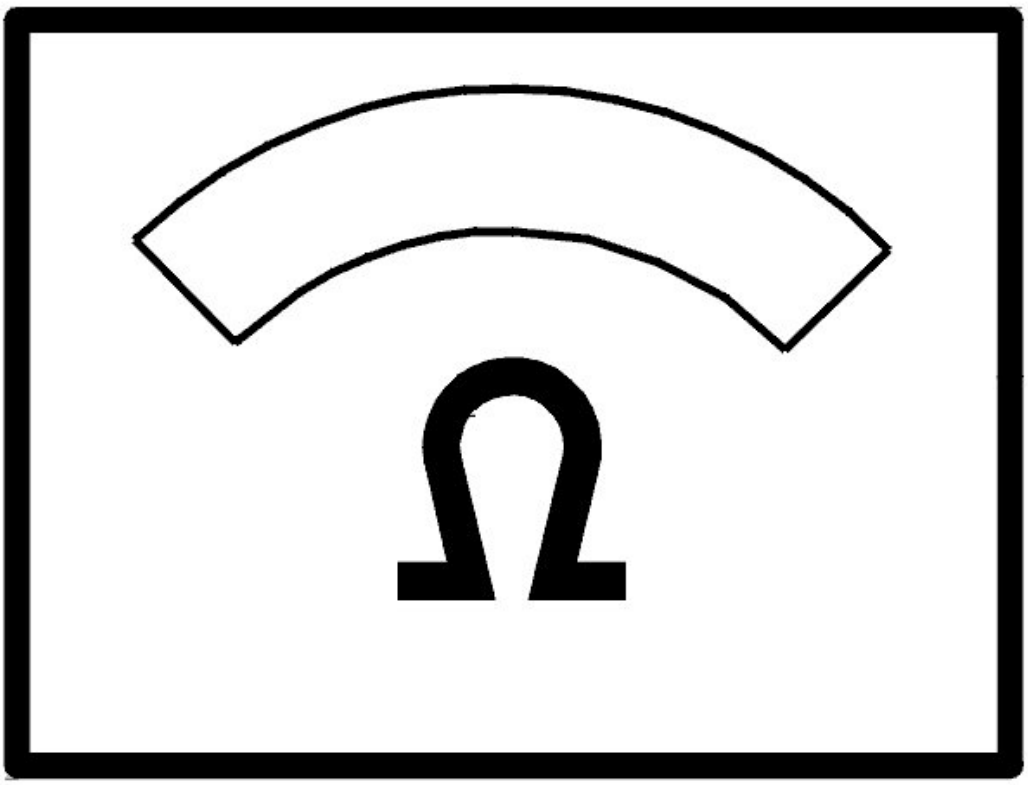
Note! When removing the transmission connector, the control module may store diagnostic trouble codes (DTCs) for the gear-shift position sensor, the shift solenoids, the temperature sensor etc.

Try a new control module if the resistance is infinite.

Other information:

- To disconnect the transmission connectors, see Connectors transmission, disconnecting / connecting See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Wiring Harness/Service and Repair/Procedures
- To replace the control module, see Transmission control module (TCM), replacing, B5244T5, AW55-50/51SN, B5254T2, AW55-50/51SN, B5254T2, AW50/51 AWD See: Transmission Control Systems/Relays and Modules - Transmission and Drivetrain/Relays and Modules - A/T/Control Module/Service and Repair
- For information about signals, see Signal description. Transmission control module (TCM), AW50/51 AWD, AW55-50/51SN See: Transmission Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Description. Transmission Control Module (TCM).



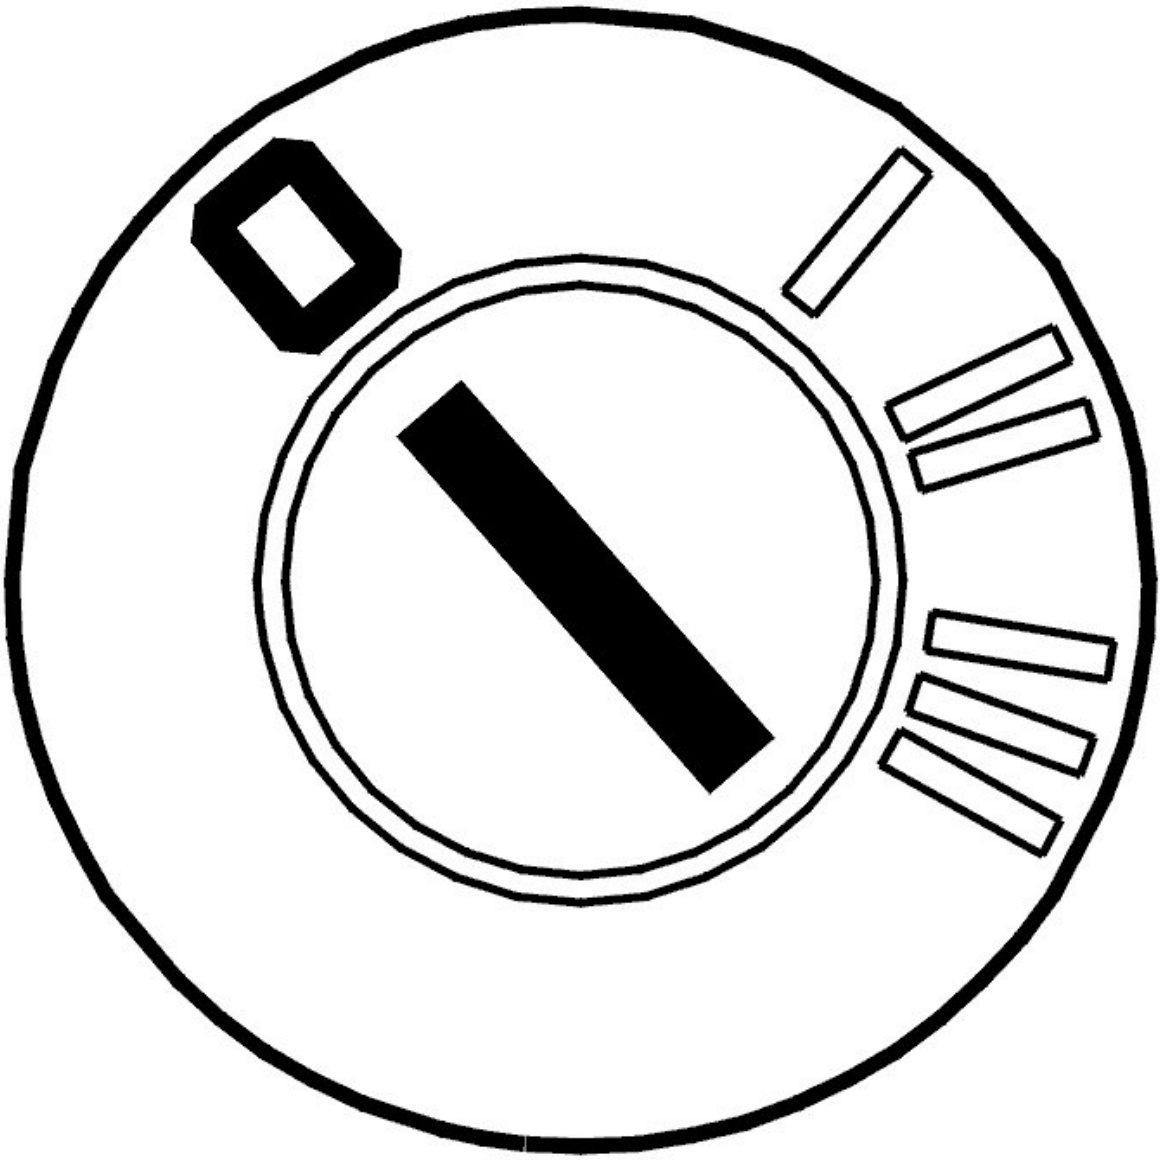


Was the resistance OK?

Yes - No Fault Found

No - Verification

Checking the wiring and component

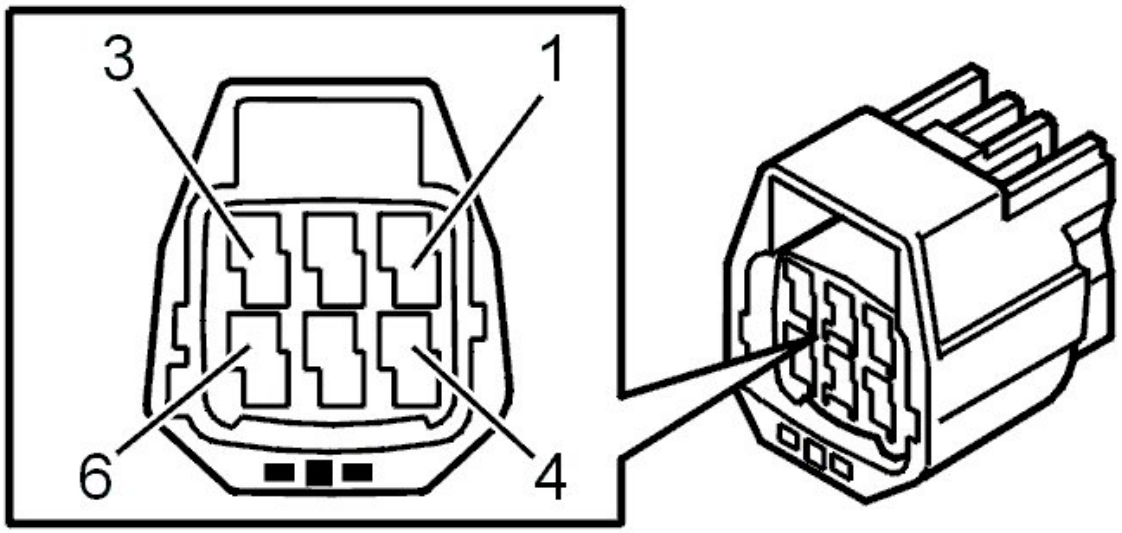


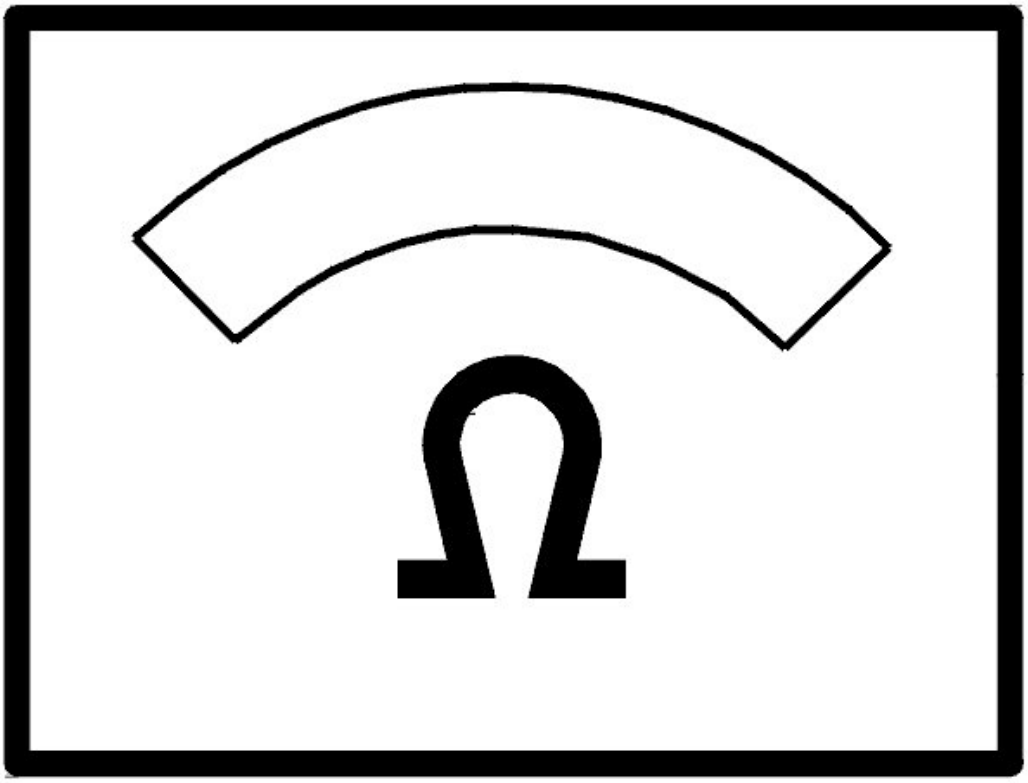
- Ignition off
- Open the transmission control system.

Check the cable between transmission connector terminal #C5 (transmission side) and the connector for solenoid S5. Check for an open-circuit according to Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault.
Check solenoid S5 by measuring the resistance between the terminal pin on solenoid S5 and the transmission housing. The resistance must be 11-15 ohms. Replace solenoid S5 if the resistance is incorrect.
Remedy as necessary.

Other information:

- To disconnect the transmission connectors, see Connectors transmission, disconnecting / connecting See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Wiring Harness/Service and Repair/Procedures
- To open the control system and to check or replace solenoid S5, see Solenoid control system, replacing See: Transmission Control Systems/Actuators and Solenoids - Transmission and Drivetrain/Actuators and Solenoids - A/T/Shift Solenoid/Service and Repair/Solenoid Control System, Replacing
- To replace the cable harness for the control system, see Wiring harness / oil temperature sensor, replacing See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Wiring Harness/Service and Repair/Removal and Replacement
- For information about signals, see Signal description. Transmission control module (TCM), AW50/51 AWD, AW55-50/51SN See: Transmission Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Description. Transmission Control Module (TCM).





Select Continue when the fault has been remedied.

Continue - Resetting the adaptation and oil quality counter

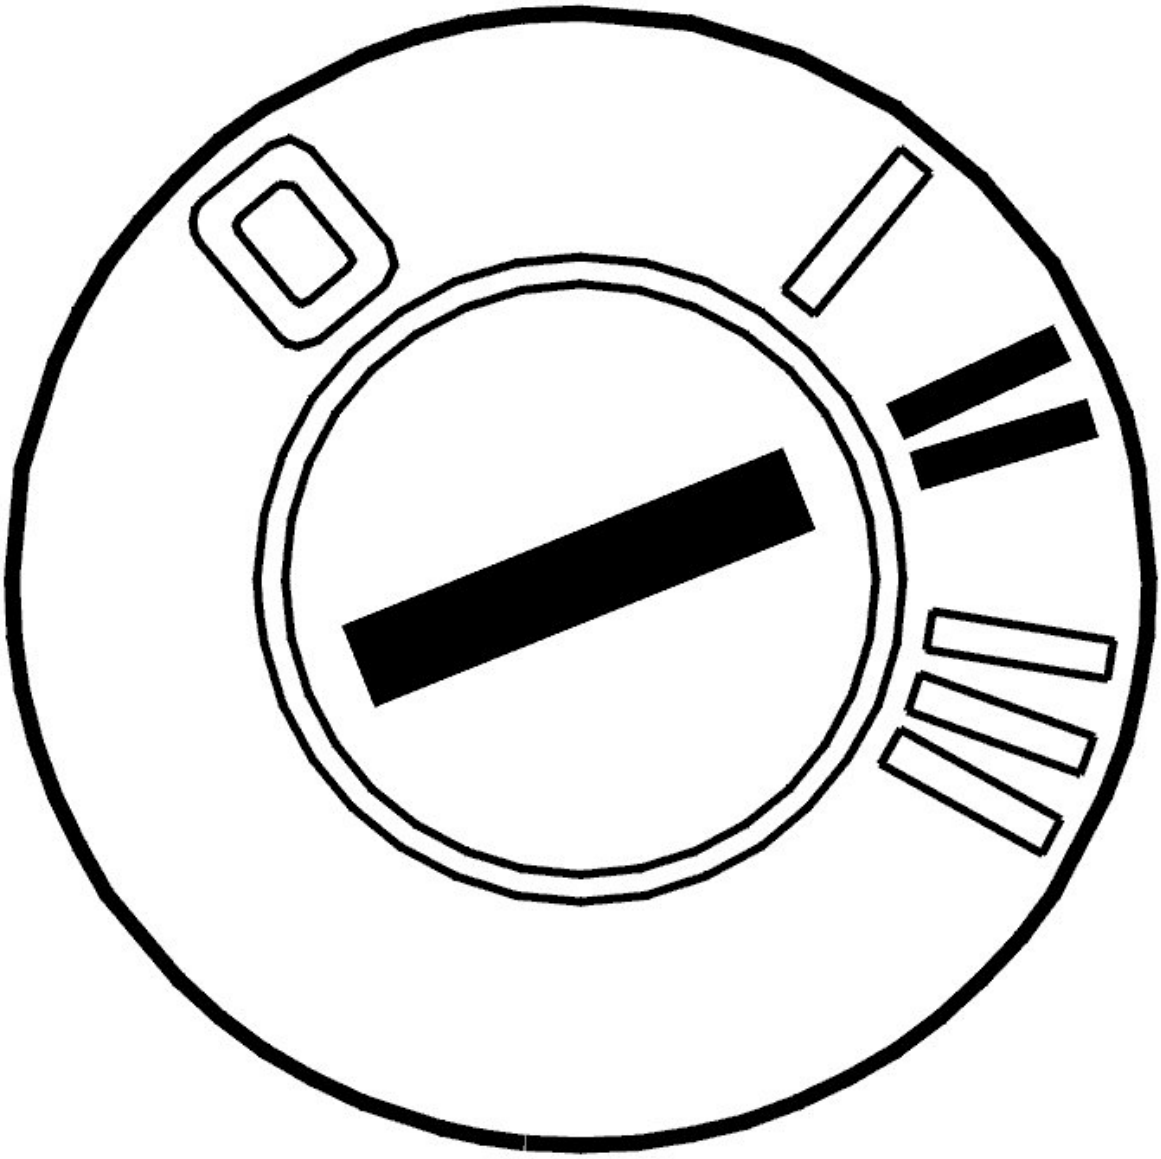
Resetting the adaptation and oil quality counter

Resetting the adaptation

Resetting adaptation and the counter for "Transmission oil change"

Hint: The transmission has torque controlled adaptive pressure control. Pressure control means that the transmission regulates the pressure itself during each gear shift. This avoids harsh gear shifting. Each gear shift is evaluated by the control module and stored in the memory. This allows for compensation for wear and tear in the transmission and clutch. It is important that the adaptation in the memory is reset after the transmission has been repaired. This is to ensure normal operation. The oil is replaced during repair; the "Transmission oil change" counter must be reset. If the counter is not reset when the fluid is drained and replaced, there is a risk that a diagnostic trouble code (DTC) will be stored in incorrect circumstances.

Note! This applies only if the transmission or one of the components in the transmission have been replaced.



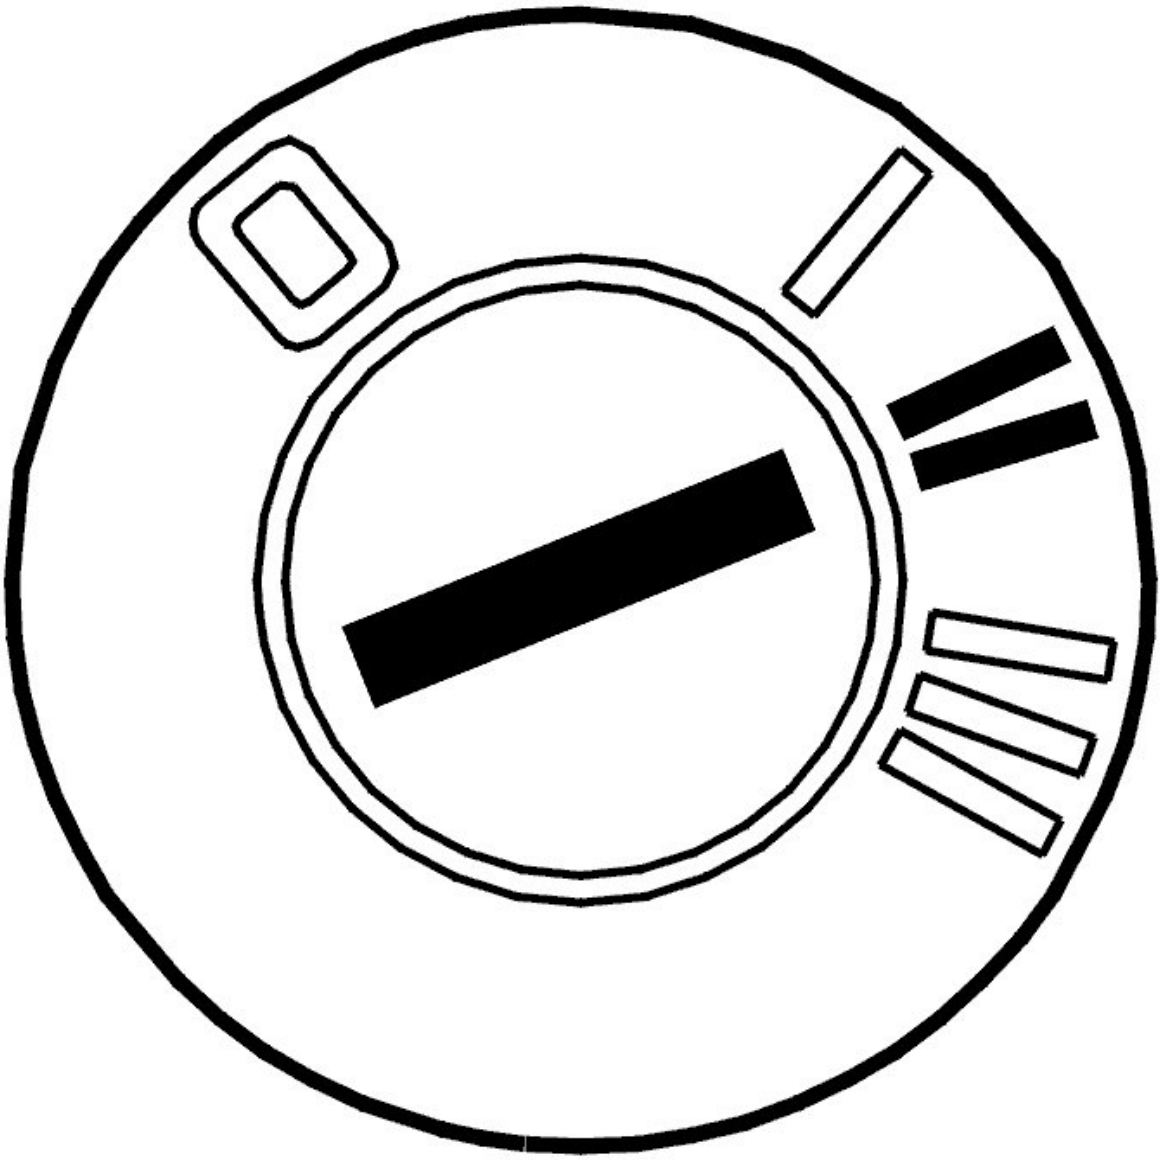
- Ignition on.

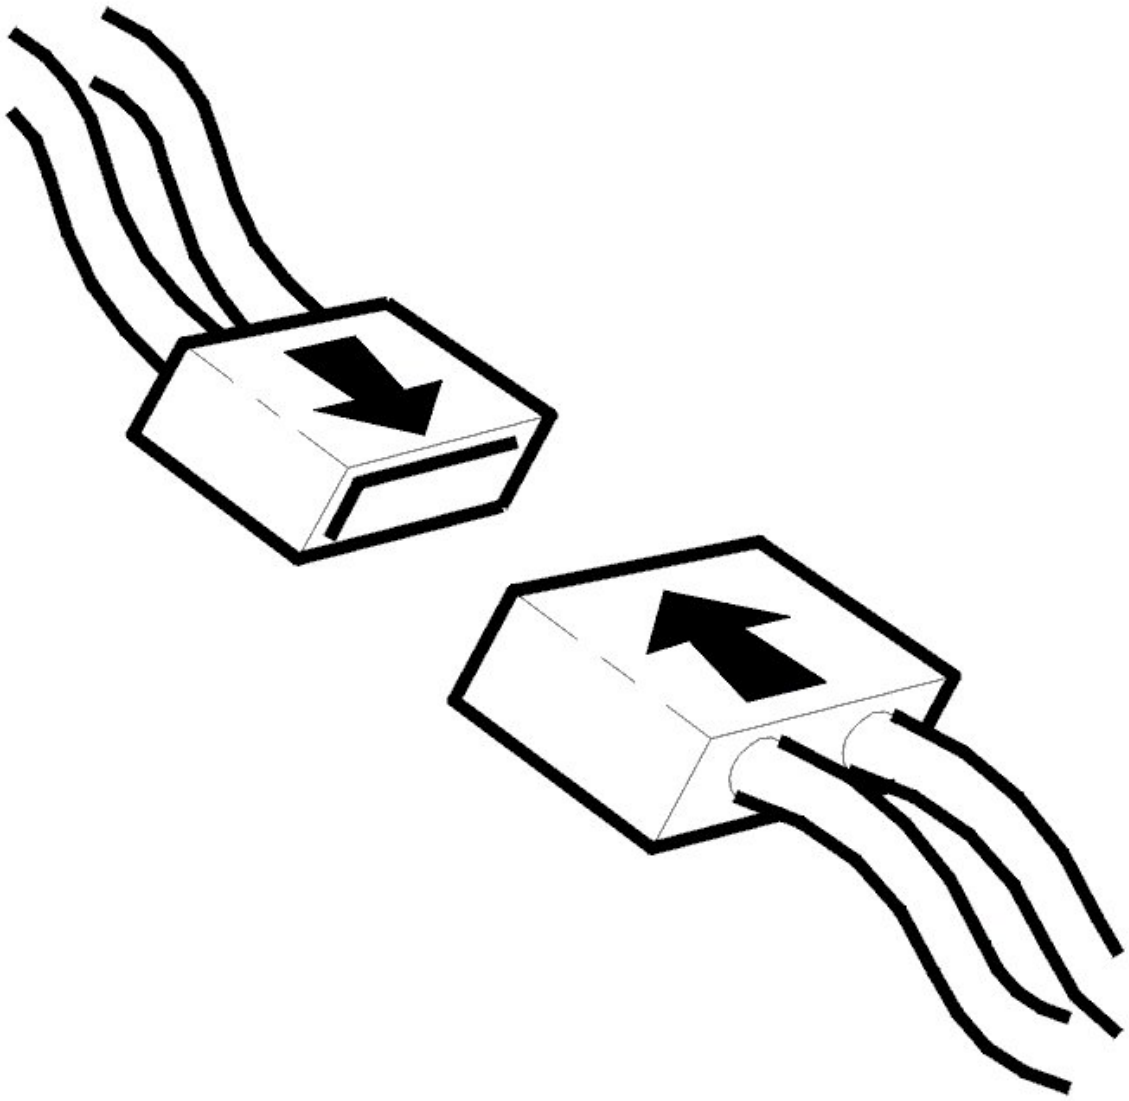
Click on the VCT2000 symbol to reset the adaptation and counter.

Continue - Verification

Verification

Hint: After carrying out the repair, check that the fault has been remedied.





- Ignition off.
- Reinstall the components, reconnect the connectors etc.
- Ignition on.
- Gear selector in position P.
- Activate solenoid S5.

The current should oscillate between 0 and 1.5 A.

Does the current oscillate?

Yes - VERIFIED

No - VERIFICATION FAILED

VERIFICATION FAILED - Fault-tracing information

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition
Shift solenoids S1, S2, S3, S4 and S5 operate in tandem to control gear-shifting. Diagnostic trouble codes (DTCs) TCM-0003, TCM-0009, TCM-0103, TCM-0109 or TCM-010C are stored if the transmission control module (TCM) registers that there is a short-circuit to ground in circuits S1, S2, S3, S4 or S5 when the solenoid should be activated.

Substitute value
- The transmission control module (TCM) "Emergency mode I" program has been initiated.

Possible source
- Short-circuit to ground in the signal cable.
- Defective solenoid.
- Internal fault in the control module.

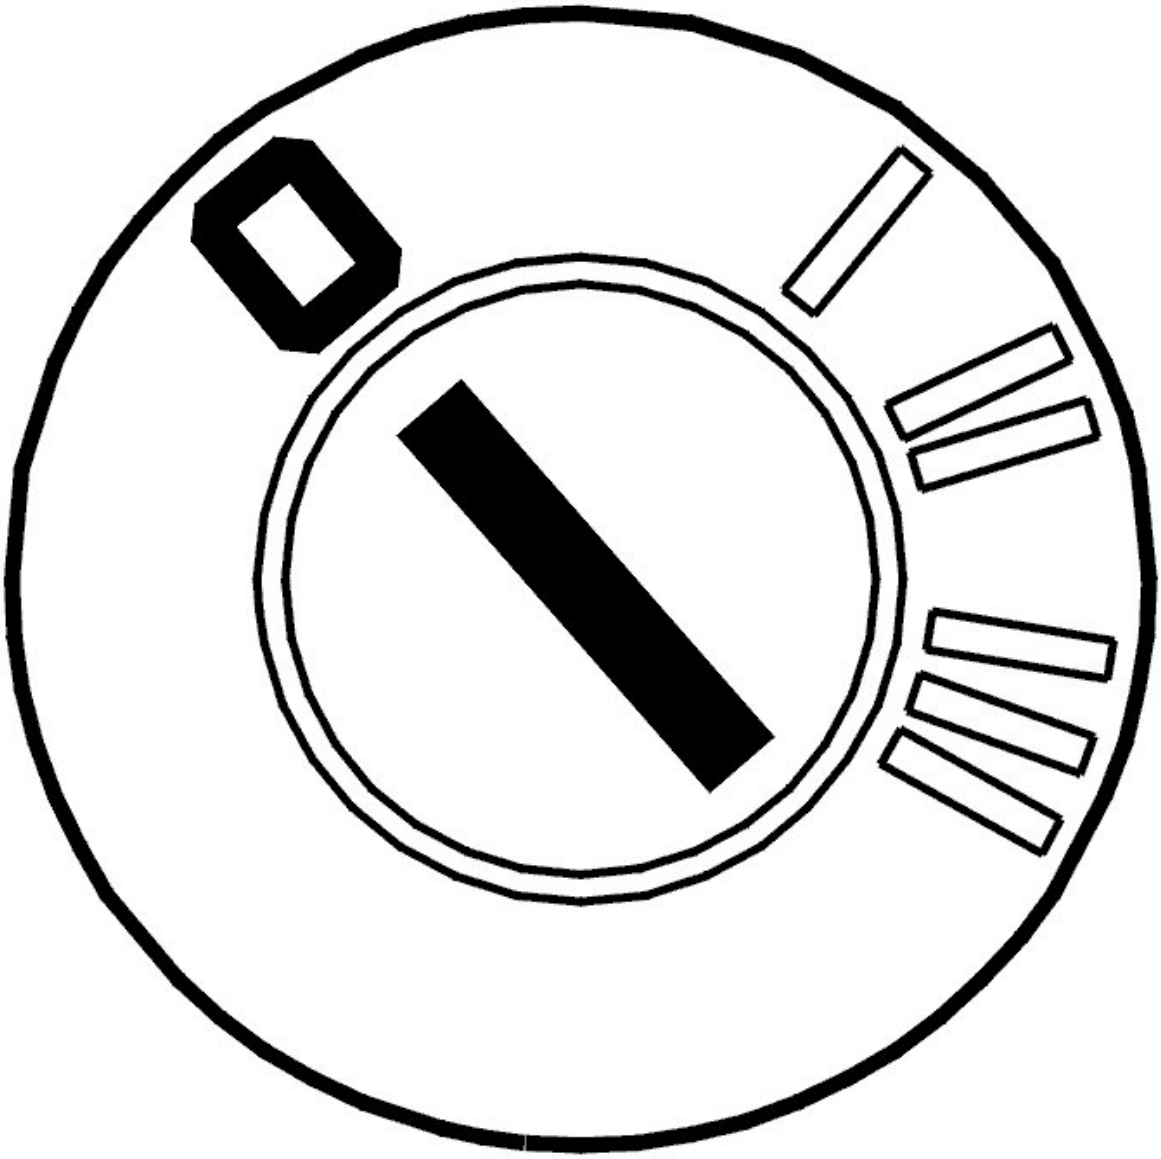
Fault symptom[s]
- General orange warning lamp lit.
- No lock-up function.
- Harsh gear shifting.
- No shifting.

Signal Too Low

Signal too low

Checking the temperature sensor

Hint: In some cases, the diagnostic trouble code (DTC) may be caused by a defective oil temperature sensor. Check the function of the oil temperature sensor first.



- Ignition off

- Read off the oil temperature.

Check that the function of the temperature sensor is OK. Test drive the car to increase the temperature of the transmission fluid. Read off the temperature again. Check that the temperature has increased.

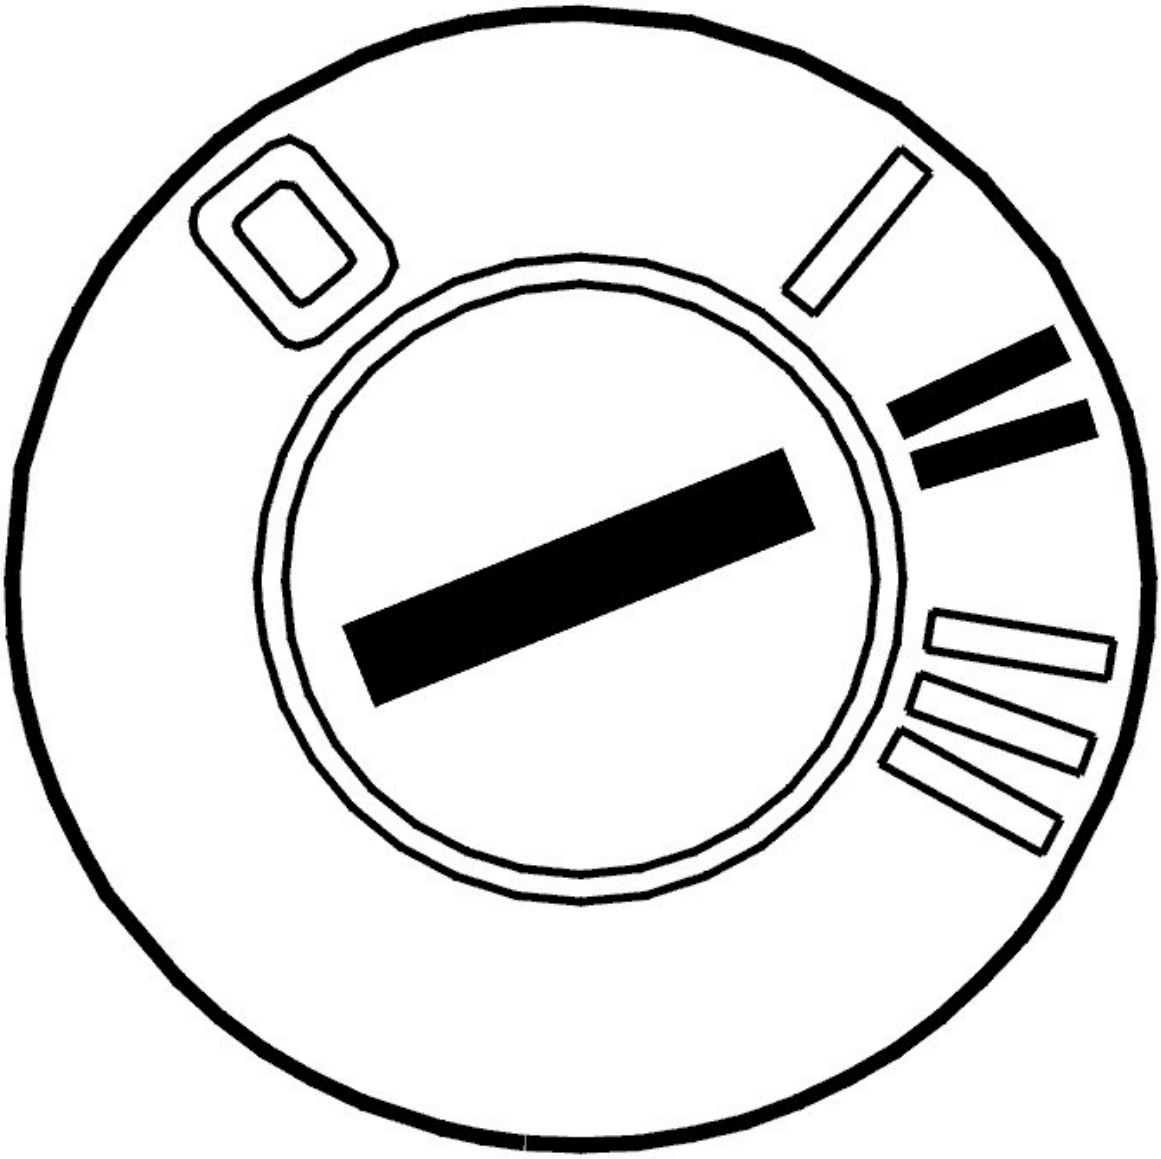
Hint: If the temperature is outside its permitted range, fault-trace the temperature sensor.

Is the oil temperature within its permitted range?

Yes - Checking shift solenoid S5

No - Checking transmission fluid temperature sensor

Checking shift solenoid S5



- Ignition on
- Gear selector in position P
- Activate solenoid S5.

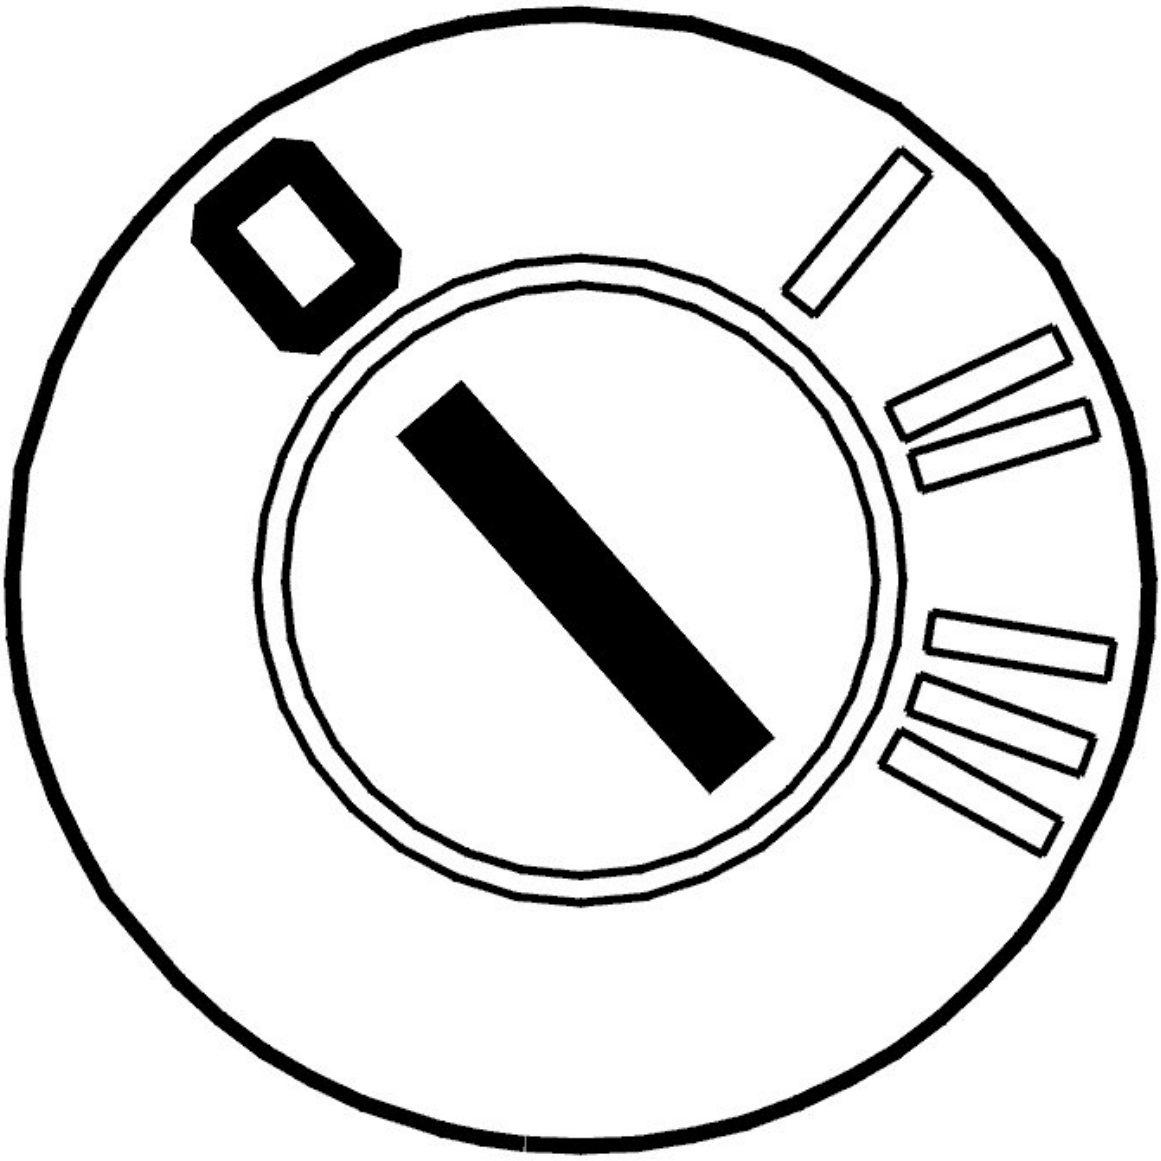
The value must change between OFF and ON.

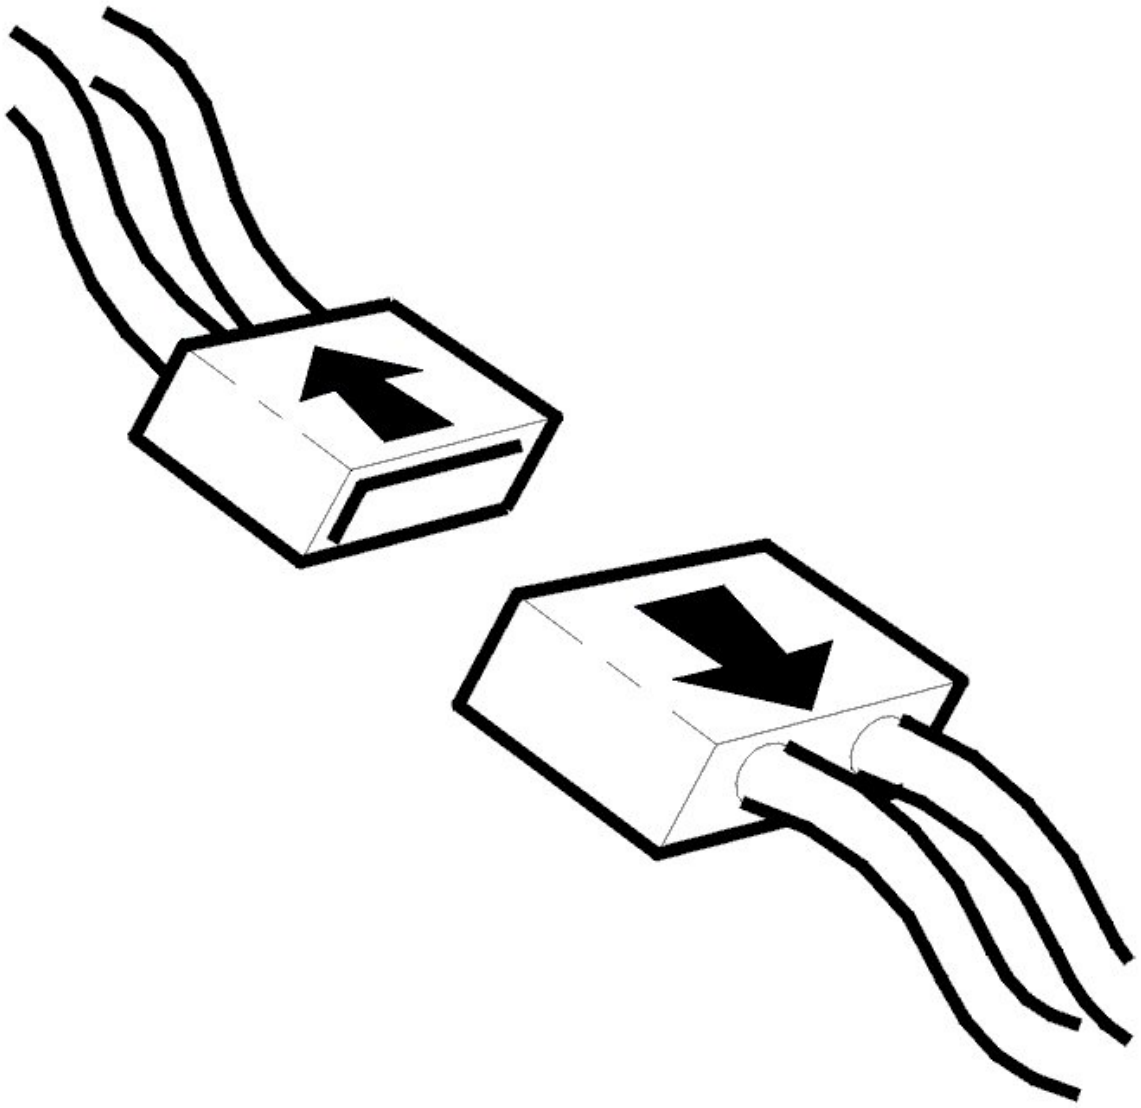
Does the value change?

Yes - Intermittent fault

No - Checking resistance

Checking resistance



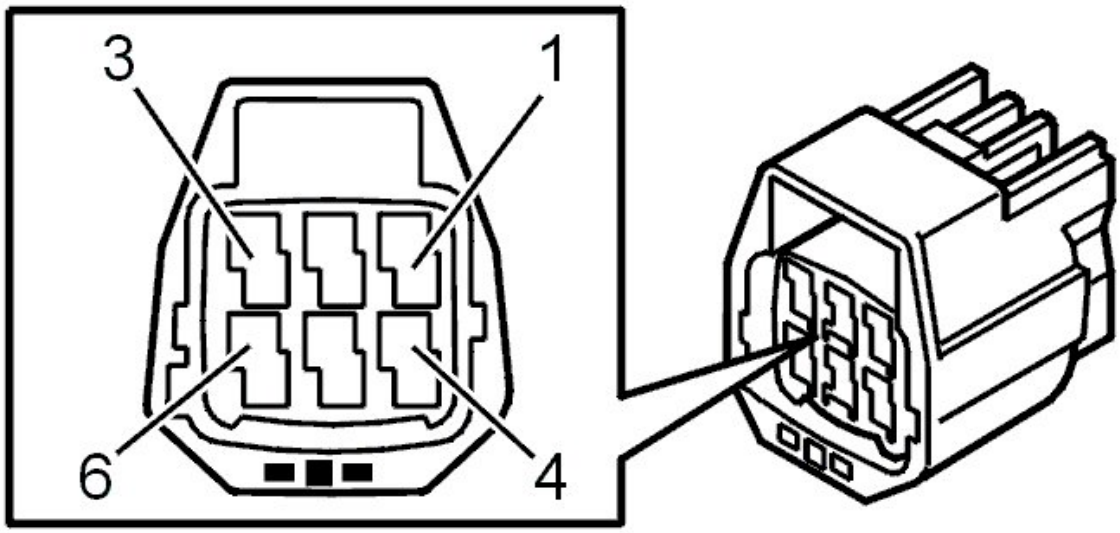


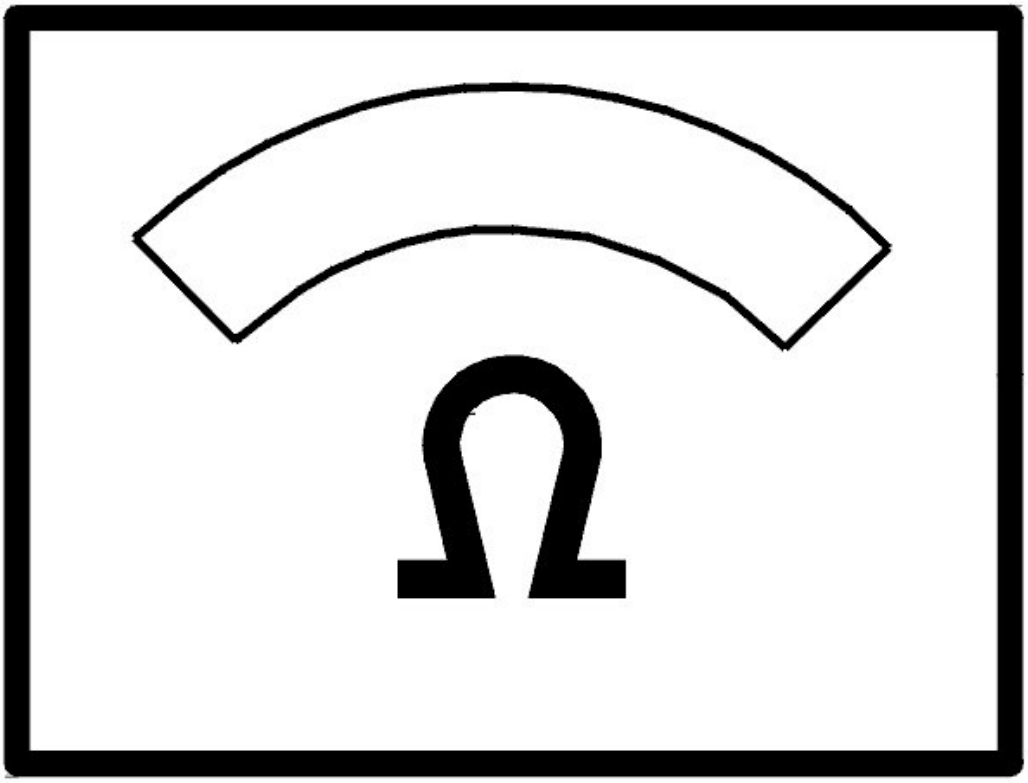
- Ignition off
- Disconnect transmission connector C.

Check solenoid S5. Measure the resistance between transmission connector terminal #C5 (transmission side) and the transmission housing. The resistance must be 11-15 ohms.

Other information:

- To disconnect the transmission connectors, see Connectors transmission, disconnecting / connecting See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Wiring Harness/Service and Repair/Procedures
- For information about signals, see Signal description. Transmission control module (TCM), AW50/51 AWD, AW55-50/51SN See: Transmission Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Description. Transmission Control Module (TCM).



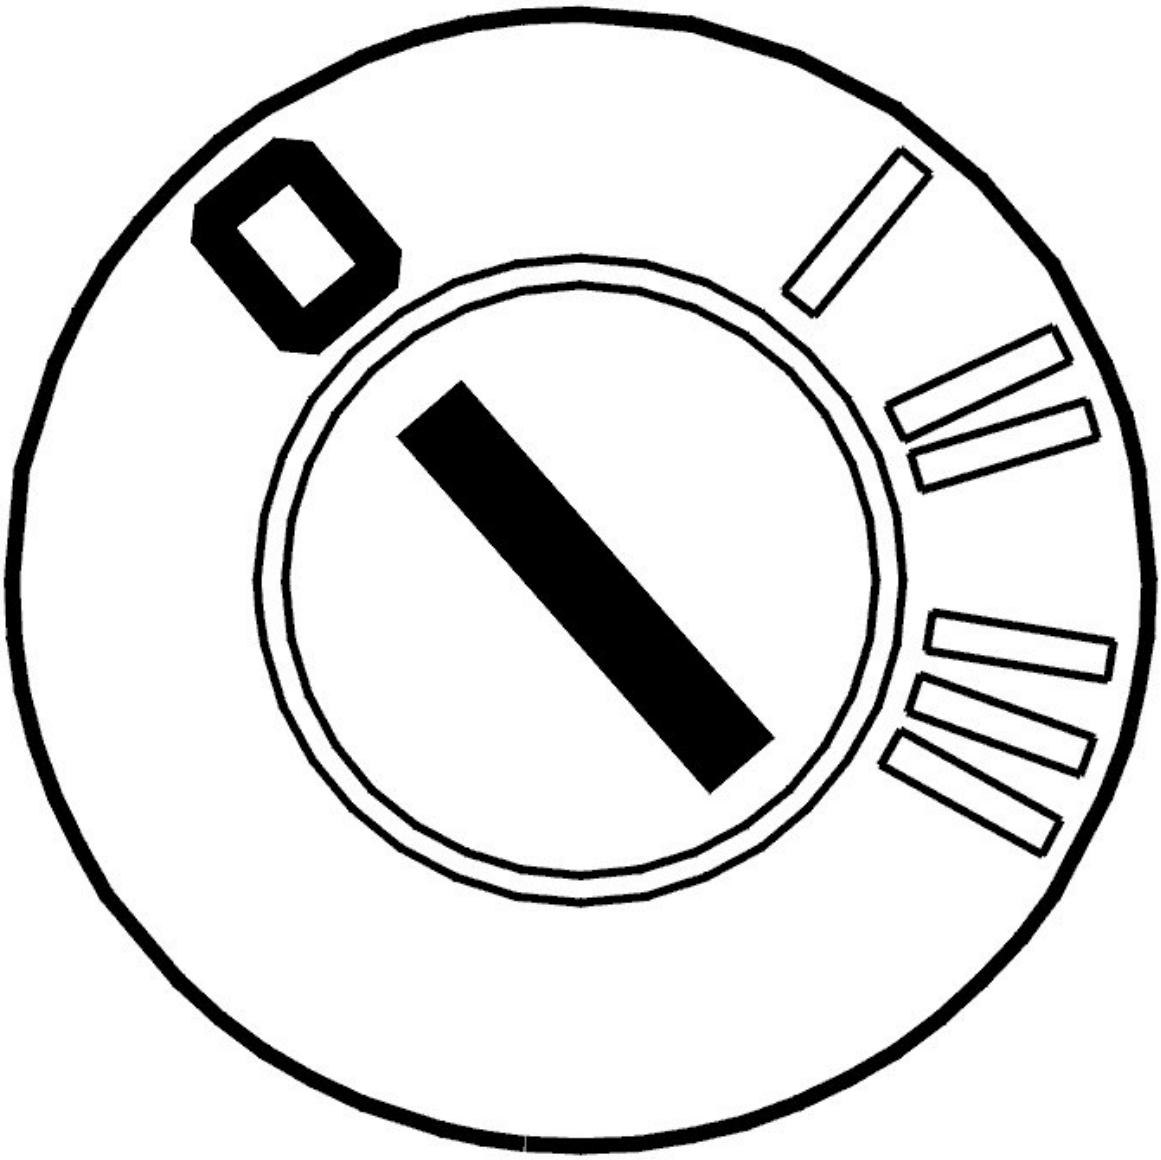


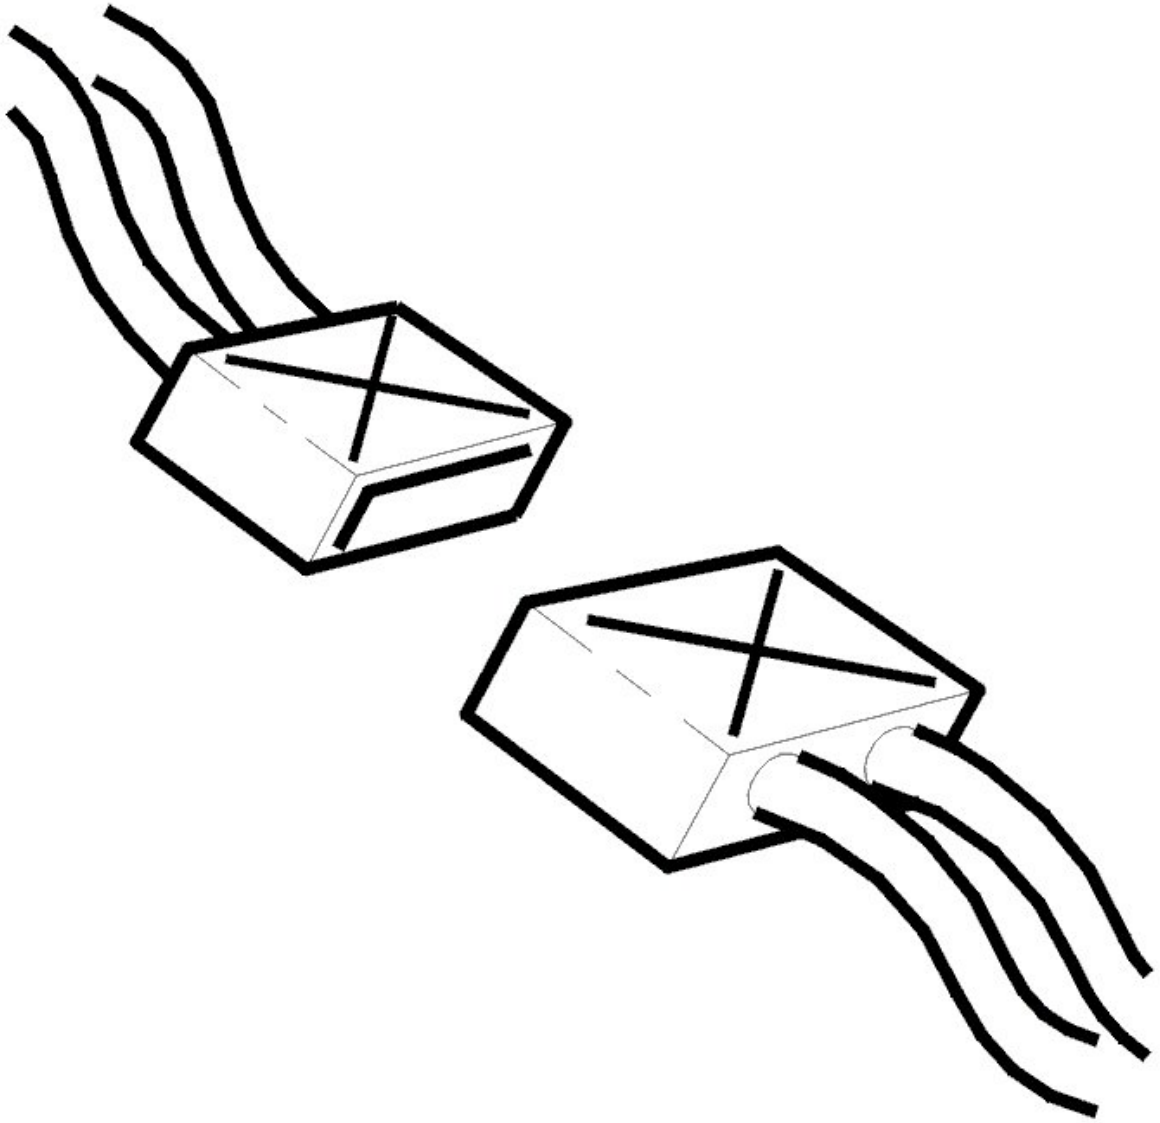
Was the resistance OK

Yes - Checking the wiring

No - Checking the wiring and component

Checking the wiring



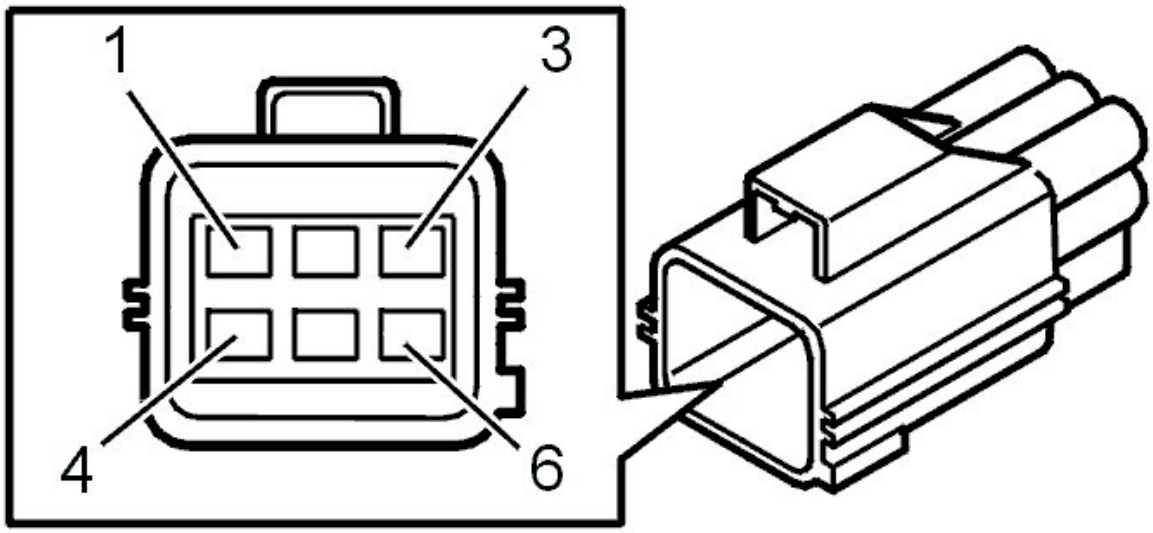


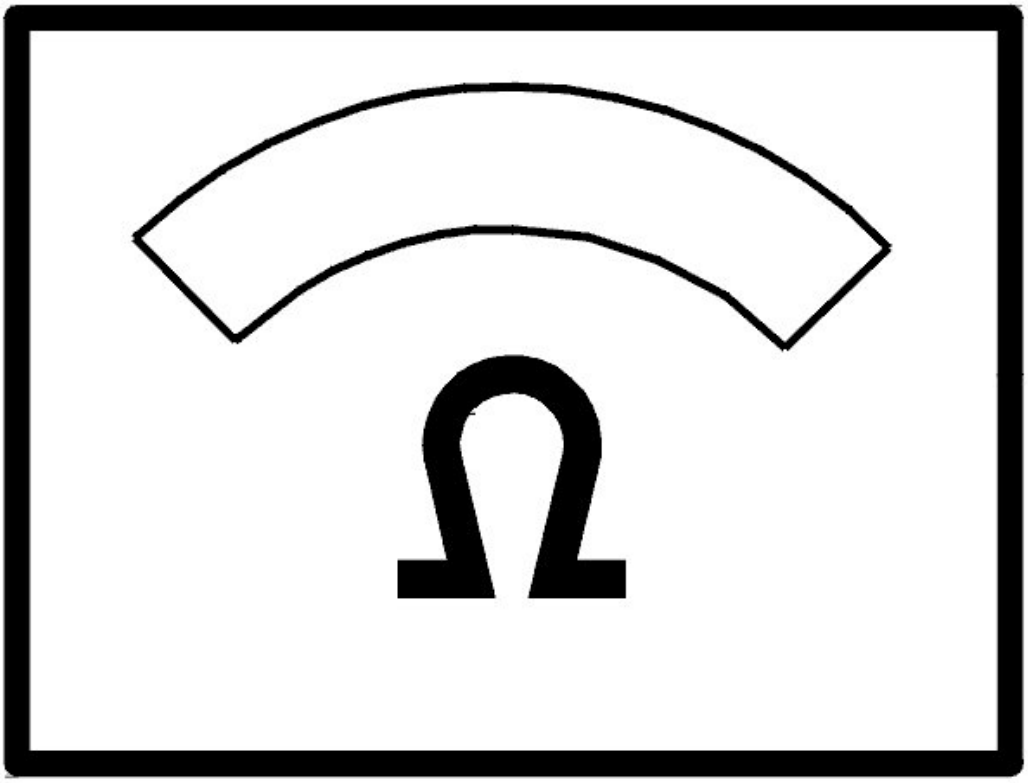
- Ignition off
- The breakout box connected
- Transmission connector C disconnected.

Check the cable between control module terminal #B6 (#A66) and transmission connector terminal #C5 (control module side). Check for a short-circuit to ground. See Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault.
Remedy as necessary.

Other information:

- To connect the breakout box, see Connecting the breakout box, B5244T5, B5254T2 See: Pinout Values and Diagnostic Parameters/Connecting the Breakout Box
- To disconnect the transmission connectors, see Connectors transmission, disconnecting / connecting See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Wiring Harness/Service and Repair/Procedures
- For information about signals, see Signal description. Transmission control module (TCM), AW50/51 AWD, AW55-50/51SN See: Transmission Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Description. Transmission Control Module (TCM).



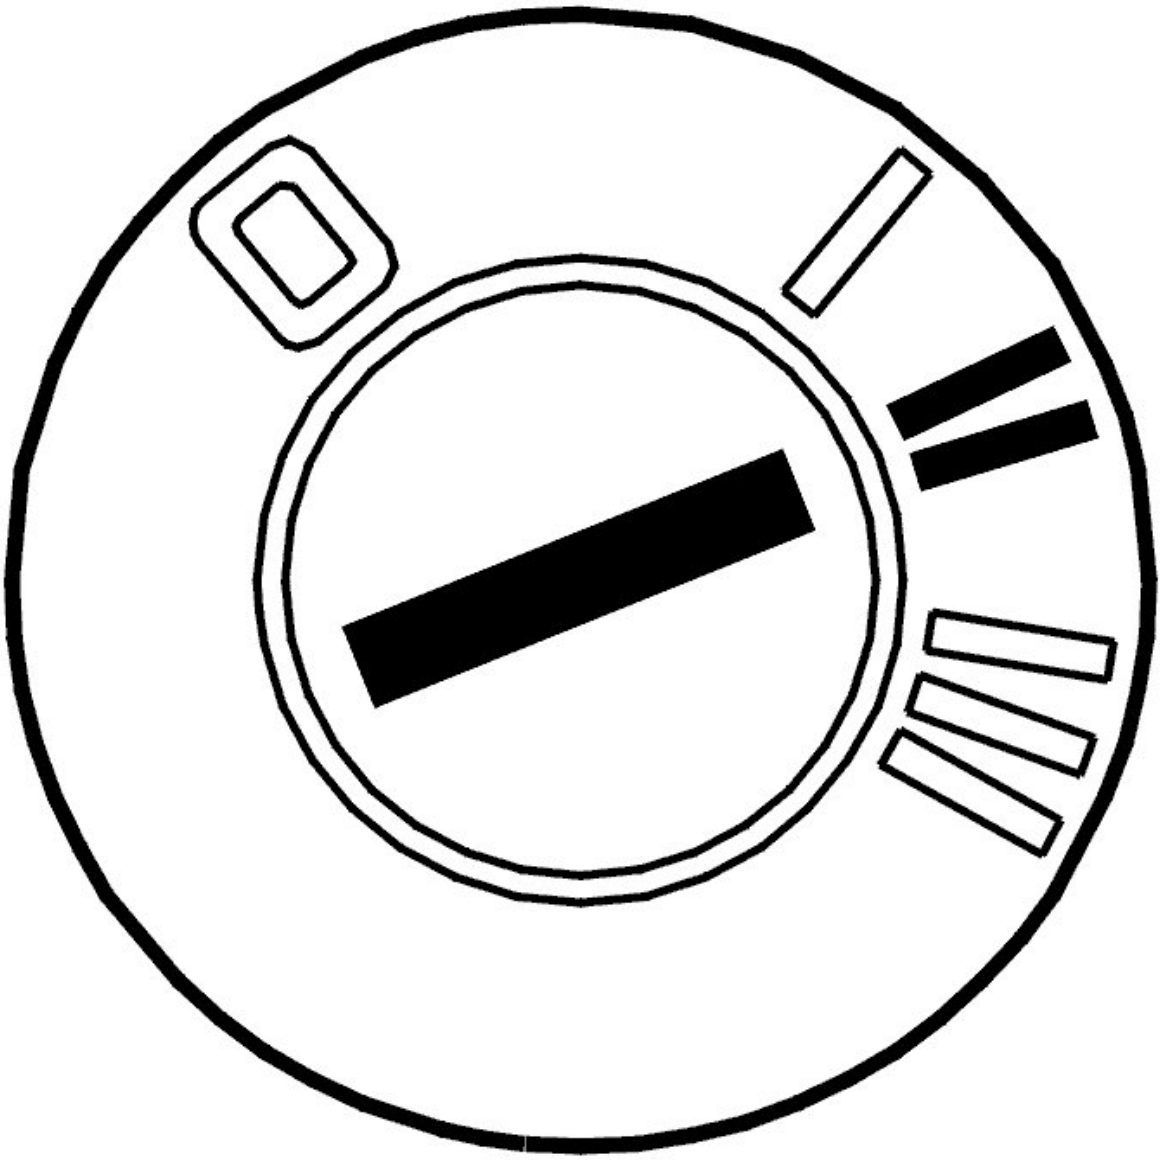


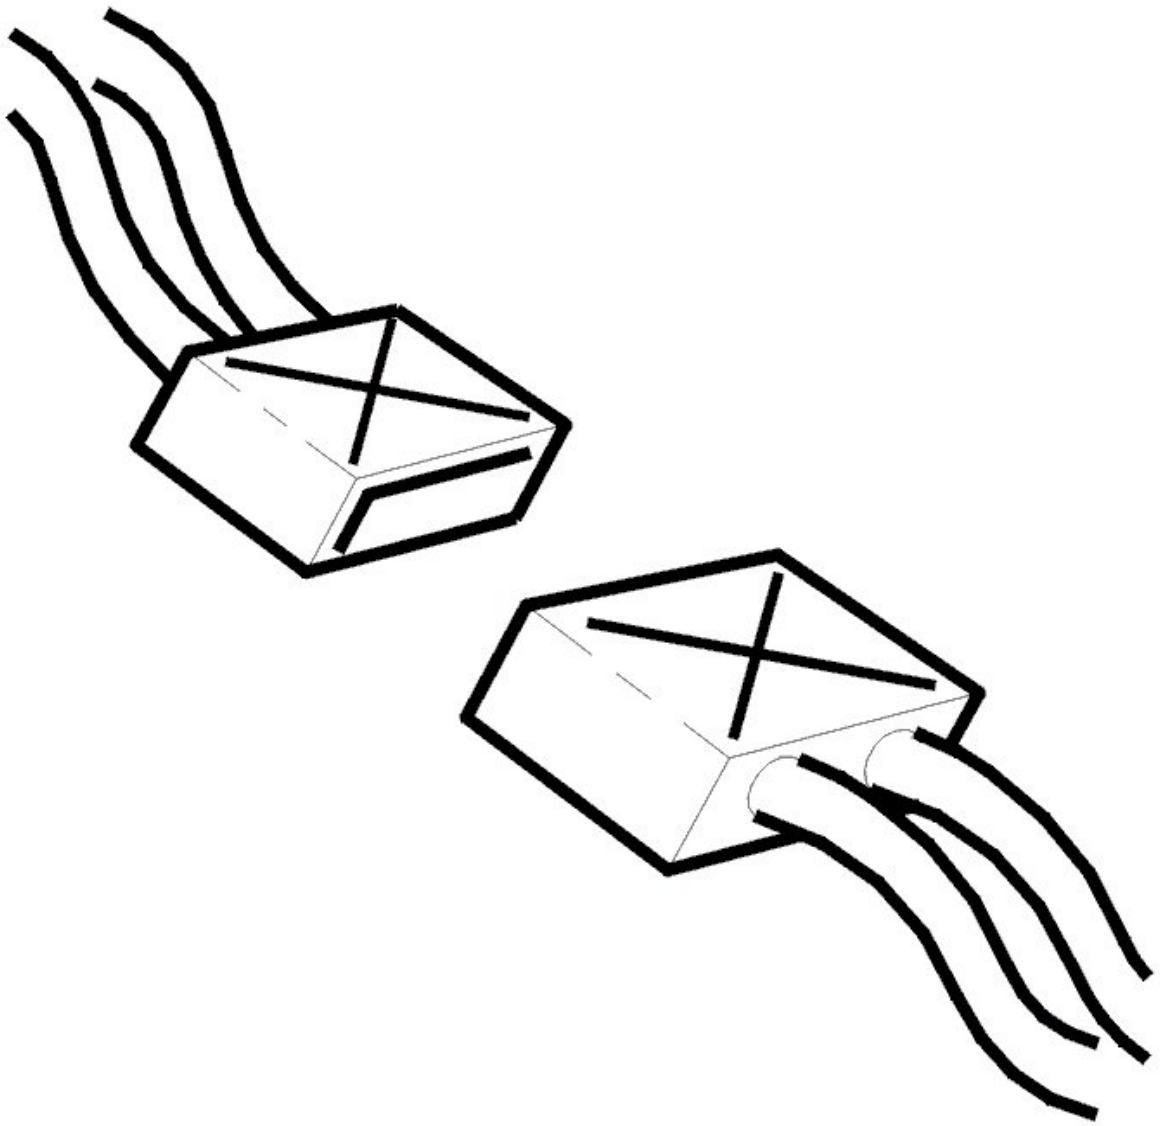
Was a fault detected?

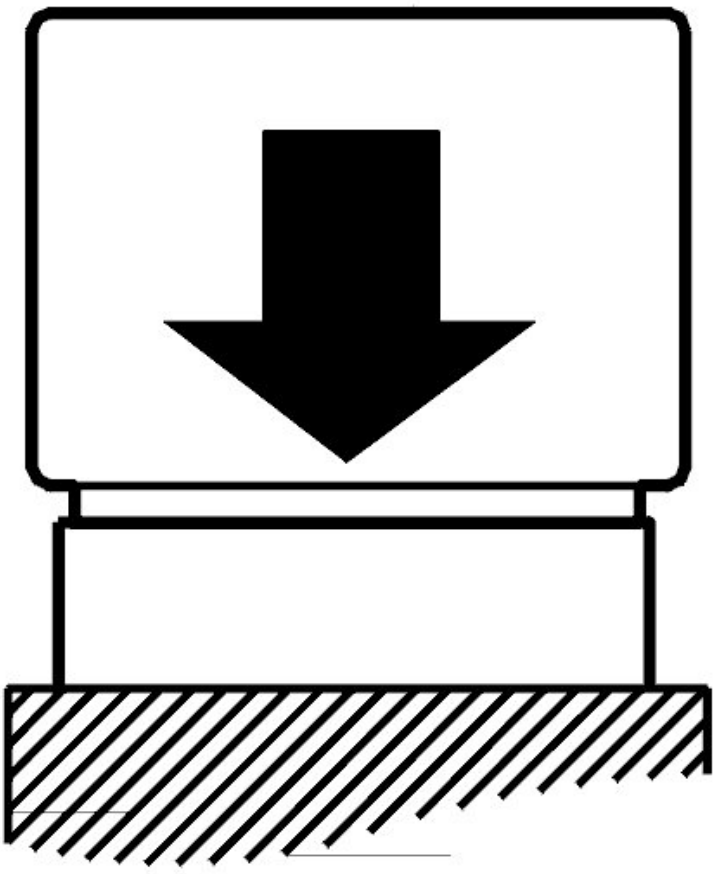
Yes - Verification

No - Checking the control module

Checking the control module







- Ignition off
- The breakout box connected
- Connect the control module.
- Transmission connector disconnected
- Ignition on
- Gear selector in position P.

Check the transmission control module (TCM) by measuring the resistance between terminals #B6 (#A66) and #A53 (#A53) on the breakout box. The resistance must be approximately 9 kohms.

Note! When removing the transmission connector, the control module may store diagnostic trouble codes (DTCs) for the gear-shift position sensor, the shift solenoids, the temperature sensor etc.

Try a new control module if the resistance is infinite.

Other information:

- To disconnect the transmission connectors, see Connectors transmission, disconnecting / connecting See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Wiring Harness/Service and Repair/Procedures

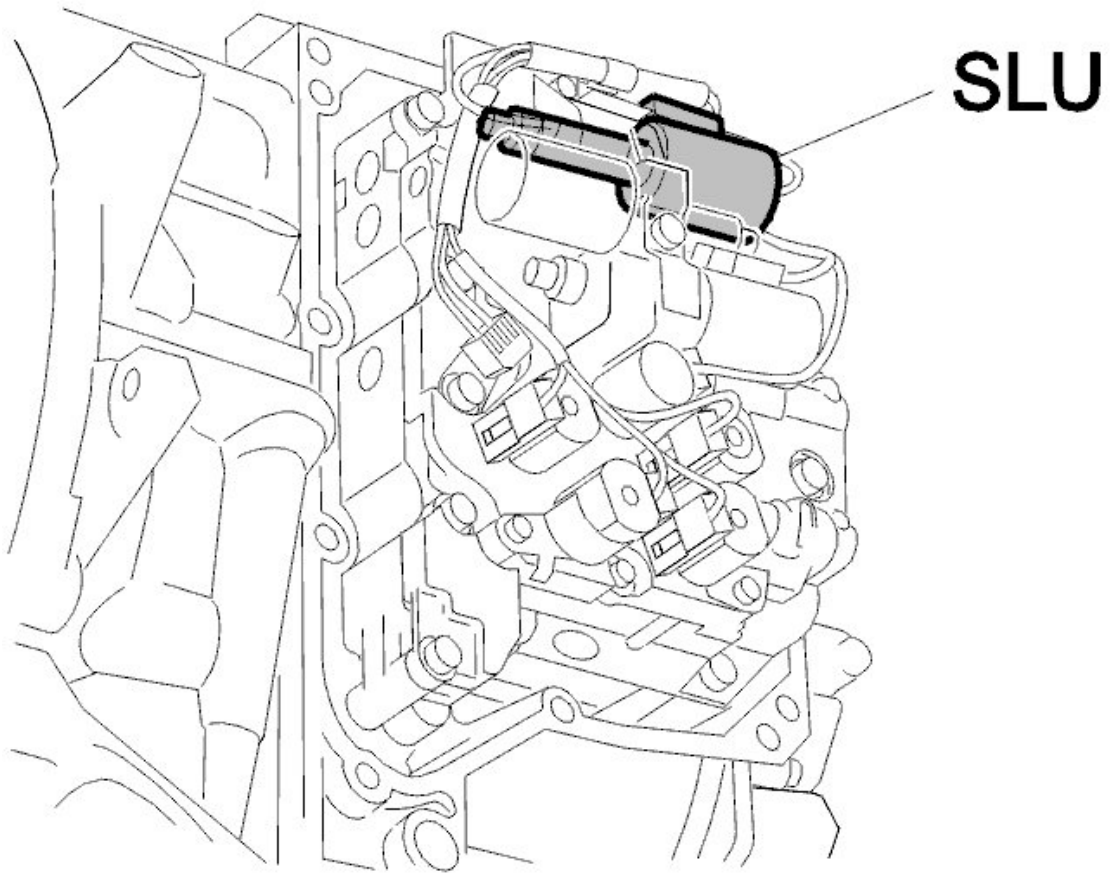
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition



Lock-up solenoid SL controls the transmission lock-up function. Solenoid SLU operates when it receives voltage from the transmission control module (TCM) and is activated under different driving conditions depending on road speed, throttle position and the driving mode selected. Diagnostic trouble code (DTC) TCM-010D is stored if the transmission control module (TCM) registers a short-circuit to supply voltage in the solenoid SLU circuit when the solenoid should not be activated. Solenoid SLU is probably activated permanently.

Substitute value

- The transmission control module (TCM) "Emergency mode I" program has been initiated.
- The transmission control module (TCM) does not activate the lock-up solenoid.

Possible source

- Short-circuit to supply voltage in the signal cable.
- Defective control module.

Fault symptom[s]

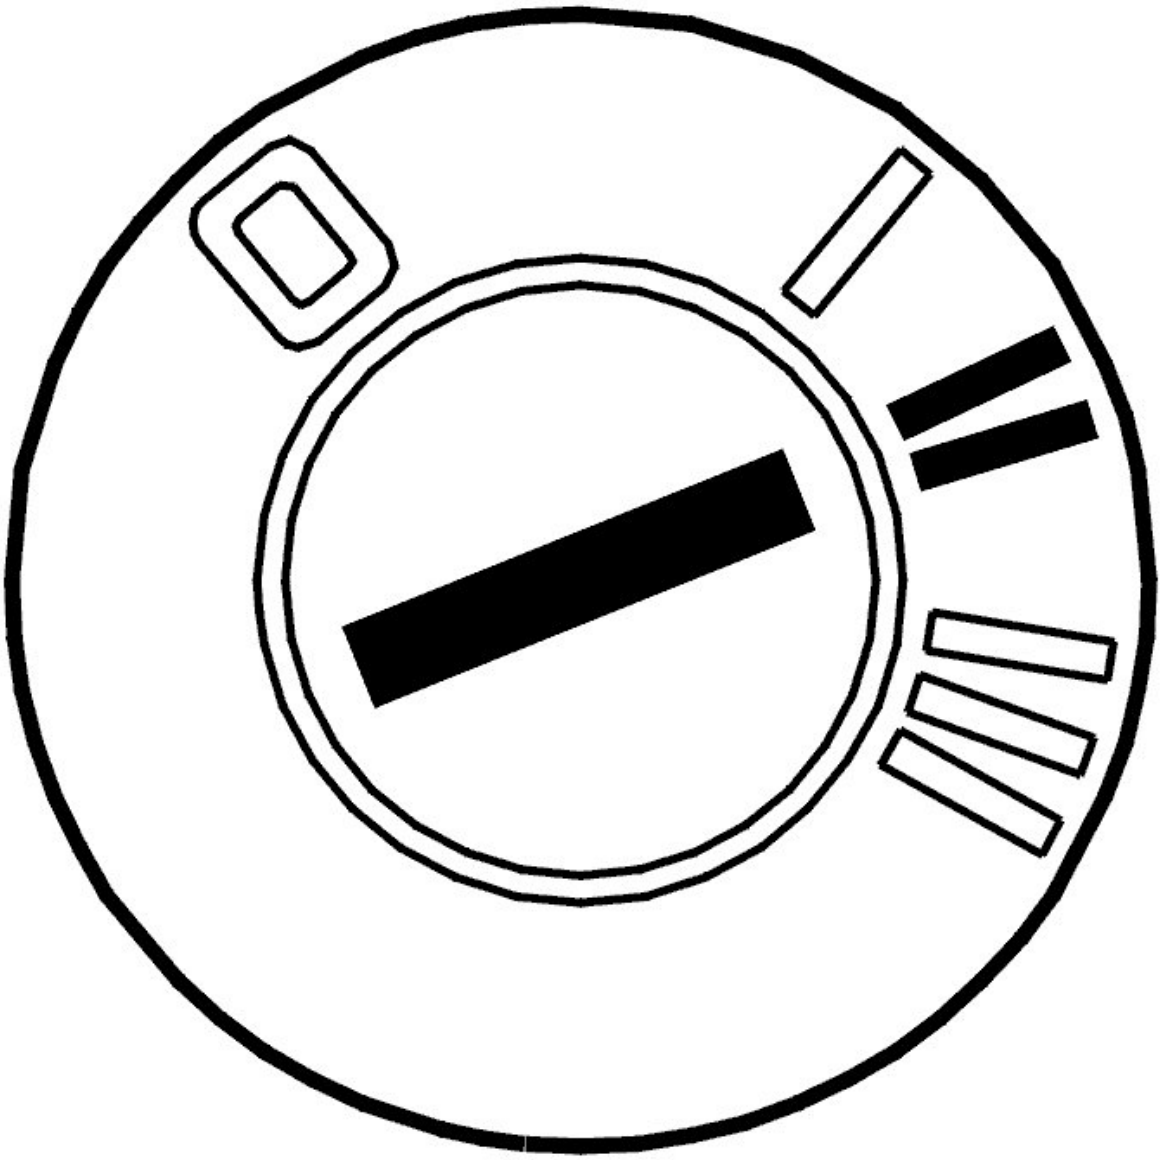
- General orange warning lamp lit.
- Harsh gear shifting.
- No shifting.
- Irregular shifting.

Hint: Harsh shifting is caused by the solenoid being permanently activated.

Signal Too High. Permanent Fault

Signal too high. Permanent fault

Checking line pressure solenoid SLU



- Ignition on
- Activate solenoid SLU.

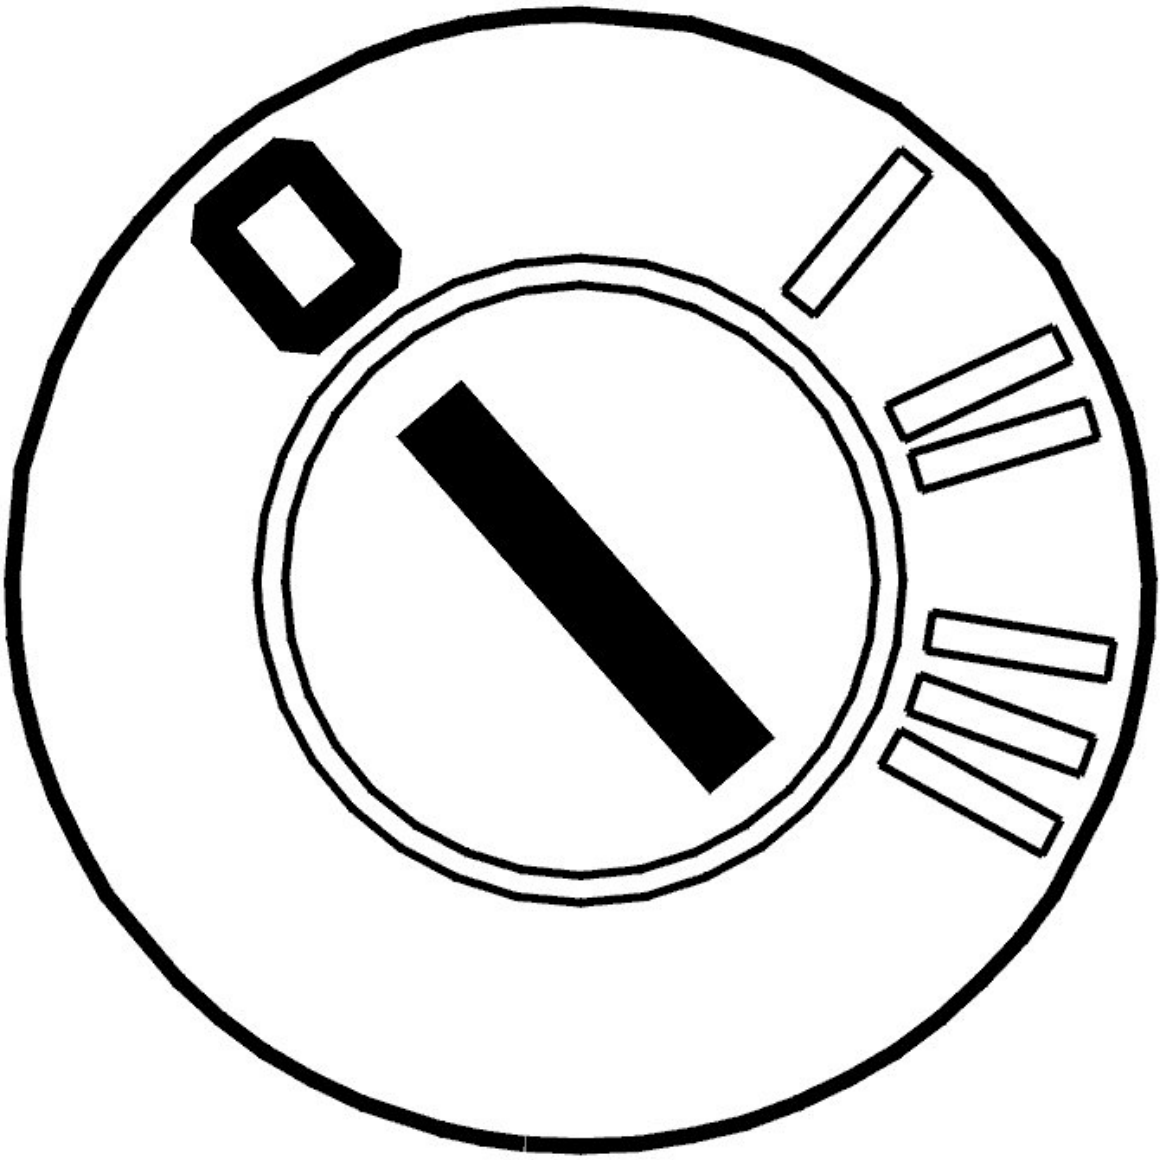
Read off the current through the solenoid SLU circuit.
The current should oscillate between 0 and 1000 mA.

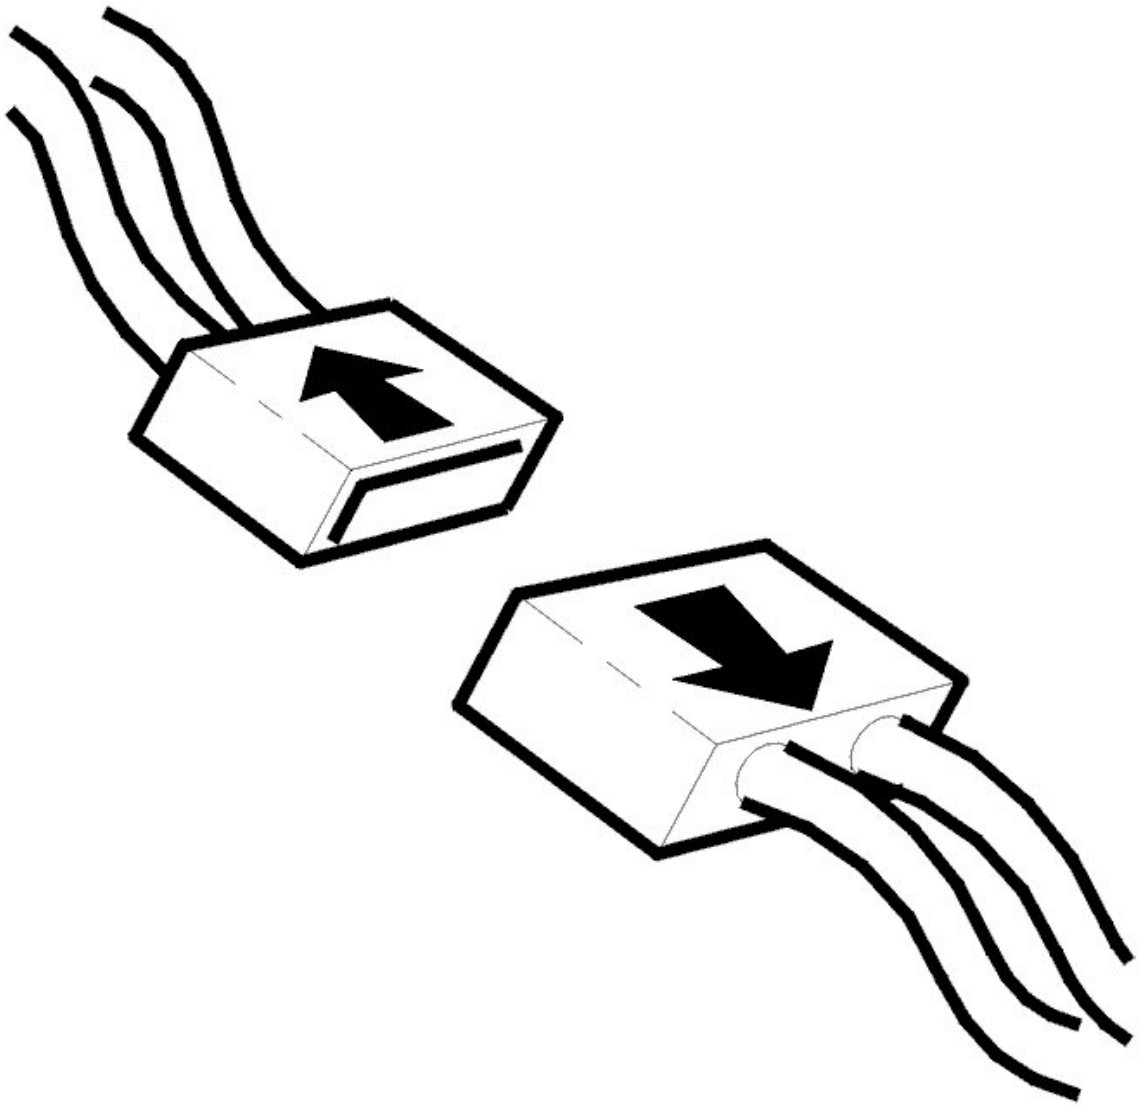
Does the current oscillate?

Yes - No Fault Found

No - Checking the wiring

Checking the wiring



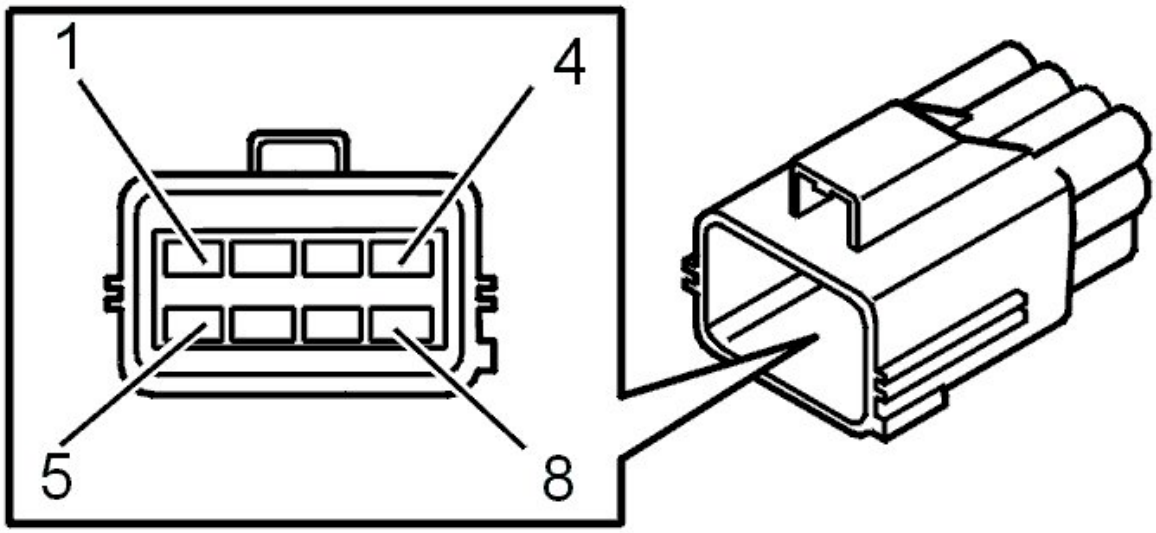


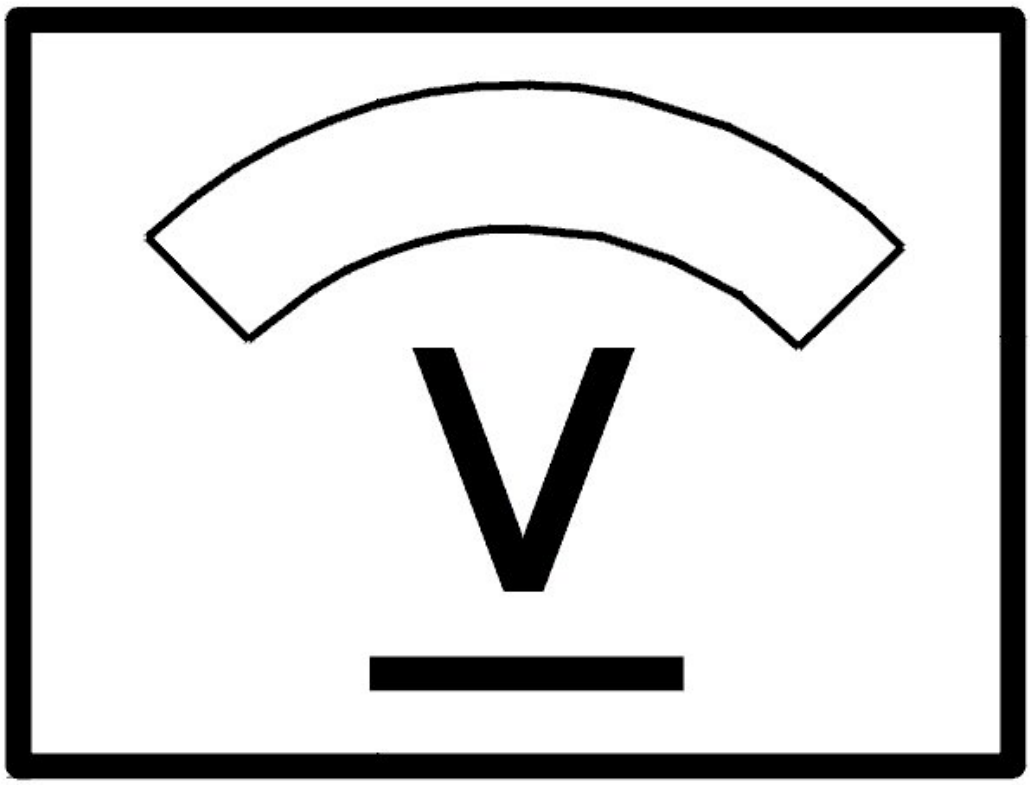
- Ignition off
- The breakout box connected
- Disconnect transmission connector D.

Check the cable between transmission control module (TCM) terminal #A51 (#A51) and transmission connector terminal #D1 (control module side). Check for a short-circuit to supply voltage. See Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault.
Check the cable between control module terminal #B9 (#A69) and transmission connector terminal #D2 (control module side). Check for a short-circuit to supply voltage. See Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault.
Also check against the other cables in the circuit. Use the relevant wiring diagram.
Remedy as necessary.

Other information:

- To connect the breakout box, see Connecting the breakout box, B5244T5, B5254T2 See: Pinout Values and Diagnostic Parameters/Connecting the Breakout Box
- To disconnect the transmission connectors, see Connectors transmission, disconnecting / connecting See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Wiring Harness/Service and Repair/Procedures
- For information about signals, see Signal description. Transmission control module (TCM), AW50/51 AWD, AW55-50/51SN See: Transmission Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Description. Transmission Control Module (TCM).



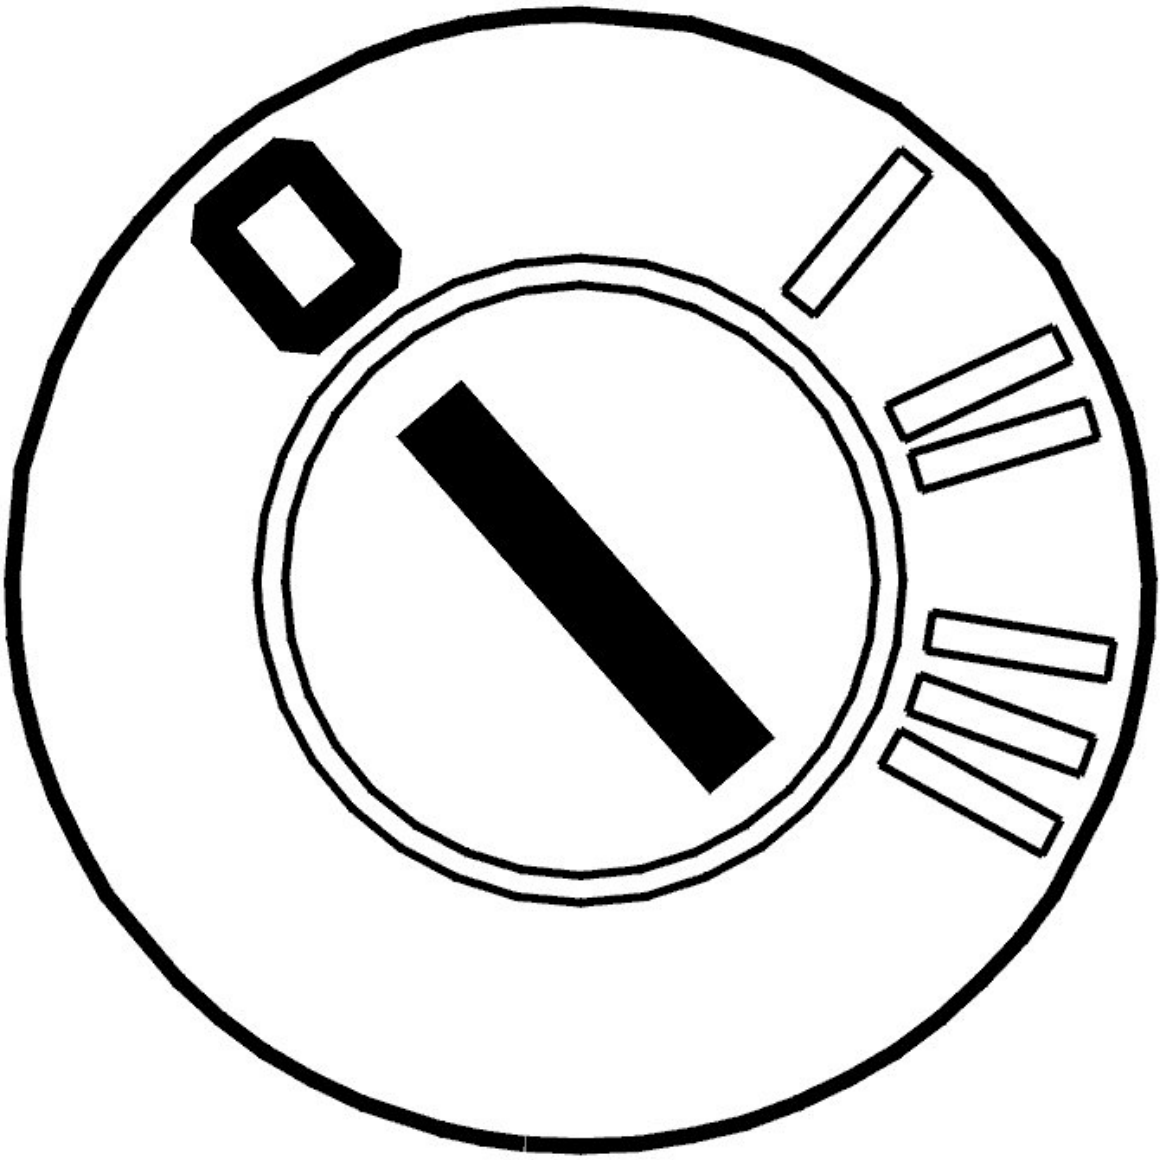


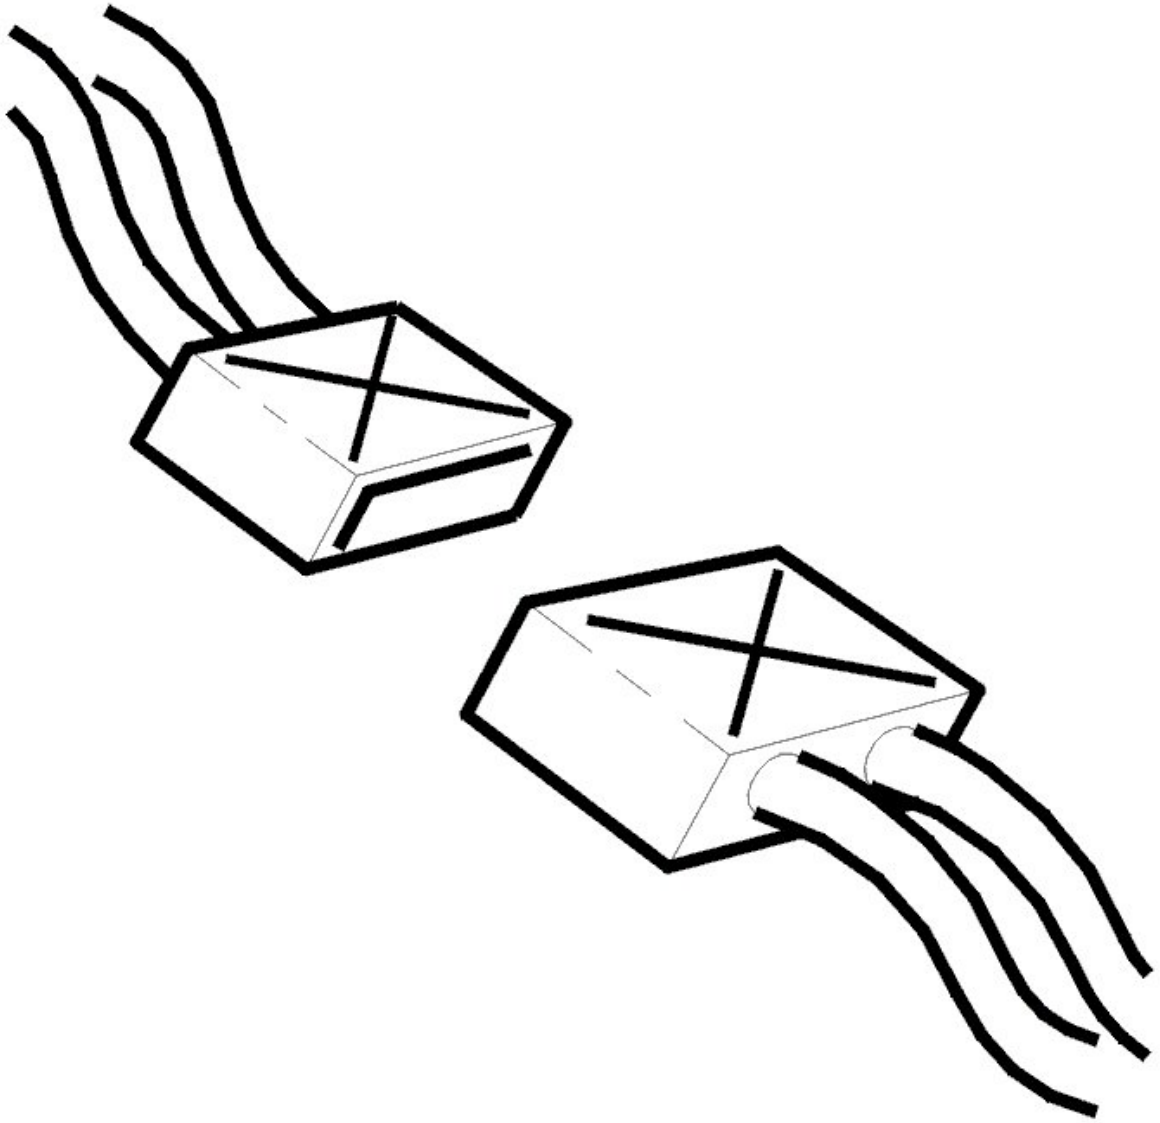
Was a fault detected?

Yes - Verification

No - Checking the wiring and component

Checking the wiring and component





- Ignition off
- Open the transmission control system.

Check the wiring between transmission connector terminal #D1 and solenoid SLU terminal #1. Check the wiring between transmission connector terminal #D2 and solenoid SLU terminal #2. Check for a short-circuit to supply voltage. See Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault.
Also check against the other cables in the circuit. Use the relevant wiring diagram.
Check solenoid SLU by measuring the resistance between terminals #1 and #2 on the connector. The resistance must be 5-5.6 ohms at 20°C.
Replace the transmission control system if the resistance is incorrect.

Other information:

- To disconnect the transmission connectors, see Connectors transmission, disconnecting / connecting See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Wiring Harness/Service and Repair/Procedures
- To replace the transmission control system, see Solenoid control system, replacing See: Transmission Control Systems/Actuators and Solenoids - Transmission and Drivetrain/Actuators and Solenoids - A/T/Shift Solenoid/Service and Repair/Solenoid Control System, Replacing
- To replace the cable harness for the control system, see Wiring harness / oil temperature sensor, replacing See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Wiring Harness/Service and Repair/Removal and Replacement
- For information about signals, see Signal description. Transmission control module (TCM), AW50/51 AWD, AW55-50/51SN See: Transmission Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Description. Transmission Control Module (TCM).

Continue - Resetting the adaptation and oil quality counter

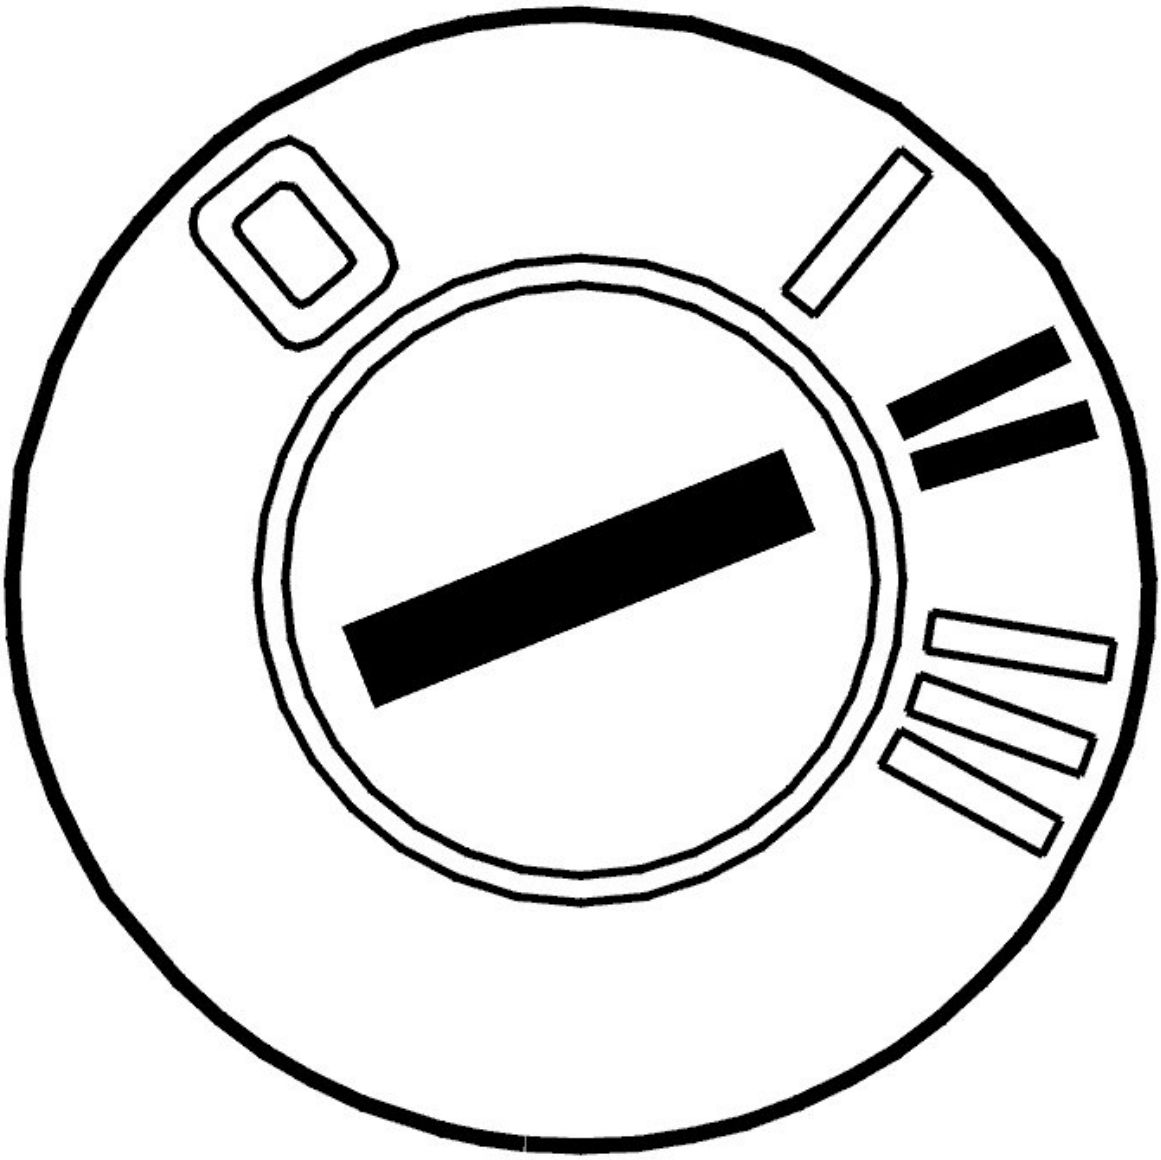
Resetting the adaptation and oil quality counter

Resetting the adaptation

Resetting adaptation and the counter for "Transmission oil change"

Hint: The transmission has torque controlled adaptive pressure control. Pressure control means that the transmission regulates the pressure itself during each gear shift. This avoids harsh gear shifting. Each gear shift is evaluated by the control module and stored in the memory. This allows for compensation for wear and tear in the transmission and clutch. It is important that the adaptation in the memory is reset after the transmission has been repaired. This is to ensure normal operation. The oil is replaced during repair; the "Transmission oil change" counter must be reset. If the counter is not reset when the fluid is drained and replaced, there is a risk that a diagnostic trouble code (DTC) will be stored in incorrect circumstances.

Note! This applies only if the transmission or one of the components in the transmission have been replaced.



- Ignition on.

Click on the VCT2000 symbol to reset the adaptation and counter.

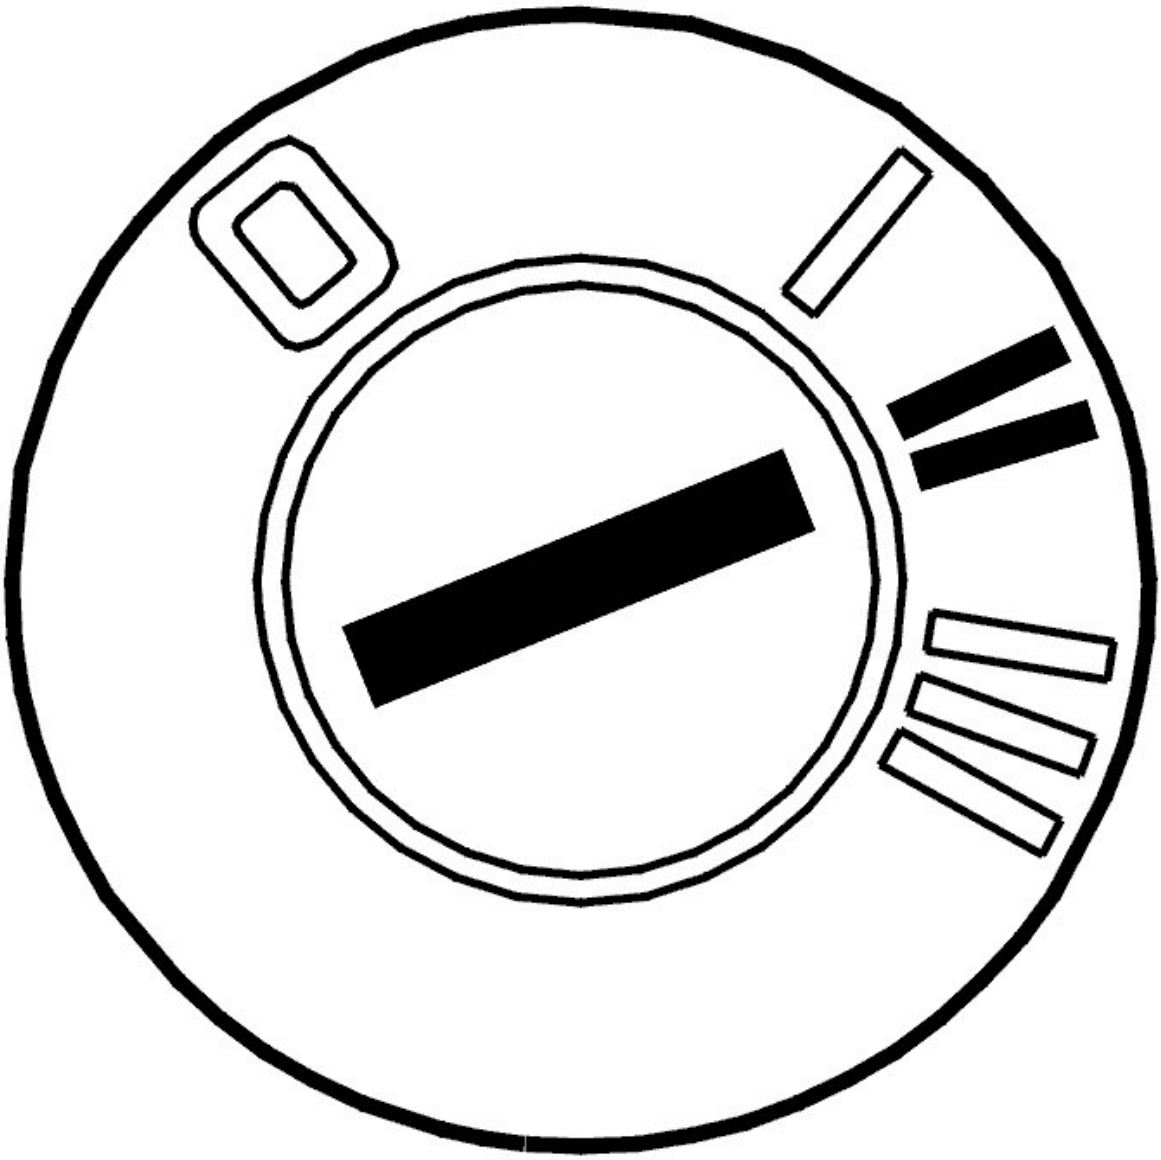
Resetting the adaptation

Resetting adaptation and the counter for "Transmission oil change"

Hint: The transmission has torque controlled adaptive pressure control. Pressure control means that the transmission regulates the pressure itself during each gear shift. This avoids harsh gear shifting. Each gear shift is evaluated by the control module and stored in the memory. This allows for compensation for wear and tear in the transmission and clutch. It is important that the adaptation in the memory is reset after the transmission has been repaired. This is to ensure normal operation. The oil is replaced during repair; the "Transmission oil change" counter must be reset. If the counter is not reset when the fluid is drained and replaced, there is a risk that a diagnostic trouble code (DTC) will be stored in incorrect circumstances.

Note! This applies only if the transmission or one of the components in the transmission have been replaced.



- Ignition on.

Click on the VCT2000 symbol to reset the adaptation and counter.

Continue - **DONE**

DONE - Verification

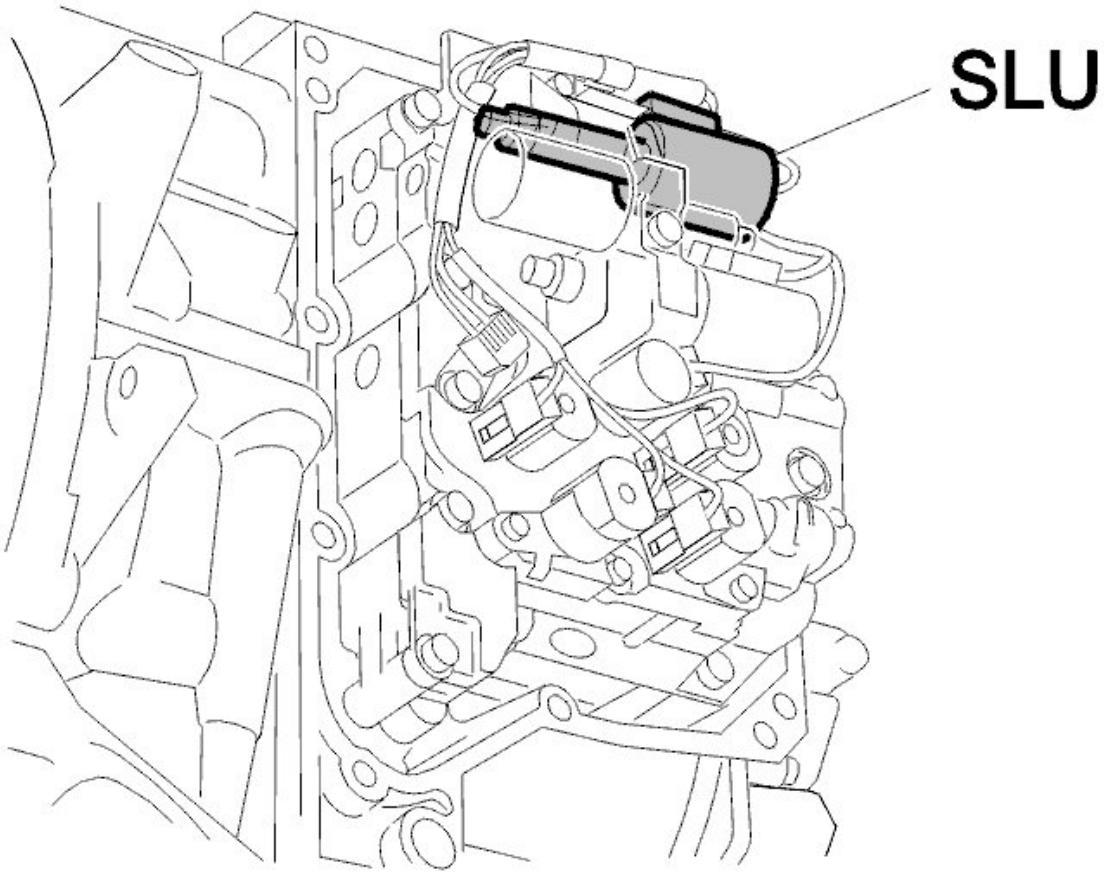
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition



Lock-up solenoid SL controls the transmission lock-up function and certain gear shifts in the transmission. Solenoid SLU operates when it receives voltage from the transmission control module (TCM) and is activated under different driving conditions depending on road speed, throttle position and the driving mode selected. Diagnostic trouble code (DTC) TCM-0110 is stored if the control module registers a short-circuit to ground in the solenoid SLU circuit when the solenoid should be activated. Solenoid SLU can probably not be activated.

Substitute value
- The transmission control module (TCM) "Emergency mode I" program has been initiated.
- The transmission control module (TCM) does not activate the lock-up solenoid.

Possible source
- Short-circuit to ground in the signal cable.
- Defective control module.
- Defective solenoid.

Fault symptom[s]
- General orange warning lamp lit.
- No shifting.
- Irregular shifting.
- No lock-up function.

Signal Too Low. Intermittent Fault

Signal too low. Intermittent fault

Intermittent fault

Check the transmission control module (TCM) and transmission connectors. Check for contact resistance and oxidation according to Checking wiring and terminals. Intermittent faults See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Intermittent Faults.
Check the wiring between transmission control module (TCM) terminal #A51 (#A51) and transmission connector terminal #D1. Check the wiring between control module terminal #B9 (#A69) and transmission connector terminal #D2. Check for an intermittent short-circuit to ground according to Checking wiring and terminals. Intermittent faults See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Intermittent Faults.

Hint: Check solenoid SLU. Measure the resistance between terminals #D1 and #D2 on transmission connector D. The resistance should be 5-5.6 ohms at 20°C.

Remedy as necessary.

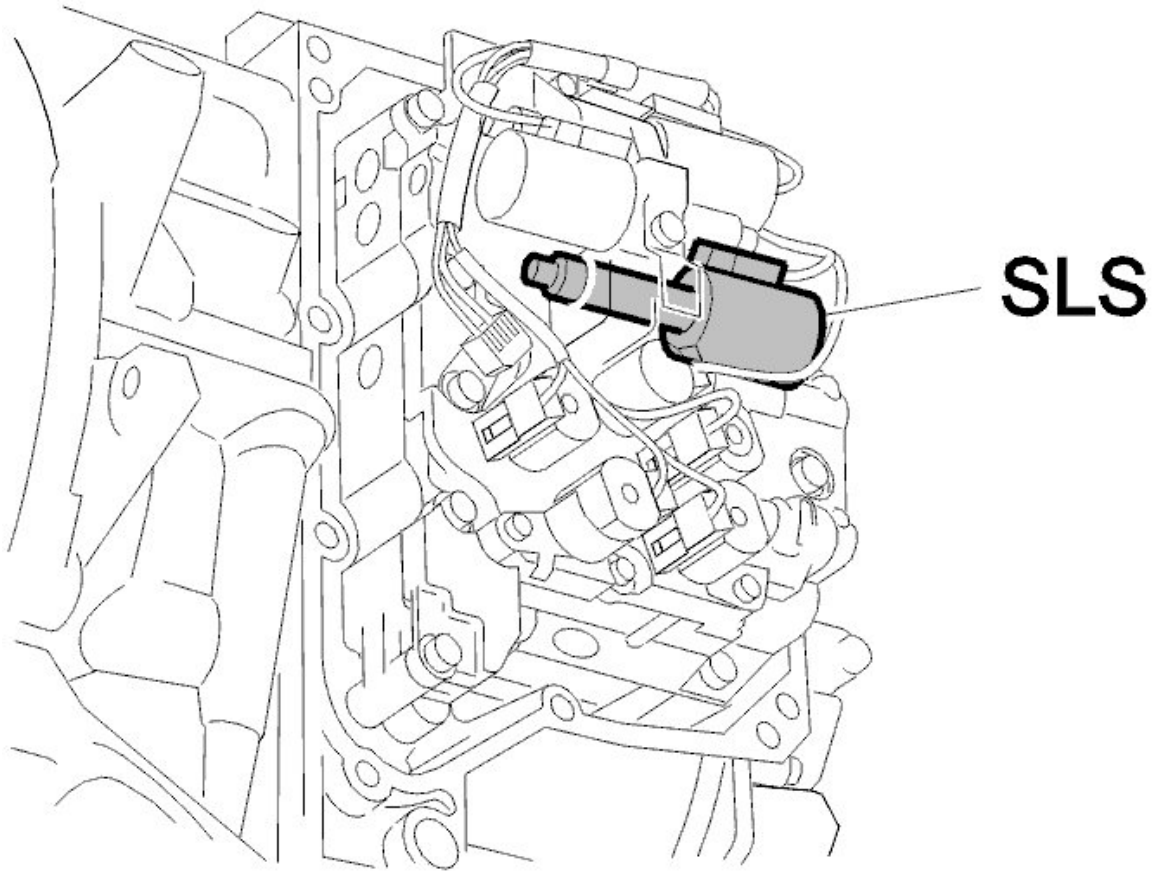
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition



Line pressure solenoid SLS regulates the line pressure in the transmission. The solenoid is controlled by a power stage in the transmission control module (TCM) output. The transmission control module (TCM) uses the power stage to control the current to the solenoid. A low amperage results in a high line pressure. A high amperage (approximately 1 A) gives a low line pressure. The amperage is primarily affected by the throttle position. Diagnostic trouble code (DTC) TCM-0112 is stored if the control module (TCM) registers a short-circuit to battery voltage in the circuit for solenoid SLS. This results in too high an amperage in the circuit. Solenoid SLS cannot then control the line pressure.

Substitute value
- The transmission control module (TCM) Emergency mode III program is initiated.

Possible source
- Short-circuit to supply voltage in the control signal wiring or signal wiring.
- Short-circuit between the control signal cable and the signal cable.
- Defective solenoid.

Fault symptom[s]

- General orange warning lamp lit.
- No shifting.
- No lock-up function.

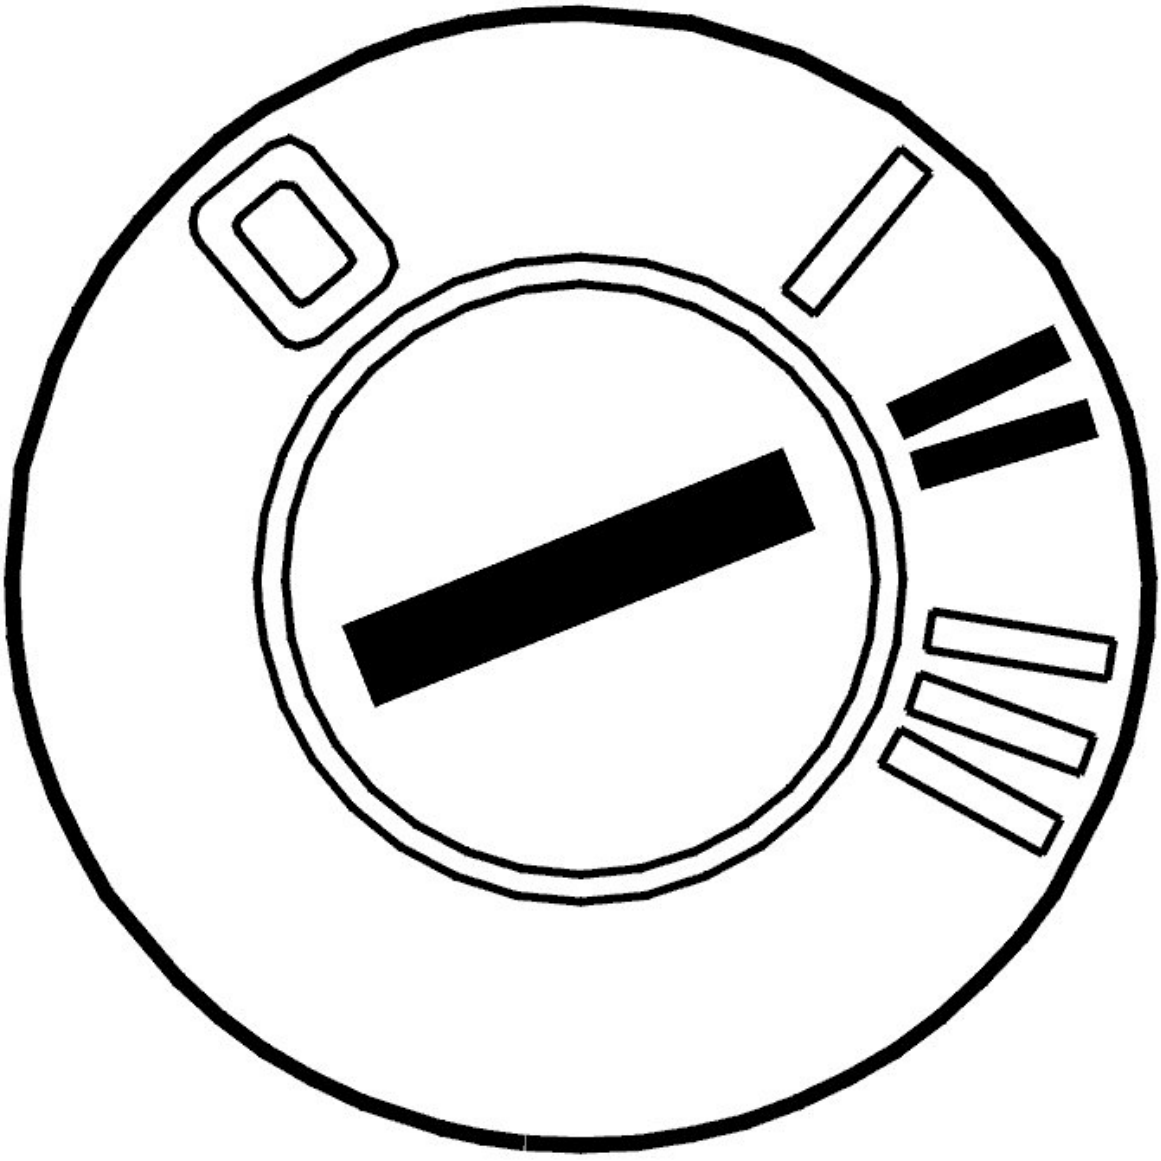
Hint: No shifting because the control module prevents activation of the solenoids.

Caution! There is a danger that this fault will cause line pressure in the transmission to be too low. This will result in a high level of wear.

Signal Too High. Permanent Fault

Signal too high. Permanent fault

Checking line pressure solenoid SLS



- Ignition on
- Activate solenoid SLS.

Read off the current through the solenoid SLS circuit.
The current should oscillate between 0 and 1000 mA.

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition

Line pressure solenoid SLS regulates the line pressure in the transmission. The solenoid is controlled by a power stage in the transmission control module (TCM) output. The transmission control module (TCM) uses the power stage to control the current to the solenoid. A low amperage results in a high line pressure. A high amperage (approximately 1 A) gives a low line pressure. The amperage is primarily affected by the throttle position. Diagnostic trouble code (DTC) TCM-113 is stored if the control module registers that there is an open-circuit in the circuit for solenoid SLS. Solenoid SLS cannot then control the line pressure.

Substitute value
- The transmission control module (TCM) Emergency mode III program is initiated.

Possible source
- Open-circuit in the control signal cable or the signal cable.
- Defective solenoid.
- Open-circuit in the power ground.
- Contact resistance in terminals.
- Defective control module.

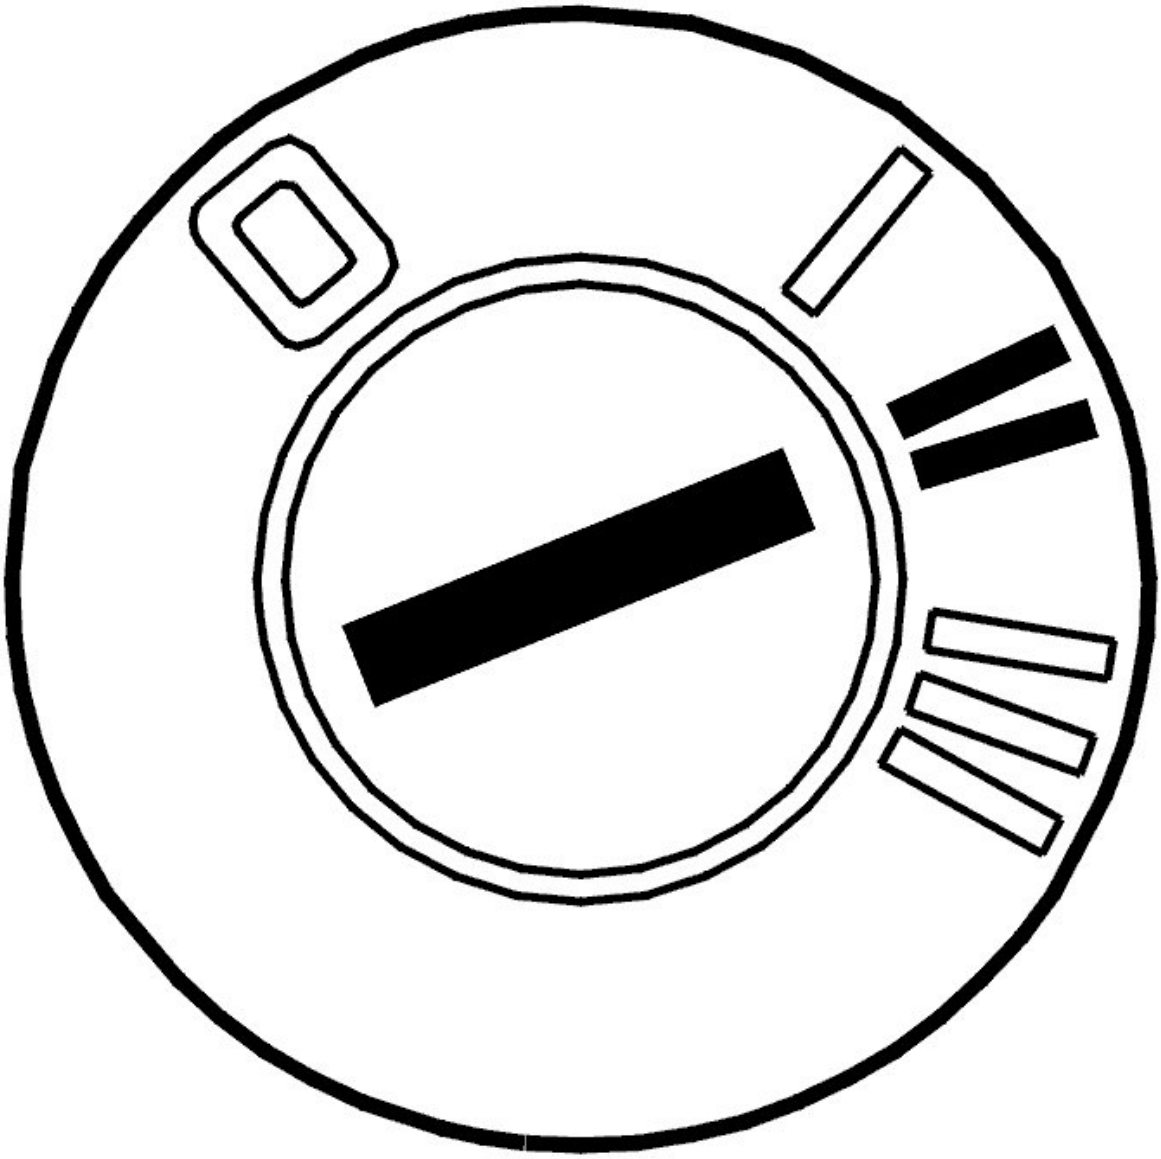
Fault symptom[s]
- General orange warning lamp lit.
- No lock-up function.
- Harsh gear shifting.

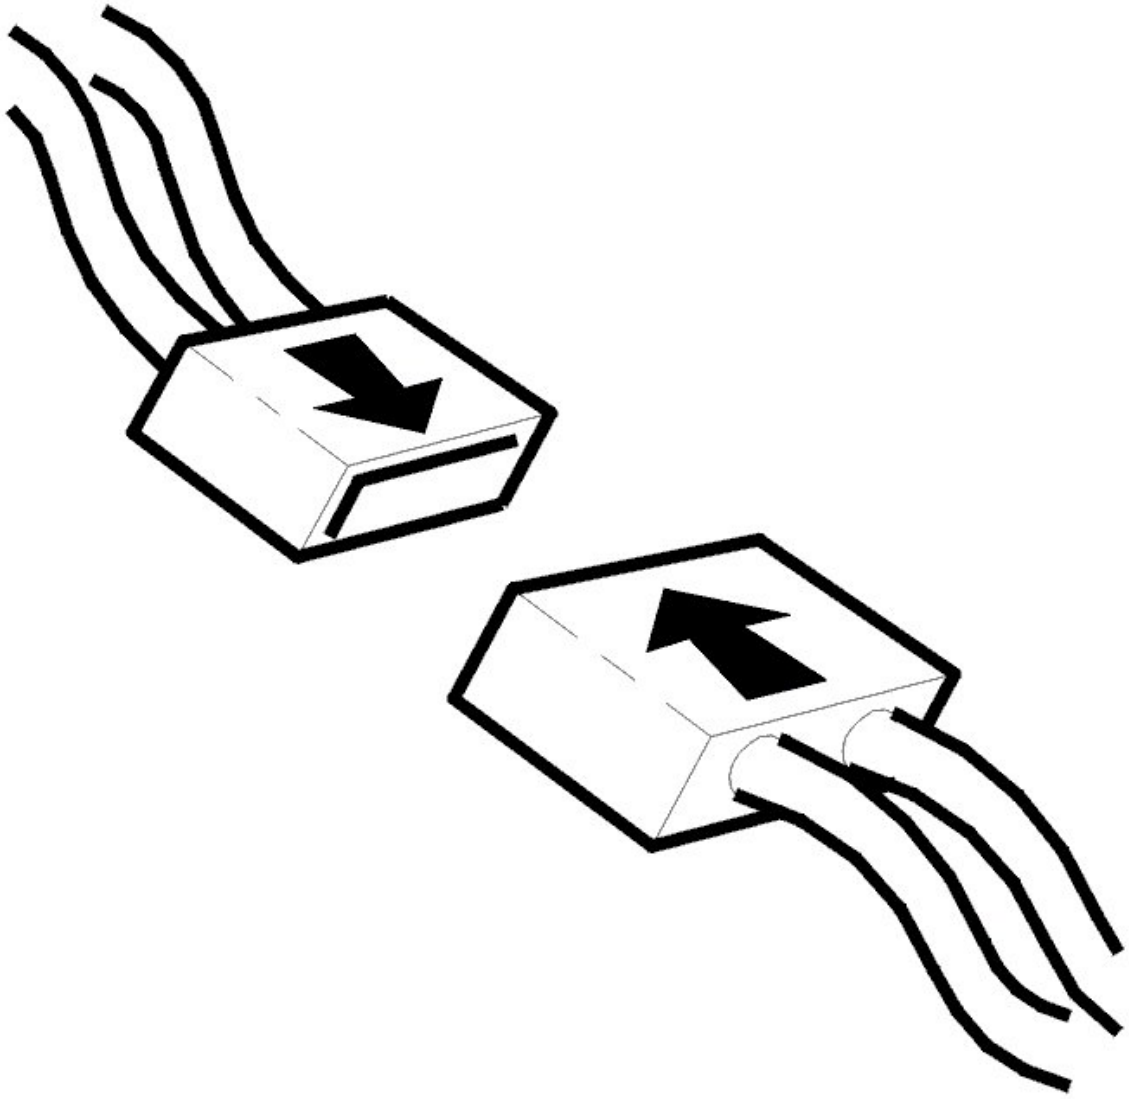
Hint: Harsh gear shifting can be caused by:
- No torque limiting request to the engine control module (ECM) when shifting.
- No line pressure solenoid SLS control. This results in constant maximum line pressure.

Signal Missing. Permanent Fault

Signal missing. Permanent fault

Checking line pressure solenoid SLS





- Ignition off
- Check the control module connector and automatic transmission connector D. Check for contact resistance and oxidation. See Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault. Remedy if necessary
- Reinstall the components, reconnect the connectors etc.
- Ignition on
- Activate solenoid SLS.

Read off the current through the solenoid SLS circuit.
The current should oscillate between 0 and 1000 mA.

Other information:

- To disconnect the transmission connectors, see Connectors transmission, disconnecting / connecting See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Wiring Harness/Service and Repair/Procedures
- To disconnect the control module, see Transmission control module (TCM), replacing, B5244T5, AW55-50/51SN, B5254T2, AW55-50/51SN, B5254T2, AW50/51 AWD See: Transmission Control Systems/Relays and Modules - Transmission and Drivetrain/Relays and Modules - A/T/Control Module/Service and Repair

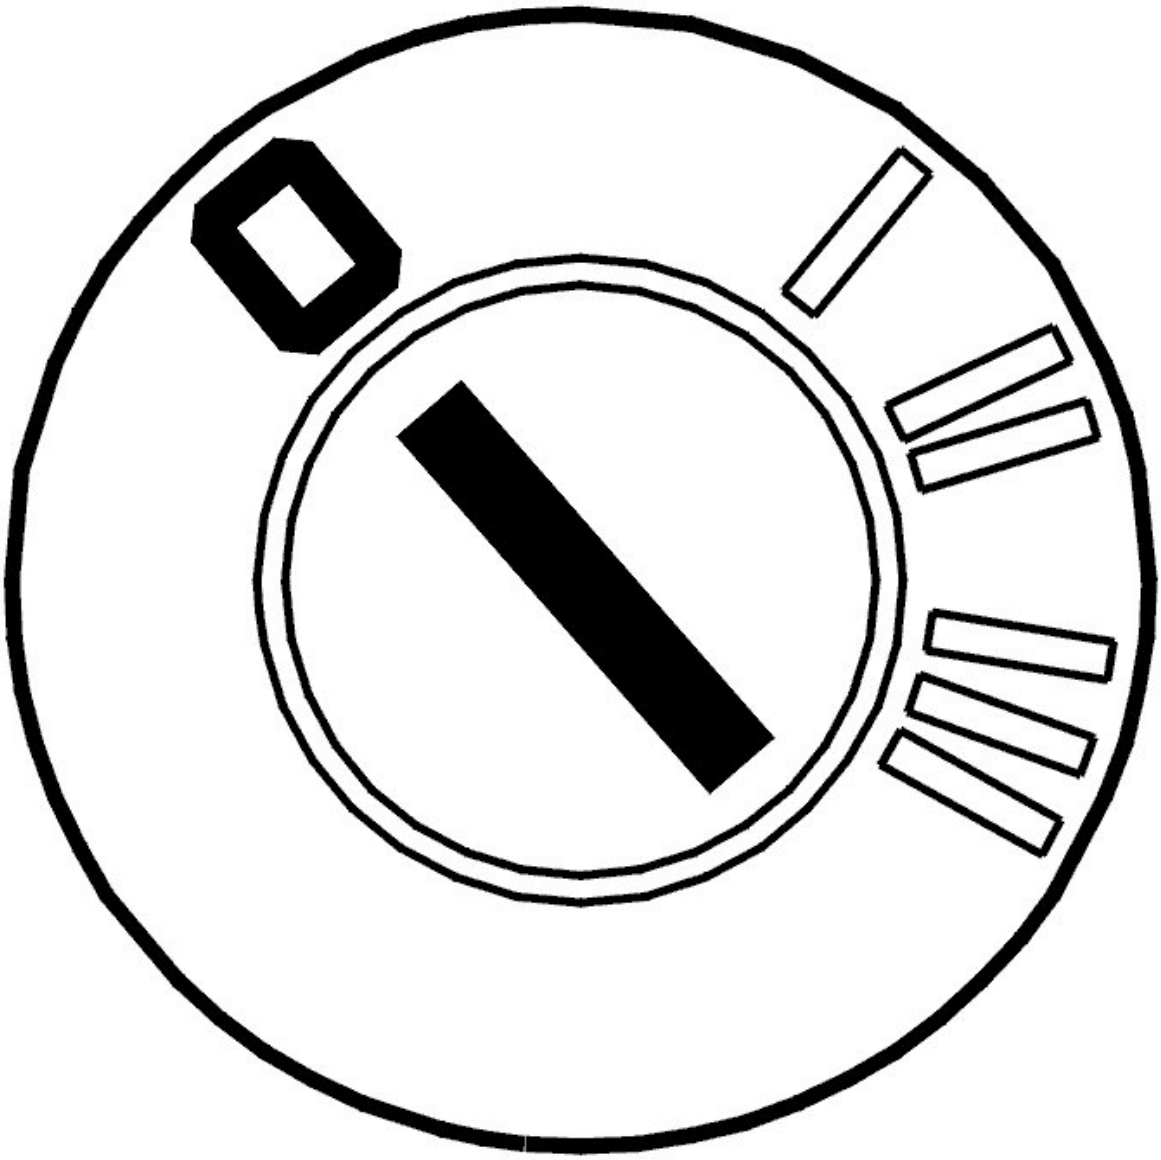
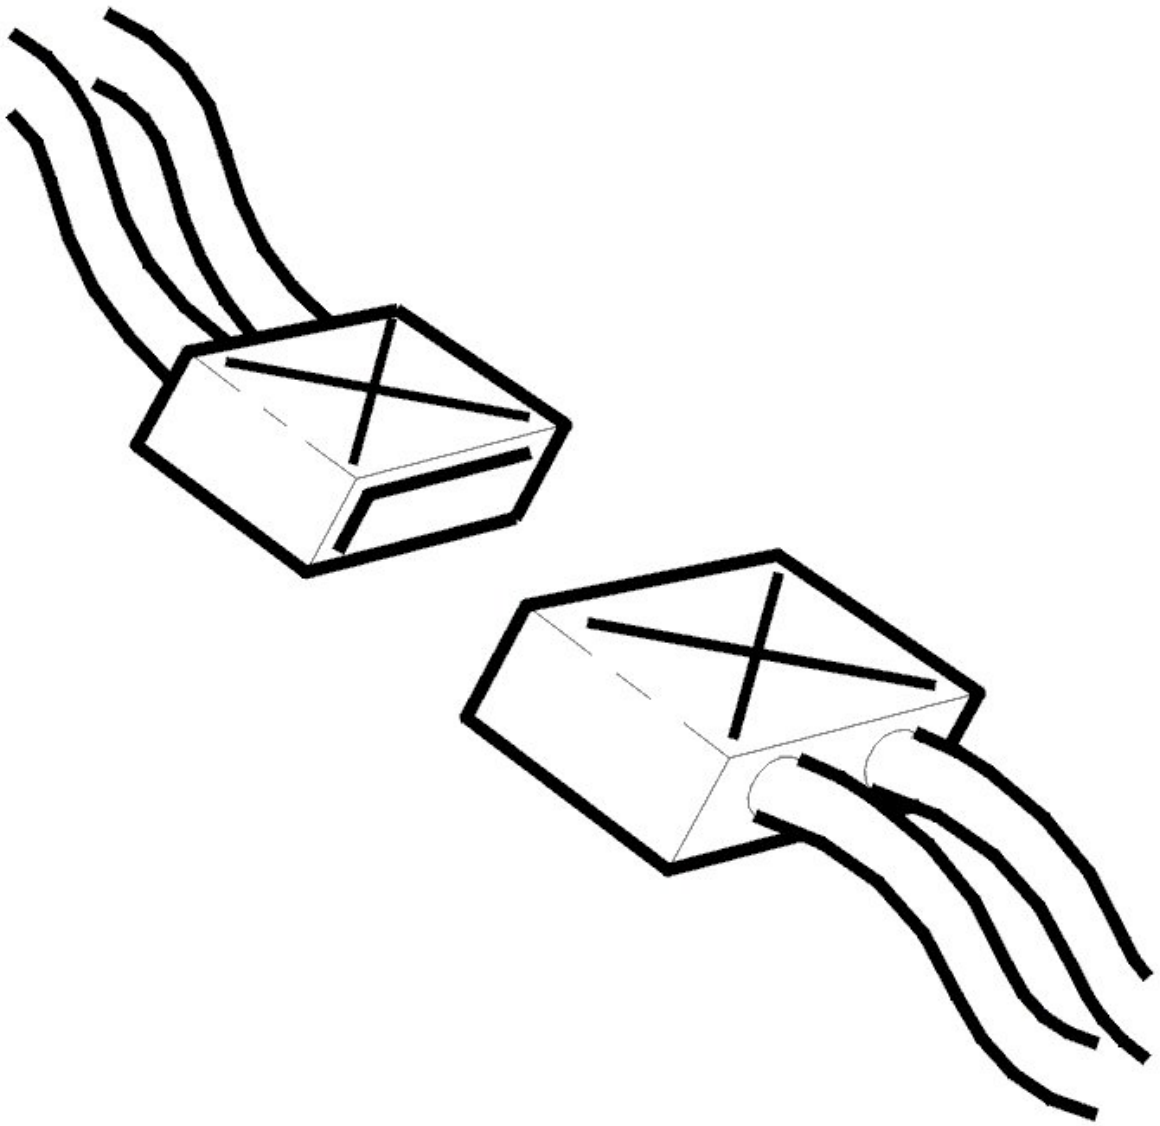
Was a fault found in the wiring?

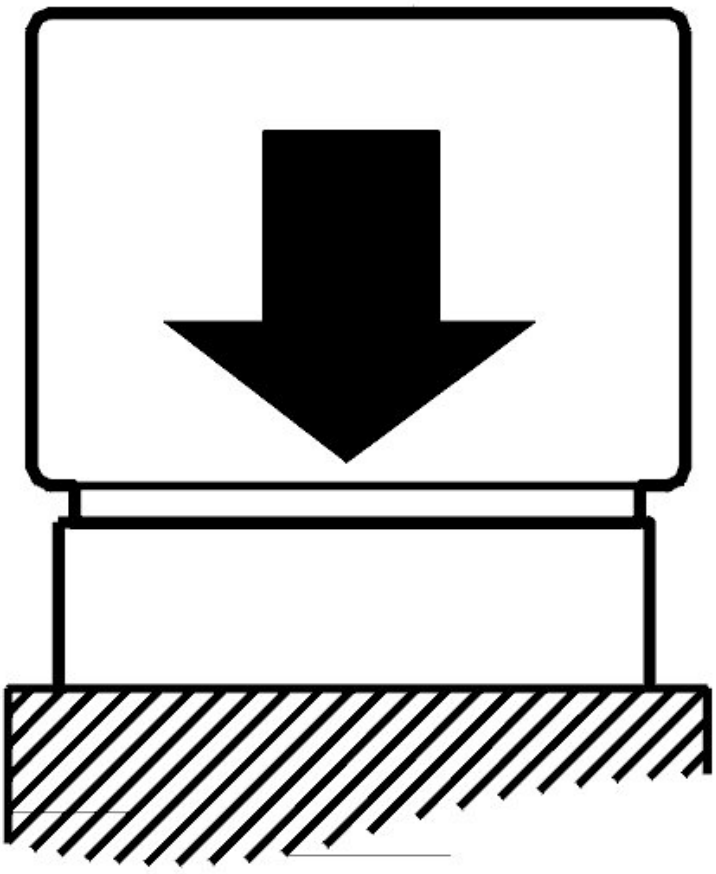
Yes - Verification

No - Checking the control module

Checking the control module







- Ignition off
- The breakout box connected
- Connect the control module.
- Transmission connector D disconnected.

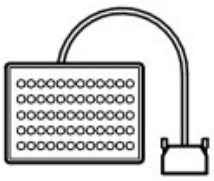
Check the transmission control module (TCM) by measuring the resistance between terminals #A49 (#A49) and #B7 (#A67) on the breakout box. The resistance must be approximately 9 kohms.

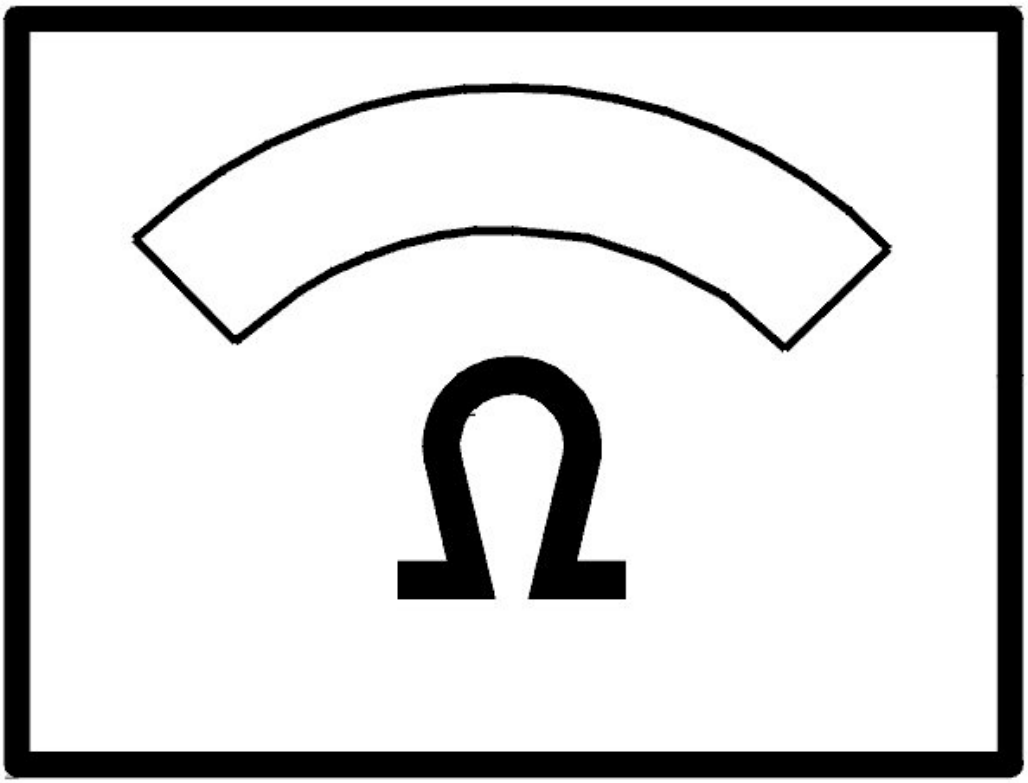
Note! When removing the transmission connector, the control module may store diagnostic trouble codes (DTCs) for the gear-shift position sensor, the shift solenoids, the temperature sensor etc.

Try a new control module if the resistance is infinite.

Other information:

- To disconnect the transmission connectors, see Connectors transmission, disconnecting / connecting See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Wiring Harness/Service and Repair/Procedures
- To replace the control module, see Transmission control module (TCM), replacing, B5244T5, AW55-50/51SN, B5254T2, AW55-50/51SN, B5254T2, AW50/51 AWD See: Transmission Control Systems/Relays and Modules - Transmission and Drivetrain/Relays and Modules - A/T/Control Module/Service and Repair
- For information about signals, see Signal description. Transmission control module (TCM), AW50/51 AWD, AW55-50/51SN See: Transmission Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Description. Transmission Control Module (TCM).



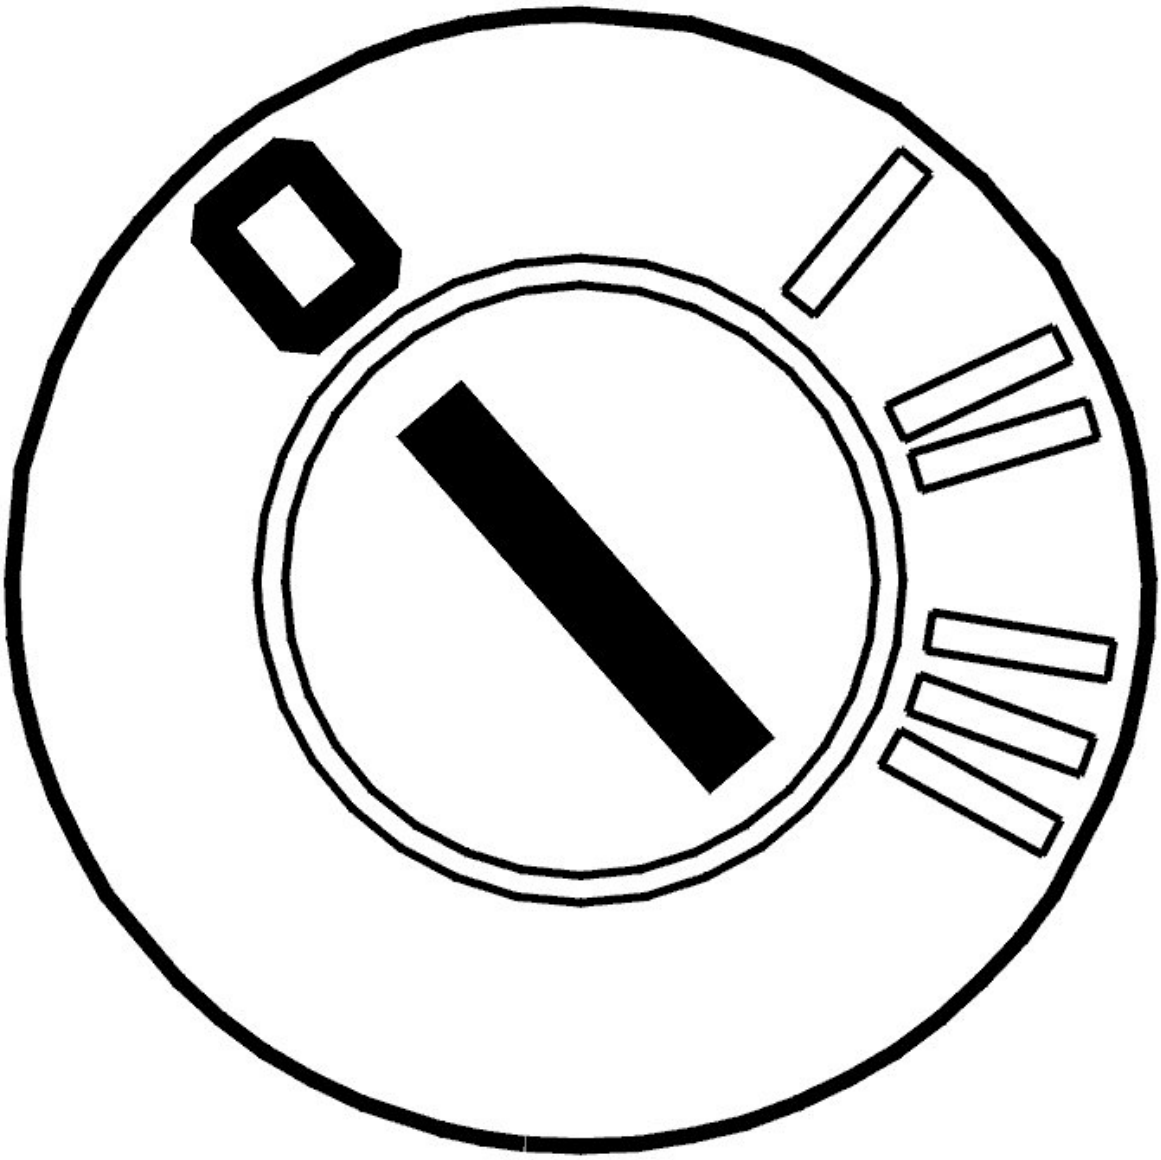


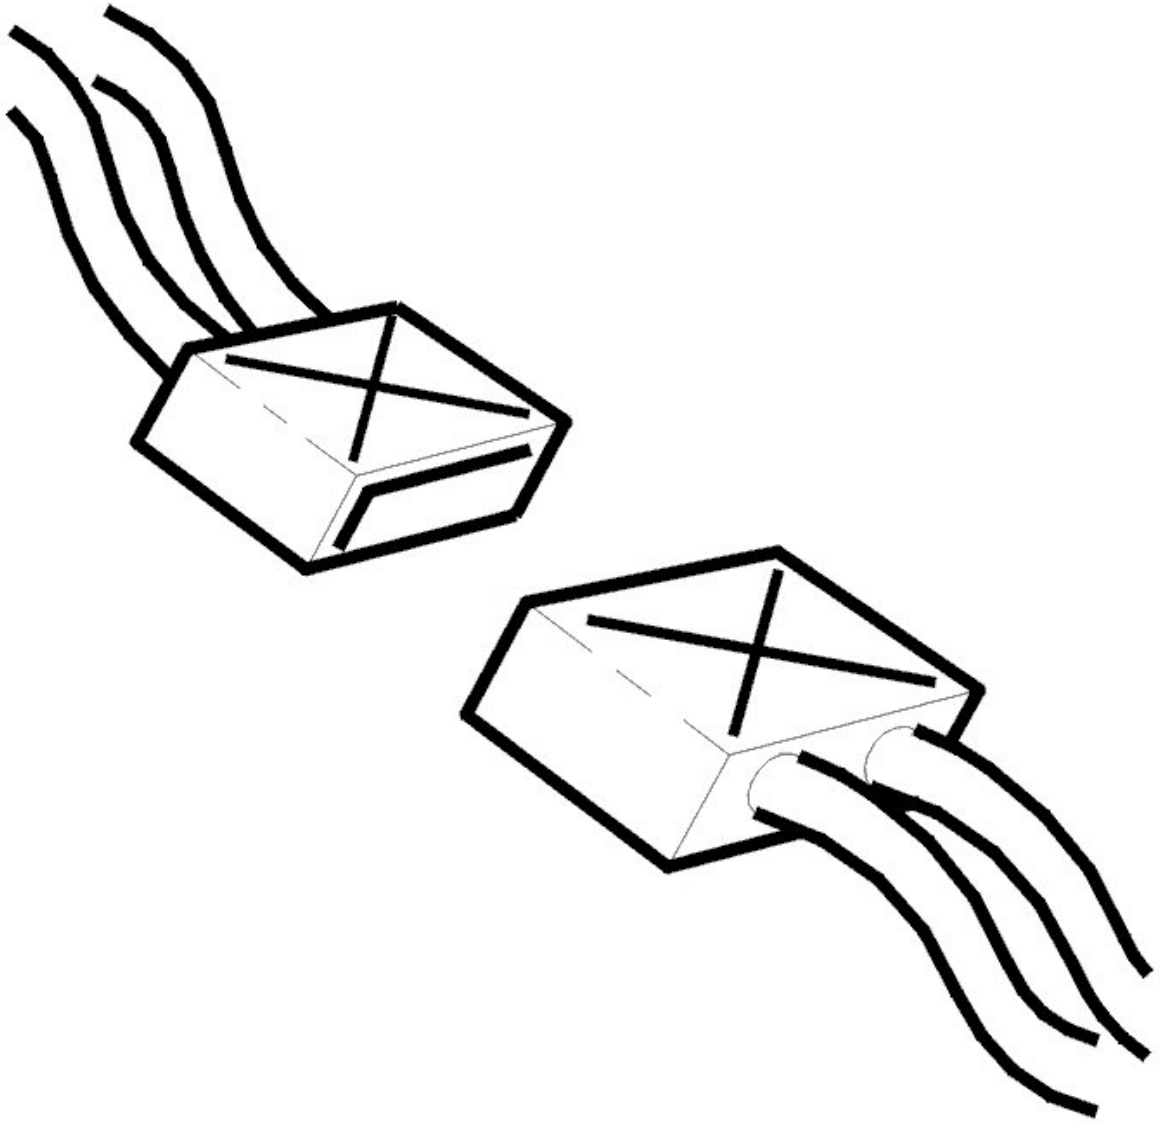
Was the resistance OK?

Yes - No Fault Found

No - Verification

Checking the wiring and component





- Ignition off
- Open the transmission control system.

Check the wiring between transmission connector terminal #D5 (transmission side) and solenoid SLS terminal #1. Check the wiring between transmission connector terminal #D6 (transmission side) and solenoid SLS terminal #2. Check for an open-circuit. See Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault.
Also check against the other cables in the circuit. Use the relevant wiring diagram.
Check the solenoid SLS by measuring the resistance between terminals #1 and #2. The resistance should be 5-5.6 ohms at 20°C. Replace the transmission control system if the resistance is incorrect.

Other information:

- To disconnect the transmission connectors, see Connectors transmission, disconnecting / connecting See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Wiring Harness/Service and Repair/Procedures

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition

Line pressure solenoid SLS regulates the line pressure in the transmission. The solenoid is controlled by a power stage in the transmission control module (TCM) output. The transmission control module (TCM) uses the power stage to control the current to the solenoid. A low amperage results in a high line pressure. A high amperage (approximately 1 A) gives a low line pressure. The amperage is primarily affected by the throttle position. Diagnostic trouble code (DTC) TCM-114 is stored if the control module registers that there is an open-circuit in the circuit for solenoid SLS. Solenoid SLS cannot then control the line pressure.

Substitute value
- The transmission control module (TCM) Emergency mode III program is initiated.

Possible source
- Open-circuit in the control signal cable or the signal cable.
- Defective solenoid.
- Open-circuit in the power ground.
- Contact resistance in terminals.
- Defective control module.

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

Fault symptom[s]

- General orange warning lamp lit.
- No lock-up function.
- Harsh gear shifting.

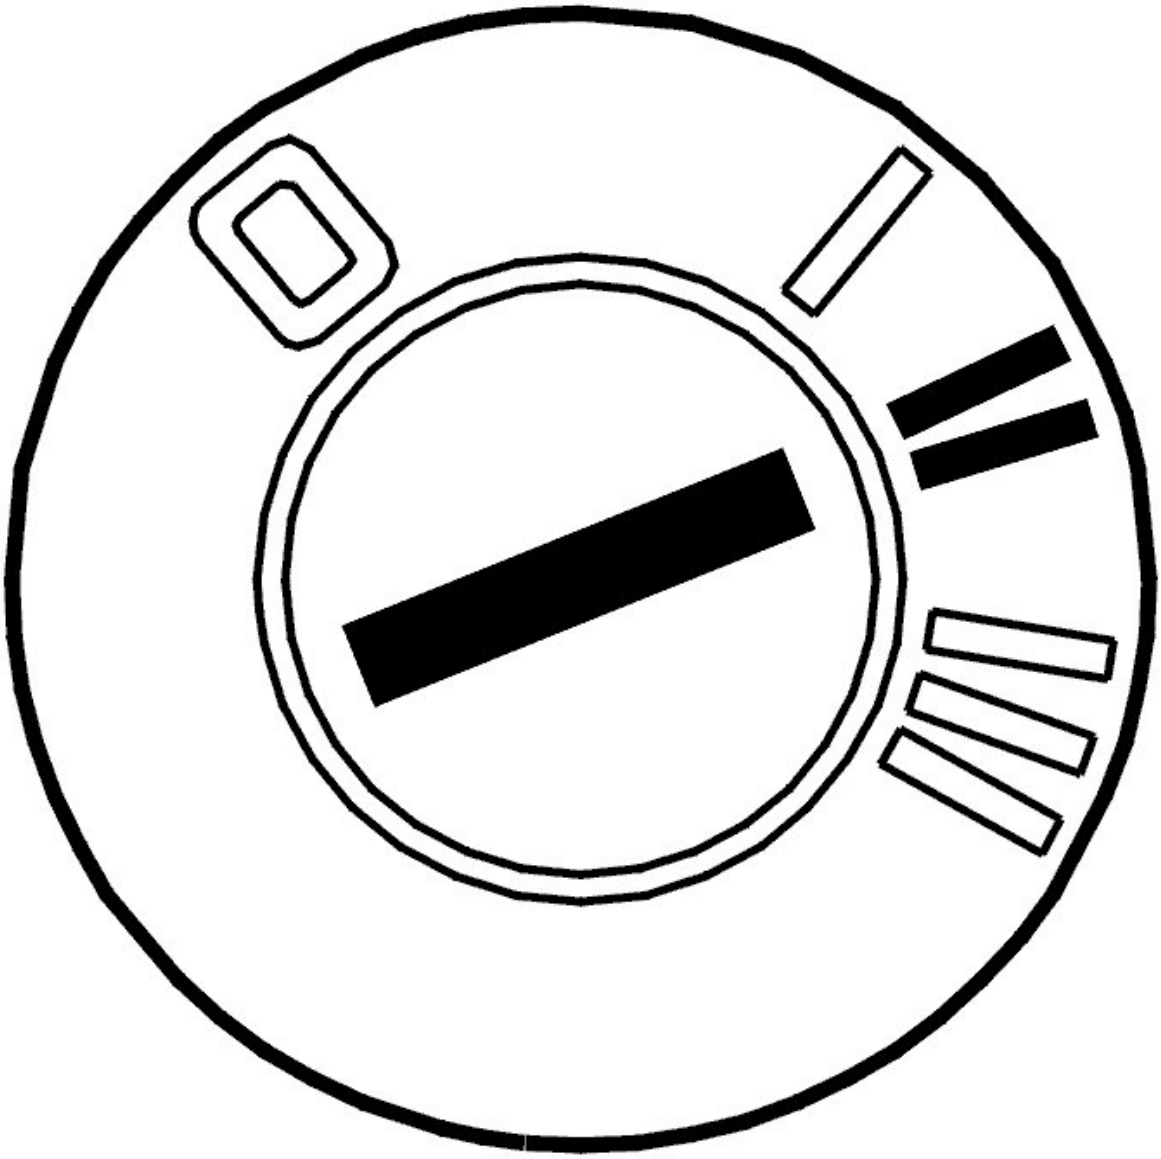
Hint: Harsh gear shifting can be caused by:

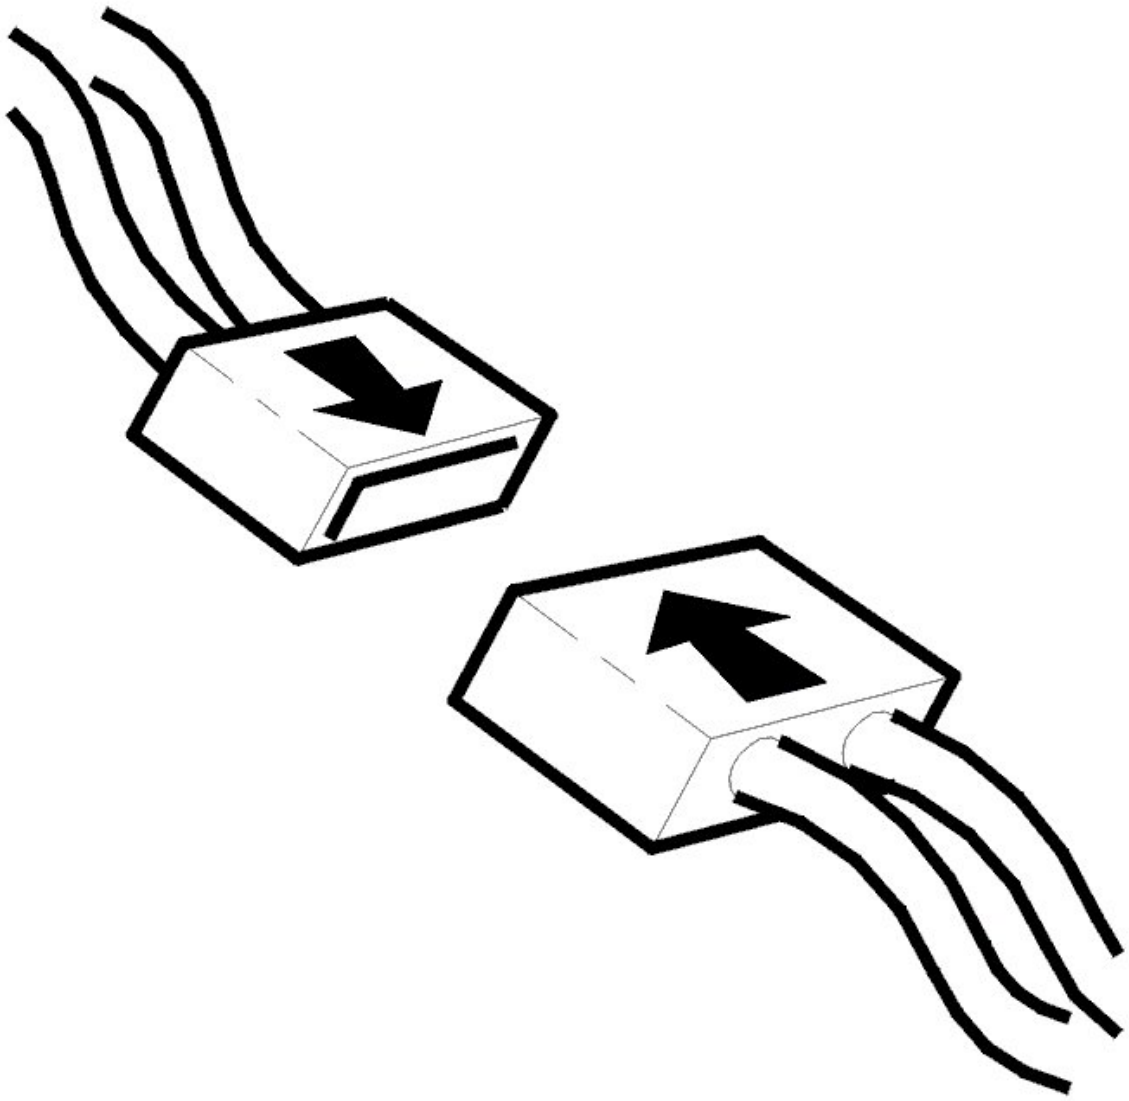
- No torque limiting request to the engine control module (ECM) when shifting.
- No line pressure solenoid SLS or SLT control. This results in constant maximum line pressure.

Signal Too Low. Permanent Fault

Signal too low. Permanent fault

Checking line pressure solenoid SLS





- Ignition off
- Check the control module connector and automatic transmission connector D. Check for contact resistance and oxidation. See Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault. Remedy if necessary
- Reinstall the components, reconnect the connectors etc.
- Ignition on
- Activate solenoid SLS.

Read off the current through the solenoid SLS circuit.
The current should oscillate between 0 and 1000 mA.

Other information:

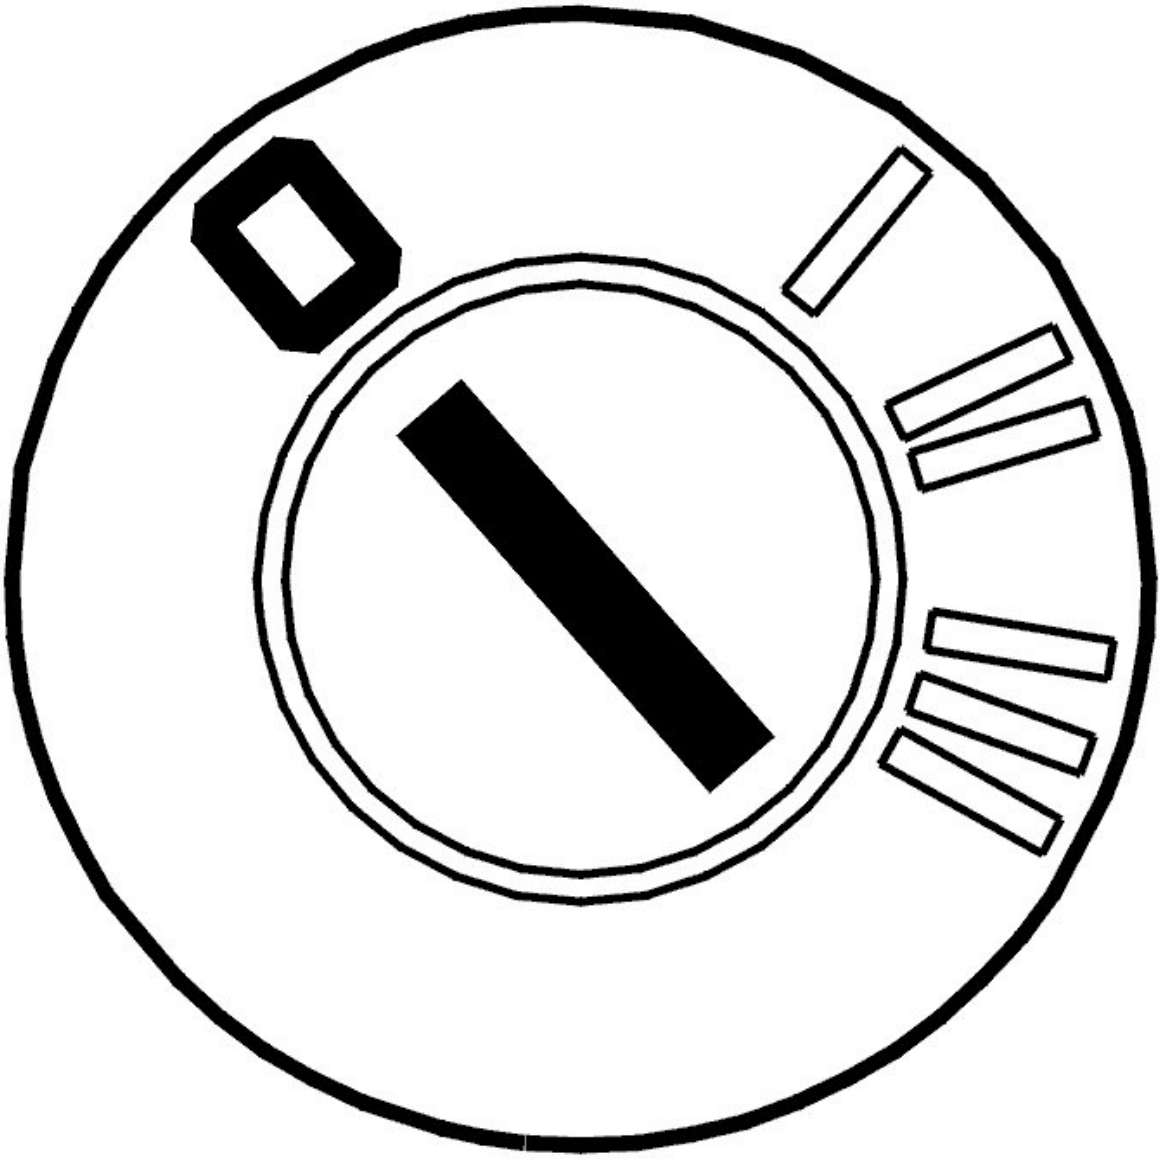
- To disconnect the transmission connectors, see Connectors transmission, disconnecting / connecting See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Wiring Harness/Service and Repair/Procedures
- To disconnect the control module, see Transmission control module (TCM), replacing, B5244T5, AW55-50/51SN, B5254T2, AW55-50/51SN, B5254T2, AW50/51 AWD See: Transmission Control Systems/Relays and Modules - Transmission and Drivetrain/Relays and Modules - A/T/Control Module/Service and Repair
- For information about signals, see Signal description. Transmission control module (TCM), AW50/51 AWD, AW55-50/51SN See: Transmission Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Description. Transmission Control Module (TCM).

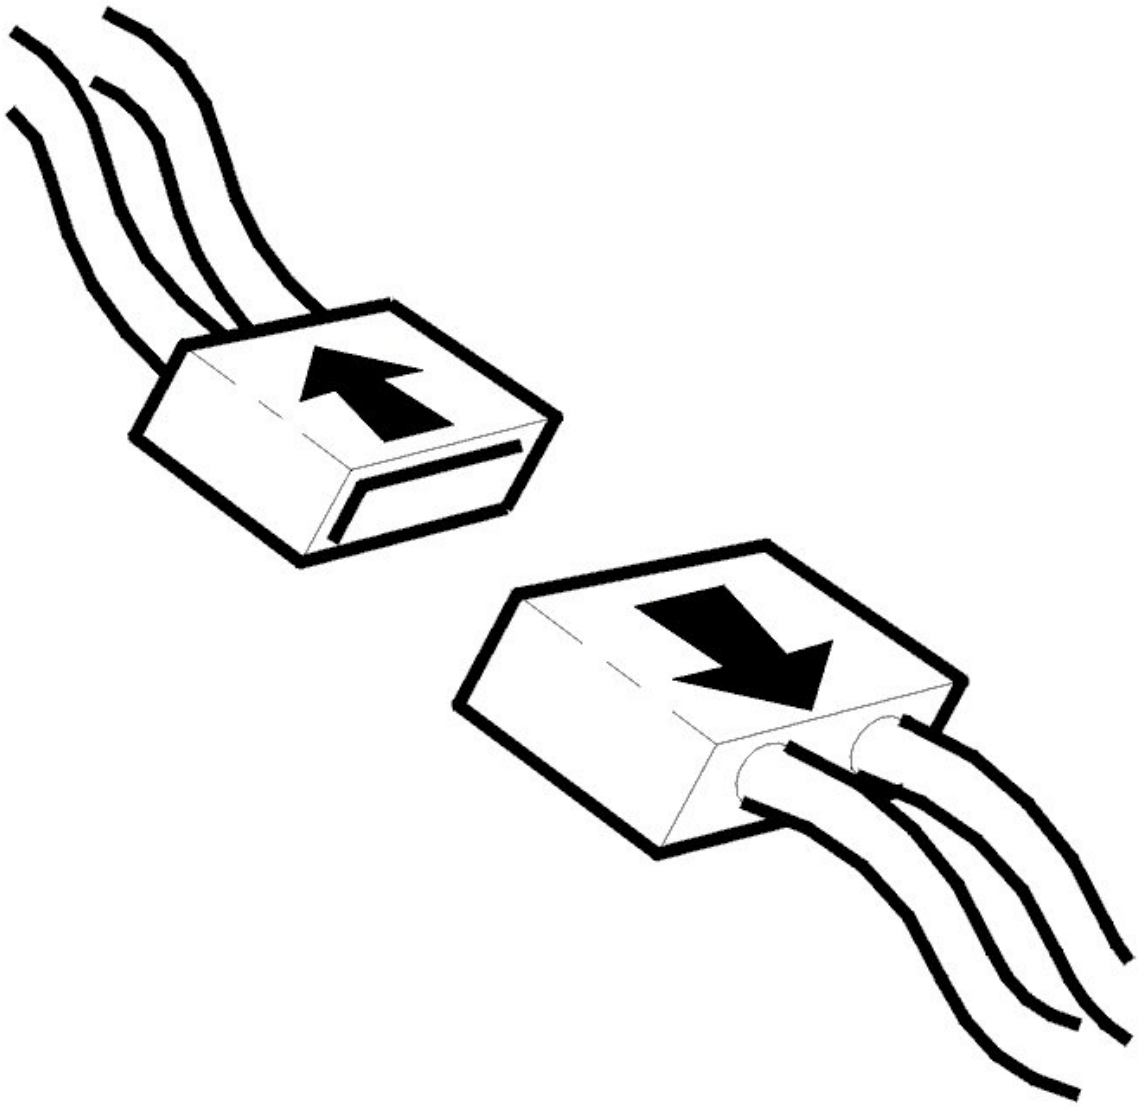
Does the current oscillate?

Yes - Fault Found

No - Checking resistance

Checking resistance



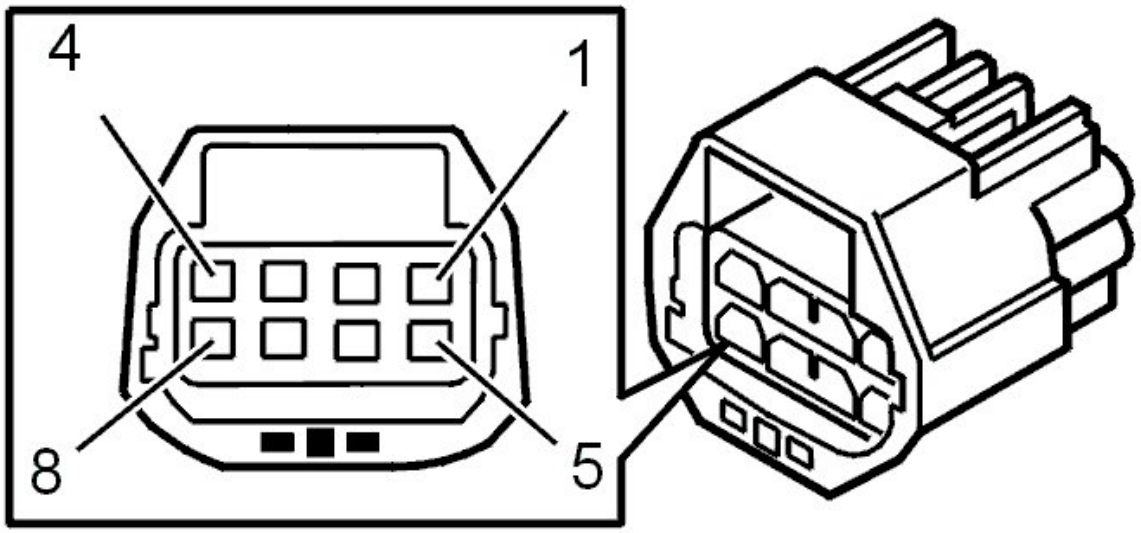


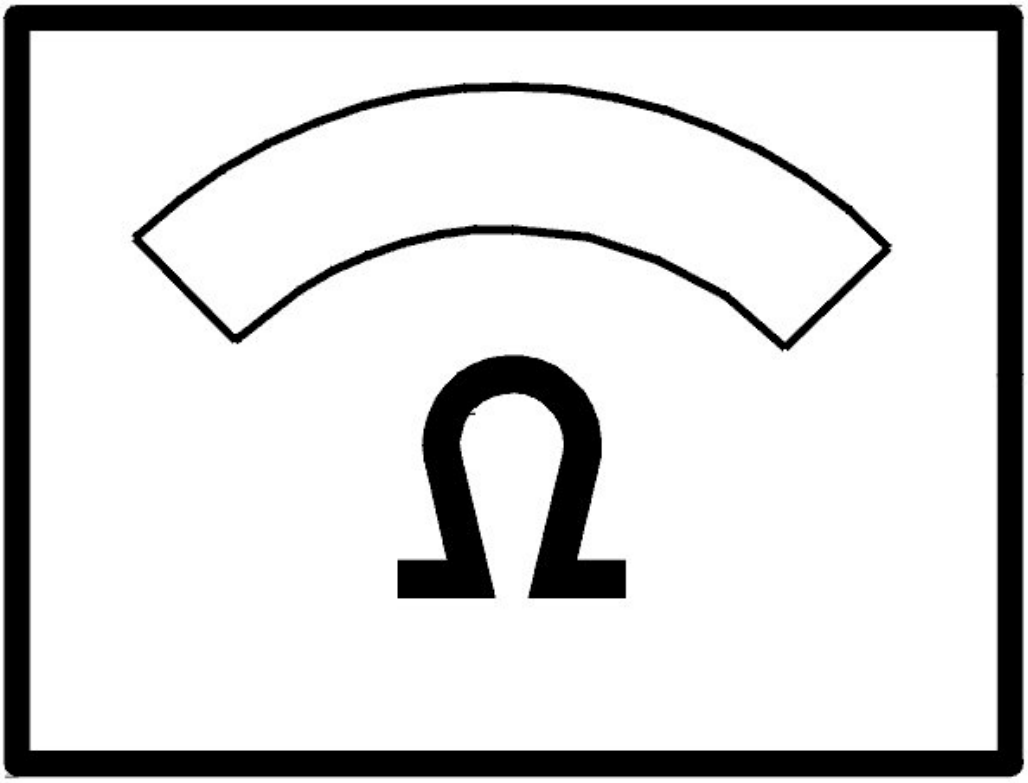
- Ignition off
- Disconnect transmission connector D.

Check solenoid SLS. Measure the resistance between terminals #D5 and #D6 on transmission connector D. The resistance should be 5-5.6 ohms at 20°C.

Other information:

- To disconnect the transmission connectors, see Connectors transmission, disconnecting / connecting See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Wiring Harness/Service and Repair/Procedures
- For information about signals, see Signal description. Transmission control module (TCM), AW50/51 AWD, AW55-50/51SN See: Transmission Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Description. Transmission Control Module (TCM).



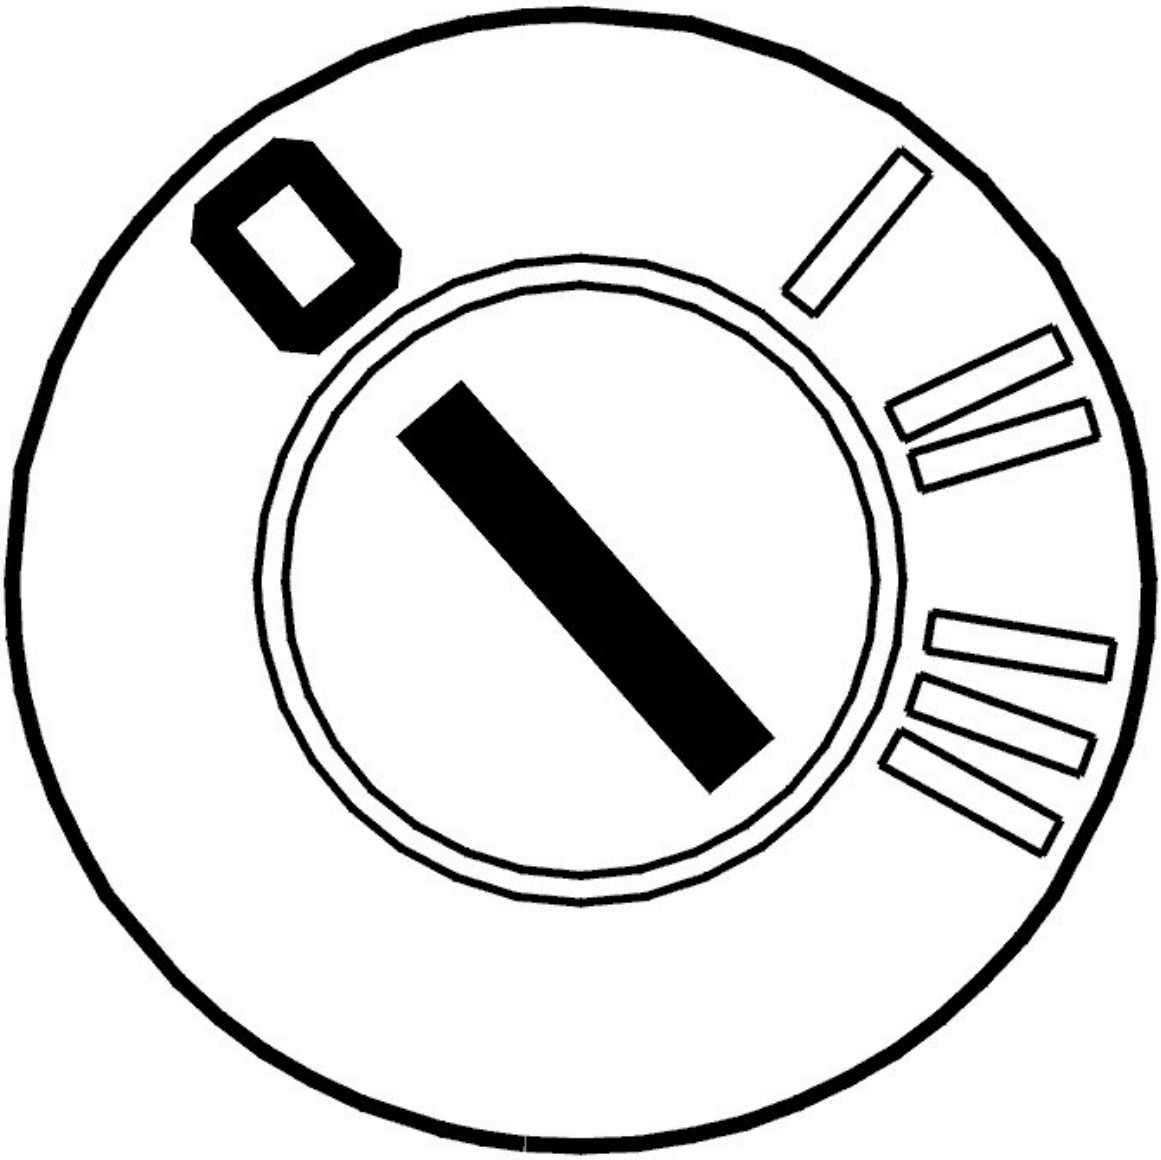


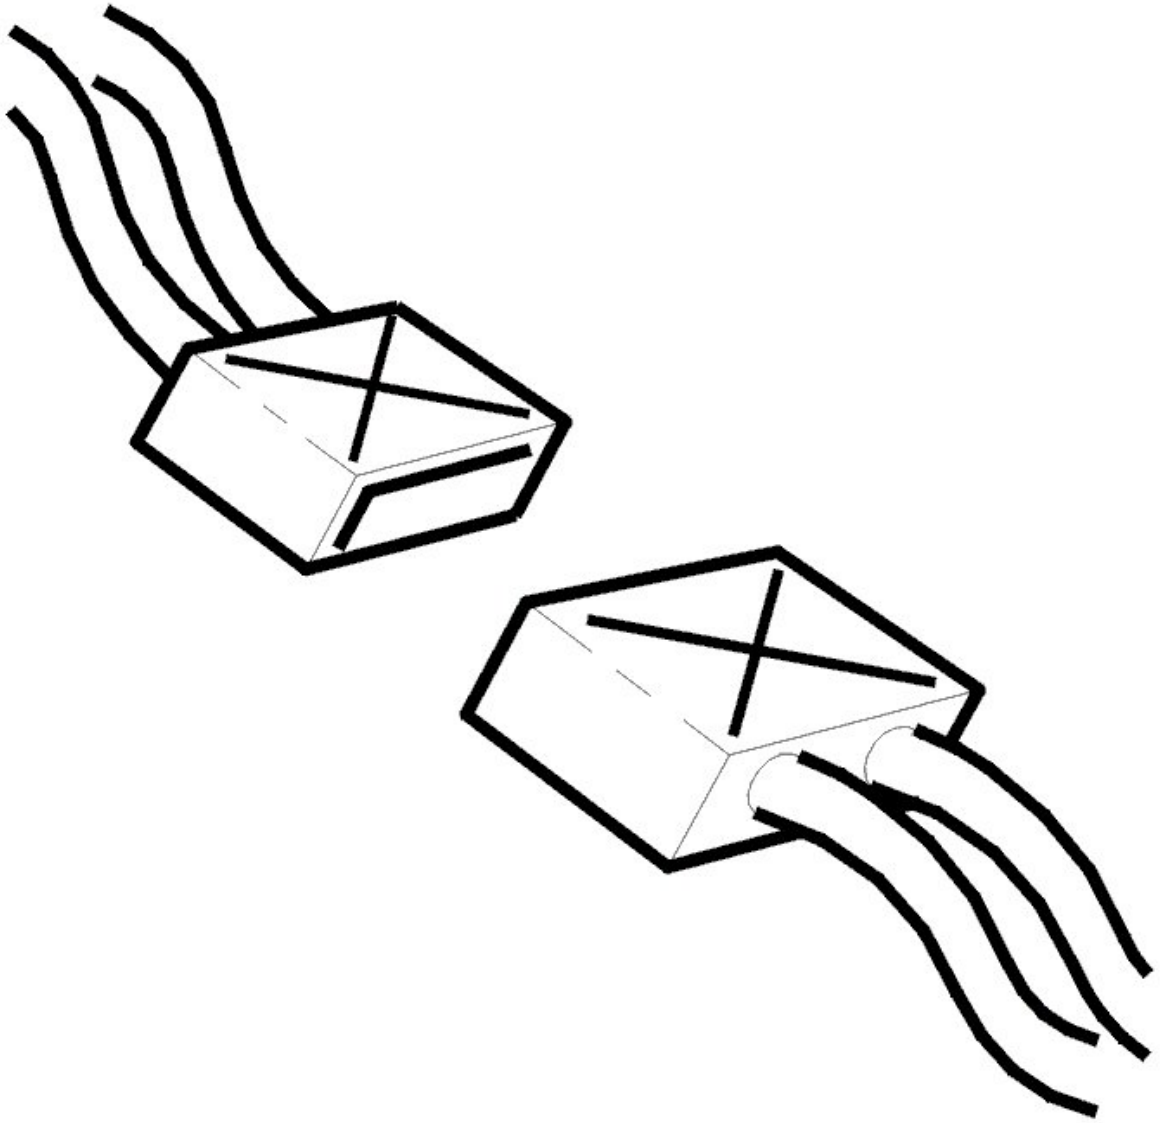
Was the resistance OK?

Yes - Checking the wiring

No - Checking the wiring and component

Checking the wiring



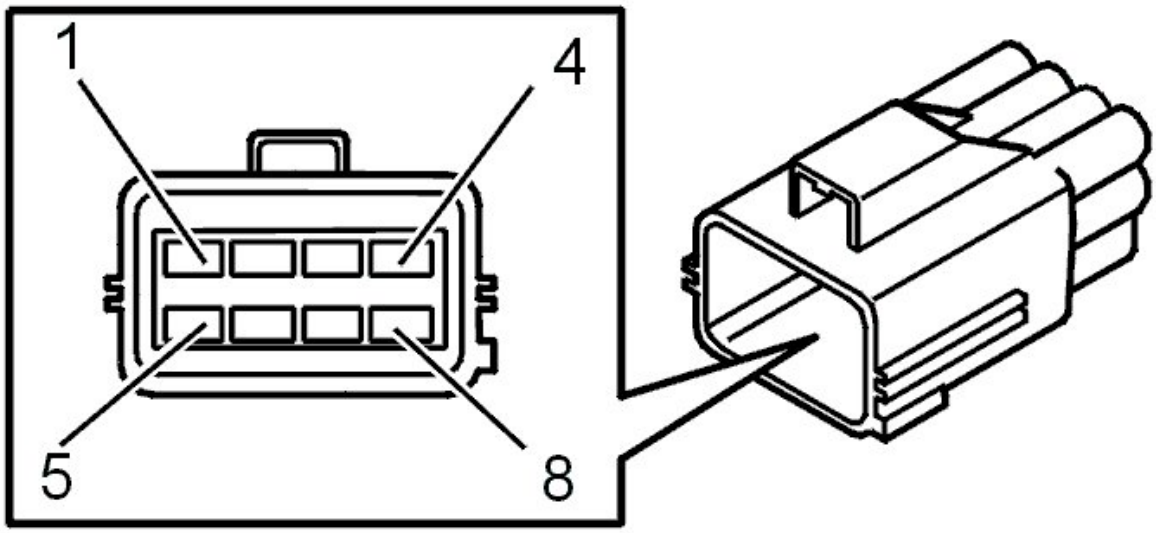


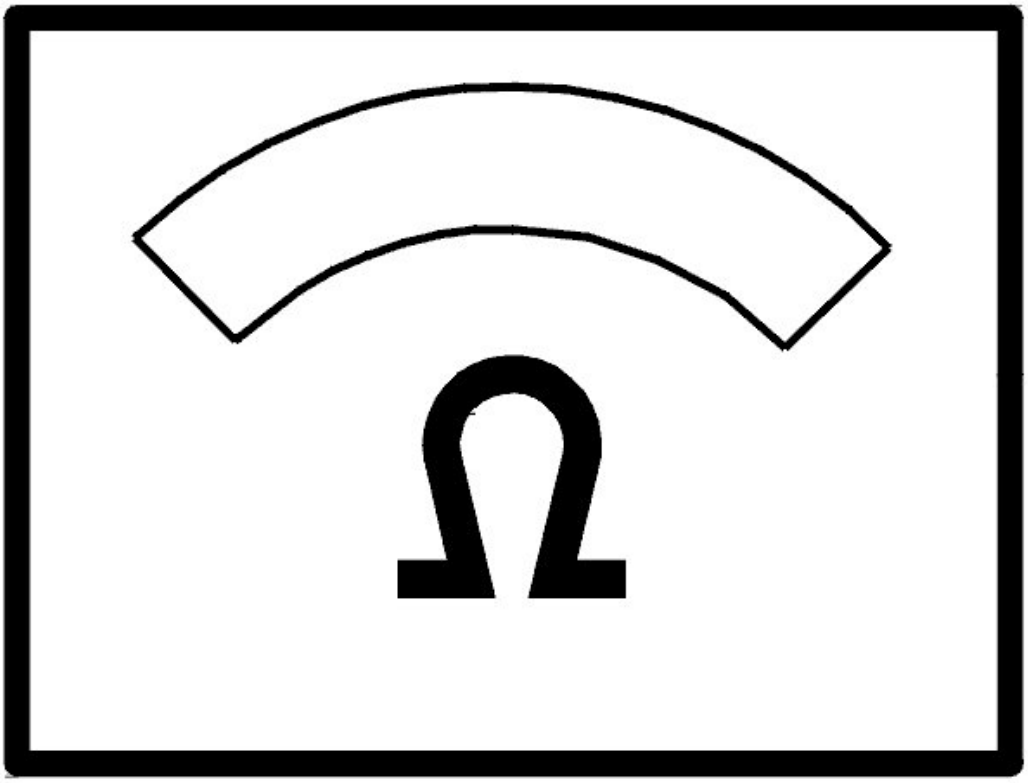
- Ignition off
- The breakout box connected
- Transmission connector D disconnected.

Check the cable between transmission control module (TCM) terminal #A49 (#A49) and transmission connector terminal #D5 (control module side). Check for a short-circuit to ground. See Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault.
Check the cable between control module terminal #B7 (#A67) and transmission connector terminal #D6 (control module side). Check for a short-circuit to ground. See Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault.
Remedy as necessary.

Other information:

- To connect the breakout box, see Connecting the breakout box, B5244T5, B5254T2 See: Pinout Values and Diagnostic Parameters/Connecting the Breakout Box
- To disconnect the transmission connectors, see Connectors transmission, disconnecting / connecting See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Wiring Harness/Service and Repair/Procedures
- For information about signals, see Signal description. Transmission control module (TCM), AW50/51 AWD, AW55-50/51SN See: Transmission Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Description. Transmission Control Module (TCM).



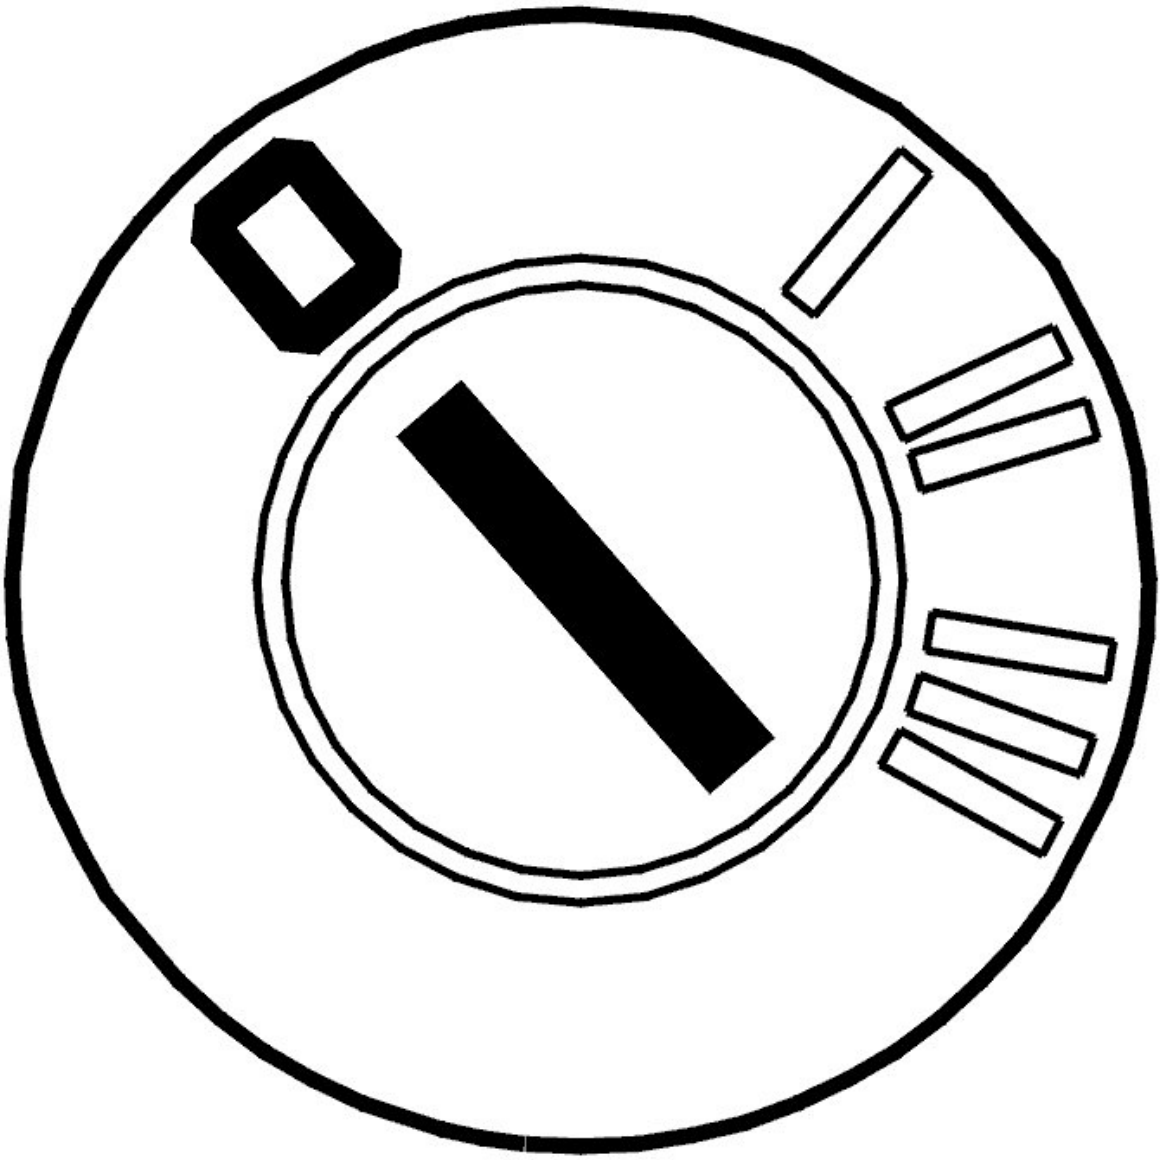


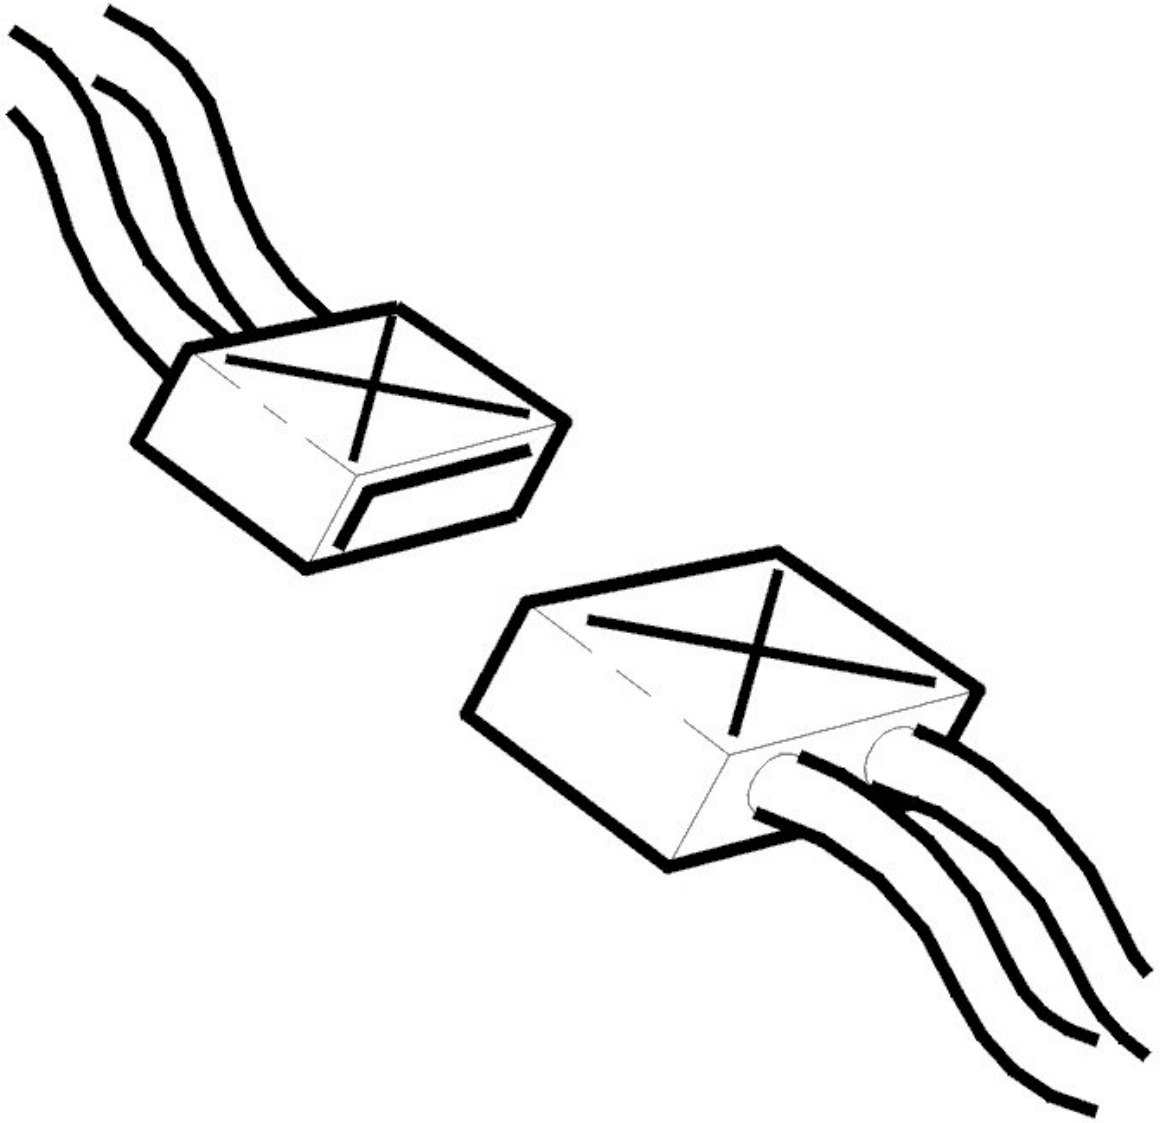
Was a fault detected?

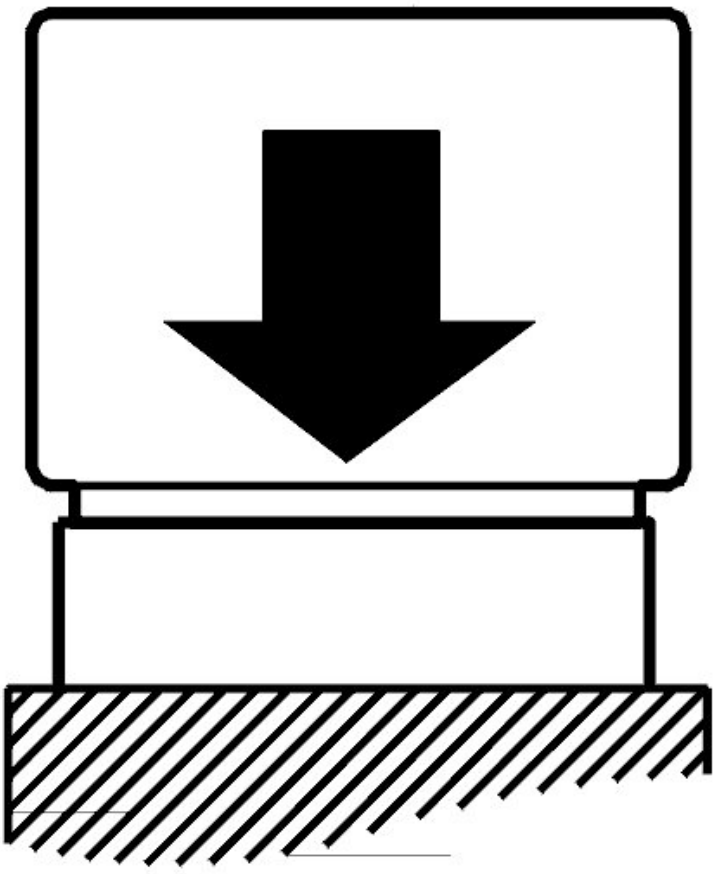
Yes - Verification

No - Checking the control module

Checking the control module







- Ignition off
- The breakout box connected
- Connect the control module.
- Transmission connector D disconnected.

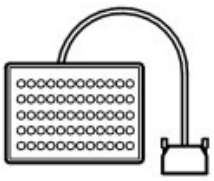
Check the transmission control module (TCM) by measuring the resistance between terminals #A49 (#A49) and #B7 (#A67) on the breakout box. The resistance must be approximately 9 kohms.

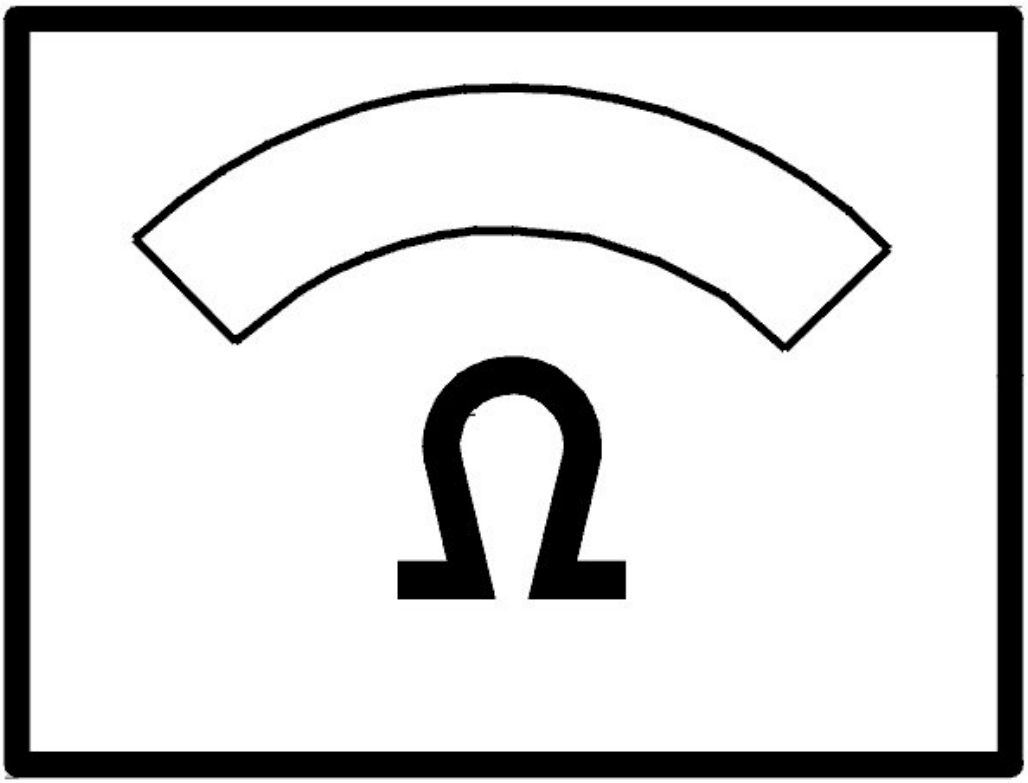
Note! When removing the transmission connector, the control module may store diagnostic trouble codes (DTCs) for the gear-shift position sensor, the shift solenoids, the temperature sensor etc.

Try a new control module if the resistance is infinite.

Other information:

- To disconnect the transmission connectors, see Connectors transmission, disconnecting / connecting See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Wiring Harness/Service and Repair/Procedures
- To replace the control module, see Transmission control module (TCM), replacing, B5244T5, AW55-50/51SN, B5254T2, AW55-50/51SN, B5254T2, AW50/51 AWD See: Transmission Control Systems/Relays and Modules - Transmission and Drivetrain/Relays and Modules - A/T/Control Module/Service and Repair
- For information about signals, see Signal description. Transmission control module (TCM), AW50/51 AWD, AW55-50/51SN See: Transmission Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Description. Transmission Control Module (TCM).



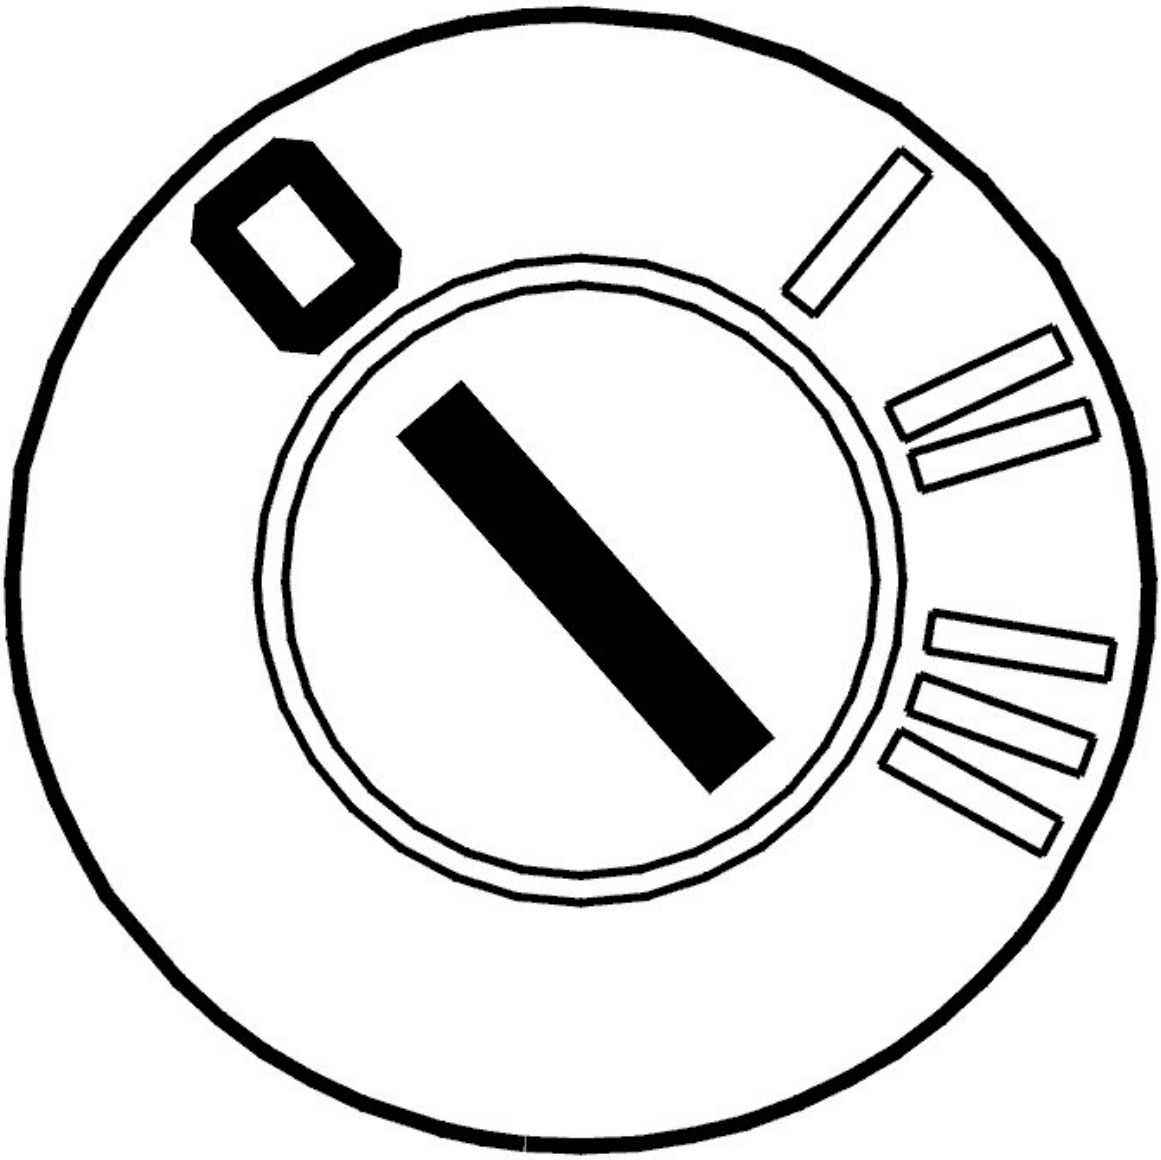


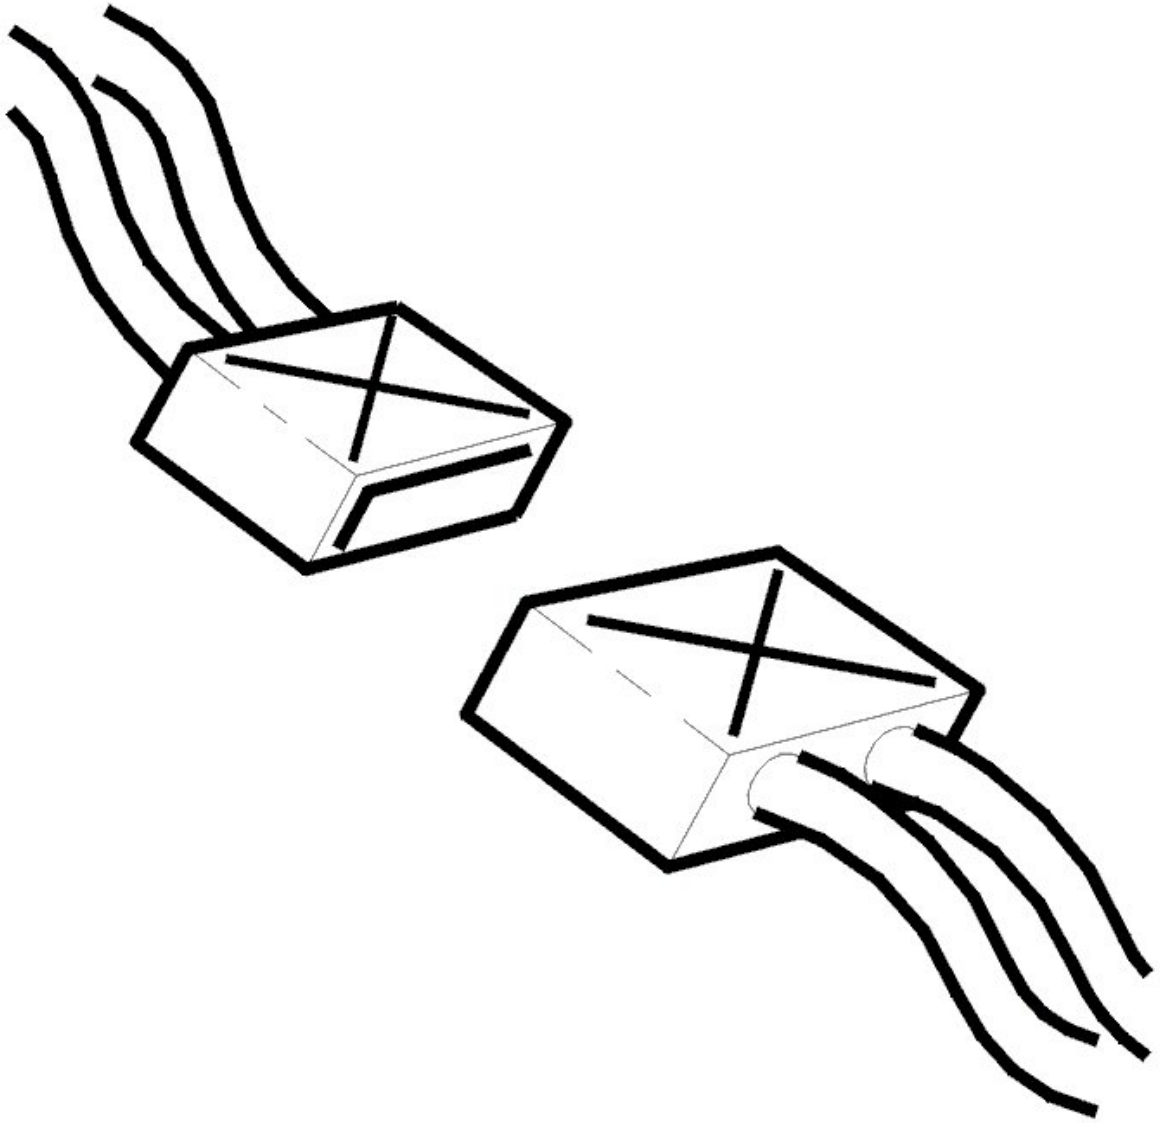
Was the resistance OK?

Yes - No Fault Found

No - Verification

Checking the wiring and component





- Ignition off
- Open the transmission control system.

Check the wiring between transmission connector terminal #D5 (transmission side) and solenoid SLS terminal #1. Check the wiring between transmission connector terminal #D6 (transmission side) and solenoid SLS terminal #2. Check for a short-circuit to ground. See Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault.

Check solenoid SLS by measuring the resistance between terminals #1 and #2 on the connector. The resistance must be 5-5.6 ohms at 20°C. Replace the transmission control system if the resistance is incorrect.

Other information:

- To disconnect the transmission connectors, see Connectors transmission, disconnecting / connecting See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Wiring Harness/Service and Repair/Procedures
- To open and replace the transmission control system, see Solenoid control system, replacing See: Transmission Control Systems/Actuators and Solenoids - Transmission and Drivetrain/Actuators and Solenoids - A/T/Shift Solenoid/Service and Repair/Solenoid Control System, Replacing
- To replace the cable harness for the control system, see Wiring harness / oil temperature sensor, replacing See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Wiring Harness/Service and Repair/Removal and Replacement
- For information about signals, see Signal description. Transmission control module (TCM), AW50/51 AWD, AW55-50/51SN See: Transmission Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Description. Transmission Control Module (TCM).

Location Of Components (Solenoids)

Continue - Resetting the adaptation and oil quality counter

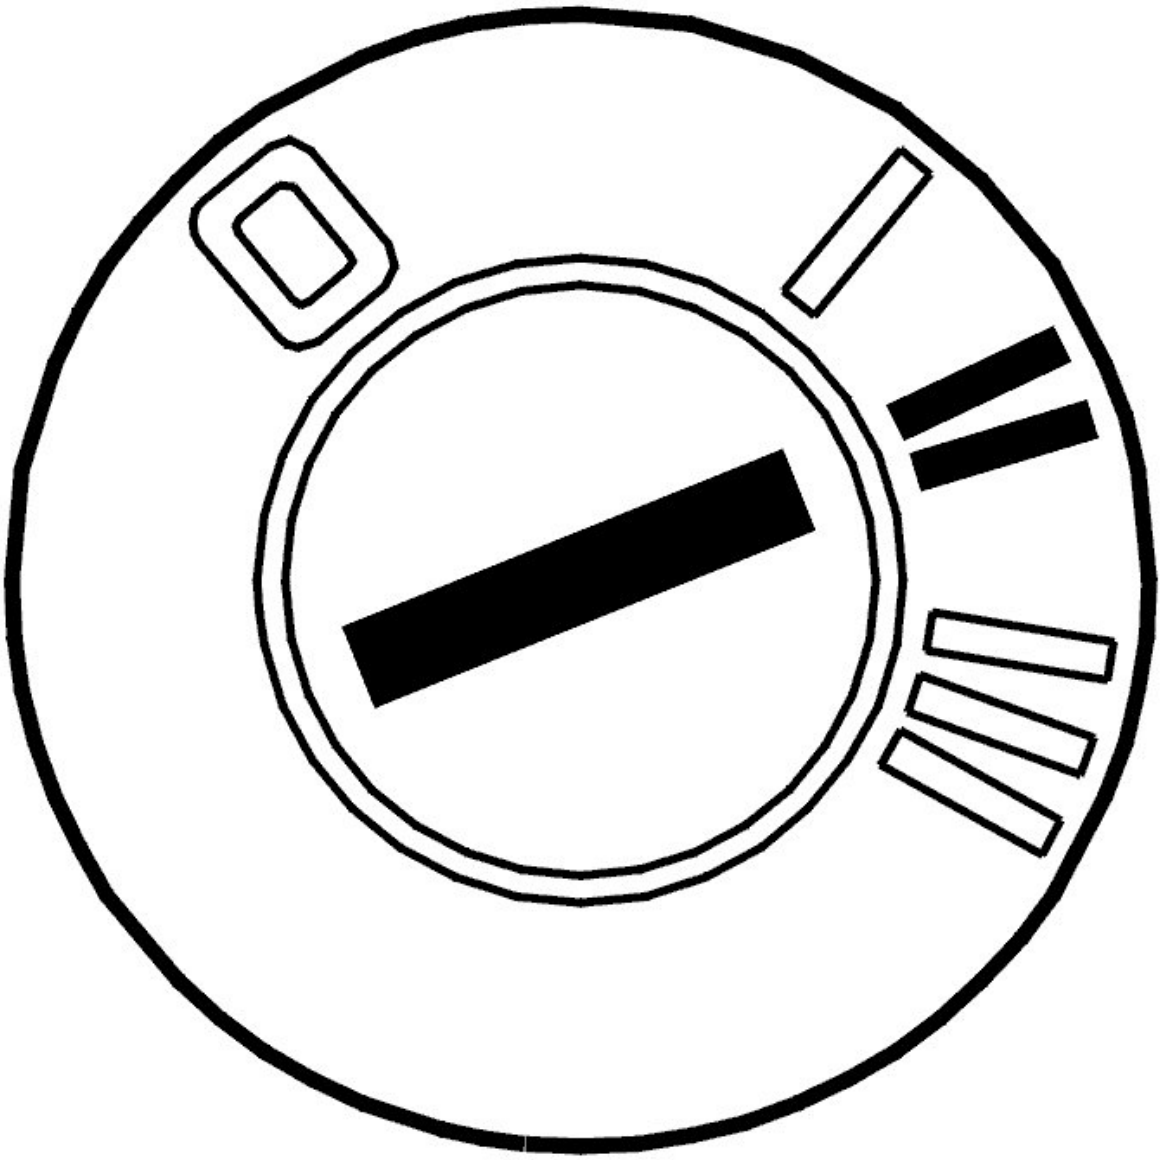
Resetting the adaptation and oil quality counter

Resetting the adaptation

Resetting adaptation and the counter for "Transmission oil change"

Hint: The transmission has torque controlled adaptive pressure control. Pressure control means that the transmission regulates the pressure itself during each gear shift. This avoids harsh gear shifting. Each gear shift is evaluated by the control module and stored in the memory. This allows for compensation for wear and tear in the transmission and clutch. It is important that the adaptation in the memory is reset after the transmission has been repaired. This is to ensure normal operation. The oil is replaced during repair; the "Transmission oil change" counter must be reset. If the counter is not reset when the fluid is drained and replaced, there is a risk that a diagnostic trouble code (DTC) will be stored in incorrect circumstances.

Note! This applies only if the transmission or one of the components in the transmission have been replaced.



- Ignition on.

Click on the VCT2000 symbol to reset the adaptation and counter.

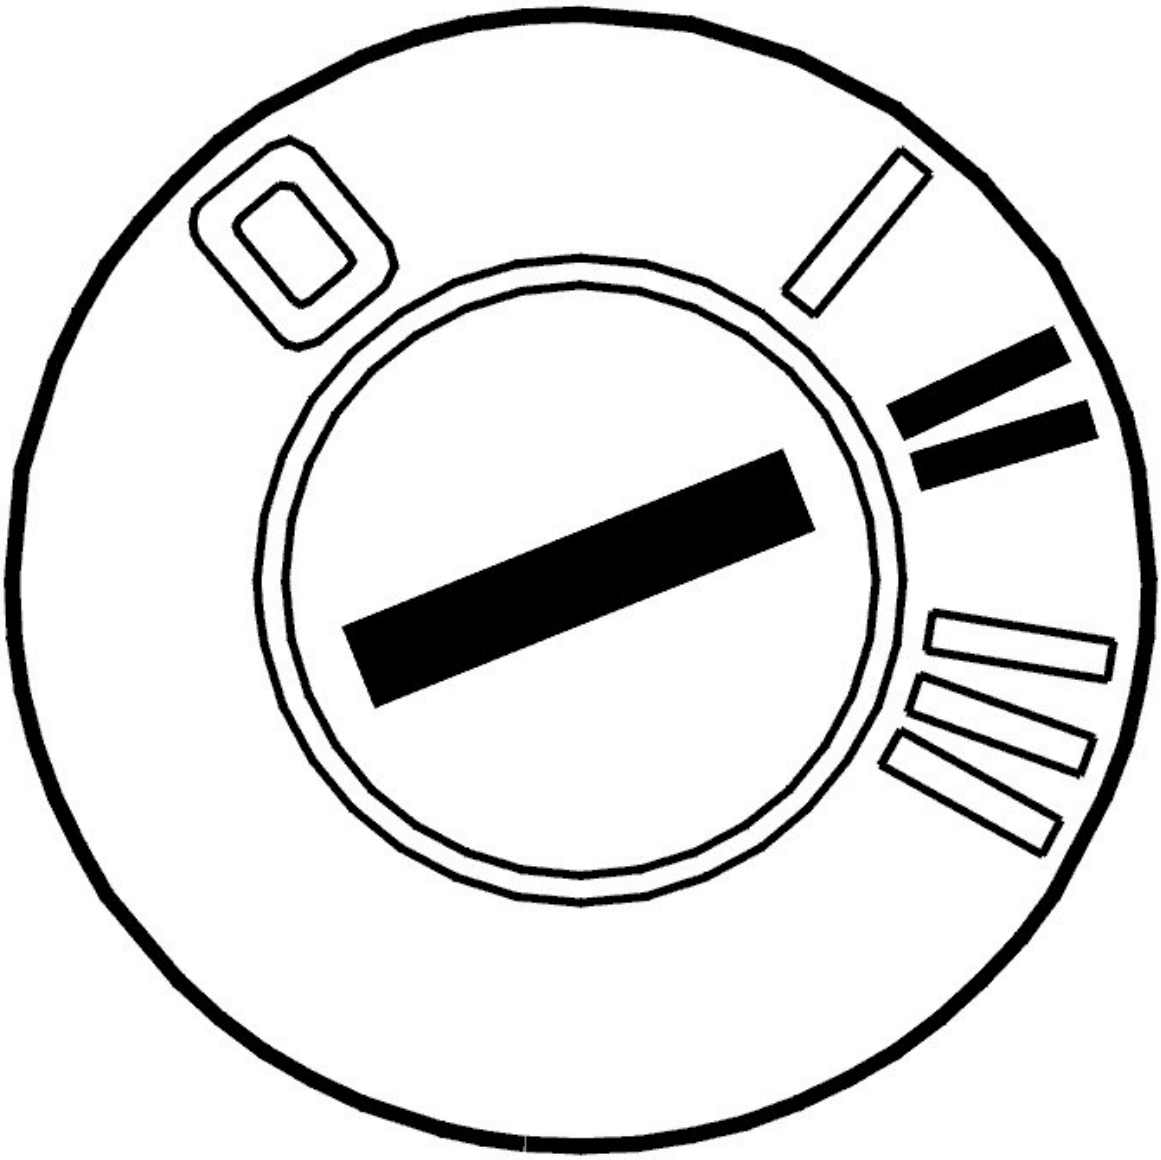
Continue - **DONE**

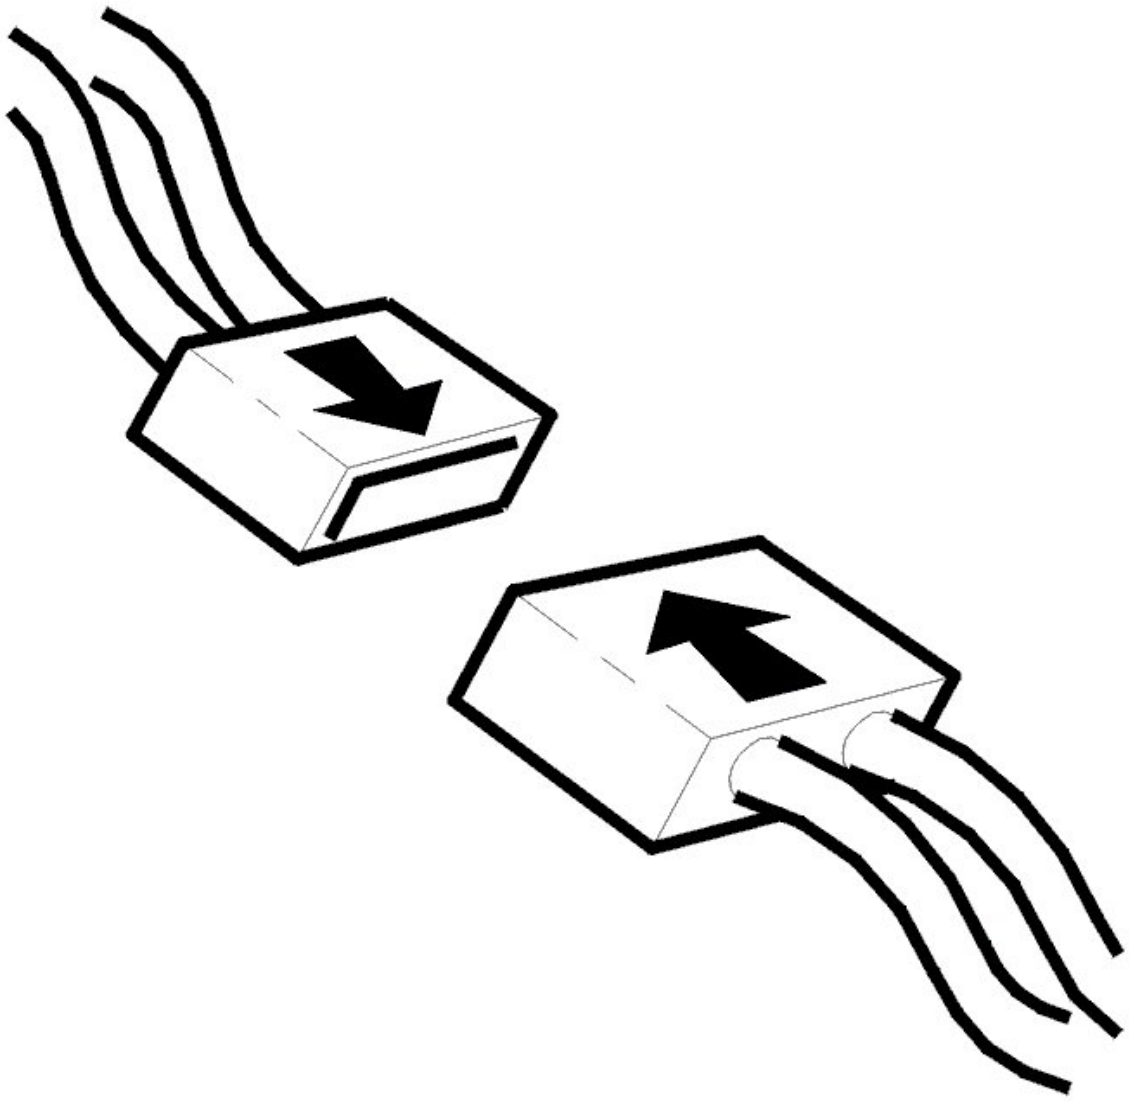
DONE - Verification

Verification

Verification

Hint: After carrying out the repair, check that the fault has been remedied.





- Ignition on.
- Activate solenoid SLS.

Read off the current through the solenoid SLS circuit.
The current should oscillate between 0 and 1000 mA.

Does the current oscillate?

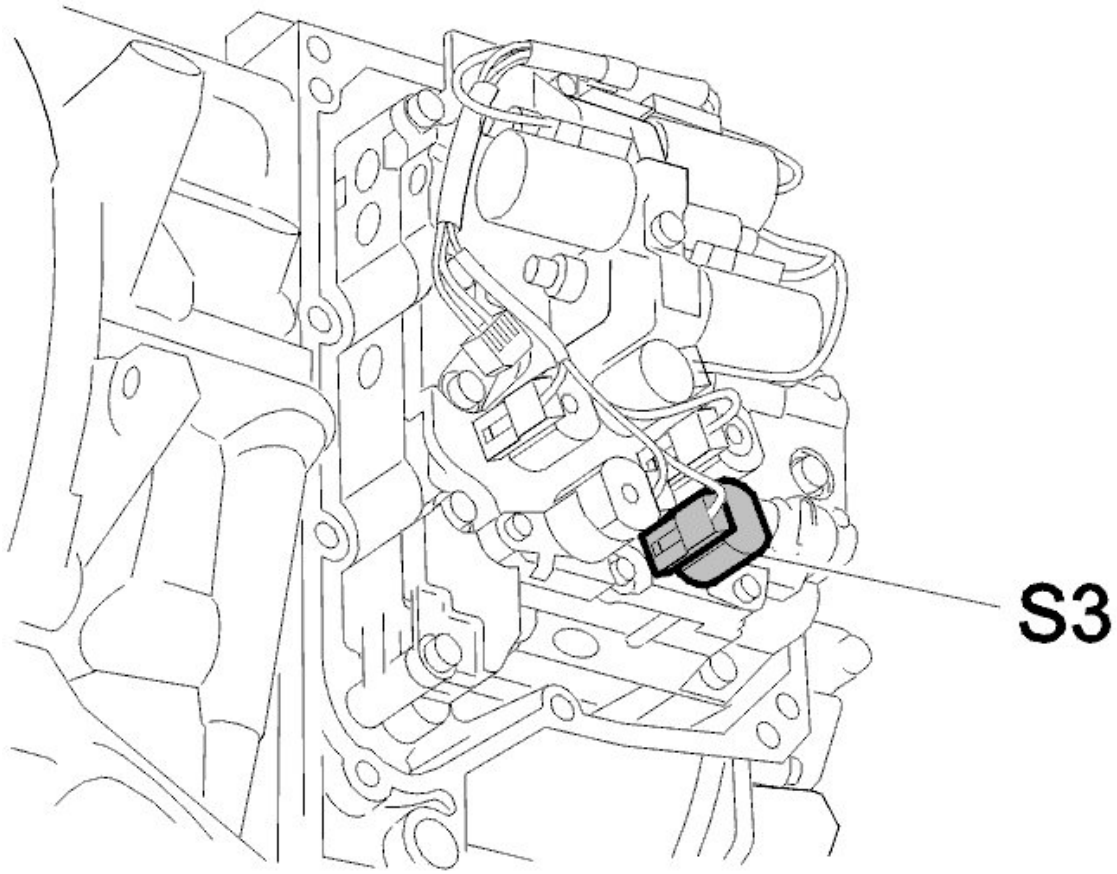
FAULT-TRACING FAILED - FAULT-TRACING FAILED

Attempt New Test - Checking line pressure solenoid SLS

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition



Transmission control module (TCM) receives a speed signal from the ABS system and from the automatic transmission speed sensor. The transmission control module (TCM) compares the speed signals from the ABS system and from the transmission speed sensor. The two signals should be approximately the same. The control module derives and compares the transmission speed with the vehicle speed. The transmission control module (TCM) uses this comparison to calculate gear-shift timing. Engine speed (RPM) and vehicle speed data affects the adjustment of system pressure, lock-up function control and engine torque reduction. The result is smooth gear-shifting. The transmission control module also derives and calculates the ABS system signal with the engine speed (RPM) signal. The control module also checks which gear is selected and compares it with the calculated gear. The ABS system and transmission speed signals should be almost identical. The engine speed (RPM) signal should be greater or lower than the ABS system speed signal (note that vehicle speed must be above 30 km/h, engine speed (RPM) above 1400 rpm and transmission oil temperature over 20°C). Diagnostic trouble code (DTC) TCM-0115 is stored if the control module detects that the transmission speed and engine speed (RPM) signals do not correspond with the programmed values and that an "incorrect" gear is selected. This is because solenoid S3 is stuck in the open or closed position.

Substitute value

- The transmission control module (TCM) Emergency mode II program is initiated.

Possible source
- The solenoid has stuck in the open or closed position.
- Defective solenoid.

Fault symptom[s]
- General orange warning lamp lit.
- No shifting.
- Harsh gear shifting.
- No lock-up function.

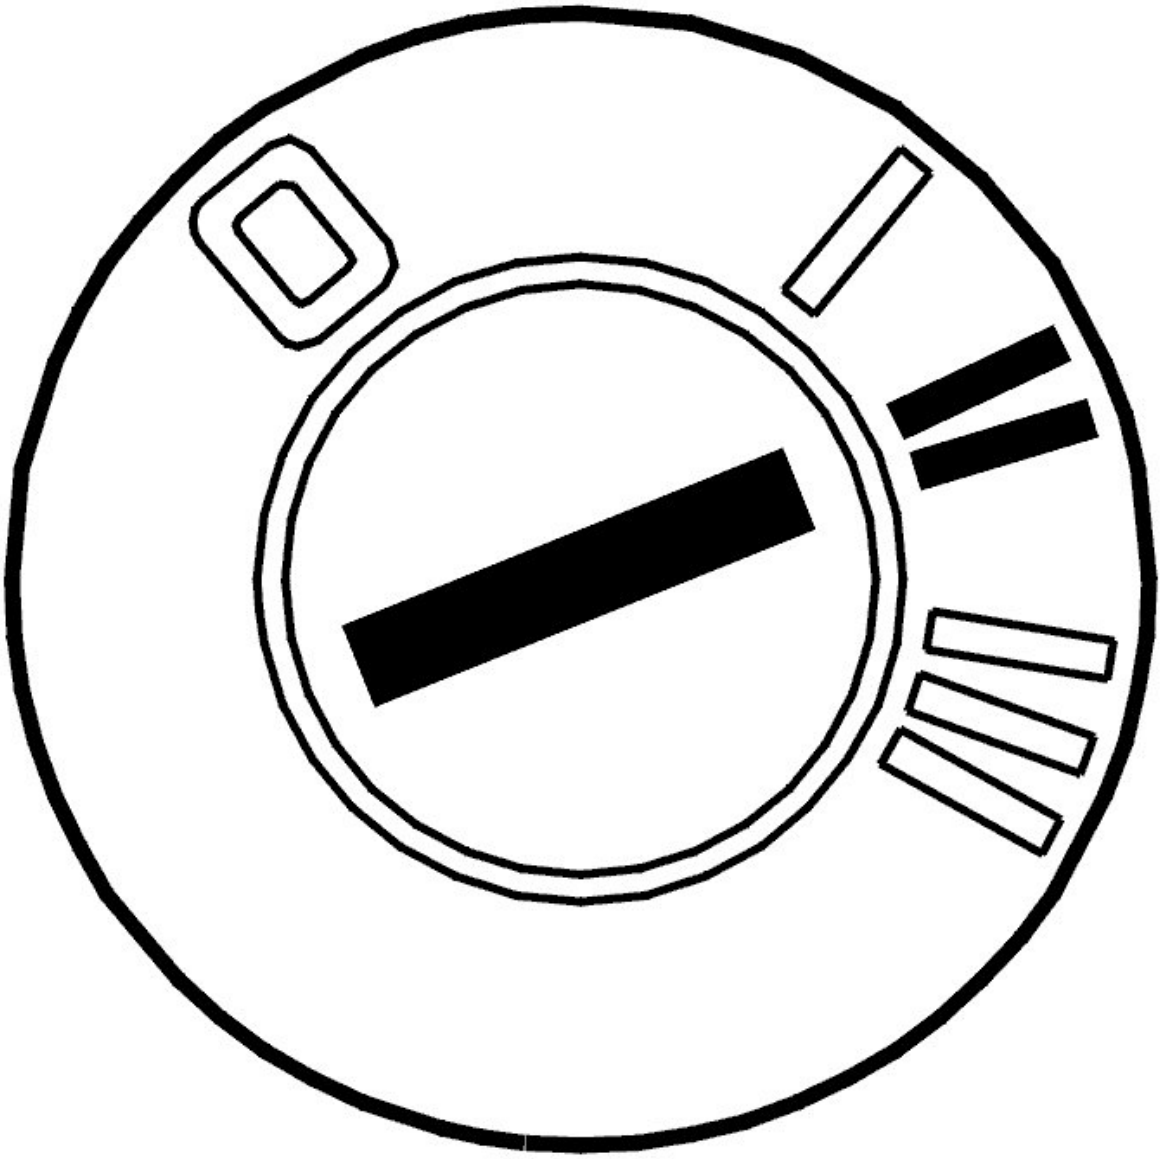
Hint: Harsh shifting because there is no line pressure solenoid SLT control. This results in constant maximum line pressure.
No shifting because the control module prevents activation of the solenoids.

Hydraulic Fault

Hydraulic fault

Checking the oil quality and the oil level in the transmission

Note! Transmission fluid quality and level are extremely important for transmission function. Therefore it is imperative that these are correct. In addition the oil level is dependent on oil temperature.



- Ignition on
- Read off the oil temperature.

Check the oil level. If the oil level is low check for leakage. Top up with oil.
Check the quality of the oil.
Replace the transmission fluid if the fluid smells burnt.
Check the transmission fluid for metal swarf. Take a sample using the dip stick.

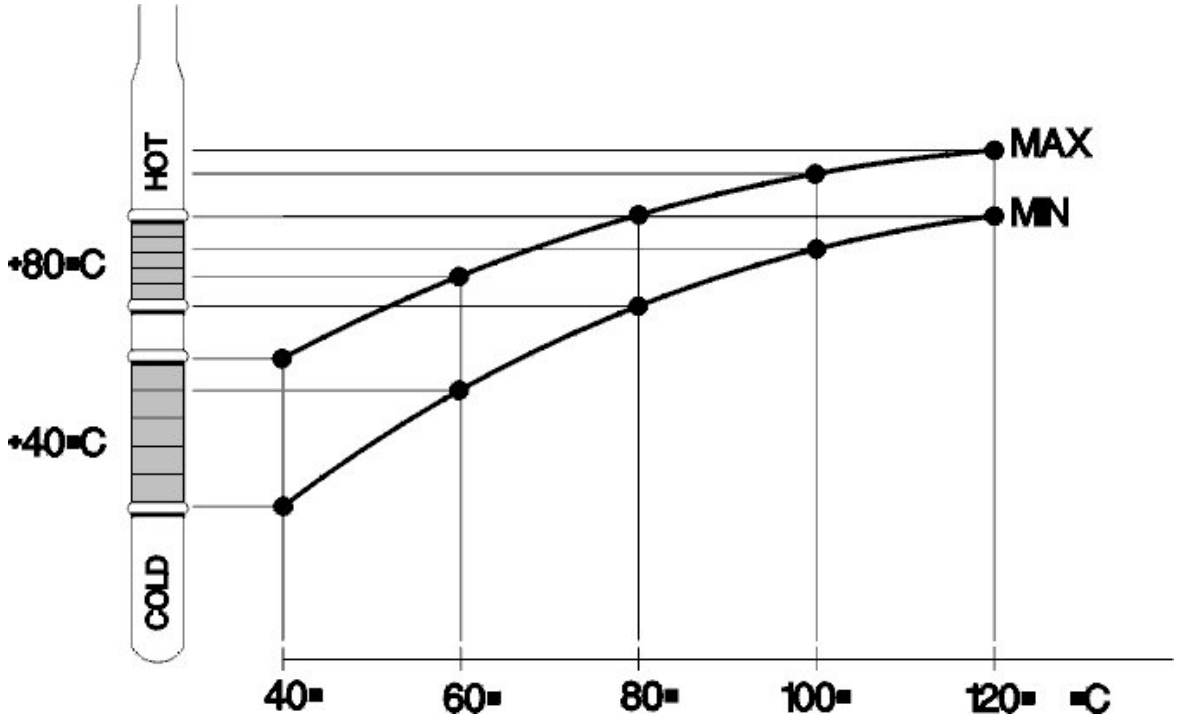
Replace the transmission if the transmission fluid contains metal swarf.

Other information:

- To replace the transmission fluid, see Transmission fluid, replacing See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Service and Repair/Removal and Replacement/Transmission Fluid, Replacing
- To check the level, see Oil level, checking See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Service and Repair/Procedures/Transmission Oil Level - Checking
- To check the quality of the transmission fluid, see the relevant service procedure.

Select an alternative below:

1. No fault detected
2. Transmission fluid replaced, the level was low or quality was poor
3. The transmission fluid contains metal swarf.



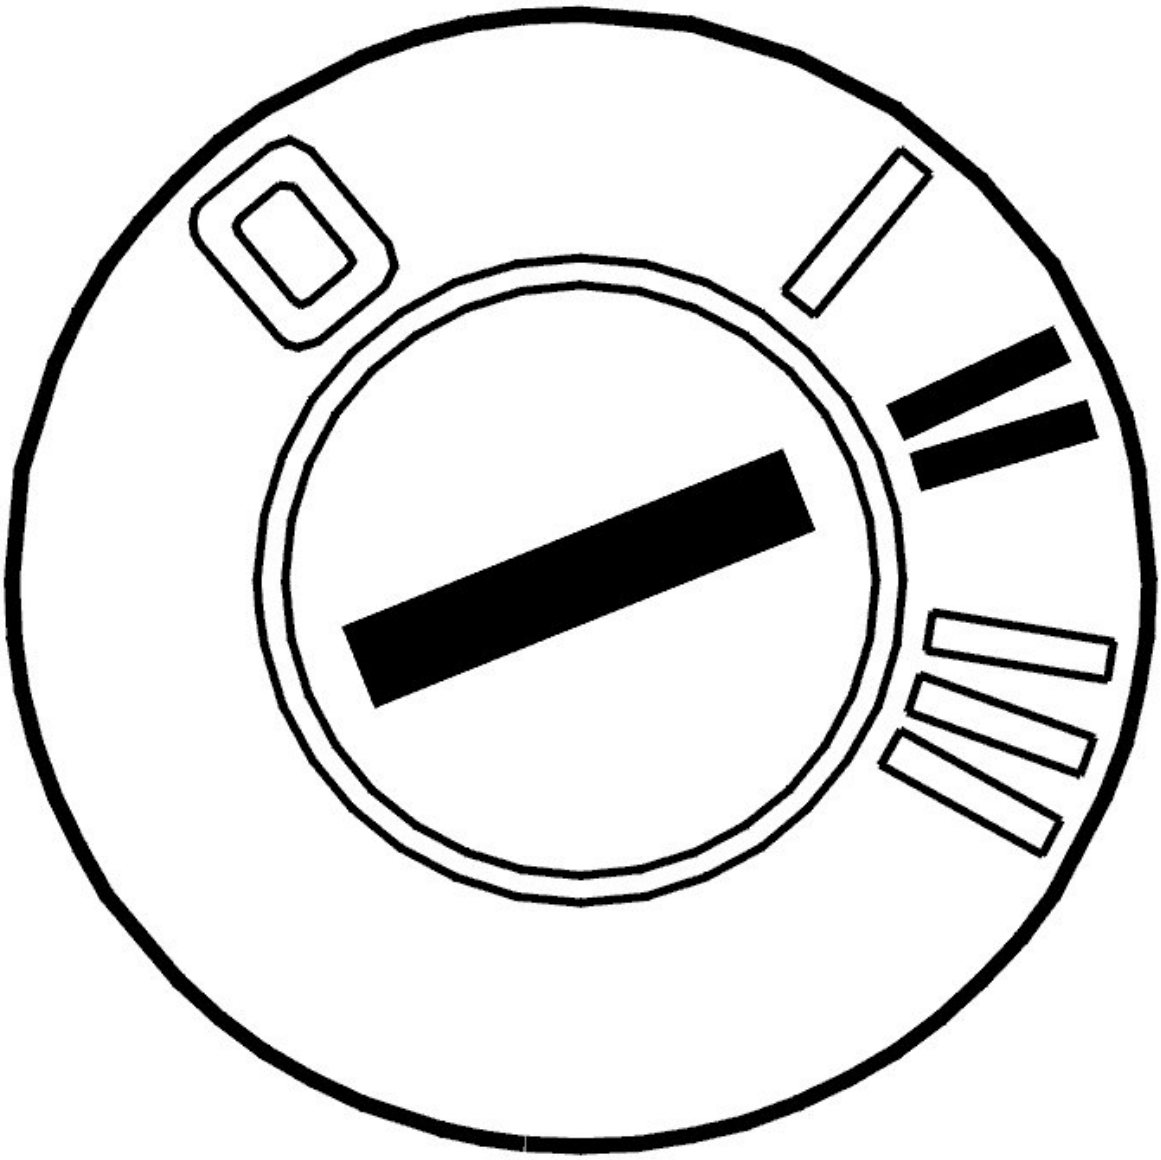
1 - Checking shift solenoid S3

2 - Resetting the adaptation and oil quality counter

3 - Replacing the transmission

Checking shift solenoid S3

Note! The transmission must not be colder than room temperature when activated.



- Ignition off
- Check the transmission and control module connectors. Check for contact resistance and oxidation. See Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault
- Ignition on
- Activate shift solenoid S3.

A "click" should be heard when the solenoid is activated. Use a stethoscope to hear the click more clearly.
There is a mechanical fault if the solenoids do not click. If the solenoid "clicks" the cause of the fault is contact resistance and oxidation.

Other information

- To access the transmission connectors, see Connectors, transmission, disconnecting / connecting, B5244T5, AW55-50/51SN, B5254T2, AW55-50/51SN, B5254T2, AW50/51 AWD See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Wiring Harness/Service and Repair/Procedures
- To access the control module connector, see Transmission control module (TCM), replacing, B5244T5, AW55-50/51SN, B5254T2, AW55-50/51SN, B5254T2, AW50/51 AWD See: Transmission Control Systems/Relays and Modules - Transmission and Drivetrain/Relays and Modules - A/T/Control Module/Service and Repair.

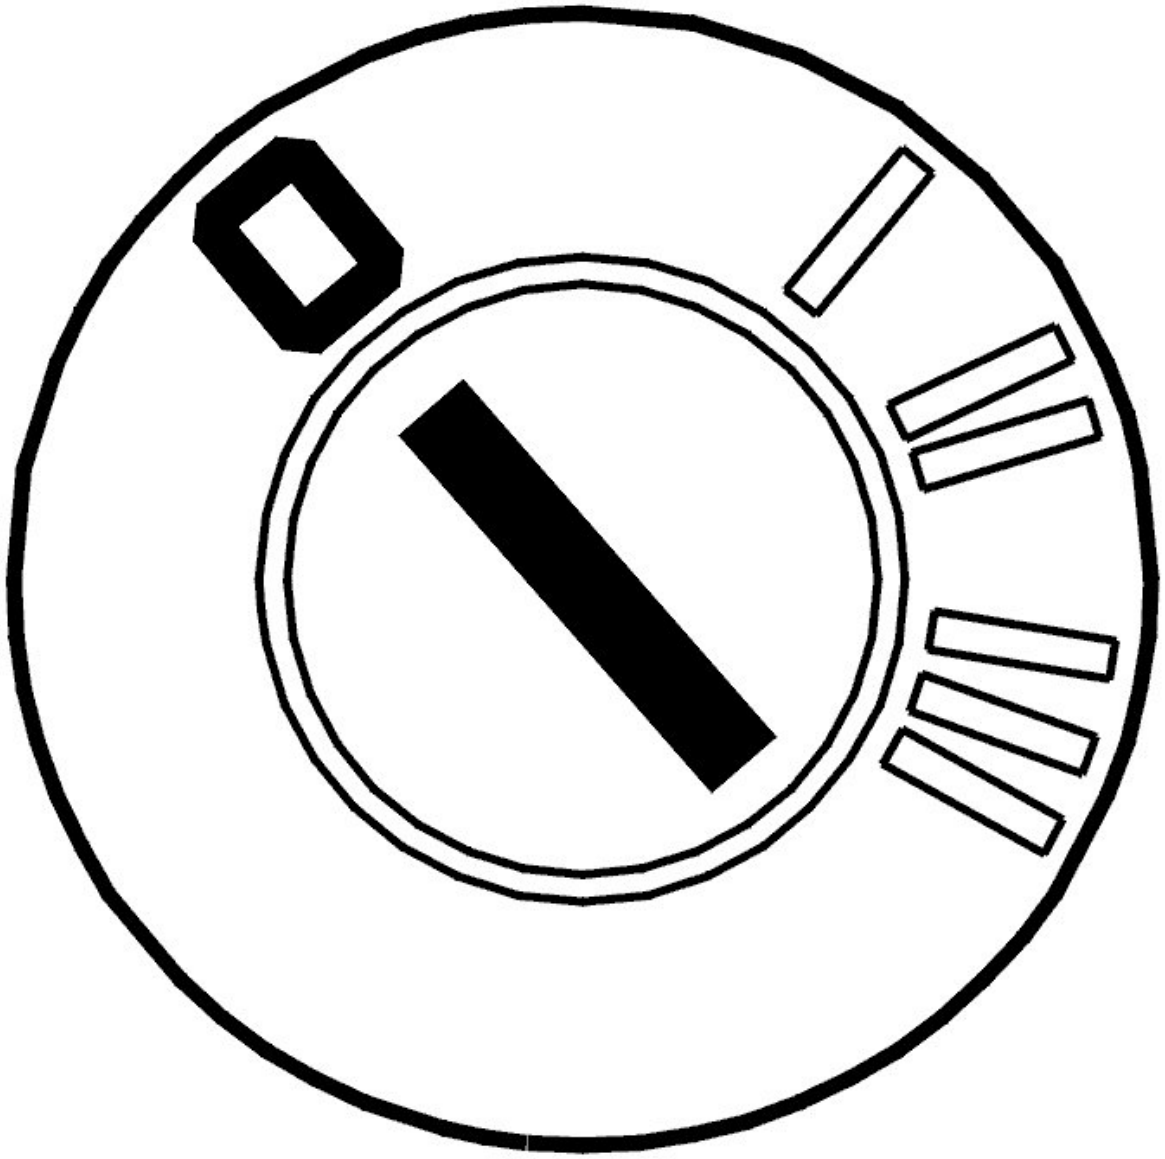
Was there a click from the solenoid?

Yes - Checking noise in the transmission

No - Checking the wiring and component

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

Checking the wiring and component



- Ignition off
- Open the transmission control system.

Check that there is no metal swarf or dirt in the control system. Replace solenoid S3 if the control system is OK.
Replace the transmission if there is any metal swarf in the control system.
Remedy as necessary.

Other information:

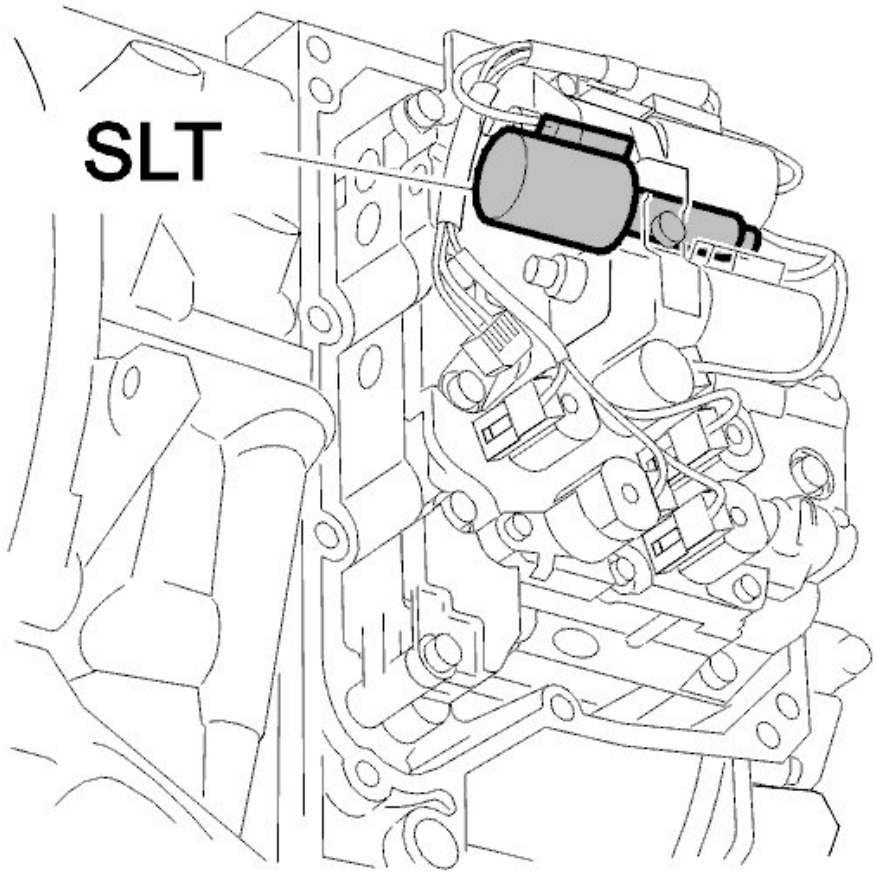
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition



Throttle solenoid SLT controls the line pressure in the transmission. The solenoid is controlled by a power stage in the transmission control module (TCM) output. The transmission control module (TCM) uses the power stage to control the current to the solenoid. A low amperage results in a high line pressure. A high amperage (approximately 1 A) gives a low line pressure. The amperage is primarily affected by the throttle position. Diagnostic trouble code (DTC) TCM-0116 is stored if the transmission control module (TCM) registers a short-circuit to battery voltage in the solenoid SLT circuit. This results in too high an amperage. Solenoid SLT cannot then control the line pressure.

Substitute value

- The transmission control module (TCM) "Emergency mode I" program has been initiated.

Possible source

- Short-circuit to supply voltage in the control signal wiring or signal wiring.
- Short-circuit between the control signal cable and the signal cable.
- Defective solenoid.

Fault symptom[s]

- General orange warning lamp lit.
- No shifting.
- Malfunction indicator lamp (MIL) lit.

- No lock-up function.

Hint: No shifting because the control module prevents activation of the solenoids.

Caution! There is a danger that this fault will cause line pressure in the transmission to be too low. This will result in a high level of wear.

Signal Too High. Intermittent Fault

Signal too high. Intermittent fault

Intermittent fault

Check the wiring between transmission control module (TCM) terminal #A52 (#A52) and transmission connector terminal #D3. Check the wiring between control module terminal #B10 (#A70) and transmission connector terminal #D4. Check for an intermittent short-circuit to supply voltage. See Checking wiring and terminals. Intermittent faults See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Intermittent Faults.

Hint: Check solenoid SLT. Measure the resistance between terminals #D3 and #D4 on transmission connector D. The resistance should be 5-5.6 ohms at 20°C.

Remedy as necessary.

FAULT FOUND - DONE

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition

Throttle solenoid SLT controls the line pressure in the transmission. The solenoid is controlled by a power stage in the transmission control module (TCM) output. The transmission control module (TCM) uses the power stage to control the current to the solenoid. A low amperage results in a high line pressure. A high amperage (approximately 1 A) gives a low line pressure. The amperage is primarily affected by the throttle position. Diagnostic trouble code (DTC) TCM-0117 is stored if the control module registers that there is an open-circuit in the circuit for solenoid SLT. Solenoid SLT cannot then control the line pressure.

Substitute value
- The transmission control module (TCM) "Emergency mode I" program has been initiated.

Possible source
- Contact resistance in terminals.
- Open-circuit in the control signal cable or the signal cable.
- Defective solenoid SLT.

Fault symptom[s]

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

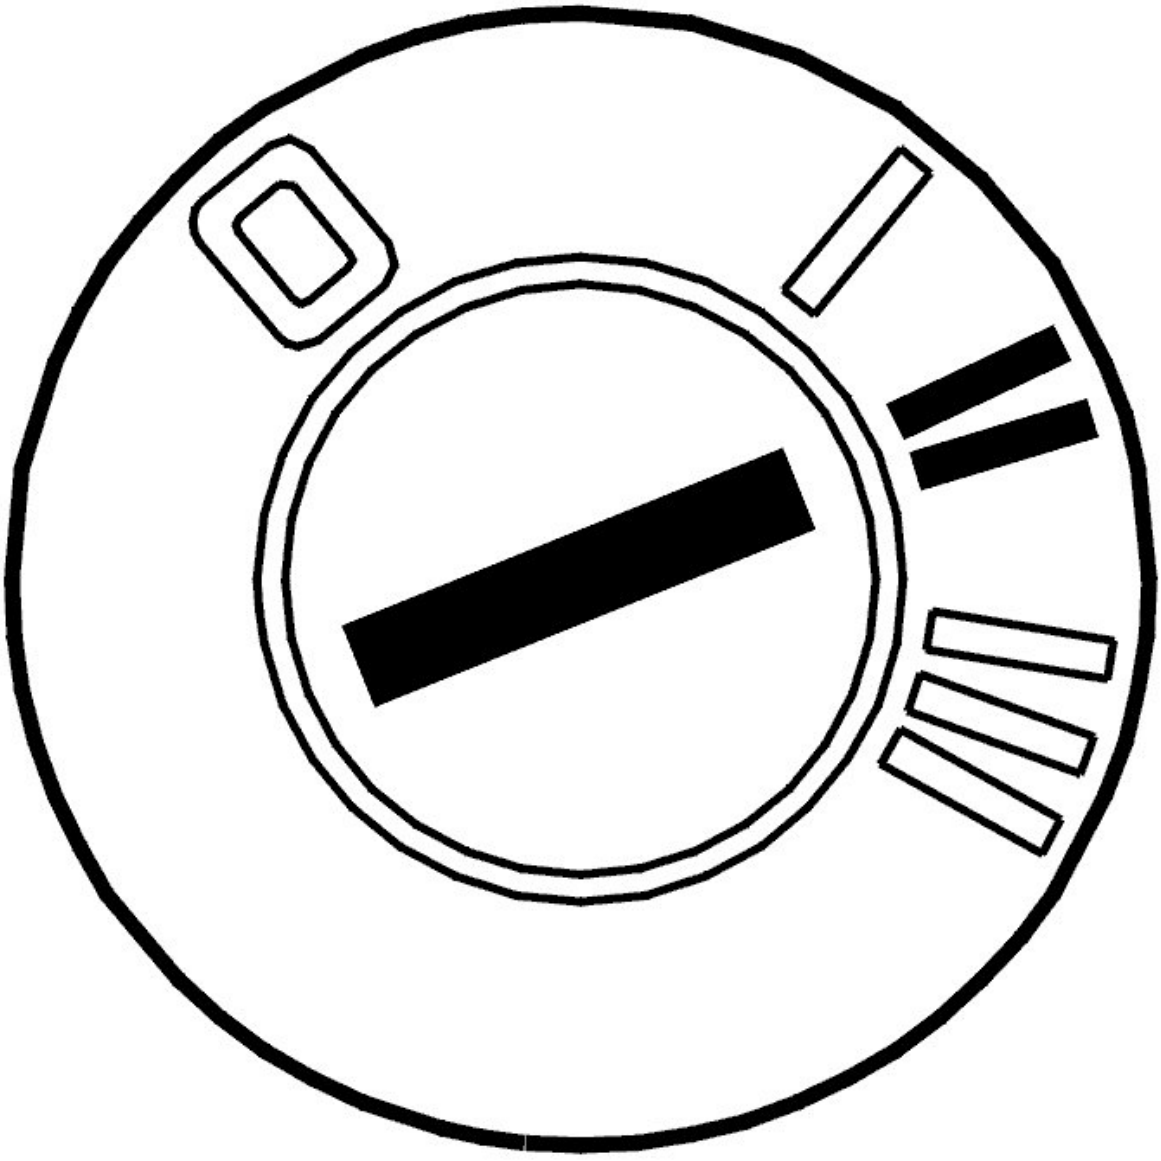
- General orange warning lamp lit.
- Malfunction indicator lamp (MIL) lit.
- No lock-up function.
- Harsh gear shifting.

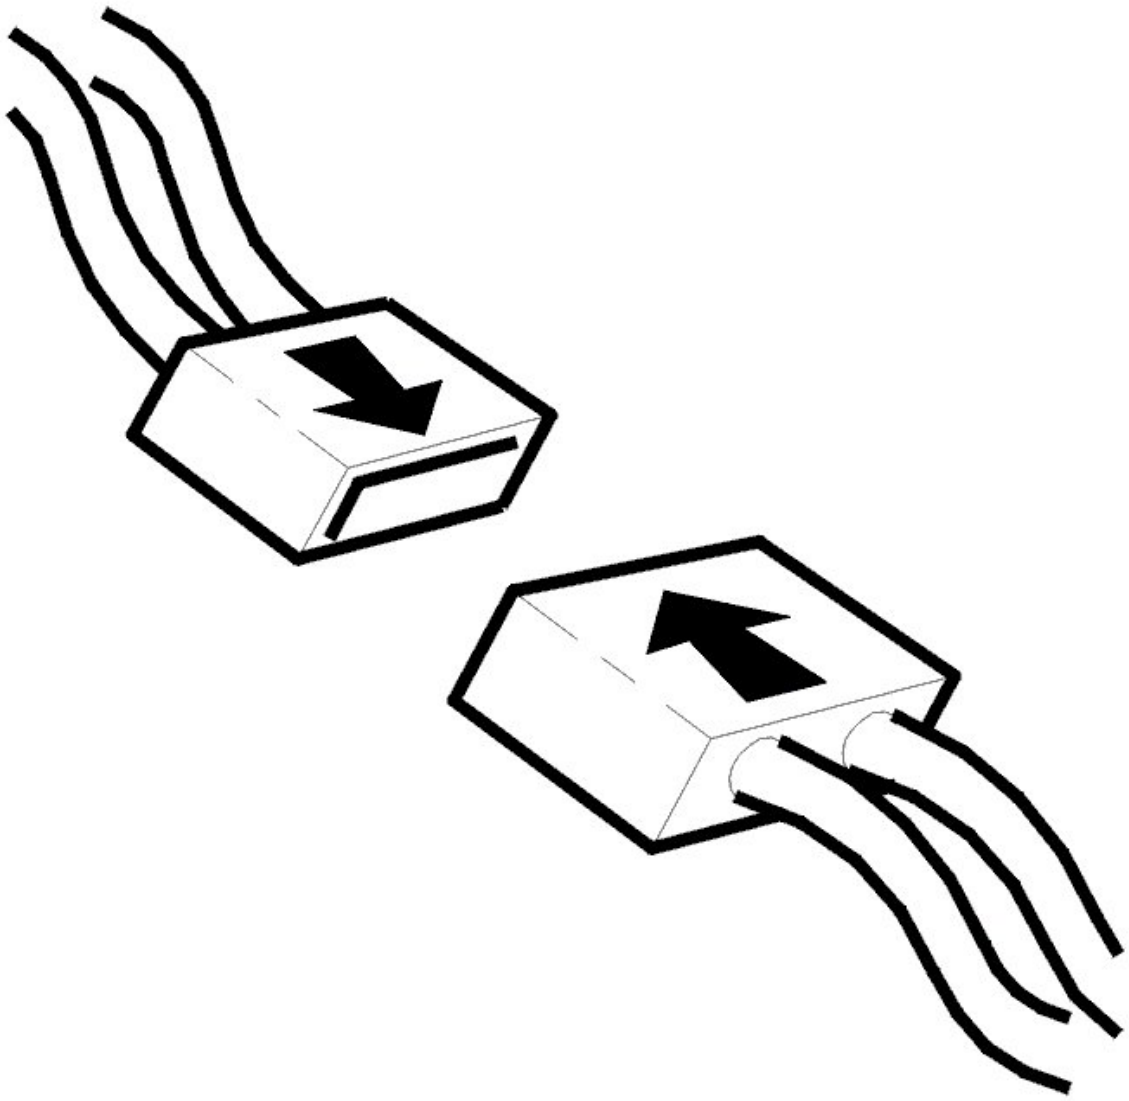
Hint: Harsh gear shifting can be caused by:
- No torque limiting request to the engine control module (ECM) when shifting.

Signal Missing. Permanent Fault

Signal missing. Permanent fault

Checking line pressure solenoid SLT





- Ignition off
- Check the control module connector and automatic transmission connector D. Check for contact resistance and oxidation. See Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault. Remedy if necessary
- Reinstall the components, reconnect the connectors etc.
- Ignition on
- Activate solenoid SLT.

Read off the current through the solenoid SLT circuit.
The current should oscillate between 0 and 1000 mA.

Other information:

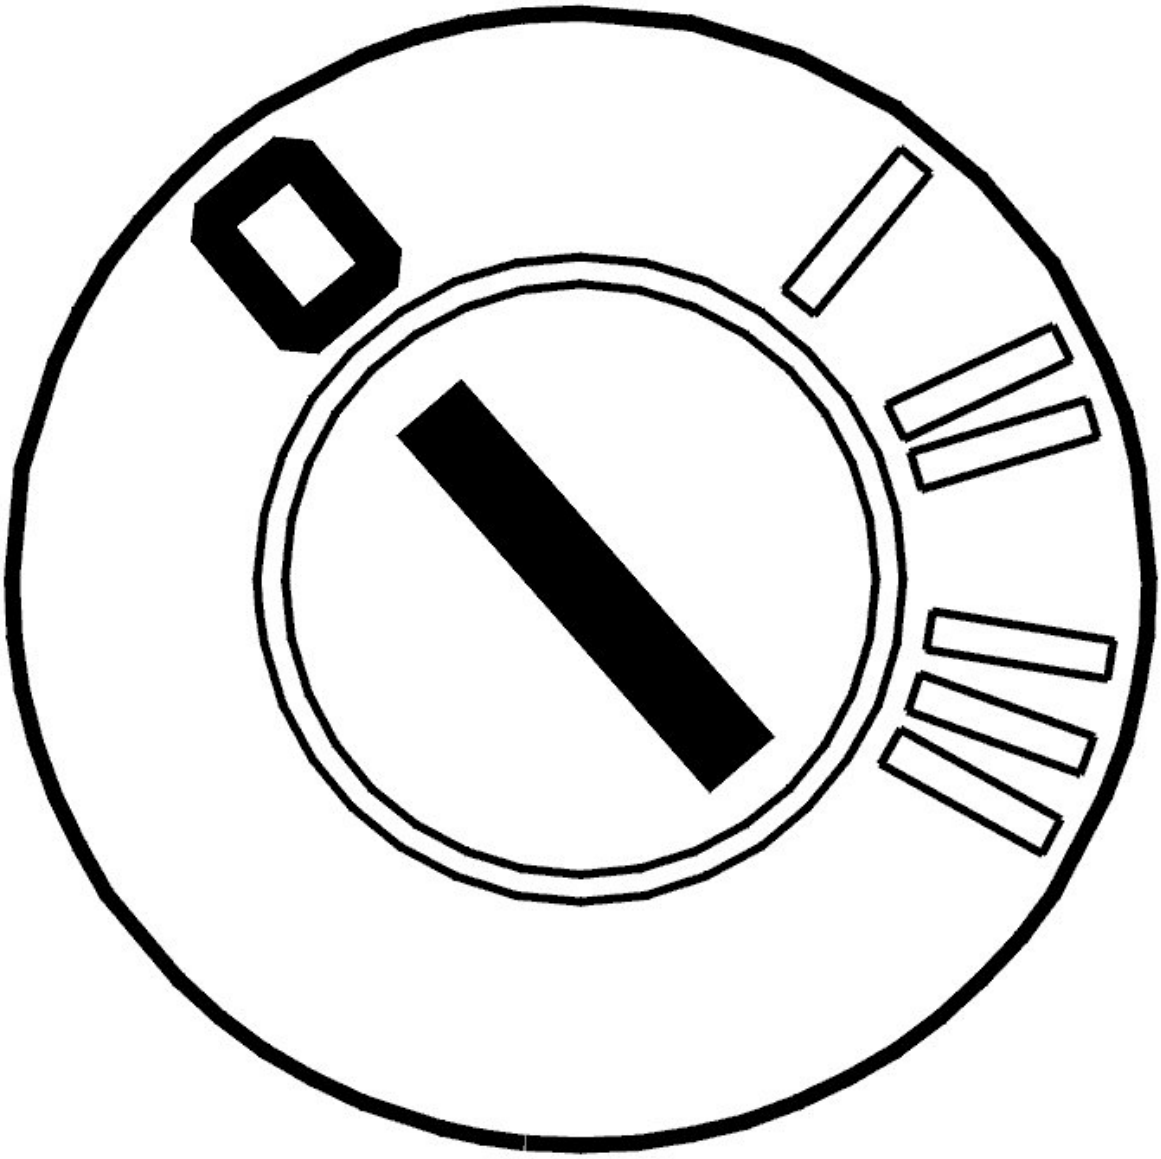
- To disconnect the transmission connectors, see Connectors transmission, disconnecting / connecting See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Wiring Harness/Service and Repair/Procedures
- To disconnect the control module, see Transmission control module (TCM), replacing, B5244T5, AW55-50/51SN, B5254T2, AW55-50/51SN, B5254T2, AW50/51 AWD See: Transmission Control Systems/Relays and Modules - Transmission and Drivetrain/Relays and Modules - A/T/Control Module/Service and Repair.

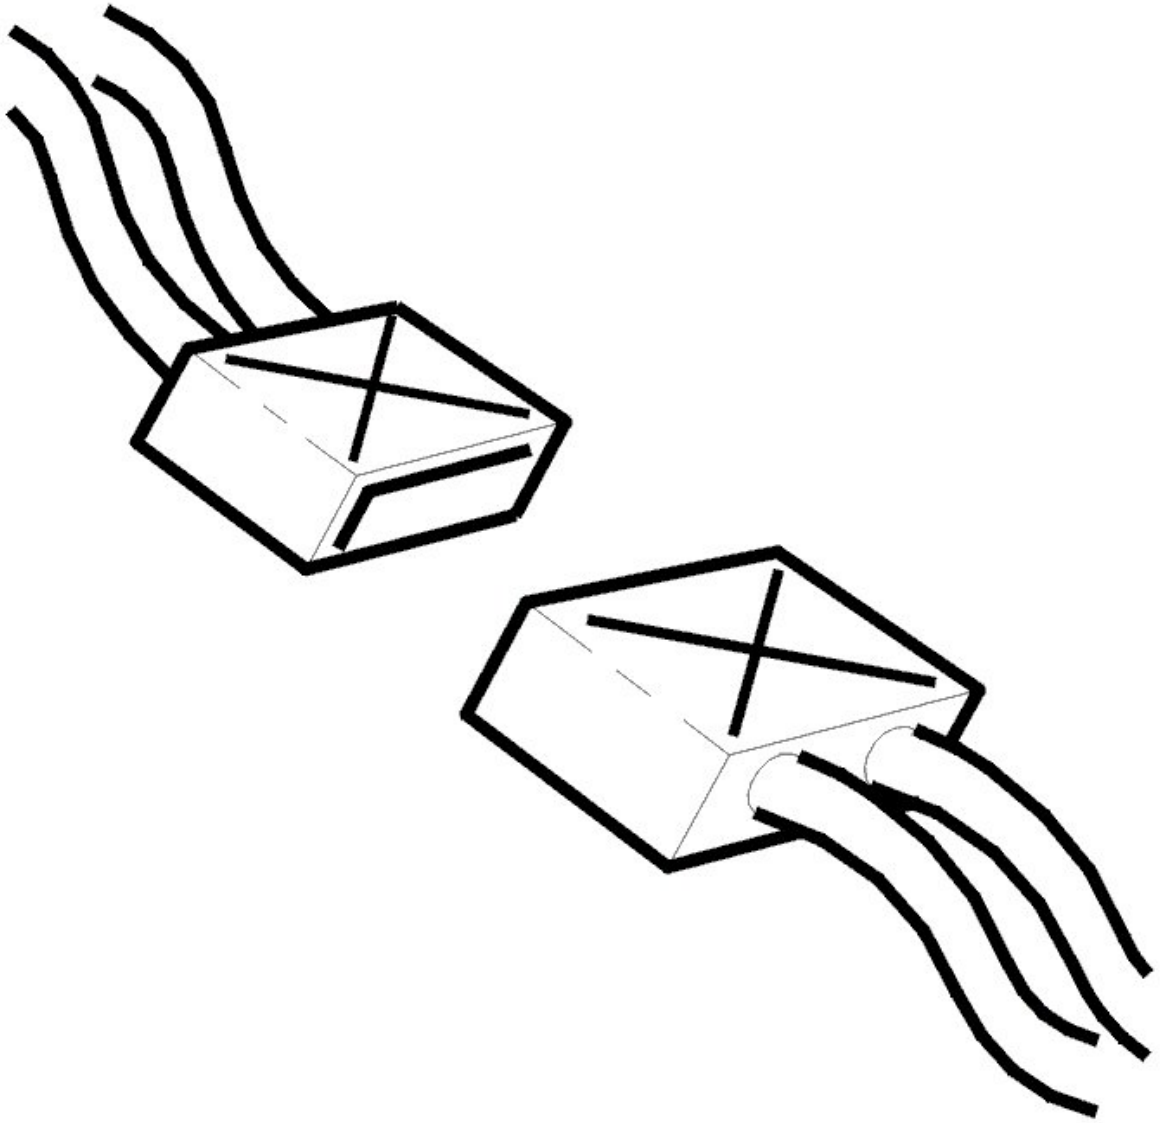
Does the current oscillate?

Yes - Fault Found

No - Checking resistance

Checking resistance



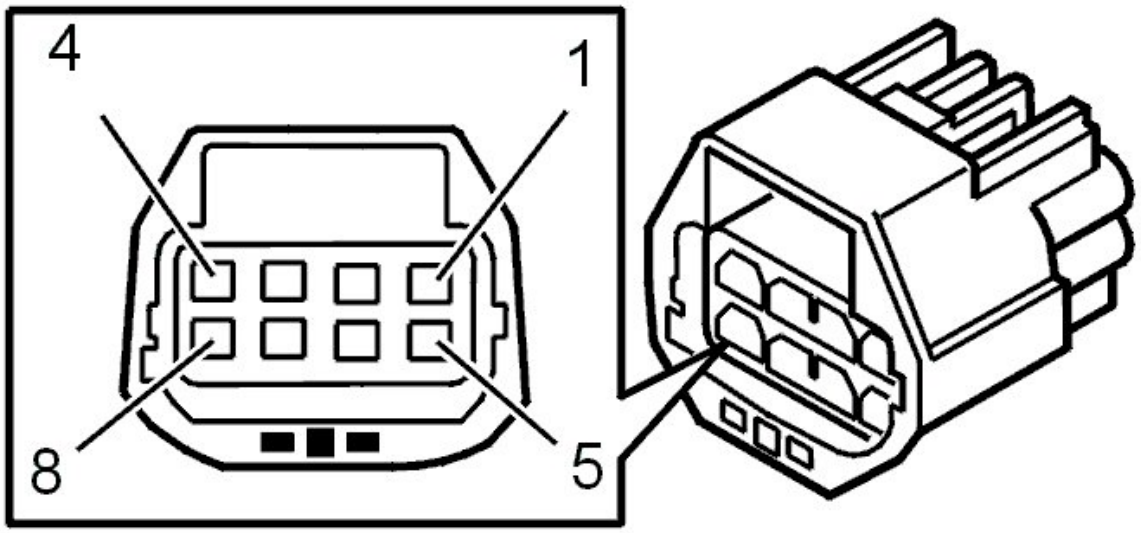


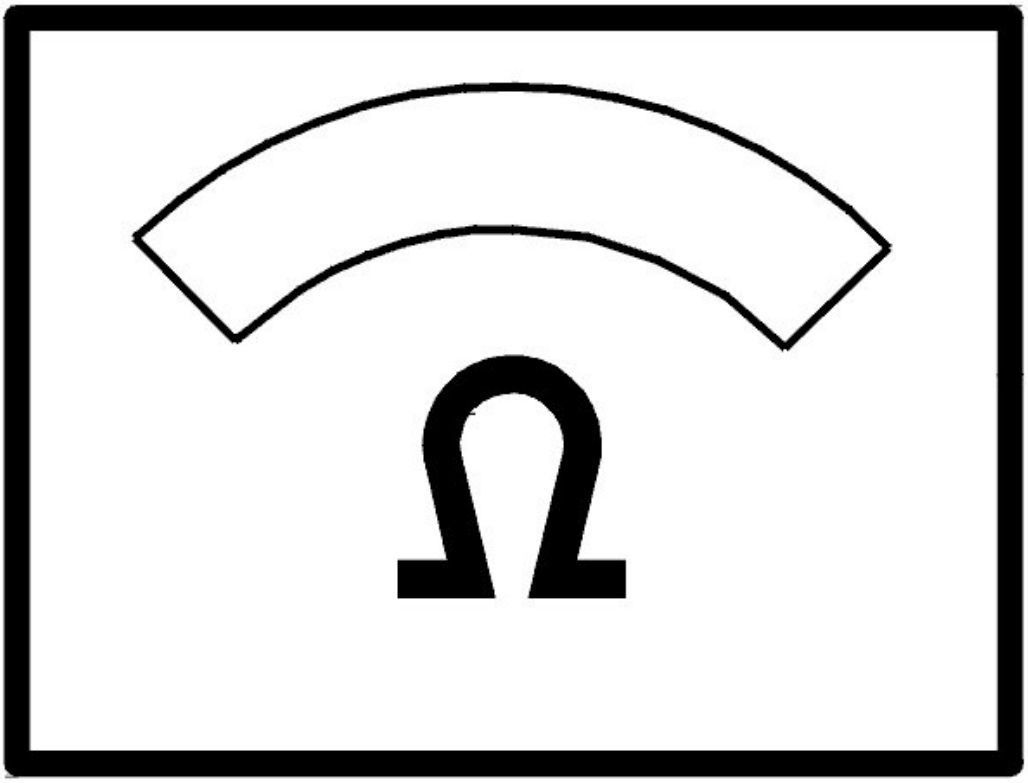
- Ignition off
- Transmission connector D disconnected.

Check the circuit for solenoid SLT. Measure the resistance between terminals #D3 and #D4 on transmission connector D. The resistance must be 5-5.6 ohms at 20°C.

Other information:

- To disconnect the transmission connectors, see Connectors transmission, disconnecting / connecting See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Wiring Harness/Service and Repair/Procedures
- For information about signals, see Signal description. Transmission control module (TCM), AW50/51 AWD, AW55-50/51SN See: Transmission Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Description. Transmission Control Module (TCM).



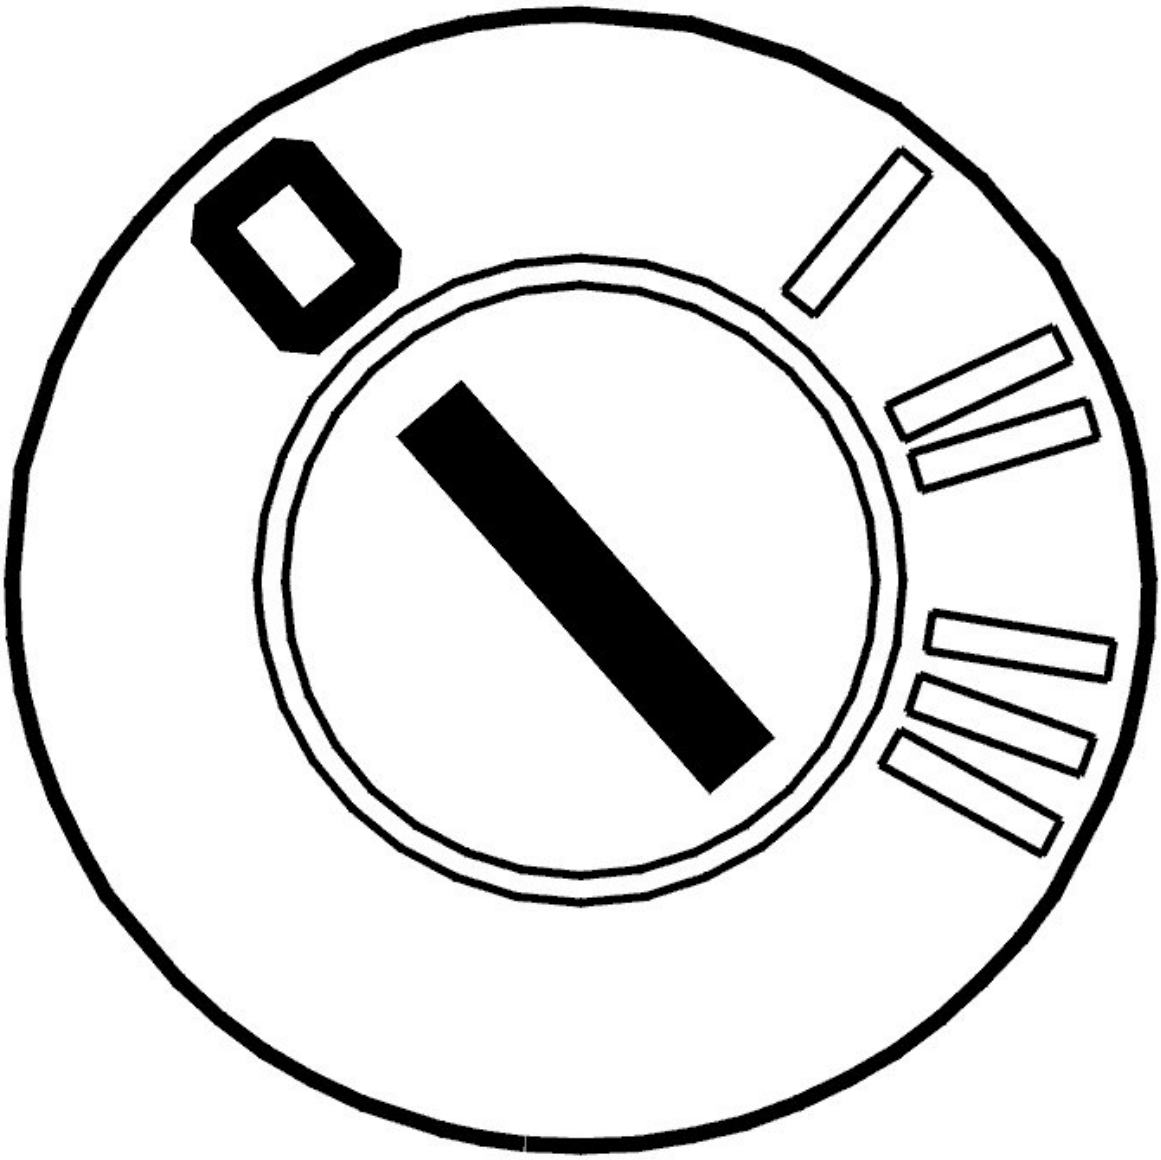


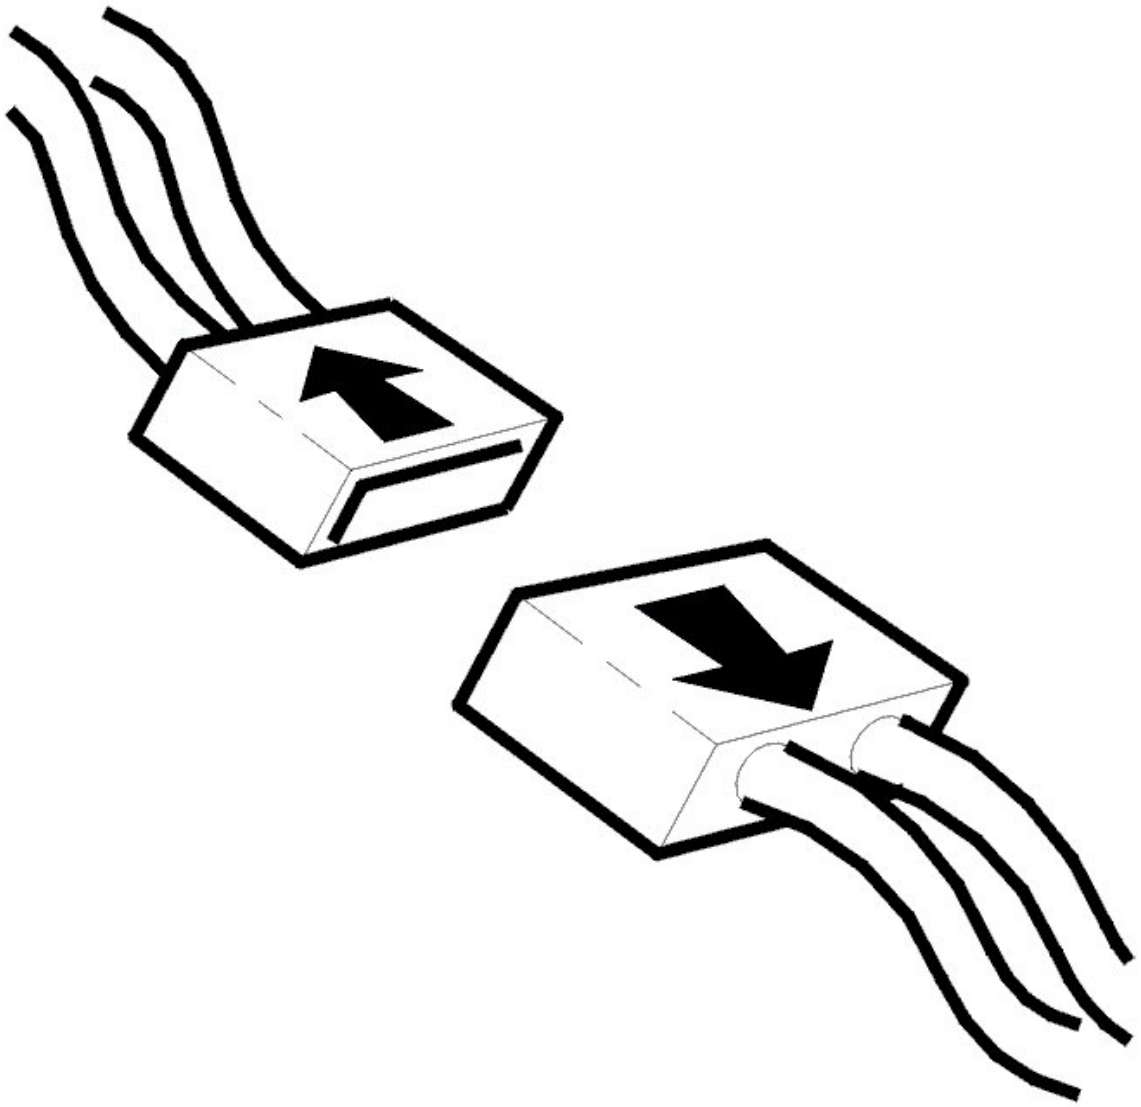
Was the resistance OK?

OK - Checking the wiring

Not OK - Checking the wiring and component

Checking the wiring



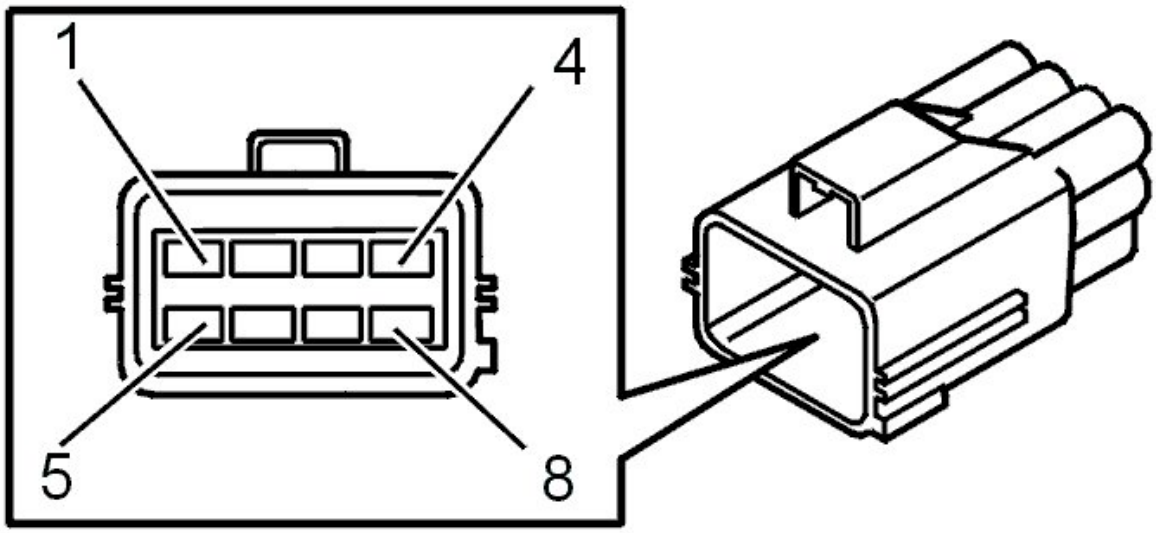


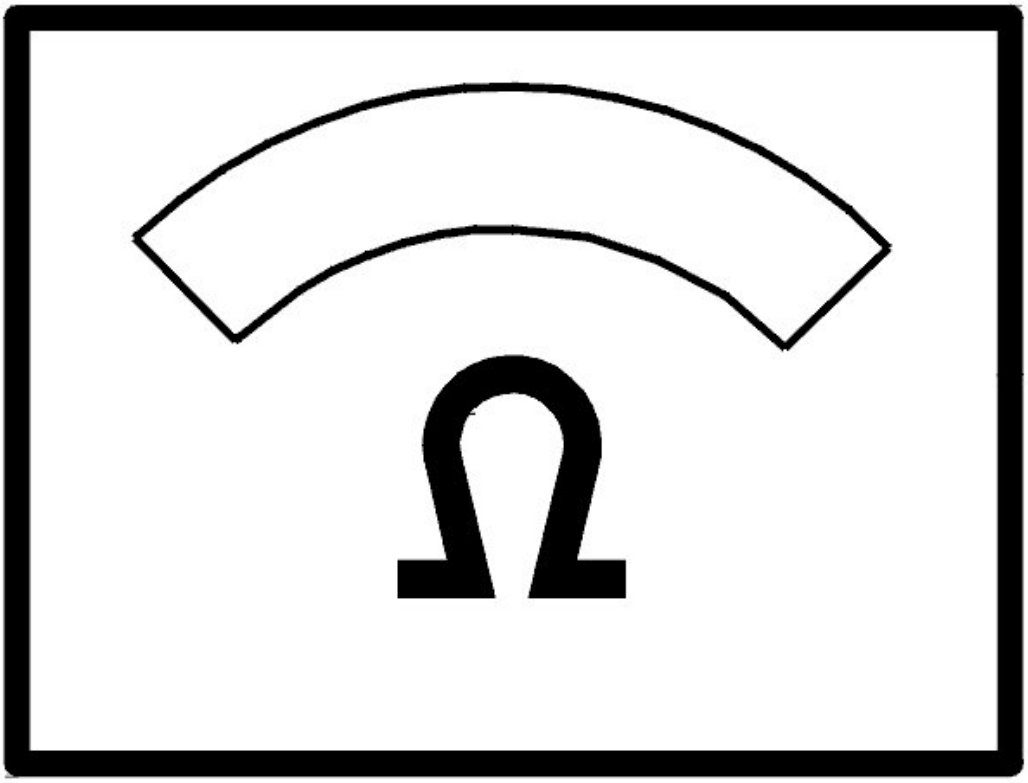
- Ignition off
- Disconnect transmission connector D.

Check the cable between transmission control module (TCM) terminal #A52 (#A52) and transmission connector terminal #D3 (control module side). Check for an open-circuit. See Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault.
Check the cable between control module terminal #B10 (#A70) and transmission connector terminal #D4 (control module side). Check for an open-circuit. See Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault.
Remedy as necessary.

Other information:

- To connect the breakout box, see Connecting the breakout box, B5244T5, B5254T2 See: Pinout Values and Diagnostic Parameters/Connecting the Breakout Box
- To disconnect the transmission connectors, see Connectors transmission, disconnecting / connecting See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Wiring Harness/Service and Repair/Procedures
- For information about signals, see Signal description. Transmission control module (TCM), AW50/51 AWD, AW55-50/51SN See: Transmission Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Description. Transmission Control Module (TCM).



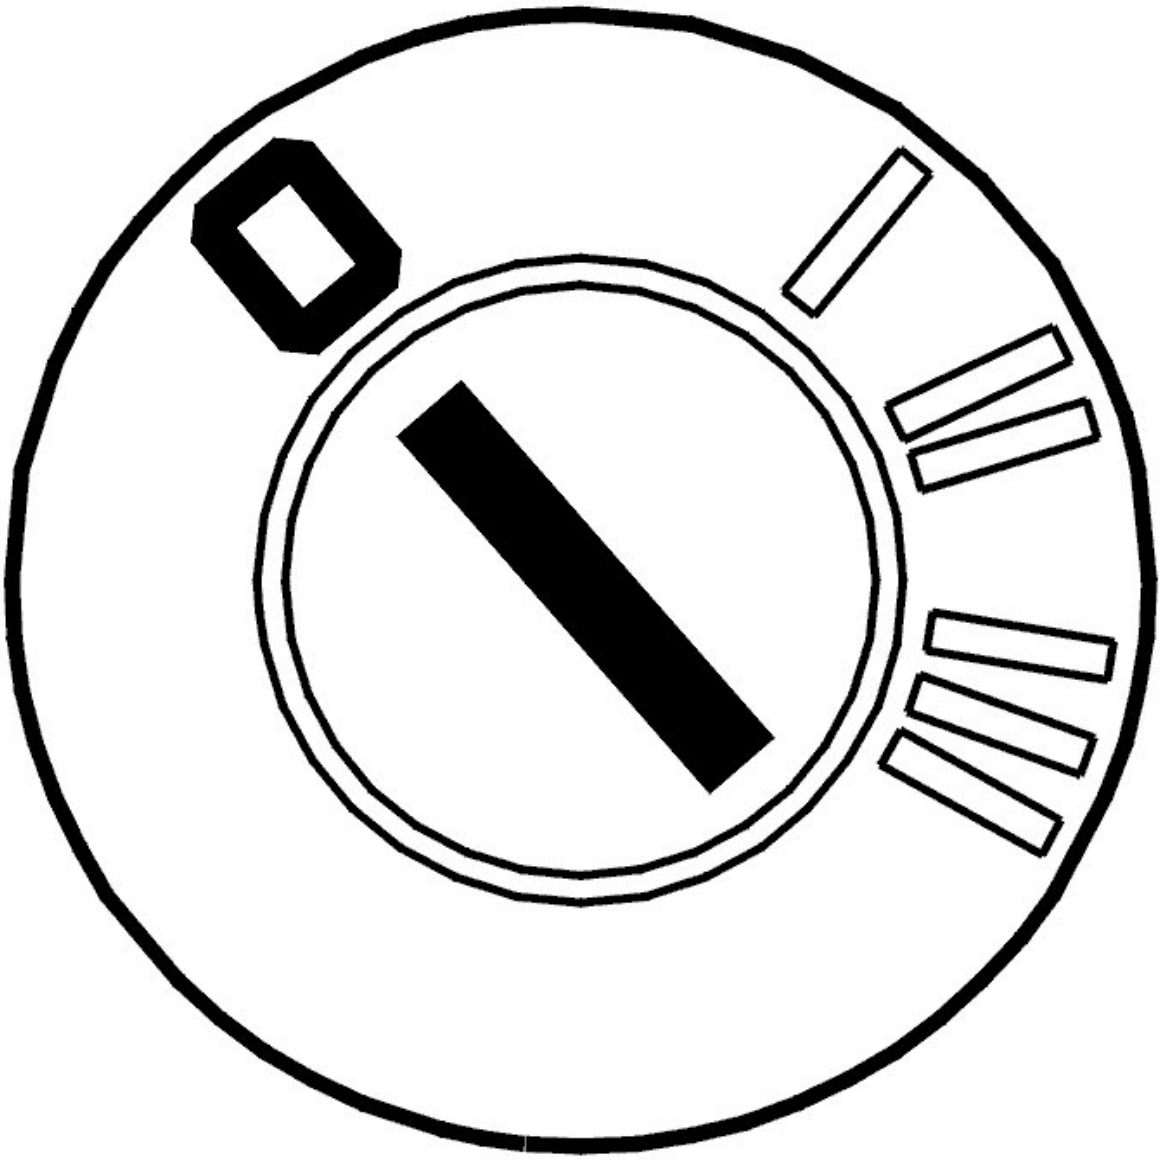


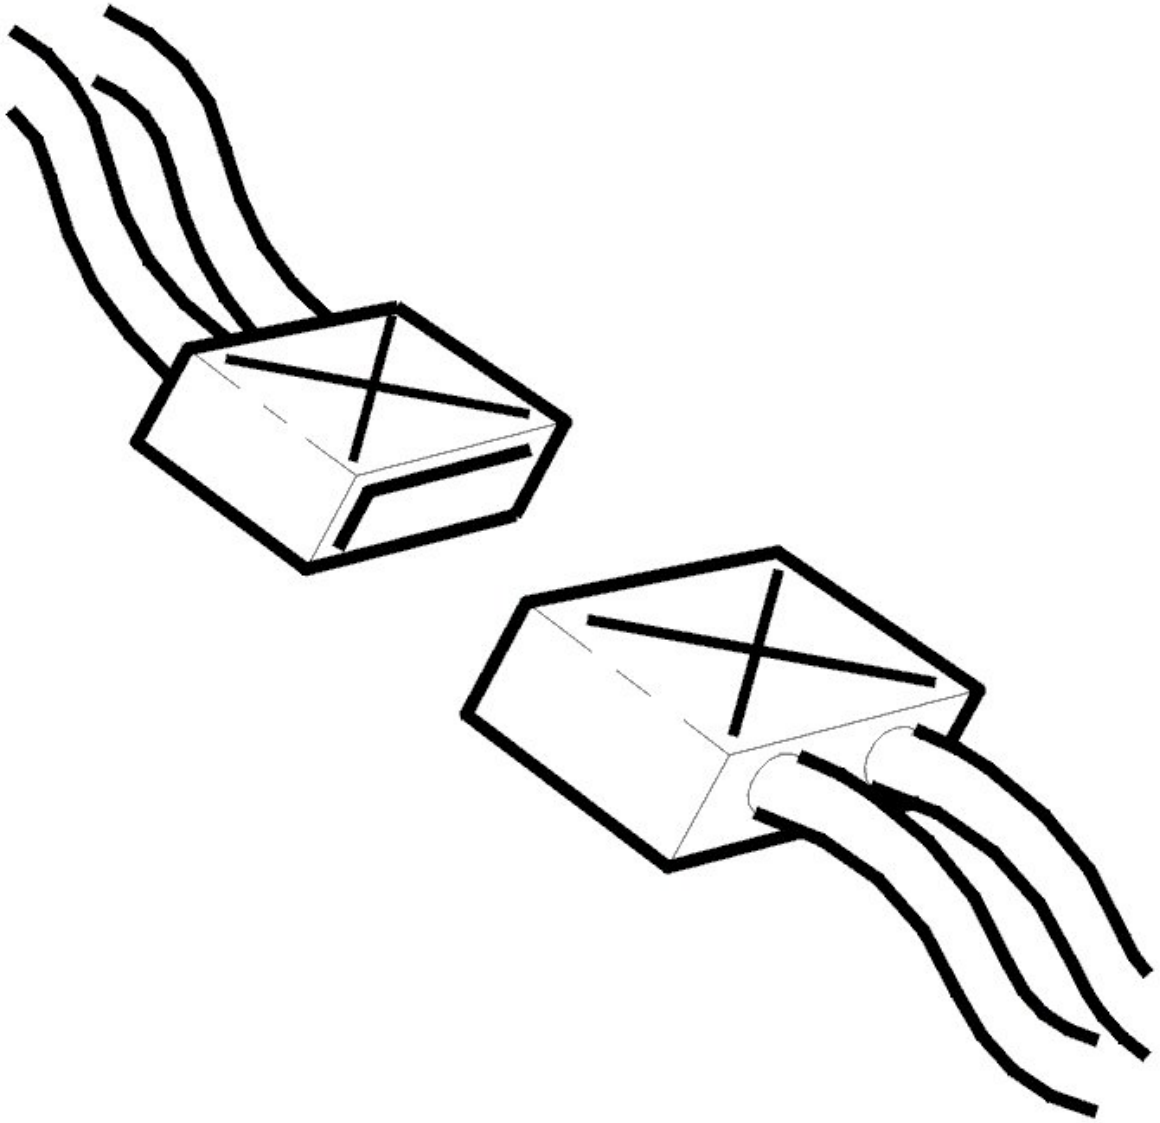
Was a fault found in the wiring?

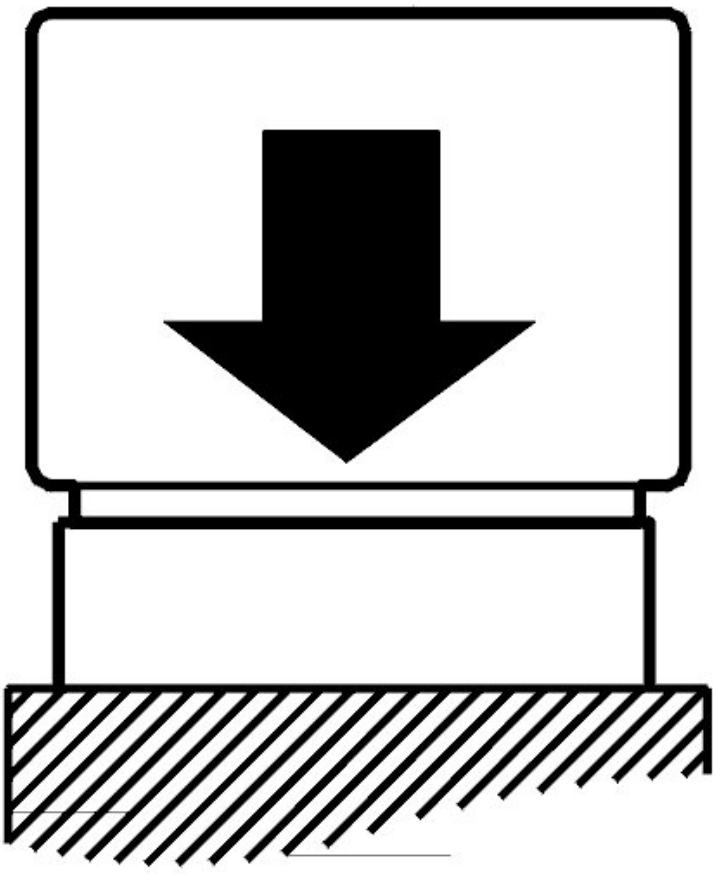
Yes - Verification

No - Checking the control module

Checking the control module







- Ignition off
- The breakout box connected
- Connect the control module.
- Transmission connector D disconnected.

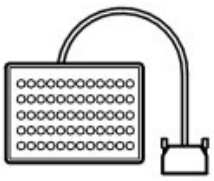
Check the transmission control module (TCM) by measuring the resistance between terminals #52 (#A52) and #B10 (#A70) on the breakout box. The resistance must be approximately 9 kohms.

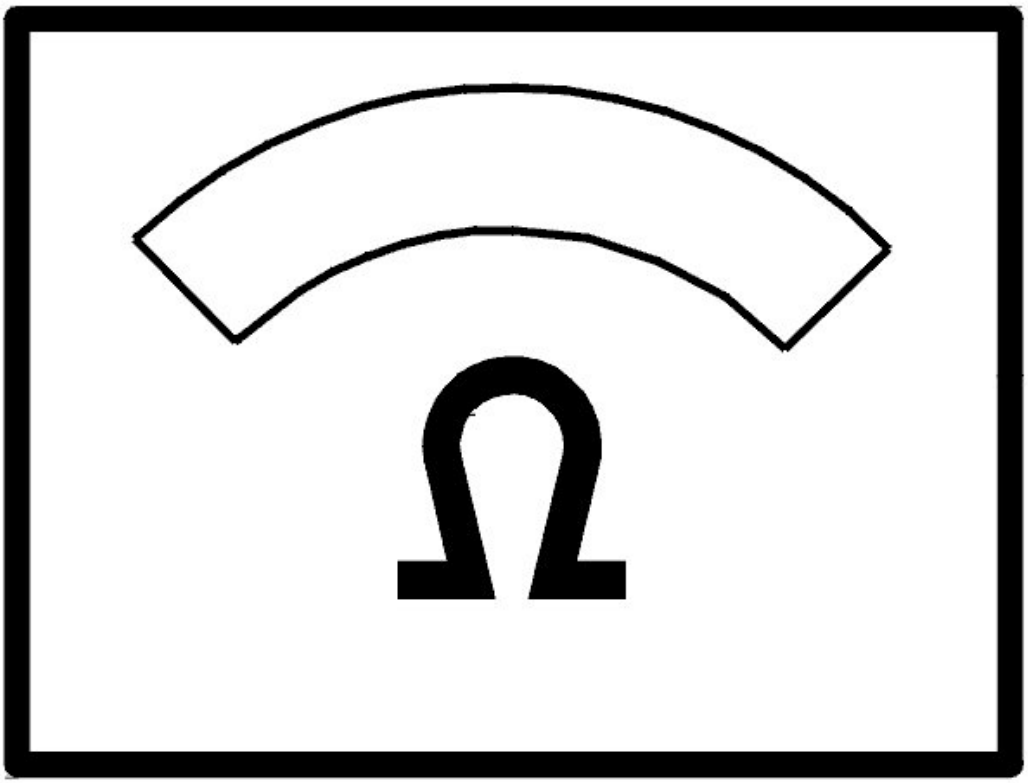
Note! When removing the transmission connector, the control module may store diagnostic trouble codes (DTCs) for the gear-shift position sensor, the shift solenoids, the temperature sensor etc.

Try a new control module if the resistance is infinite.

Other information:

- To disconnect the transmission connectors, see Connectors transmission, disconnecting / connecting See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Wiring Harness/Service and Repair/Procedures
- To replace the control module, see Transmission control module (TCM), replacing, B5244T5, AW55-50/51SN, B5254T2, AW55-50/51SN, B5254T2, AW50/51 AWD See: Transmission Control Systems/Relays and Modules - Transmission and Drivetrain/Relays and Modules - A/T/Control Module/Service and Repair
- For information about signals, see Signal description. Transmission control module (TCM), AW50/51 AWD, AW55-50/51SN See: Transmission Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Description. Transmission Control Module (TCM).



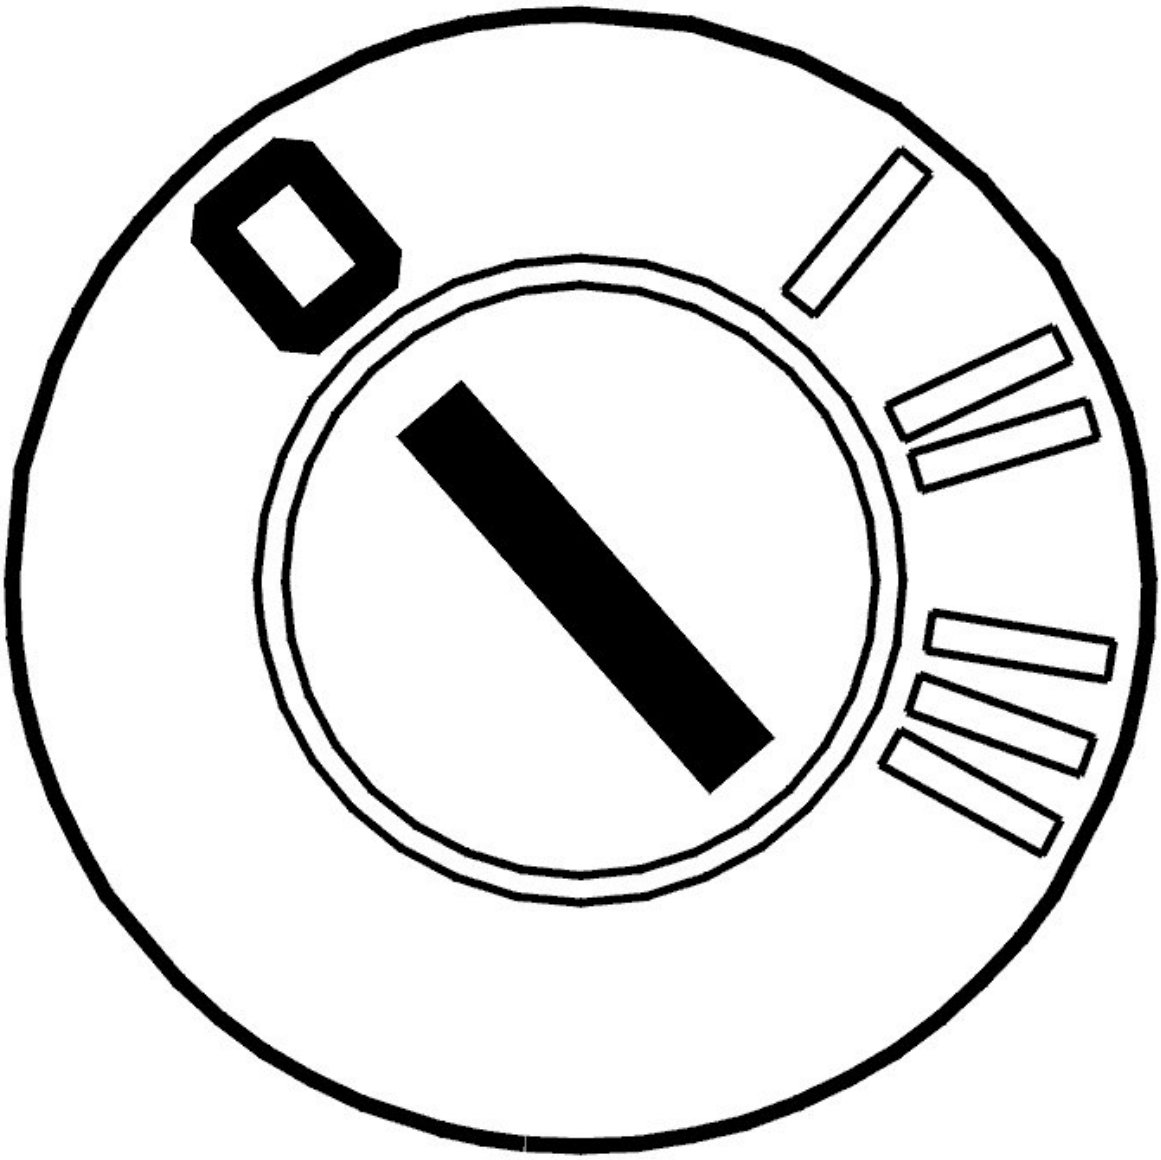


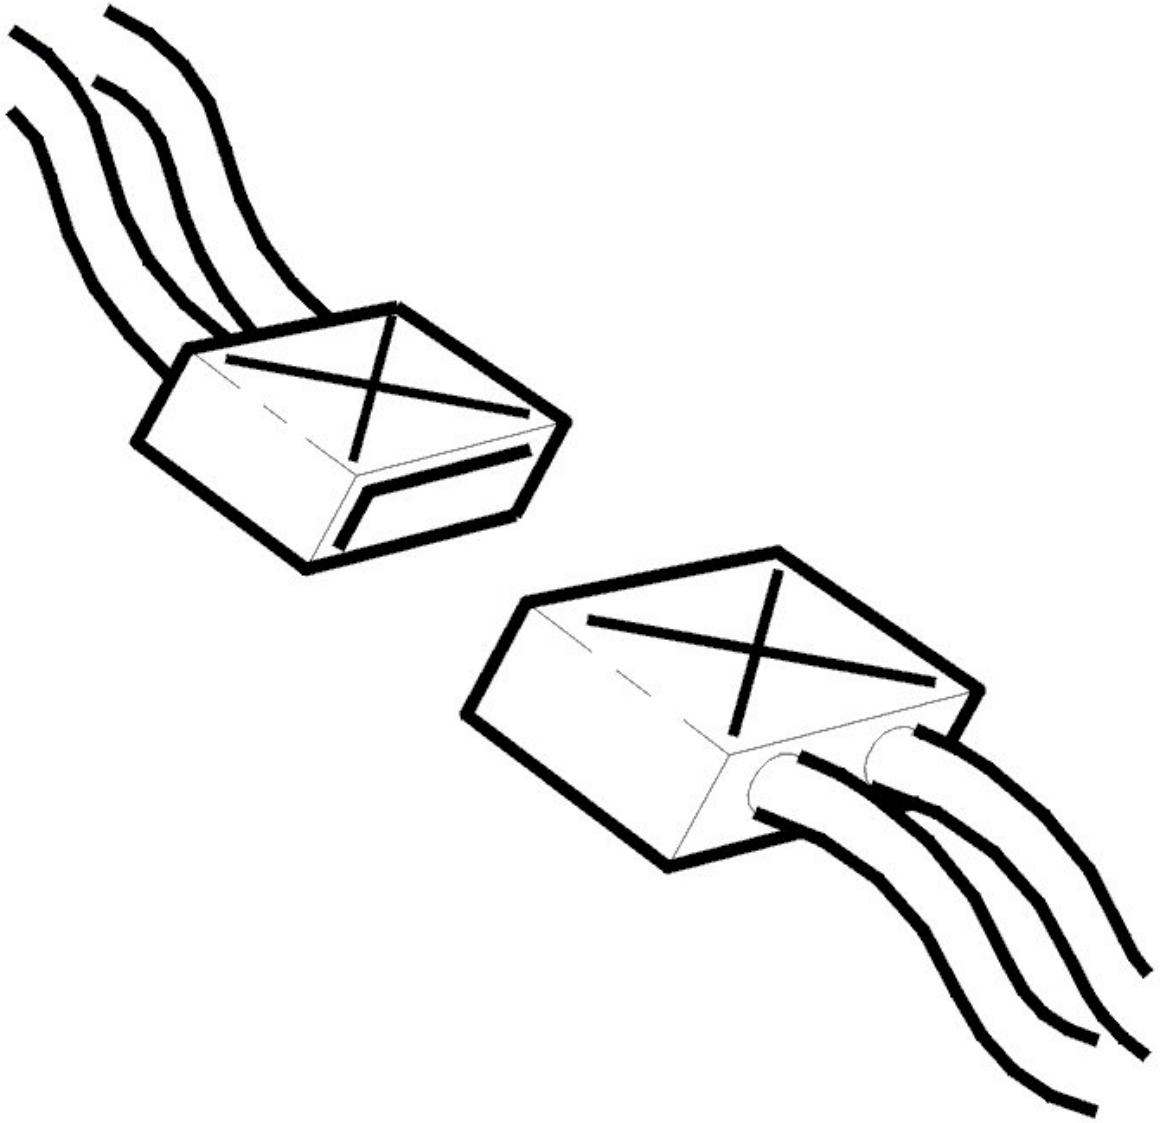
Was the resistance OK?

Yes - No Fault Found

No - Verification

Checking the wiring and component





- Ignition off
- Open the transmission control system.

Check the wiring between transmission connector terminal #D3 and solenoid SLT terminal #1. Check the wiring between transmission connector terminal #D4 and solenoid SLT terminal #2. Check for an open-circuit. See Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault.
Also check against the other cables in the circuit. Use the relevant wiring diagram.
Check solenoid SLT by measuring the resistance between terminals #1 and #2 on the connector. The resistance must be 5-5.6 ohms at 20°C.
Replace the control system if the resistance is incorrect.

Other information:

- To disconnect the transmission connectors, see Connectors transmission, disconnecting / connecting See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Wiring Harness/Service and Repair/Procedures
- To open and replace the transmission control system, see Solenoid control system, replacing See: Transmission Control Systems/Actuators and Solenoids - Transmission and Drivetrain/Actuators and Solenoids - A/T/Shift Solenoid/Service and Repair/Solenoid Control System, Replacing
- To replace the cable harness for the control system, see Wiring harness / oil temperature sensor, replacing See: Transmission and Drivetrain/Automatic Transmission/Transaxle/Wiring Harness/Service and Repair/Removal and Replacement
- For information about signals, see Transmission Control Systems; Specifications. See: Transmission Control Systems/Specifications

Location Of Components (Solenoids)

Continue - Resetting the adaptation and oil quality counter

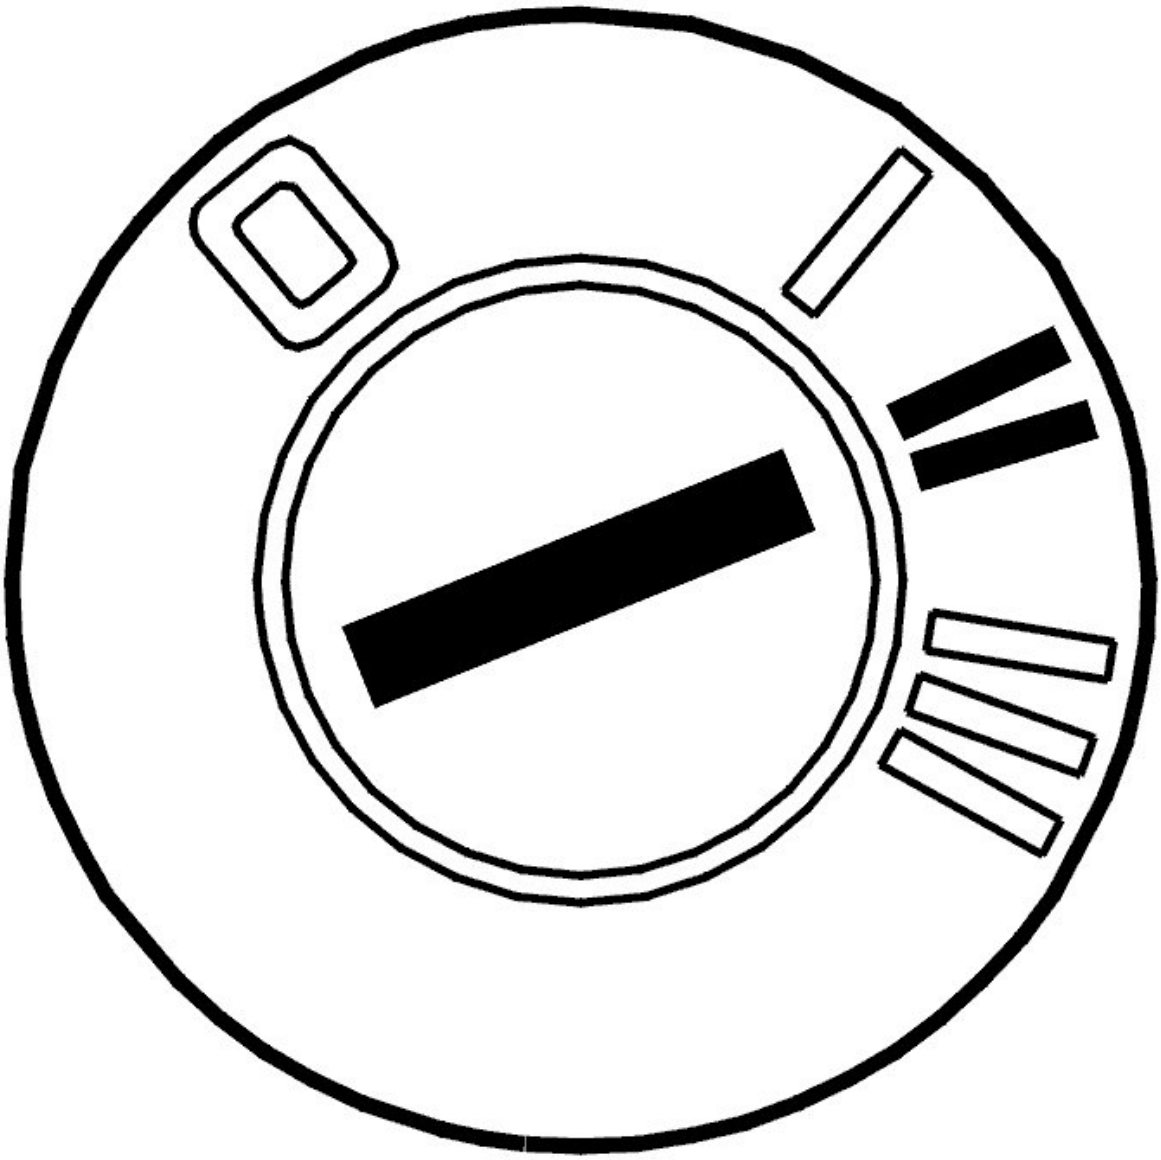
Resetting the adaptation and oil quality counter

Resetting the adaptation

Resetting adaptation and the counter for "Transmission oil change"

Hint: The transmission has torque controlled adaptive pressure control. Pressure control means that the transmission regulates the pressure itself during each gear shift. This avoids harsh gear shifting. Each gear shift is evaluated by the control module and stored in the memory. This allows for compensation for wear and tear in the transmission and clutch. It is important that the adaptation in the memory is reset after the transmission has been repaired. This is to ensure normal operation. The oil is replaced during repair; the "Transmission oil change" counter must be reset. If the counter is not reset when the fluid is drained and replaced, there is a risk that a diagnostic trouble code (DTC) will be stored in incorrect circumstances.

Note! This applies only if the transmission or one of the components in the transmission have been replaced.



- Ignition on.

Click on the VCT2000 symbol to reset the adaptation and counter.

Continue - **DONE**

DONE - Verification

Verification

Verification

Hint: After carrying out the repair, check that the fault has been remedied.

Diagnostic Trouble Code (DTC) Information

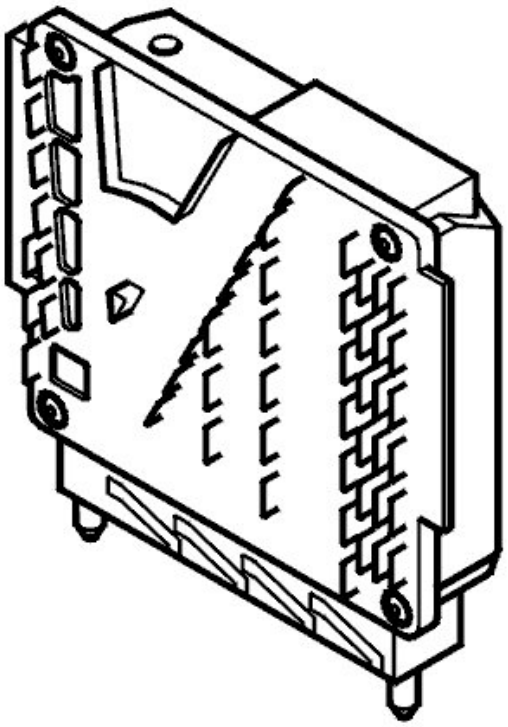
Diagnostic trouble code information

Condition



Solenoids are controlled by output stages in the transmission control unit (TCM). The control unit opens the output stages when the solenoids should be activated, and voltage is supplied to the circuit. If the control unit registers that there is an internal fault in the output stage circuit for solenoid S1, S2, S3, S4, S5, SLU, SLT or SLS diagnostic trouble code TCM-0060, TCM-0120, TCM-0121, TCM-0122, TCM-0123 or TCM-0124 will be stored depending on the output stage.

Substitute value
- Transmission control unit help program "Limp-home" has started to work.

Possible source
- Internal fault in control unit.

Fault symptom[s]
- Orange general warning lamp is on.

- Malfunction indicator light (MIL) is on.
- Lock up function not working.
- Rough gear shifts.
- Gear shifts not working.

Hint:
- Rough gear shifts can be caused by:
- No reduction of system pressure during gear shifts
- No request for torque limitation to the engine control unit during gear shifts

Gear shift failure is caused by the transmission control unit interrupting all solenoid activation.

Internal Fault

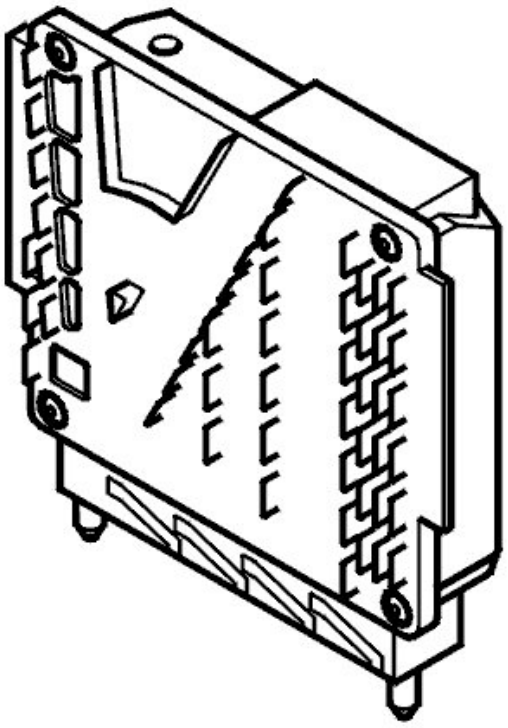
Attempt New Test - Replacing the control module

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code information

Condition



Solenoids are controlled by output stages in the transmission control unit (TCM). The control unit opens the output stages when the solenoids should be activated, and voltage is supplied to the circuit. If the control unit registers that there is an internal fault in the output stage circuit for solenoid S1, S2, S3, S4, S5, SLU, SLT or SLS diagnostic trouble code TCM-0060, TCM-0120, TCM-0121, TCM-0122, TCM-0123 or TCM-0124 will be stored depending on the output stage.

Substitute value
- Transmission control unit help program "Limp-home" has started to work.

Possible source
- Internal fault in control unit.

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

Fault symptom[s]
- Orange general warning lamp is on.
- Malfunction indicator light (MIL) is on.
- Lock up function not working.
- Rough gear shifts.
- Gear shifts not working.

Hint:
- Rough gear shifts can be caused by:
- No reduction of system pressure during gear shifts
- No request for torque limitation to the engine control unit during gear shifts

Gear shift failure is caused by the transmission control unit interrupting all solenoid activation.

Internal Fault

Internal fault

Replacing the control module

The control module has registered an internal fault.

Caution! A new control module is delivered without software. The control module must be programmed in order to function after replacement.

For further information about programming and replacing the control module, see Transmission control module (TCM), replacing, B5244T5, AW55-50/51SN, B5254T2, AW55-50/51SN, B5254T2, AW50/51 AWD See: Transmission Control Systems/Relays and Modules - Transmission and Drivetrain/Relays and Modules - A/T/Control Module/Service and Repair.

Diagnostic Trouble Code (DTC) Information

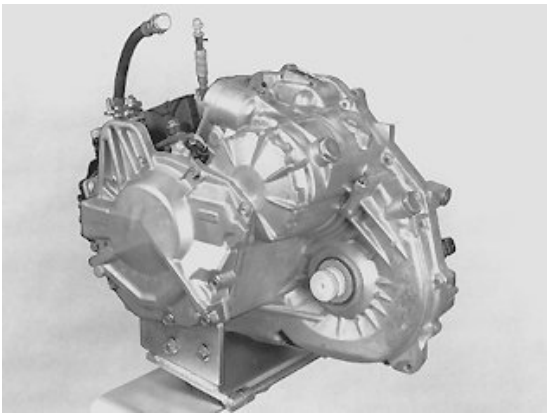
Diagnostic trouble code (DTC) information

Condition



The driving section of the transmission is disengaged when certain conditions are met:
- Stationary
- Engine idling
- Stop pedal depressed
- Gear position D, 3 or 4.

The function decreases fuel consumption and vibration from the transmission when running the engine at idle speed.
Diagnostic trouble code (DTC) TCM-012A is stored if the transmission control module (TCM) registers that clutch C1 disengages incorrectly.

Substitute value
- None.

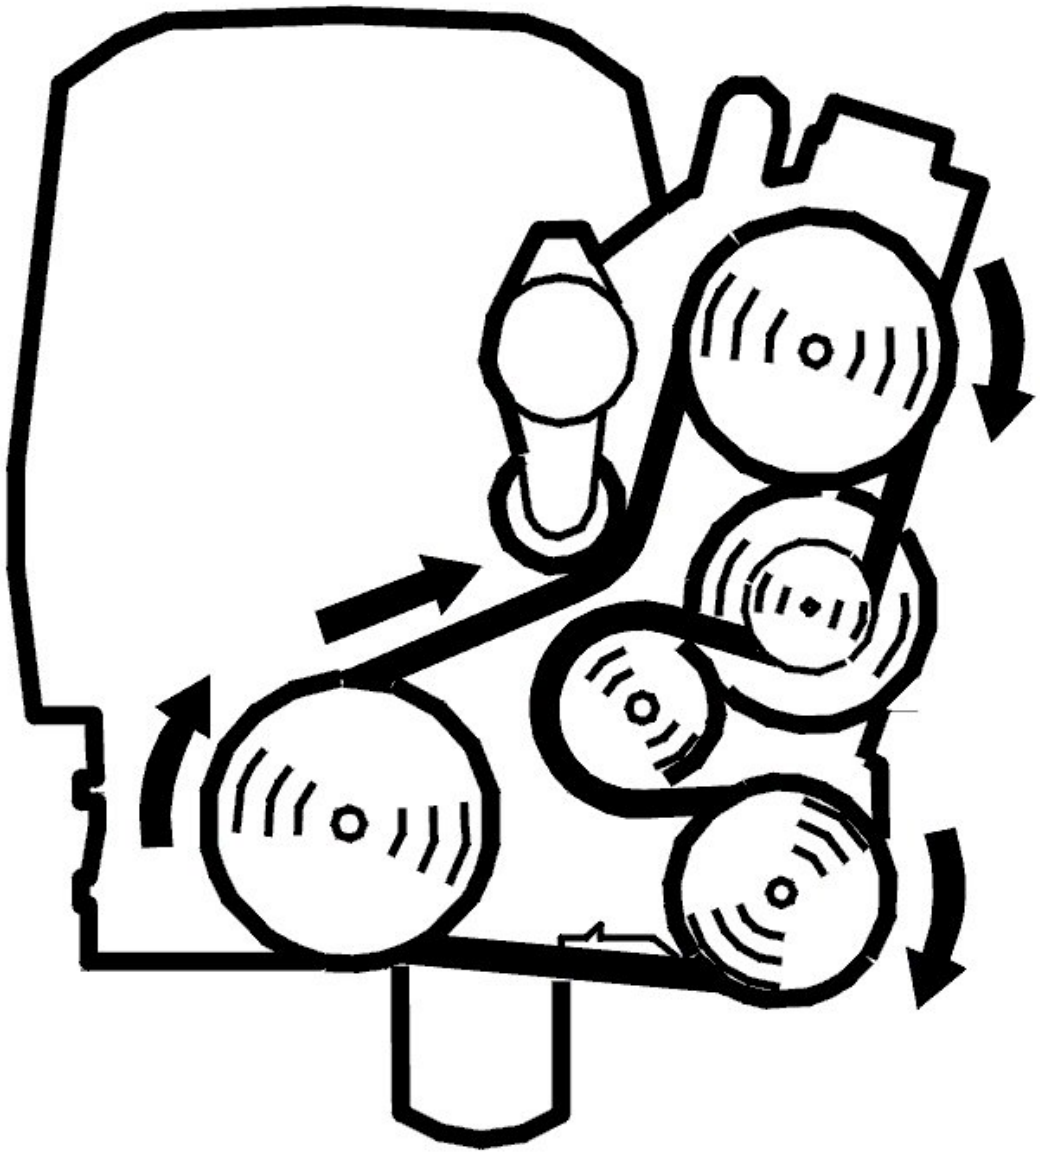
Possible source
- Shift solenoid S1 has jammed in the OFF position
- Shift solenoid S2 has jammed in the ON position
- Solenoid SLT has jammed in the OFF position
- Internal fault in the transmission
- Defective control module.

Fault symptom[s]
- General orange warning lamp lit
- Malfunction indicator lamp (MIL) lit.

Faulty Connection

Faulty connection

Checking the neutral check



- Ignition off
- Check the transmission connectors and the control module connector. Check for contact resistance and oxidation. See Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault
- Reconnect the connectors, reinstall components etc.
- Raise the car so that the drive wheels can rotate freely
- Start the car
- Move the gear selector to position D. Accelerate so that the speed exceeds 50 km/h
- Brake the wheels and let the engine run at idling speed without touching the accelerator pedal (AP). The neutral check must display the status as "Active" (this may take up to 30 seconds)
- Brake the wheels. Move the gear selector to position D. Carefully depress the accelerator. Check that the neutral check changes to the "Inactive" status.

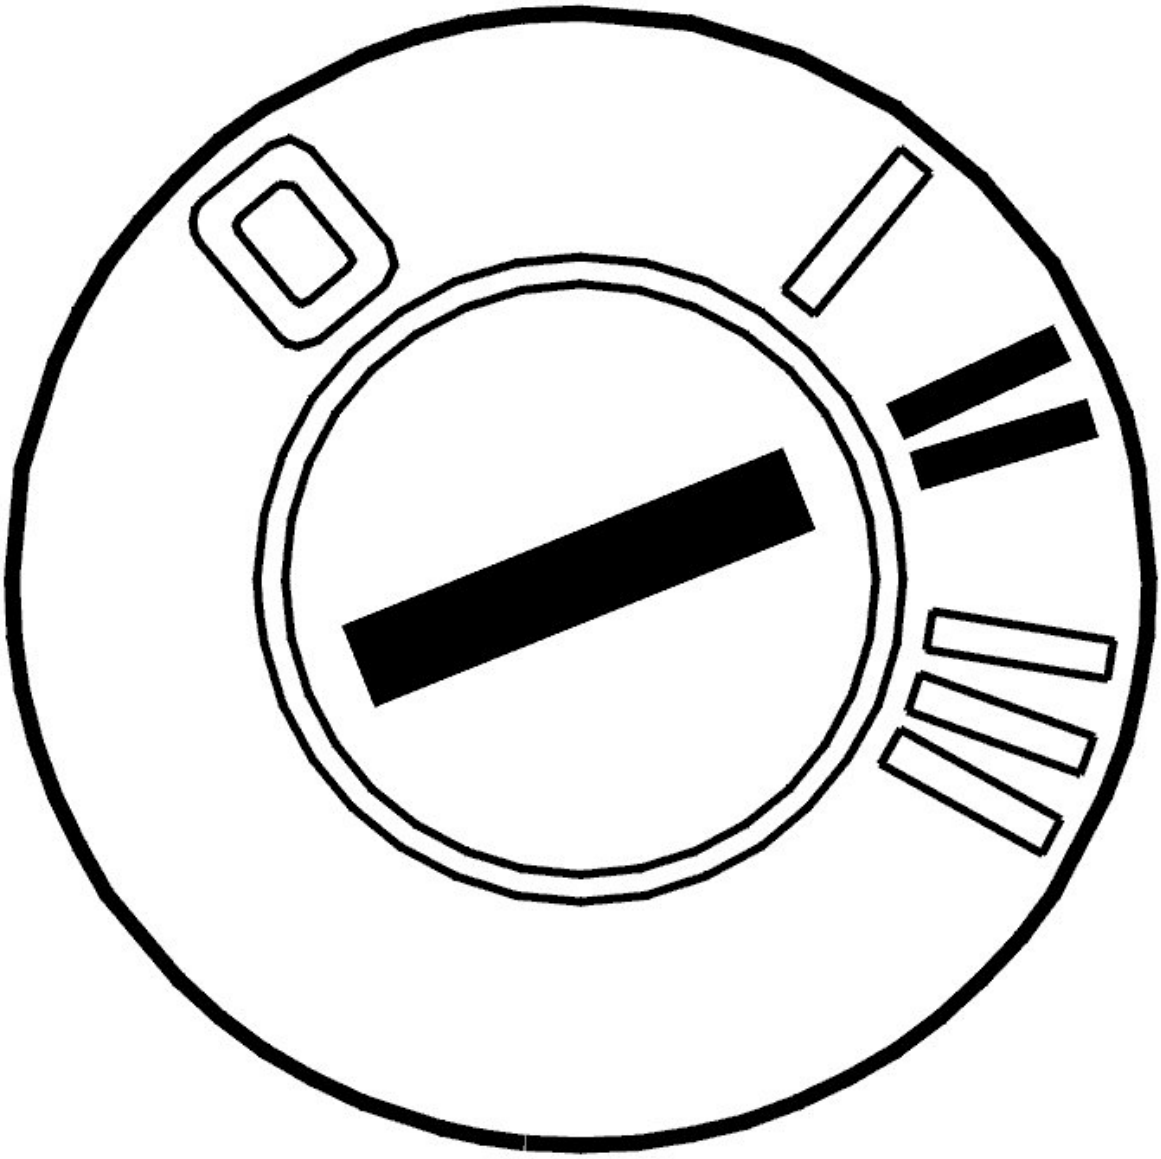
Check that the function operates in gear positions 4, 3 and 2.

Does the status change?

Yes - Fault Found

No - Checking shift solenoids S1 and S2

Checking shift solenoids S1 and S2



- Ignition on
- Gear selector in position P
- Activate solenoids S1 and S2 individually.

Note! Select to read the status for the solenoid that should be activated.

The value should shift between OFF and ON and a " clicking sound" should be heard in the transmission (at 20° C).

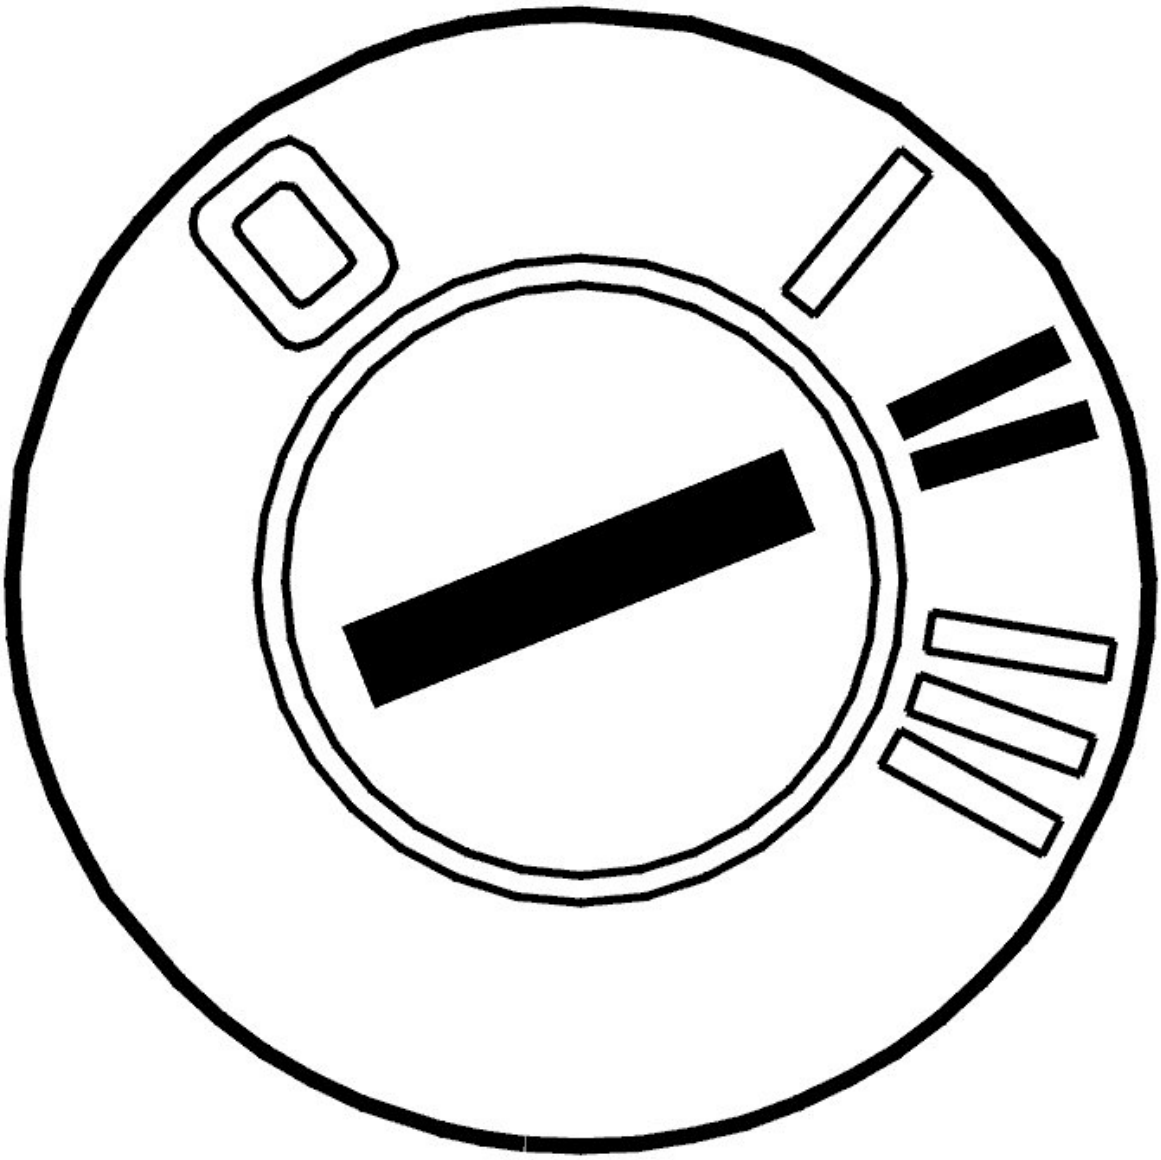
Does the value change?

Yes - Checking solenoid SLT

No - Replacing the transmission control system

Checking solenoid SLT

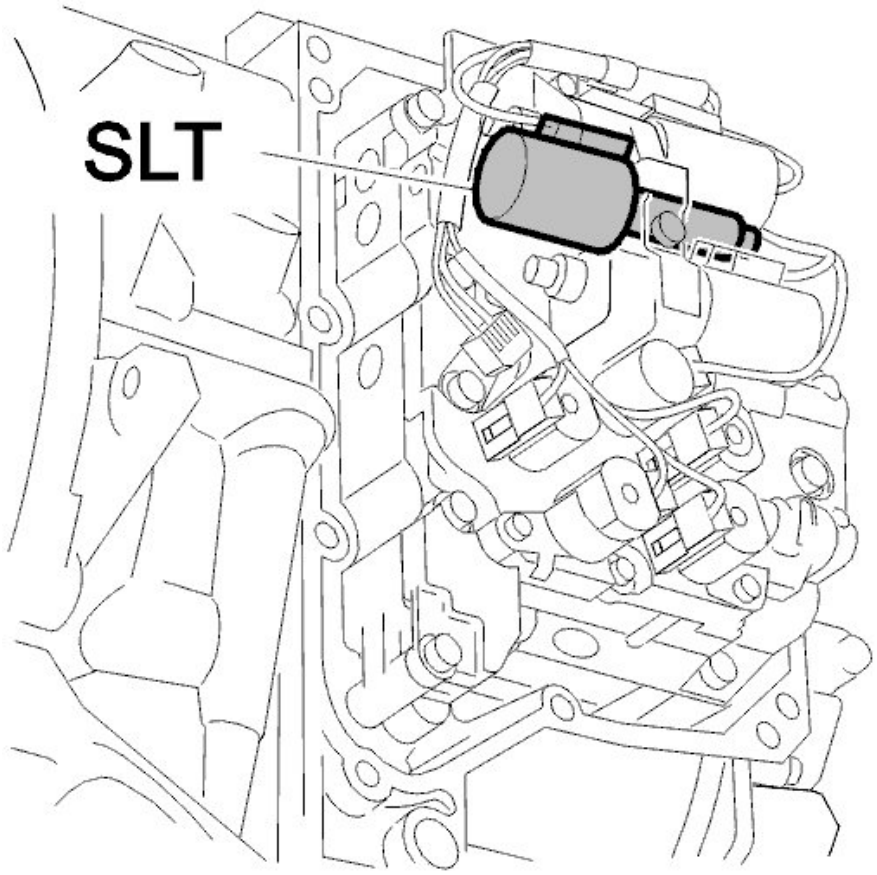
Note! The transmission must not be colder than room temperature when activated.



- Ignition on
- Activate solenoid SLT.

Check that the solenoid " clicks" on activation. Use a stethoscope to hear the sound more clearly.
If no "click" is heard, this indicates that there is a mechanical fault.

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2



Was solenoid SLT OK?

Yes - No Fault Found

No - Replacing the transmission control system

Replacing the transmission control system

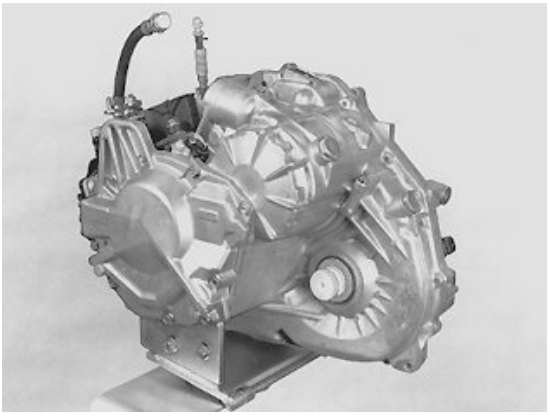
- Replace the faulty shift solenoid.

The transmission control system must be replaced if there is a fault in solenoid SLT. To replace the solenoids and the transmission control system, see Solenoid control system, replacing See: Transmission Control Systems/Actuators and Solenoids - Transmission and Drivetrain/Actuators and Solenoids - A/T/Shift Solenoid/Service and Repair/Solenoid Control System, Replacing.



Continue - Resetting the adaptation and oil quality counter

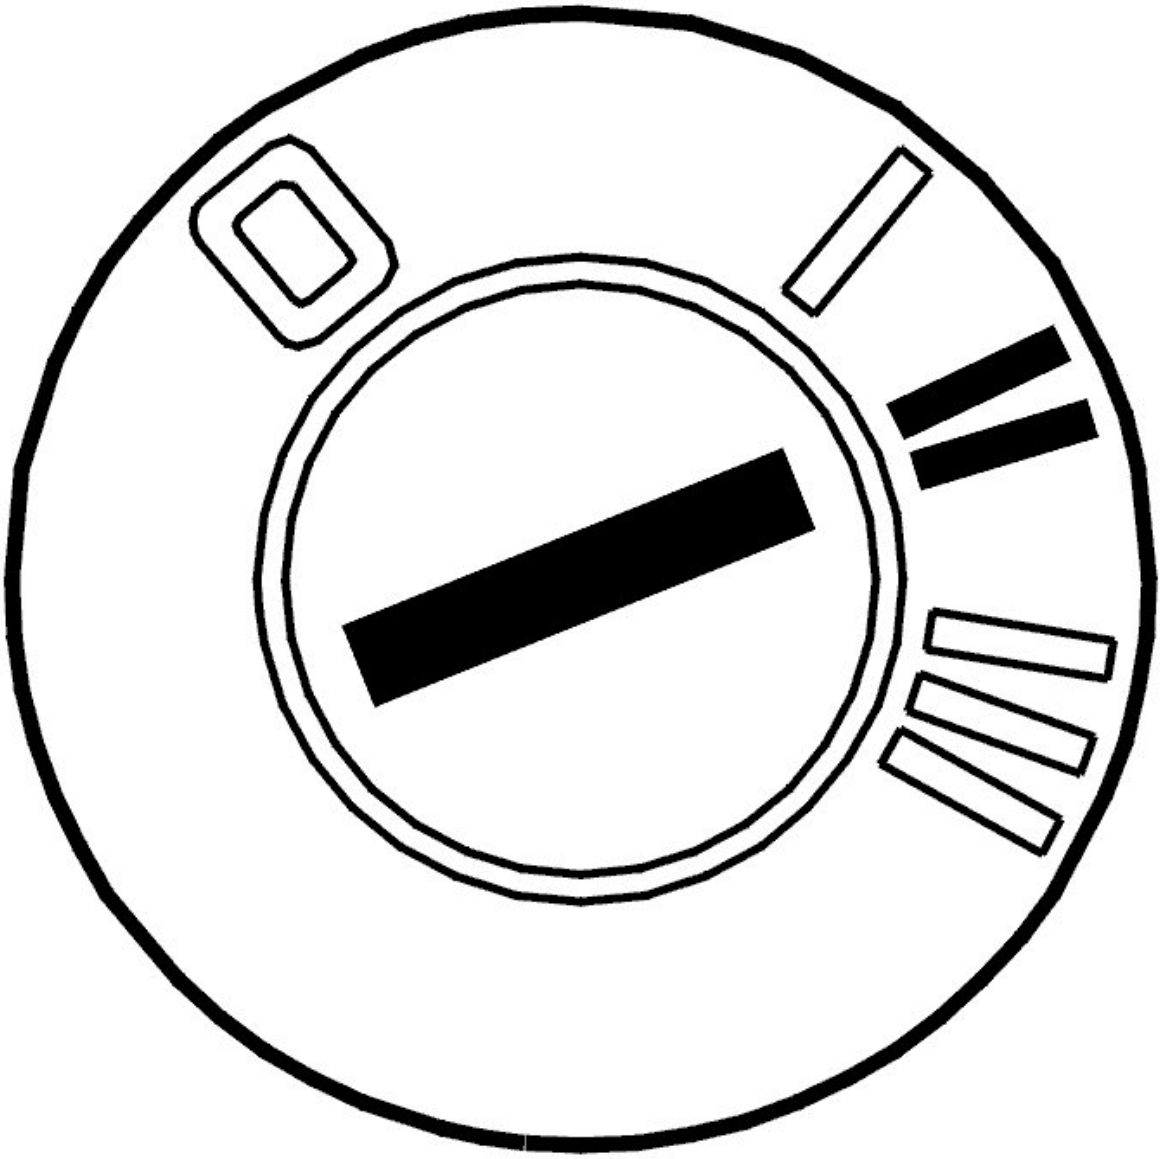
Resetting the adaptation and oil quality counter

Resetting the adaptation

Resetting adaptation and the counter for "Transmission oil change"

Hint: The transmission has torque controlled adaptive pressure control. Pressure control means that the transmission regulates the pressure itself during each gear shift. This avoids harsh gear shifting. Each gear shift is evaluated by the control module and stored in the memory. This allows for compensation for wear and tear in the transmission and clutch. It is important that the adaptation in the memory is reset after the transmission has been repaired. This is to ensure normal operation. The oil is replaced during repair; the "Transmission oil change" counter must be reset. If the counter is not reset when the fluid is drained and replaced, there is a risk that a diagnostic trouble code (DTC) will be stored in incorrect circumstances.

Note! This applies only if the transmission or one of the components in the transmission have been replaced.



- Ignition on.

Click on the VCT2000 symbol to reset the adaptation and counter.

Diagnostic Trouble Code (DTC) Information

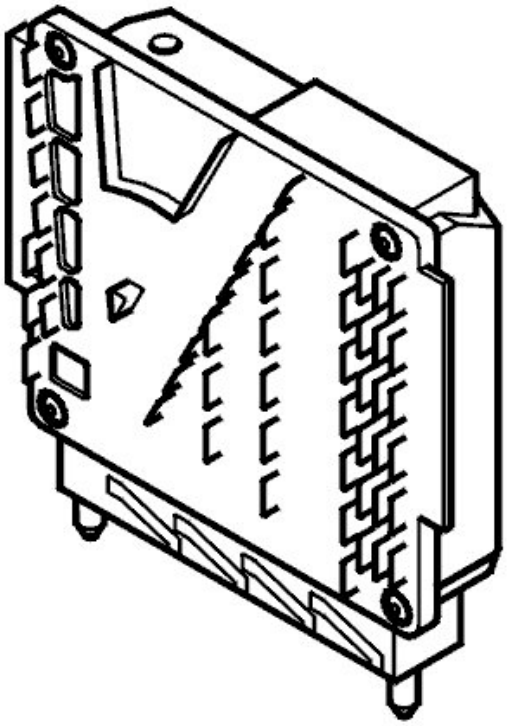
Diagnostic trouble code (DTC) information TCM-E000

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

Condition



The control modules transmit and receive information via a standardized serial communication method - CAN (Controller Area Network). The diagnostic trouble code (DTC) is stored if the control module registers serious interference (CAN communication blocked).

Note! In the event of system communication problems, it is not possible to communicate with the control module. Therefore it will only be possible to read off the fault if it is intermittent.

Substitute value

- Control module shuts itself off ("bus-off").

  Hint: The control module will remain shut off until the power supply is broken (15, 30, X). When the power supply is connected the control module will make a new attempt to communicate.

Possible source

- Short-circuit between the control area network (CAN) wiring
- Open-circuit in the control area network (CAN) wiring
- Damaged pins on Transmission control module (TCM).
- Internal fault in the control module
- Internal fault in another control module in the same part of the control area network (CAN).

Fault symptom[s]

- No shifting.
- Text window and warning symbol/Yellow symbol and text message

Signal Missing

Signal missing

General information

Note! Figures shown are only examples.

Hint: For general information about CAN-troubleshooting, see:

- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

General about CAN-related diagnostic trouble codes.

CEM-DF01 - DF17can only be stored in Central electronic module (CEM). These diagnostic trouble codes are stored when an electric fault is detected in CAN-lines. Start with these diagnostic trouble codes first.
CEM-1AXX only stored in Central electronic module (CEM). One diagnostic trouble code for every control module on the CAN-net. These diagnostic trouble codes indicate that Central electronic module (CEM) does not receive any reply from other control modules.
XXX-E000 (HS-CAN)/E001 (LS-CAN) can be stored in all CAN-connected control modules. These diagnostic trouble codes indicate that the control module has detected interference on the CAN-net.
XXX-E003 can be stored in all CAN-connected control modules except in Central electronic module (CEM). The control modules on the CAN-net listen for a message (identity number) that is sent out at regular intervals from Central electronic module (CEM). This diagnostic trouble code indicates that the control module has not received any identity number, or that the expected number is not correct. Interference on the CAN-net can also store this diagnostic trouble code.

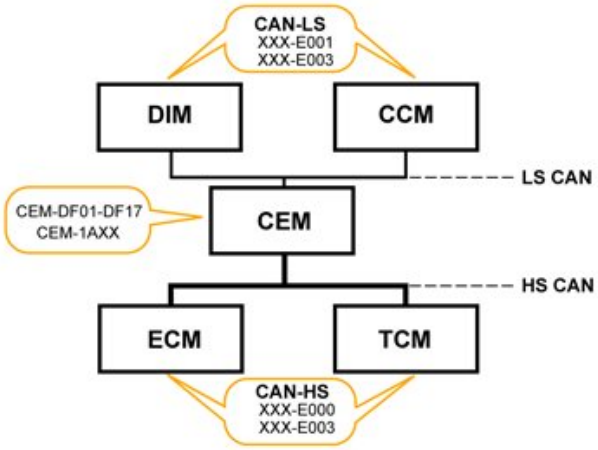
Note! In case of CAN-related faults, it is likely that a combination of above diagnostic trouble codes occur.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

If a communication diagnostic trouble code can be read from the control module, the malfunction is probably intermittent.
Intermittent fault in the voltage supply and ground to a control module on the CAN network results in the Central electronic module (CEM) storing a diagnostic trouble code (DTC) for an open-circuit in communication with the control module where the voltage supply does not work. There will probably not be a diagnostic trouble code (DTC) in the control module where the open-circuit in the voltage supply occurred as the control module cannot store a diagnostic trouble code (DTC) when it is not supplied with power.

Note! Central electronic module (CEM) should not be replaced in case of CAN-fault, unless troubleshooting reveals that Central electronic module (CEM) has an internal fault.

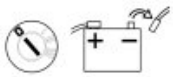
Caution! During this fault-tracing use the wiring diagram to provide support when taking readings.



Select "Continue".

Continue - Checking resistance in CAN-net

Checking resistance in CAN-net



- Ignition off
- Disconnect the battery negative lead
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Measure resistance between the following connections on the OBDII-box/diagnostics socket.

- #6 and #14. The resistance should be approx. 55 - 65 ohms.
- If resistance is approx. 120 ohms, this indicates open circuit in the circuit so that only one terminating resistor (120 ohms) has been measured.
- If resistance is above 1 kohms this indicates open circuit/high contact resistance somewhere in the circuit.
- If resistance is below 55 ohms this indicates short-circuiting/contact resistance between the CAN-lines somewhere in the circuit.

Hint: For HS-CAN (High Speed) the terminating resistors are located in Brake control module (BCM) and in Engine control module (ECM).

Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

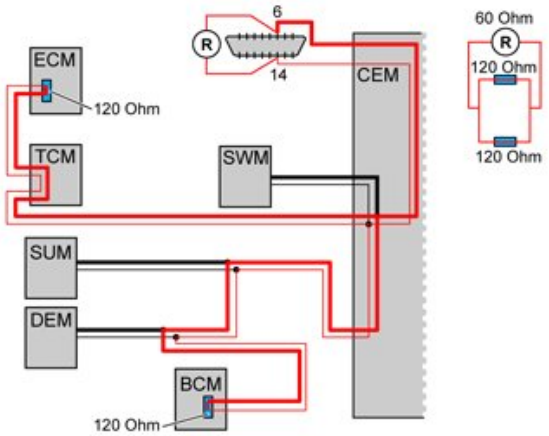
Note! Resistance measurement measures only main lines in the CAN-net (in circuit where both terminating resistors are found), not branches to certain control modules. See wiring diagram for vehicle model in question.Open circuit on branching without a terminating resistor cannot be detected with this measurement. However, short-circuiting on a branch can be detected. To measure resistance in the CAN-net to control modules located in a branching of their own, the measurement shall be done against the CAN-net at that control module. The values shall be as above.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy wiring as necessary.

Other information

- Battery, disconnecting See: Starting and Charging/Battery/Service and Repair/Procedures/Battery, Disconnecting
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

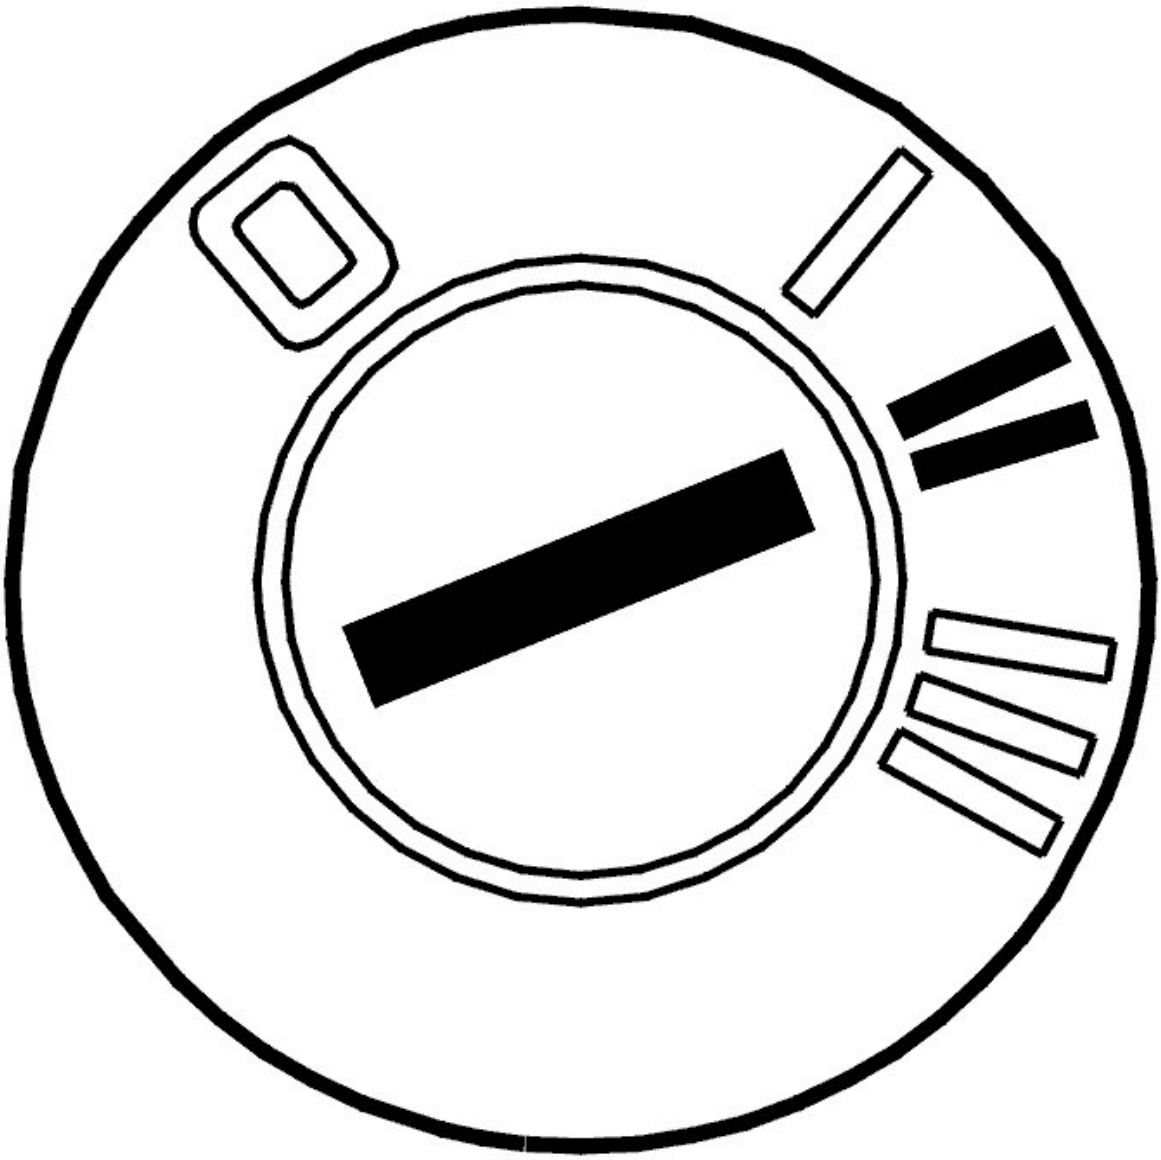


Was a fault detected?

Yes - Verification

No - Checking short-circuiting to ground/voltage in CAN-net

Checking the traffic load on the CAN cables



- Connect the battery
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Faults in the CAN network may be due to a control module sending faulty messages that disrupt normal communication. When messages are sent incorrectly, this results in a considerable increase in the amount of traffic on the CAN network. Check the load by measuring the average voltage value on the CAN cables in relation to ground.
For further information, see the wiring diagram.
Measure voltage between the following connections on the OBDII-box/diagnostics socket.
- #6 and #4 (ground). The voltage should be approx: 2,8 - 3,2 V.
- #14 and #4 (ground). The voltage should be approx: 1,8 - 2,2 V.
- #6 and #14. The voltage shall be between approx. 0.55-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Hint: DiCE Error Frame Finder can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools: **951 3010** (memory card) as well as associated TJ 20402.

- Ignition on.
- Connect DiCE Error Frame Finder to the diagnostics socket.
- Note the blue LED-indicator. The indicator flashes to show detection of fault messages.

Note! Certain interference may occur without any real fault!

Cable fault

- Shake the cables lightly and pull lightly on the connections during the check to locate any fault. Note the blue LED-indicator.

"Chatting" control modules

- "Chatting" control modules may be difficult to find and troubleshooting may take time. Let the vehicle stand with DiCE connected for an extended time period. Afterwards, activate functions to provoke a malfunction. It may take up to several hours before the fault messages are sent. When the indicator starts to flash, remove the fuse for one control module at a time until the indicator stops flashing. When the indicator stops flashing, restore the fuse for the relevant control module and check that the indicator starts to flash again. Then it is likely that the problem is identified.

Remedy wiring as necessary.

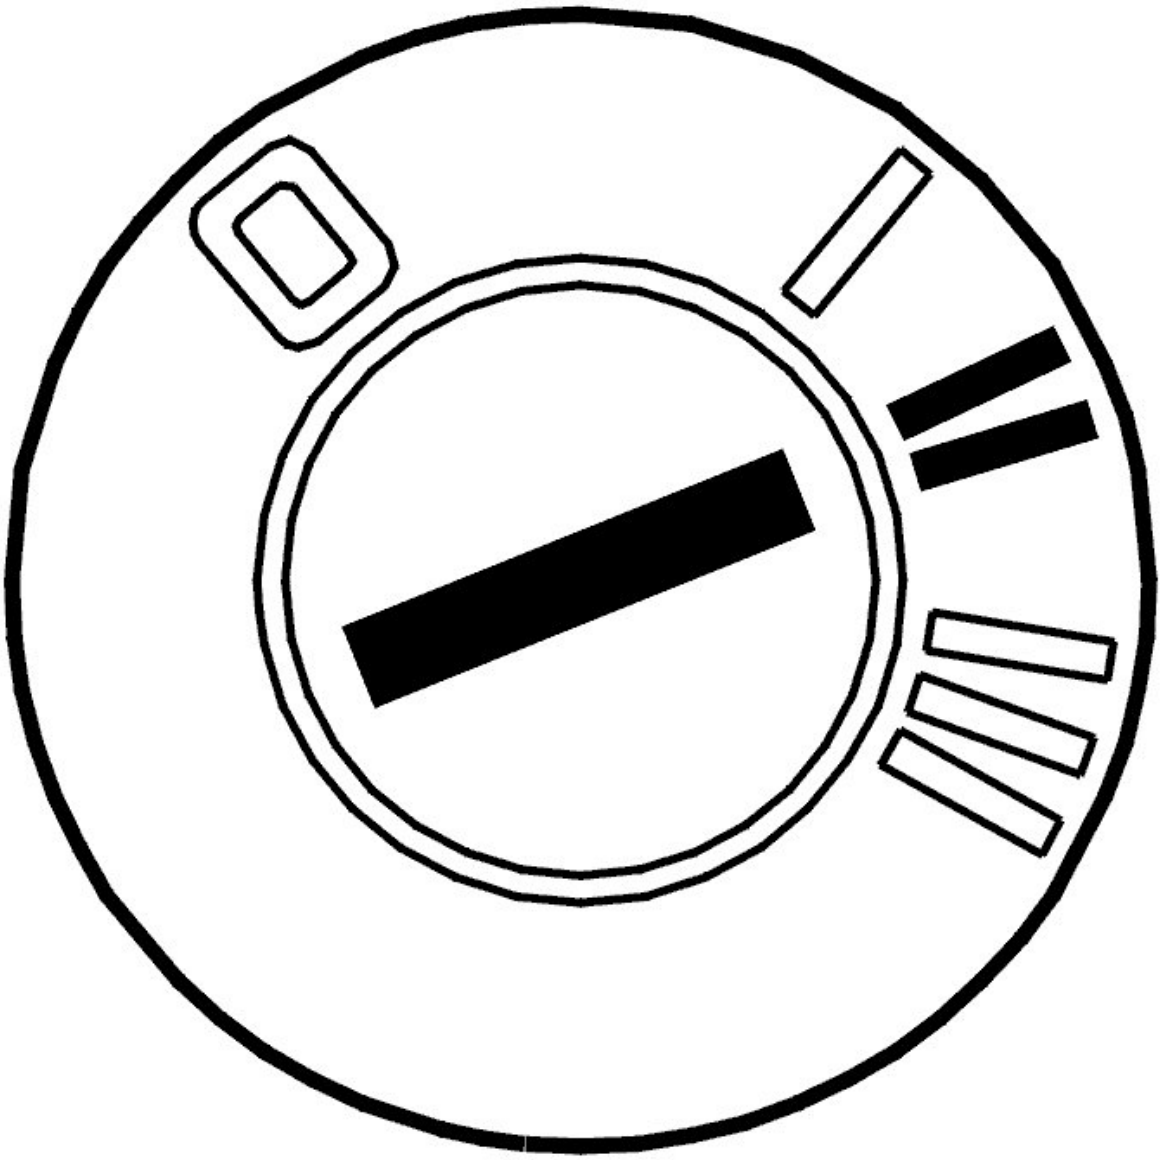
Was a fault detected?

Yes - Identifying a control module in the CAN network

No - respectively

Identifying a control module in the CAN network



Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:

- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Hint: DiCE Error Frame Finder can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools: **951 3010** (memory card) as well as associated TJ 20402.

If the load on the CAN network is too high, this may be due to a control module sending faulty messages on the CAN network (known as a disruptive control module). The fault may also be due to an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The faults can occur without a diagnostic trouble code (DTC) being stored by the control modules. The voltage can be measured between the CAN cables in order to check the load on the CAN network.

Note! It is not necessarily the control module(s) that stored the diagnostic trouble code (DTC) that is communicating faultily. Faulty messages can come from any control module in the same section of the CAN network. However, faulty communication in one network cannot affect the communication on the other network. In other words, faulty communication on the LS-CAN cannot disrupt communication on the HS-CAN and vice versa.

- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Check communication/load on CAN-net by measuring voltage between CAN-L and CAN-H. Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #6 and #14. The average value of the voltage must be approximately 0.6-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

In order to identify which control module has faulty communication, cut the power supply to one control module at a time. Check the voltage in the

CAN cables again. The easiest way to cut the power supply is to remove the fuse(s) for the relevant control module. Repeat until the voltage between the CAN wiring drops to the normal level.

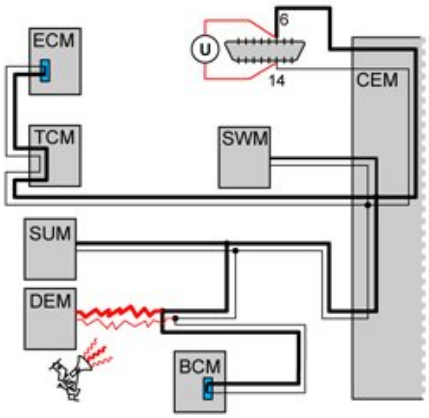
Note! When connecting and disconnecting individual control modules, other diagnostic trouble codes (DTCs) may be stored in certain control modules.

Hint: When the suspected defective control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the malfunction appears and disappears. Switch off the ignition between each check.

Note! Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.

A control module that is communicating incorrectly must be replaced. See Repairing and installing/Removing, replacing and installing.

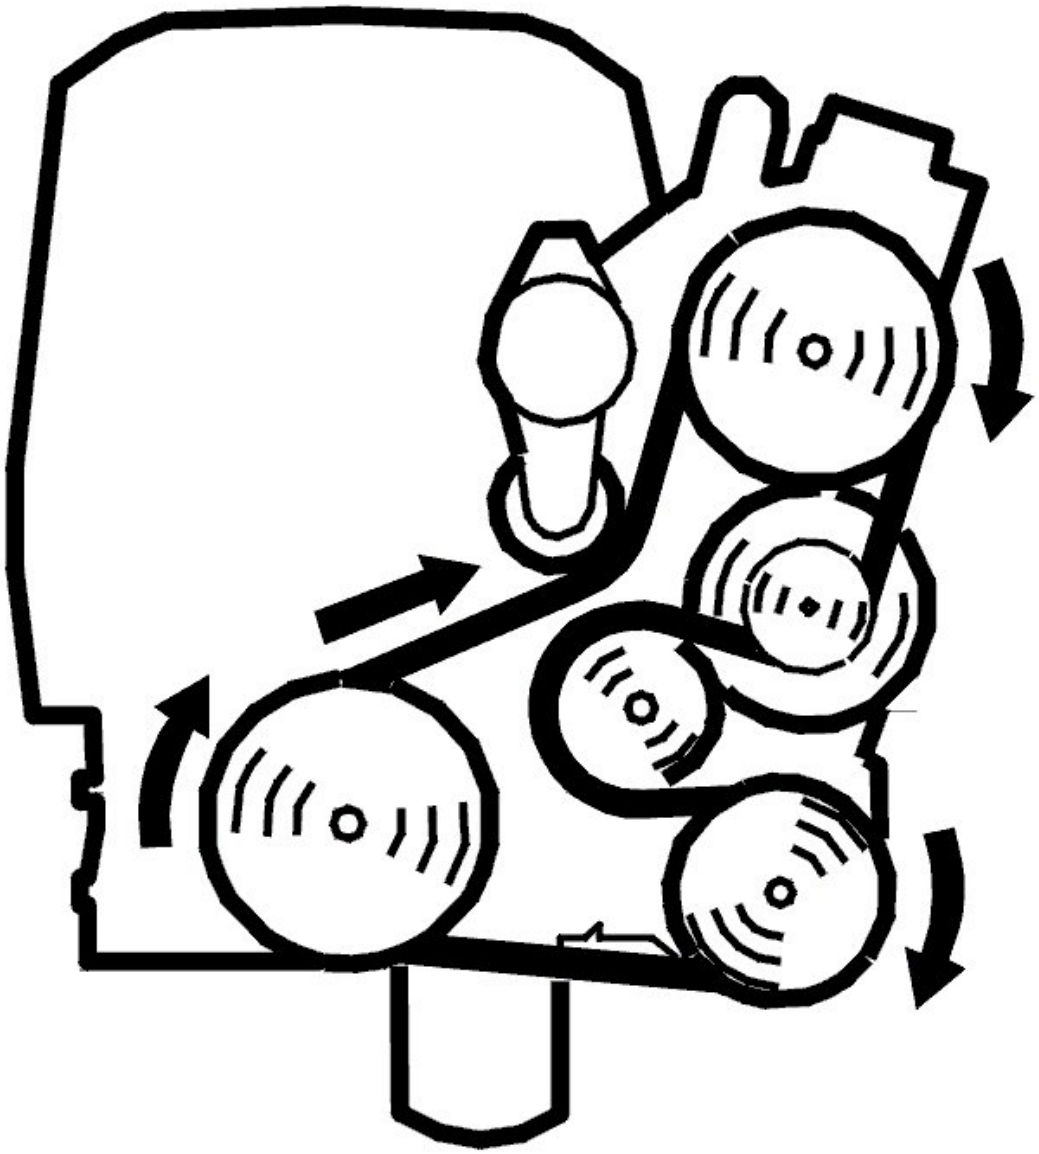
Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

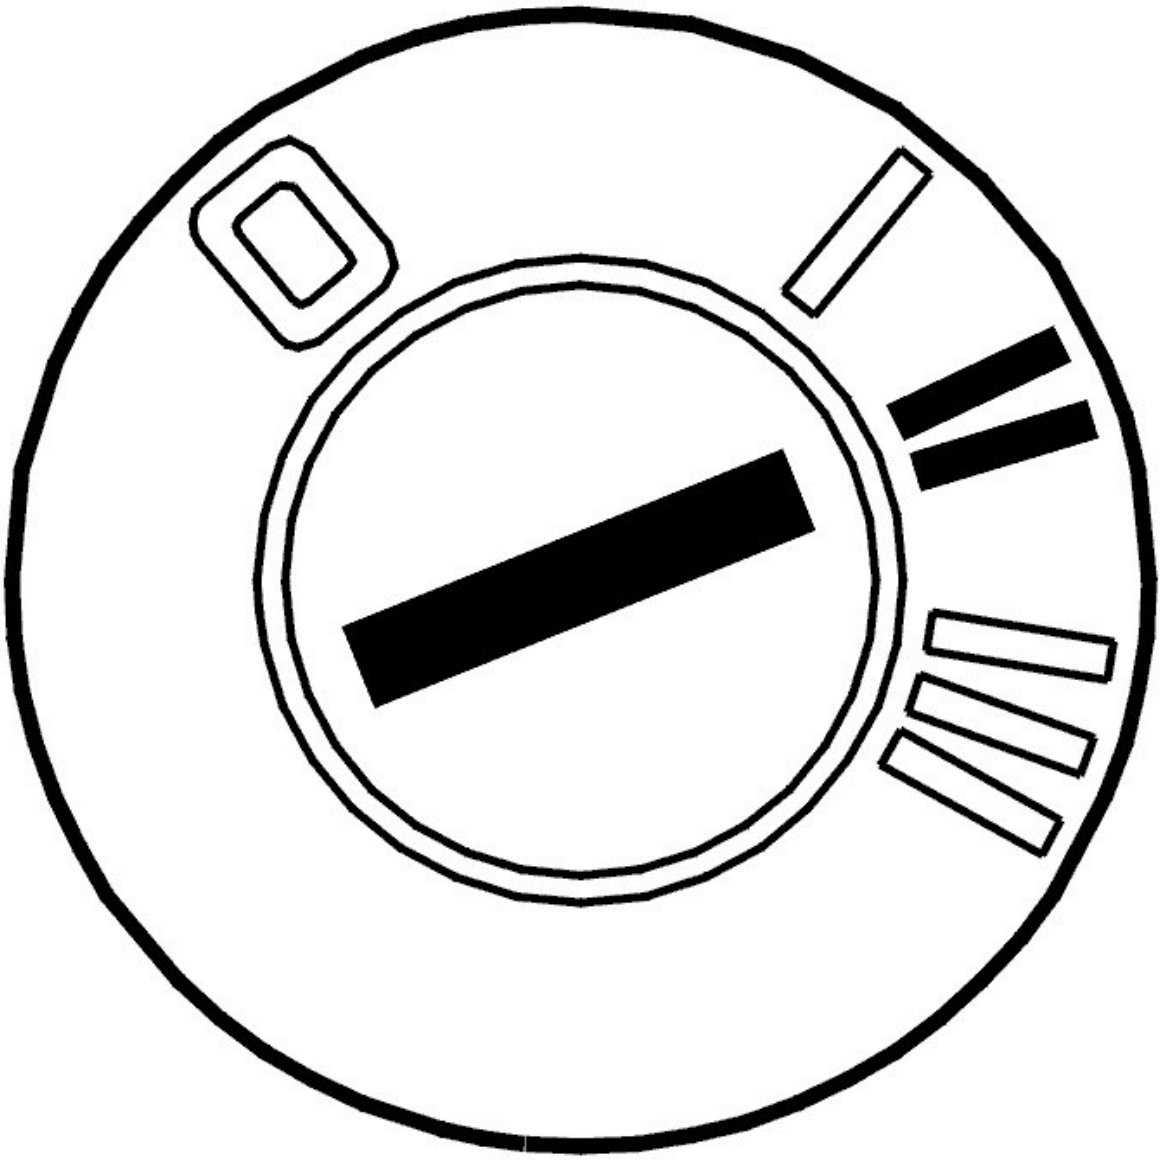


Continue - Verification

Verification

Hint: After rectifying a fault, a verification should be carried out.





- Reinstall the connectors, components etc.
- Ignition on.

Note! For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

- Erase diagnostic trouble codes (DTCs) in all control modules.
- Ignition off.
- Ignition on.
- Start the vehicle. Allow the vehicle to run for 10 minutes.
- Read out the diagnostic trouble codes in the vehicle via the DIAGNOSTICS tab.

Does the diagnostic trouble code (DTC) for faulty communication return?

Yes - Fault-tracing information

No - Fault Found

Fault-tracing information

Information

Fault-tracing information

The fault should have been detected and remedied. As this is not the case fault-tracing has failed.
Exit fault-tracing for this diagnostic trouble code (DTC) or make another attempt.

Do you want to exit fault-tracing?

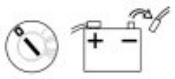
No - Attempt New Test

FAULT-TRACING FAILED - FAULT-TRACING FAILED

Attempt New Test - General information

Checking short-circuiting to ground/voltage in CAN-net



- Ignition off.
- Disconnect the battery negative lead.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Checking for a short-circuit to ground

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #6 and #4 (ground). Measurement is shown in the figure. The resistance should be above 1 kohms.
- #14 and #4 (ground). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and ground.

Checking for a short-circuit to voltage

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #6 and #16 (voltage). Measurement is shown in the figure. The resistance should be above 1 kohms.
- #14 and #16 (voltage). The resistance should be above 1 kohms.

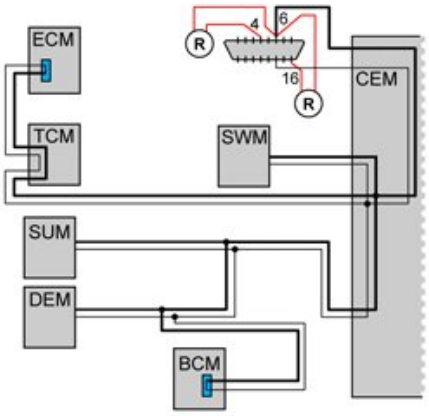
If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and voltage cable.
Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

Hint: Part the CAN-net at suitable points to decide where a short-circuit may be found.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy wiring as necessary.

Other information
- Battery, disconnecting See: Starting and Charging/Battery/Service and Repair/Procedures/Battery, Disconnecting
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

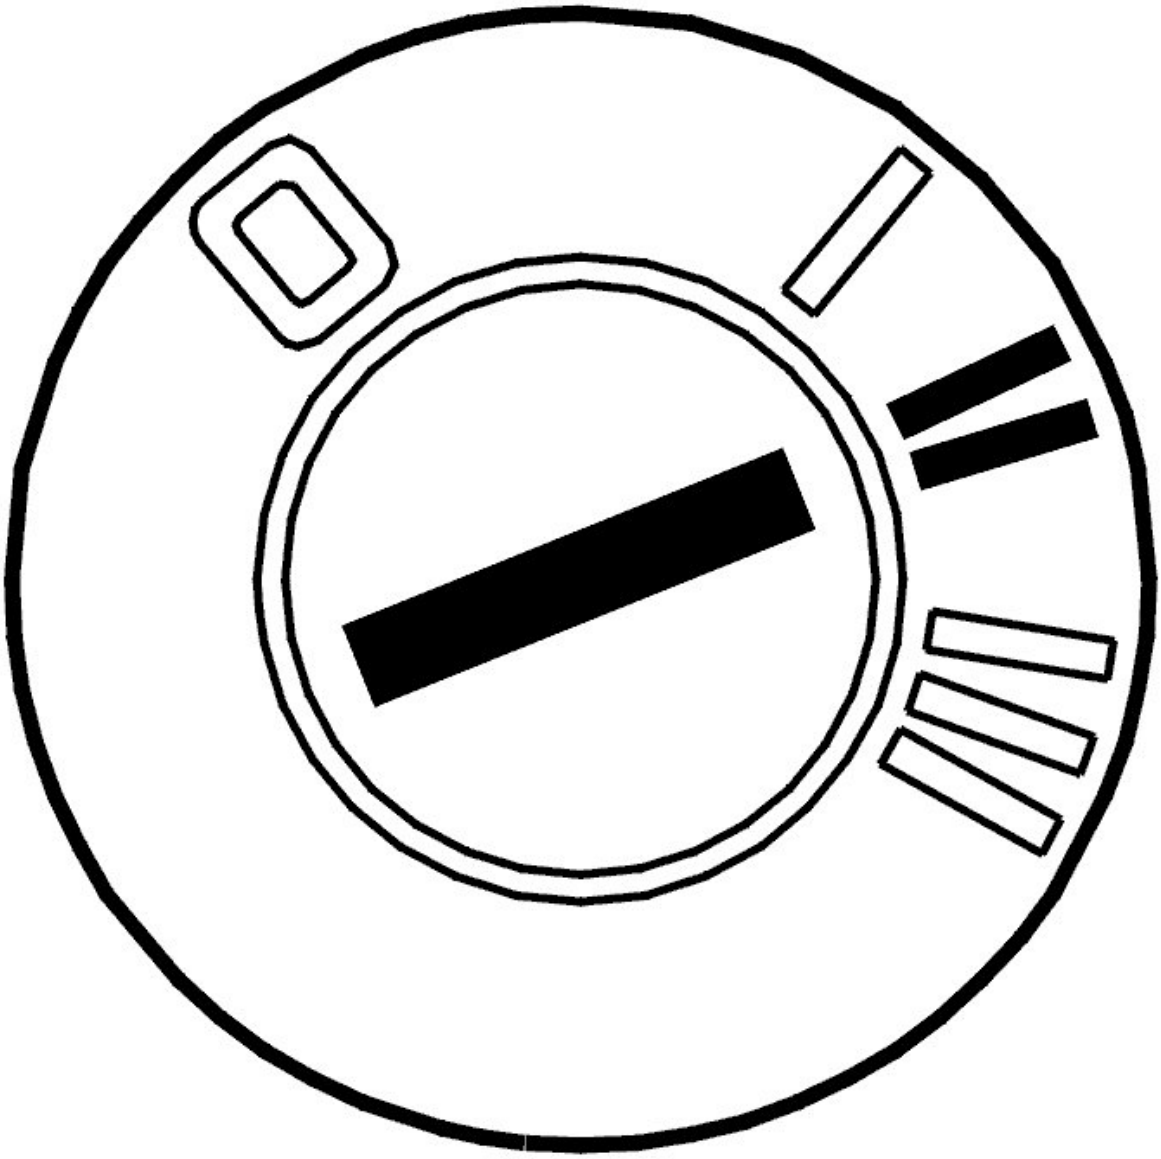


Was a fault detected?

Yes - Verification

No - Checking the traffic load on the CAN cables

Checking voltage-drop in cable for CAN-H and CAN-L, respectively



- Connect the battery.
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

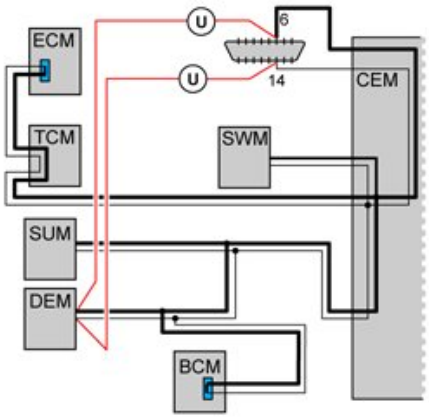
In principle, the voltage measured in each cable in the CAN-net shall be the same at each control module in the network. This means that the voltage-drop in the cable for CAN-H and CAN-L, respectively, between the control modules should be very low. If there is a voltage-difference in the CAN-lines between the diagnostics socket/Central electronic module (CEM) and a control module due to, e.g., contact resistance in a connector or branching, communication may be lost/interfered with.
Check if there is voltage-drop in the cable for CAN-H and CAN-L between the diagnostics socket/Central electronic module (CEM) and the control module where there is problem with communication.
Carry out the following:
Measure voltage between the following connections on the OBDII-box/diagnostics socket.
- #6 and corresponding connection on relevant control module for CAN-H. The voltage shall be lower than 50 mV.
- #14 and corresponding connection on relevant control module for CAN-L. The voltage shall be lower than 50 mV.

If voltage is too high, this indicates too high contact resistance in cable, connector, or branching. Check the circuit between the diagnostics socket and control module in question for contact resistance and oxidation.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy wiring as necessary.

Other information
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

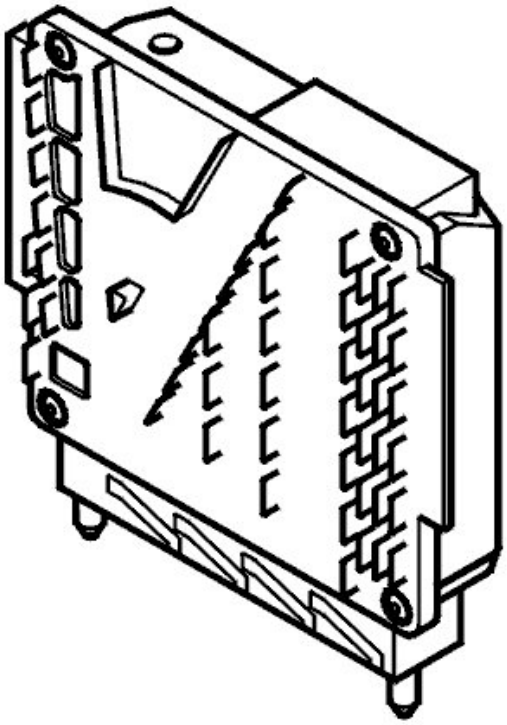


Continue - Verification

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information TCM-E003

Condition



The control module compares its configuration ID with the signal configuration transmitted on the control area network (CAN) by the central electronic module (CEM). If the configuration IDs do not correspond the fault code is stored. The diagnostic trouble code (DTC) is also stored if the communication between the control module and the central electronic module (CEM) is interrupted.

Note! In the event of open-circuit in both the control area network (CAN) cables, it is not possible to communicate with the control module. Therefore it will only be possible to read off the diagnostic trouble code (DTC) if this type of fault is intermittent. When the diagnostic trouble code (DTC) is stored, the control module responds to the diagnostic command, however normal control area network (CAN) communication does not work. ("Expulsion mode")

Substitute value
- The transmission control module (TCM) "Emergency mode I" program has been initiated.

Possible source
- Faulty control area network (CAN) configuration ID. (The node is not intended for this car, for example a used control module with different software/hardware.)
- Open-circuit in the control area network (CAN) wiring between the control module and the central electrical module (CEM).

Fault symptom[s]
- No shifting.

Signal Missing

Signal missing

General information

Note! Figures shown are only examples.

Hint: For general information about CAN-troubleshooting, see:
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

General about CAN-related diagnostic trouble codes.
CEM-DF01 - DF17can only be stored in Central electronic module (CEM). These diagnostic trouble codes are stored when an electric fault is detected in CAN-lines. Start with these diagnostic trouble codes first.
CEM-1AXX only stored in Central electronic module (CEM). One diagnostic trouble code for every control module on the CAN-net. These diagnostic trouble codes indicate that Central electronic module (CEM) does not receive any reply from other control modules.
XXX-E000 (HS-CAN)/E001 (LS-CAN) can be stored in all CAN-connected control modules. These diagnostic trouble codes indicate that the control module has detected interference on the CAN-net.

XXX-E003 can be stored in all CAN-connected control modules except in Central electronic module (CEM). The control modules on the CAN-net listen for a message (identity number) that is sent out at regular intervals from Central electronic module (CEM). This diagnostic trouble code indicates that the control module has not received any identity number, or that the expected number is not correct. Interference on the CAN-net can also store this diagnostic trouble code.

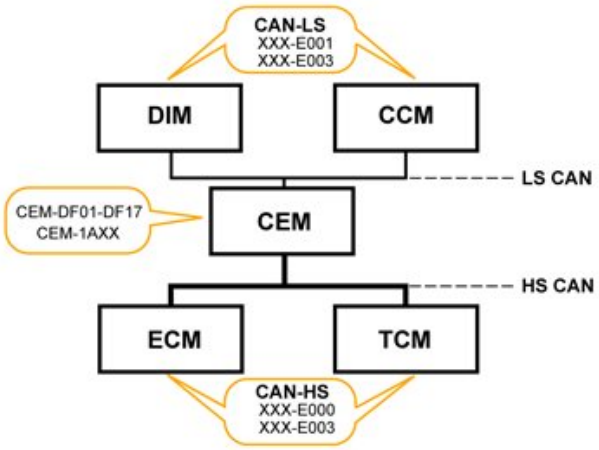
Note! In case of CAN-related faults, it is likely that a combination of above diagnostic trouble codes occur.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

If a communication diagnostic trouble code can be read from the control module, the malfunction is probably intermittent.
Intermittent fault in the voltage supply and ground to a control module on the CAN network results in the Central electronic module (CEM) storing a diagnostic trouble code (DTC) for an open-circuit in communication with the control module where the voltage supply does not work. There will probably not be a diagnostic trouble code (DTC) in the control module where the open-circuit in the voltage supply occurred as the control module cannot store a diagnostic trouble code (DTC) when it is not supplied with power.

Note! Central electronic module (CEM) should not be replaced in case of CAN-fault, unless troubleshooting reveals that Central electronic module (CEM) has an internal fault.

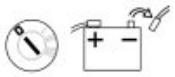
Caution! During this fault-tracing use the wiring diagram to provide support when taking readings.



Select "Continue".

Continue - Checking resistance in CAN-net

Checking resistance in CAN-net



- Ignition off
- Disconnect the battery negative lead
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #6 and #14. The resistance should be approx. 55 - 65 ohms.
- If resistance is approx. 120 ohms, this indicates open circuit in the circuit so that only one terminating resistor (120 ohms) has been measured.
- If resistance is above 1 kohms this indicates open circuit/high contact resistance somewhere in the circuit.
- If resistance is below 55 ohms this indicates short-circuiting/contact resistance between the CAN-lines somewhere in the circuit.

Hint: For HS-CAN (High Speed) the terminating resistors are located in Brake control module (BCM) and in Engine control module (ECM).

Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

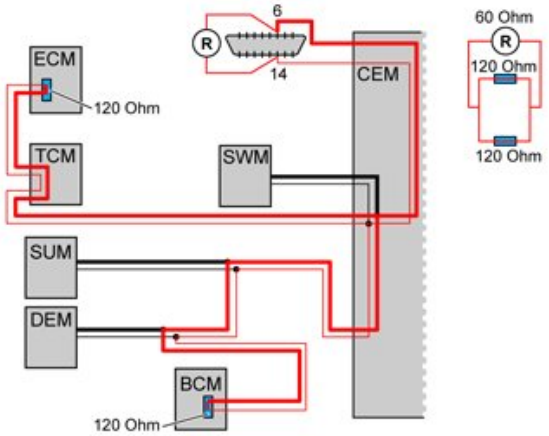
Note! Resistance measurement measures only main lines in the CAN-net (in circuit where both terminating resistors are found), not branches to certain control modules. See wiring diagram for vehicle model in question.Open circuit on branching without a terminating resistor cannot be detected with this measurement. However, short-circuiting on a branch can be detected. To measure resistance in the CAN-net to control modules located in a branching of their own, the measurement shall be done against the CAN-net at that control module. The values shall be as above.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy wiring as necessary.

Other information

- Battery, disconnecting See: Starting and Charging/Battery/Service and Repair/Procedures/Battery, Disconnecting
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

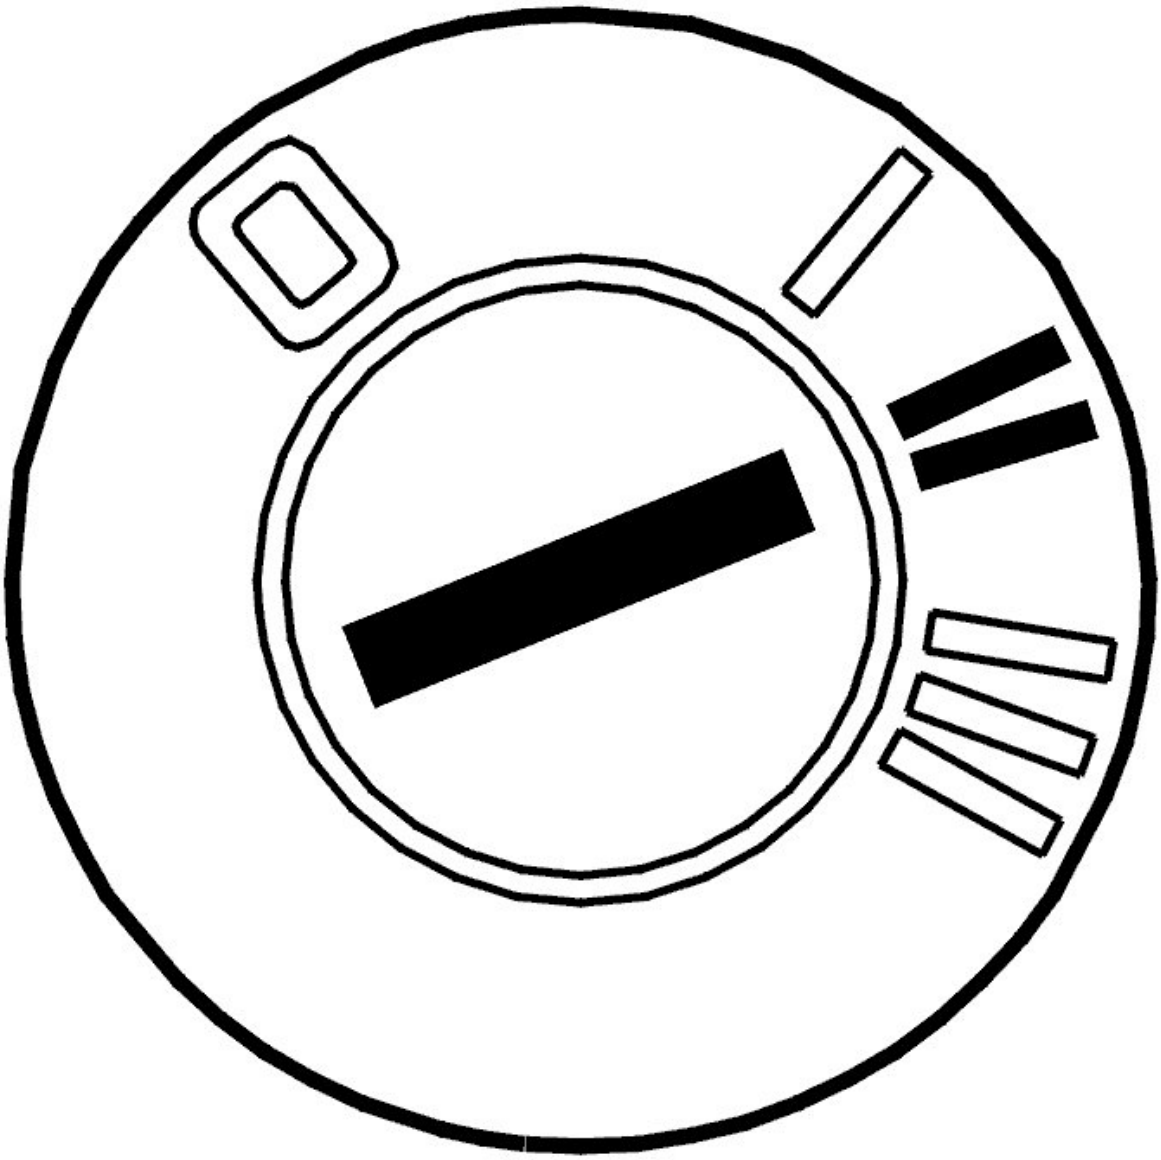


Was a fault detected?

Yes - Verification

No - Checking short-circuiting to ground/voltage in CAN-net

Checking the traffic load on the CAN cables



- Connect the battery
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Faults in the CAN network may be due to a control module sending faulty messages that disrupt normal communication. When messages are sent incorrectly, this results in a considerable increase in the amount of traffic on the CAN network. Check the load by measuring the average voltage value on the CAN cables in relation to ground.
For further information, see the wiring diagram.
Measure voltage between the following connections on the OBDII-box/diagnostics socket.
- #6 and #4 (ground). The voltage should be approx: 2,8 - 3,2 V.
- #14 and #4 (ground). The voltage should be approx: 1,8 - 2,2 V.
- #6 and #14. The voltage shall be between approx. 0.55-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Hint: DiCE Error Frame Finder can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools: **951 3010** (memory card) as well as associated TJ 20402.

- Ignition on.
- Connect DiCE Error Frame Finder to the diagnostics socket.
- Note the blue LED-indicator. The indicator flashes to show detection of fault messages.

Note! Certain interference may occur without any real fault!

Cable fault

- Shake the cables lightly and pull lightly on the connections during the check to locate any fault. Note the blue LED-indicator.

"Chatting" control modules

- "Chatting" control modules may be difficult to find and troubleshooting may take time. Let the vehicle stand with DiCE connected for an extended time period. Afterwards, activate functions to provoke a malfunction. It may take up to several hours before the fault messages are sent. When the indicator starts to flash, remove the fuse for one control module at a time until the indicator stops flashing. When the indicator stops flashing, restore the fuse for the relevant control module and check that the indicator starts to flash again. Then it is likely that the problem is identified.

Remedy wiring as necessary.

Other information

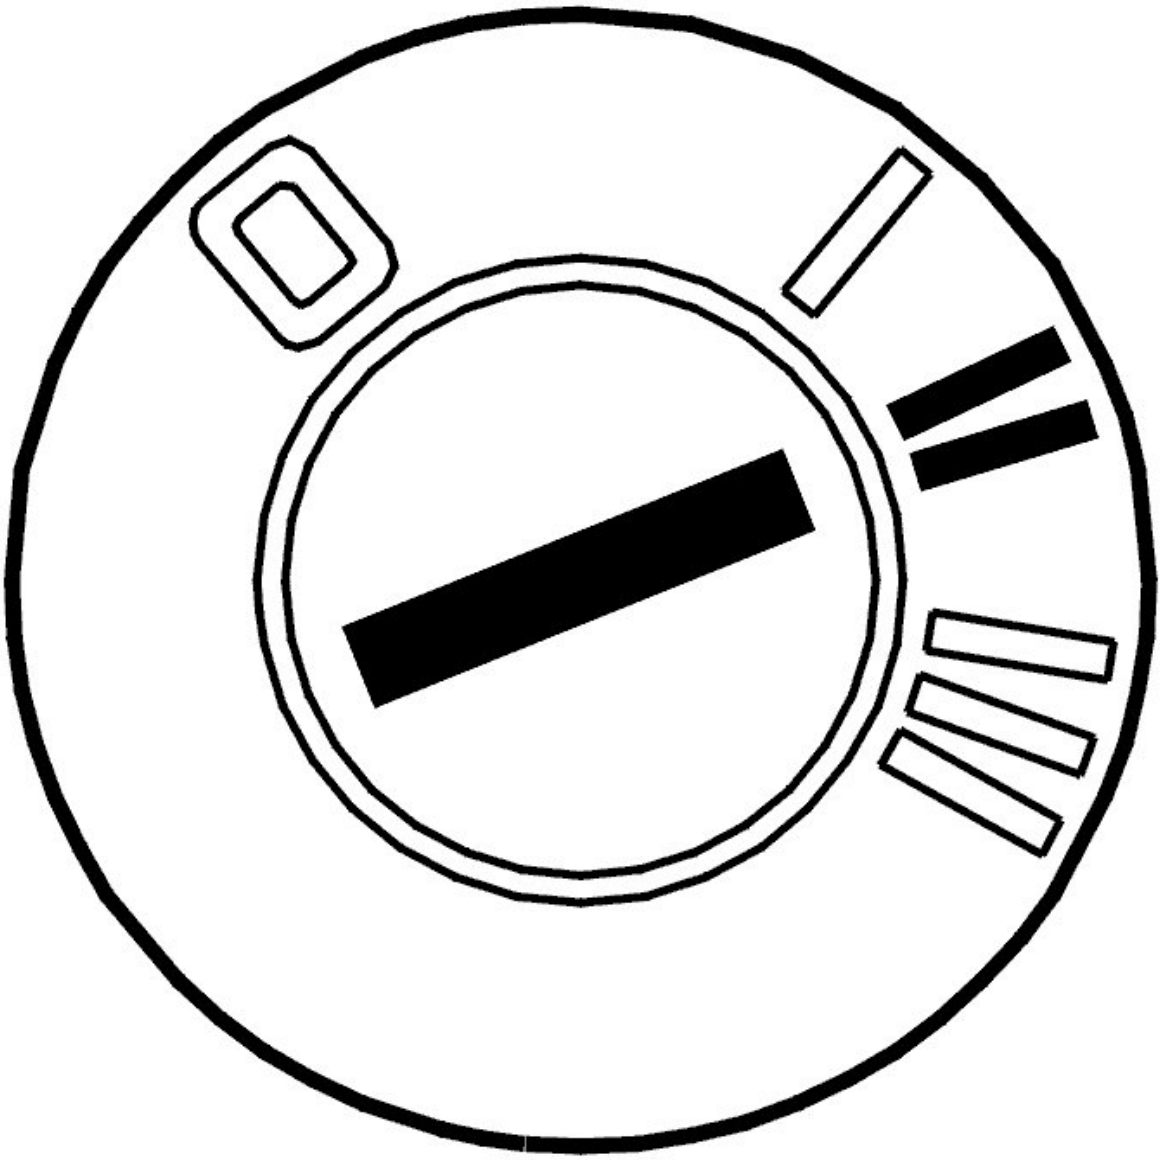
Was a fault detected?

Yes - Identifying a control module in the CAN network

No - respectively

Identifying a control module in the CAN network



Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:

- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Hint: DiCE Error Frame Finder can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools: **951 3010** (memory card) as well as associated TJ 20402.

If the load on the CAN network is too high, this may be due to a control module sending faulty messages on the CAN network (known as a disruptive control module). The fault may also be due to an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The faults can occur without a diagnostic trouble code (DTC) being stored by the control modules. The voltage can be measured between the CAN cables in order to check the load on the CAN network.

Note! It is not necessarily the control module(s) that stored the diagnostic trouble code (DTC) that is communicating faultily. Faulty messages can come from any control module in the same section of the CAN network. However, faulty communication in one network cannot affect the communication on the other network. In other words, faulty communication on the LS-CAN cannot disrupt communication on the HS-CAN and vice versa.

- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Check communication/load on CAN-net by measuring voltage between CAN-L and CAN-H. Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #6 and #14. The average value of the voltage must be approximately 0.6-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

In order to identify which control module has faulty communication, cut the power supply to one control module at a time. Check the voltage in the

CAN cables again. The easiest way to cut the power supply is to remove the fuse(s) for the relevant control module. Repeat until the voltage between the CAN wiring drops to the normal level.

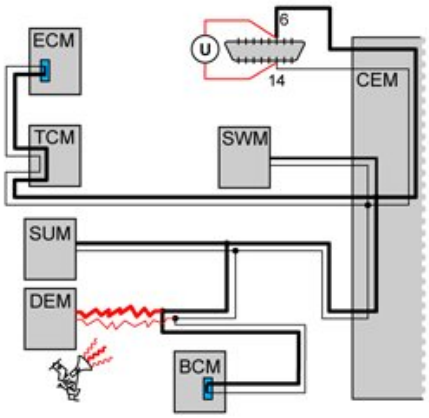
Note! When connecting and disconnecting individual control modules, other diagnostic trouble codes (DTCs) may be stored in certain control modules.

Hint: When the suspected defective control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the malfunction appears and disappears. Switch off the ignition between each check.

Note! Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.

A control module that is communicating incorrectly must be replaced. See Repairing and installing/Removing, replacing and installing.

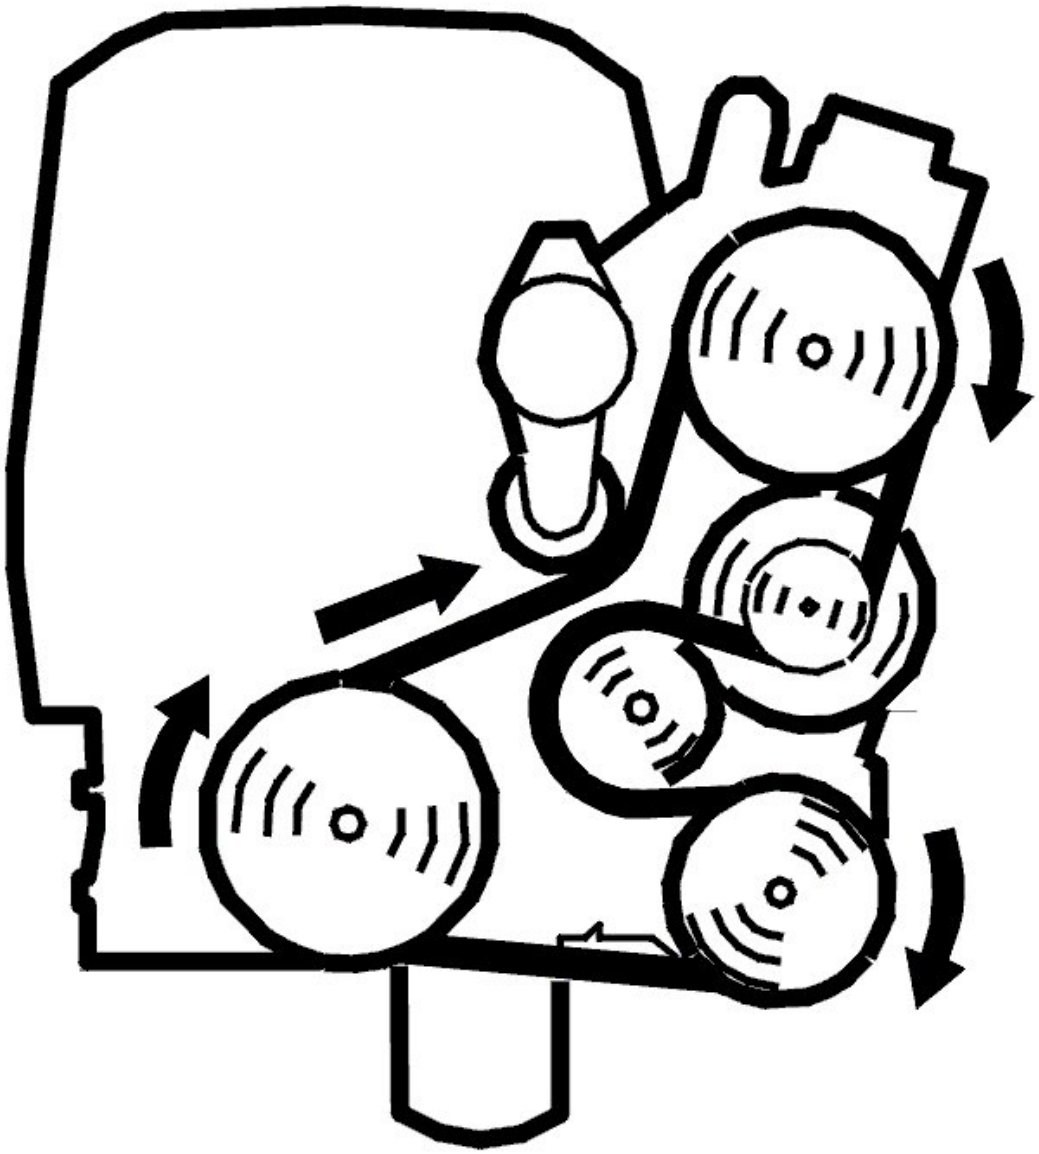
Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

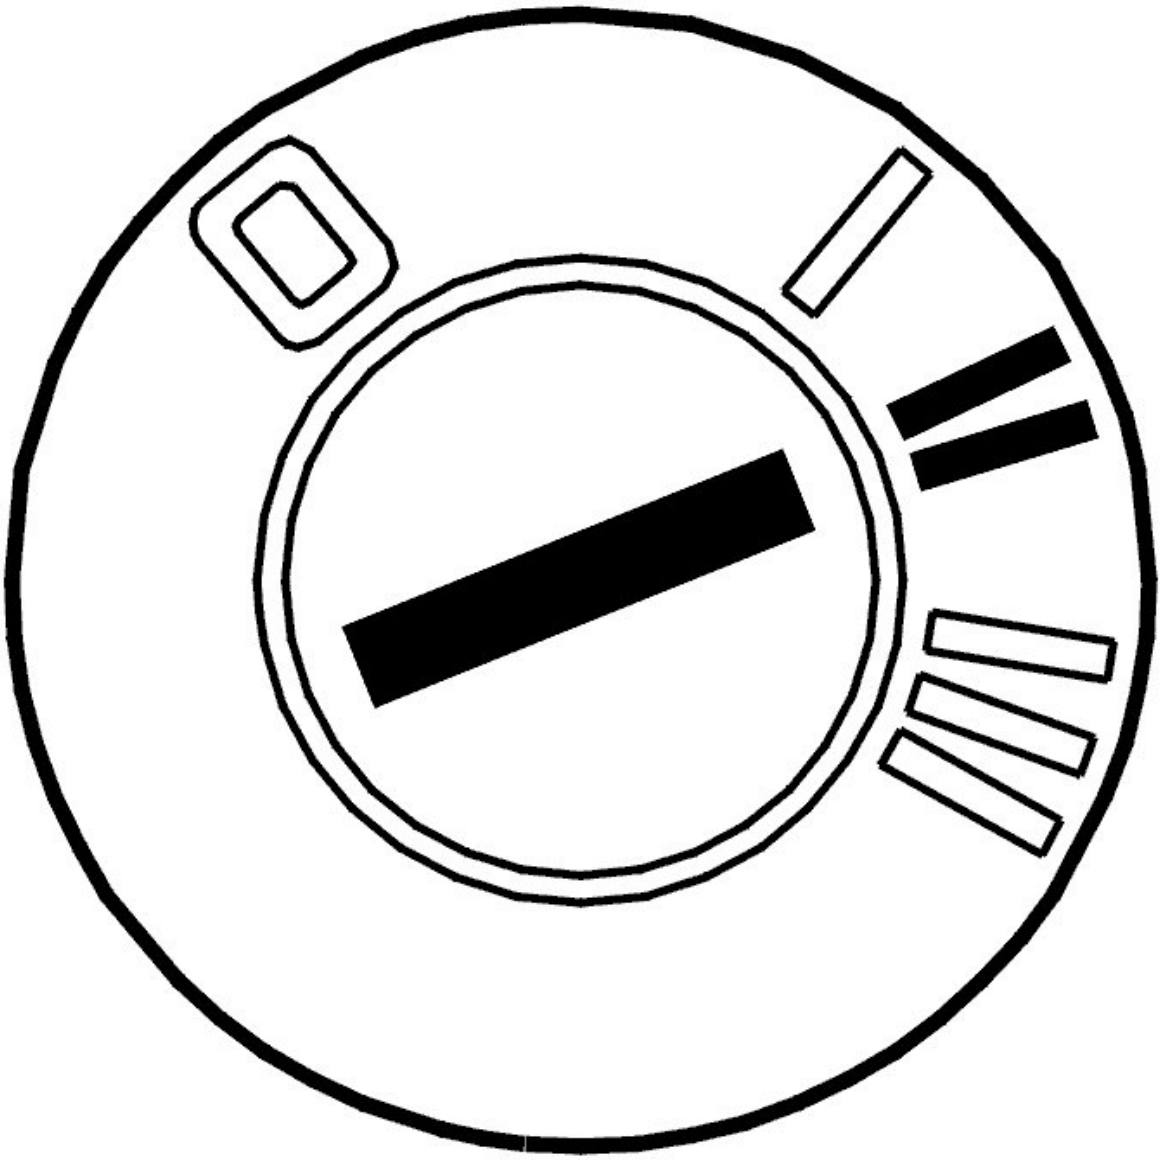


Continue - Verification

Verification

Hint: After rectifying a fault, a verification should be carried out.





- Reinstall the connectors, components etc.
- Ignition on.

Note! For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

- Erase diagnostic trouble codes (DTCs) in all control modules.
- Ignition off.
- Ignition on.
- Start the vehicle. Allow the vehicle to run for 10 minutes.
- Read out the diagnostic trouble codes in the vehicle via the DIAGNOSTICS tab.

Does the diagnostic trouble code (DTC) for faulty communication return?

Yes - Fault-tracing information

No - Fault Found

Fault-tracing information

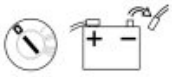
FAULT-TRACING FAILED - FAULT-TRACING FAILED

Attempt New Test - General information

Checking short-circuiting to ground/voltage in CAN-net



- Ignition off.
- Disconnect the battery negative lead.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Checking for a short-circuit to ground

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #6 and #4 (ground). Measurement is shown in the figure. The resistance should be above 1 kohms.
- #14 and #4 (ground). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and ground.

Checking for a short-circuit to voltage

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #6 and #16 (voltage). Measurement is shown in the figure. The resistance should be above 1 kohms.
- #14 and #16 (voltage). The resistance should be above 1 kohms.

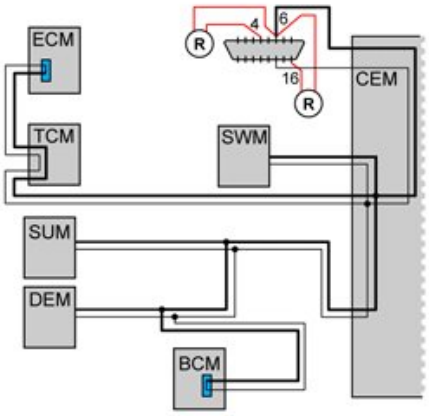
If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and voltage cable.
Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

Hint: Part the CAN-net at suitable points to decide where a short-circuit may be found.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy wiring as necessary.

Other information
- Battery, disconnecting See: Starting and Charging/Battery/Service and Repair/Procedures/Battery, Disconnecting
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

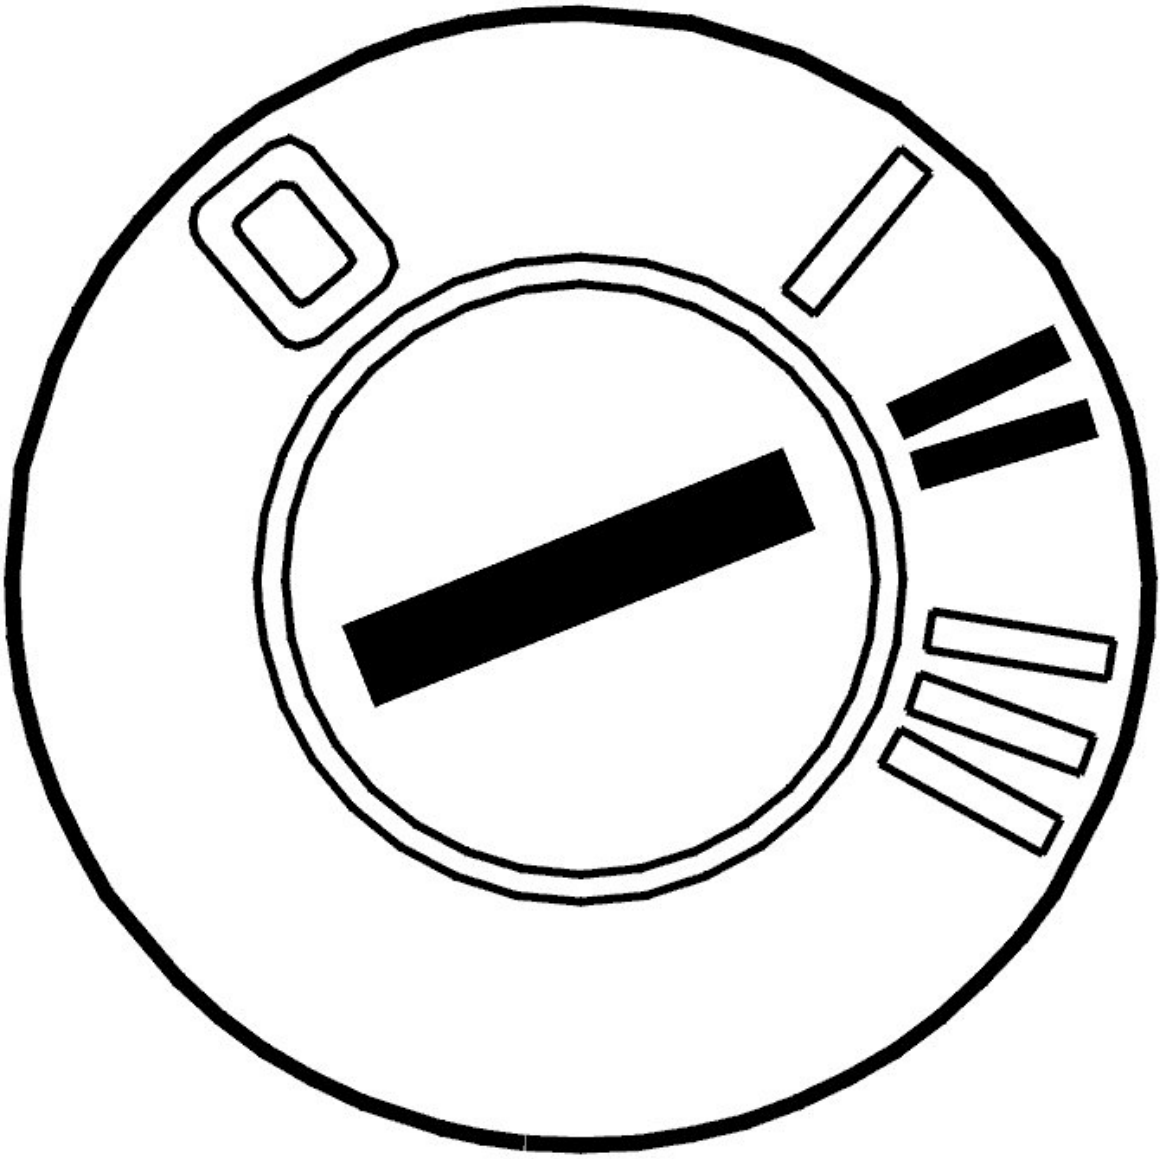


Was a fault detected?

Yes - Verification

No - Checking the traffic load on the CAN cables

Checking voltage-drop in cable for CAN-H and CAN-L, respectively



- Connect the battery.
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

In principle, the voltage measured in each cable in the CAN-net shall be the same at each control module in the network. This means that the voltage-drop in the cable for CAN-H and CAN-L, respectively, between the control modules should be very low. If there is a voltage-difference in the CAN-lines between the diagnostics socket/Central electronic module (CEM) and a control module due to, e.g., contact resistance in a connector or branching, communication may be lost/interfered with.
Check if there is voltage-drop in the cable for CAN-H and CAN-L between the diagnostics socket/Central electronic module (CEM) and the control module where there is problem with communication.
Carry out the following:
Measure voltage between the following connections on the OBDII-box/diagnostics socket.
- #6 and corresponding connection on relevant control module for CAN-H. The voltage shall be lower than 50 mV.
- #14 and corresponding connection on relevant control module for CAN-L. The voltage shall be lower than 50 mV.

If voltage is too high, this indicates too high contact resistance in cable, connector, or branching. Check the circuit between the diagnostics socket and control module in question for contact resistance and oxidation.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy wiring as necessary.

Communication Fault

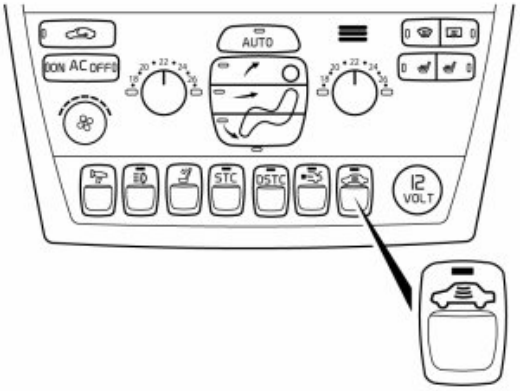
Communication fault

Checking for permanent or intermittent faults

Open the driver's door window. Lock the car using the remote control.
Wait 25 seconds until the vehicle has been alarmed. Trigger the alarm by inserting a hand through the window and unlocking the door from the inside using the internal door handle.

Note! On vehicles with deadlocks, these must be deactivated first. Press the button for the reduced locking position to activate deadlocks.

The function can be engaged in ignition position I and 0. It can also be engaged after the ignition has been switched off, for up to one minute after the ignition key has been removed from the ignition switch. The switch has an integrated light emitting diode for indicating that the function has been activated. A message also appears in the display in the Driver information module (DIM),however, not when the key has been removed. The switches may be positioned differently than shown in the image, depending on the vehicle's configuration and equipment.

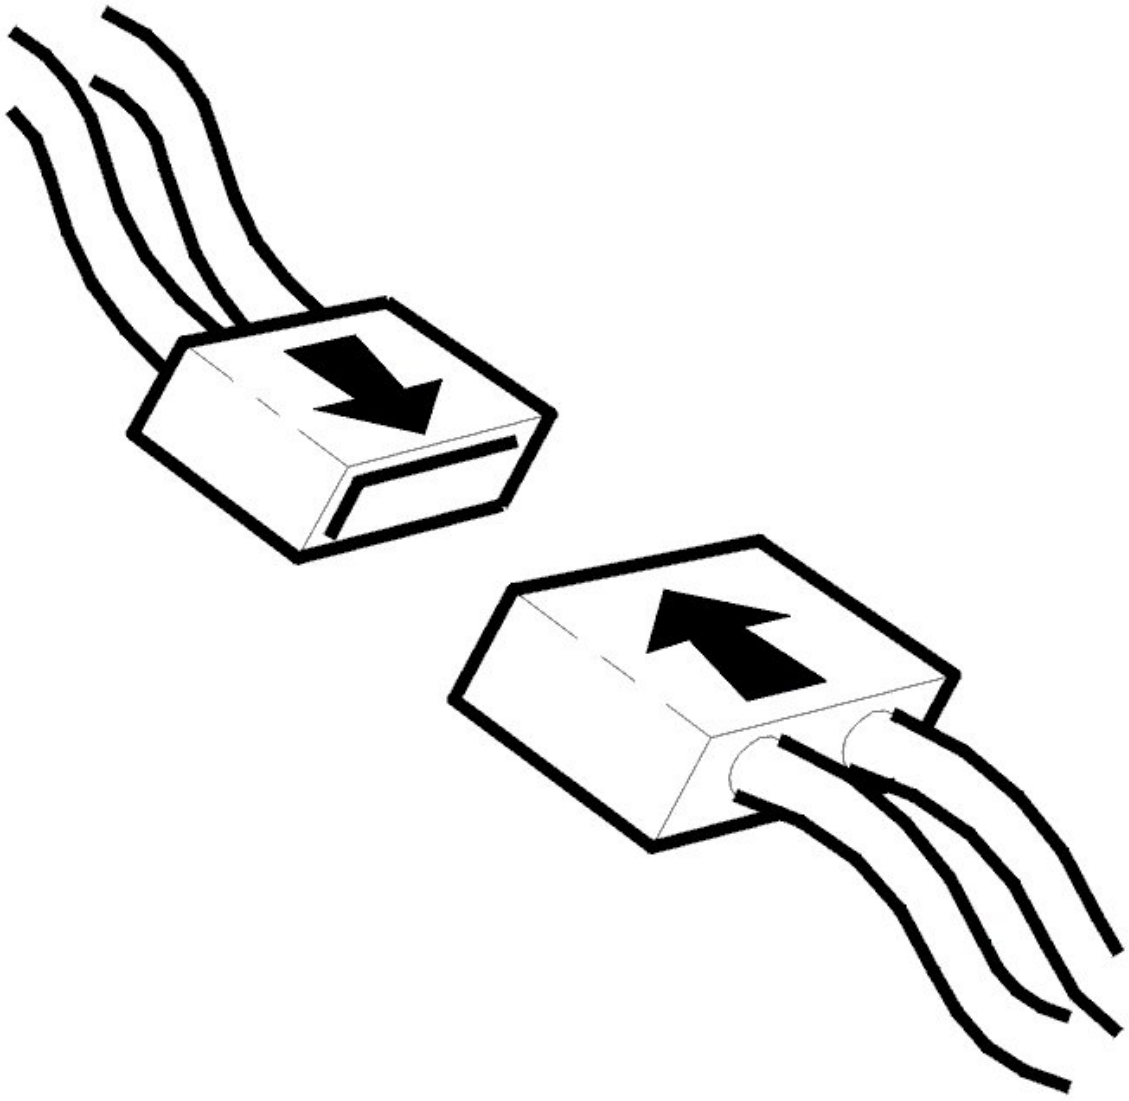


Is the siren triggered?

Yes - Intermittent fault

No - Checking the connectors

Checking the connectors



- Check the connectors for the siren, upper electronic control module and cable harness. Check for contact resistance and oxidation. In particular, check for any damage
- Reinstall the components, reconnect the connectors etc.

Open the driver's door window. Lock the car using the remote control.
Wait 25 seconds until the vehicle has been alarmed. Trigger the alarm by inserting a hand through the window and unlocking the door from the inside using the internal door handle.

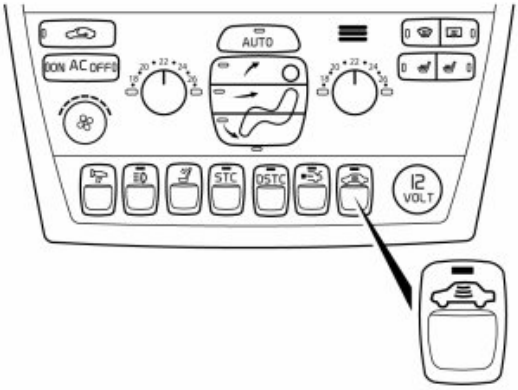
Note! On vehicles with deadlocks, these must be deactivated first. Press the button for the reduced locking position to activate deadlocks.

The function can be engaged in ignition position I and 0. It can also be engaged after the ignition has been switched off, for up to one minute after the ignition key has been removed from the ignition switch. The switch has an integrated light emitting diode for indicating that the function has been activated. A message also appears in the display in the Driver information module (DIM),however, not when the key has been removed. The switches may be positioned differently than shown in the image, depending on the vehicle's configuration and equipment.

Other information:

- To access the siren connector, see Siren, replacing See: Accessories and Optional Equipment/Antitheft and Alarm Systems/Alarm Horn/Service and Repair
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals.

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2



Is the siren triggered?

Yes - Verification

No - Checking for open-circuits and short-circuits

Checking for open-circuits and short-circuits

Check that the fuses in the fusebox in the passenger compartment are intact.
Check the cable between control module terminal #21 and siren terminal #2. Check for a short-circuit to ground. Check for an open-circuit. Check for a short-circuit to supply voltage.
Check the wiring from the fuse in the passenger compartment to siren connector terminal #1. Check for an open-circuit. Check for a short-circuit to ground.

Other information:

- For further information about signals and other values, see Signal specification See: Body and Frame/Body Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Description / Specification/Signal Specification, Upper Electronic Module (UEM)
- To connect the breakout box, see Connecting the breakout box See: Body and Frame/Body Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box
- To access the siren connector, see Siren, replacing See: Accessories and Optional Equipment/Antitheft and Alarm Systems/Alarm Horn/Service and Repair
- For further information about the fuses and relays, see the Wiring Diagram
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals.

Remedy as necessary.

Was a fault detected?

Yes - Verification

No - Replacing the component

Replacing the component

Replace the siren. See Siren, replacing See: Accessories and Optional Equipment/Antitheft and Alarm Systems/Alarm Horn/Service and Repair.
The siren must be configured after replacement. Click on the VCT2000 symbol for configuration.

Continue - Verification

Intermittent fault

Check the connectors for the upper electronic module (UEM) and the siren. Check for contact resistance and oxidation. Check for loose connections.
Check that the fuses in the fusebox in the passenger compartment are intact.
Check the cable between control module terminal #21 and siren terminal #2. Check for an intermittent short-circuit to ground. Check for an intermittent open-circuit. Check for an intermittent short-circuit to supply voltage.
Check the cable between ground terminal 31/94 and siren connector terminal #3. Check for an intermittent open-circuit.
Check the cable between the fuse in the fusebox in the passenger compartment and siren connector terminal #1. Check for an intermittent open-circuit. Check for an intermittent short-circuit to ground.
Try replacing the siren if no fault is found.

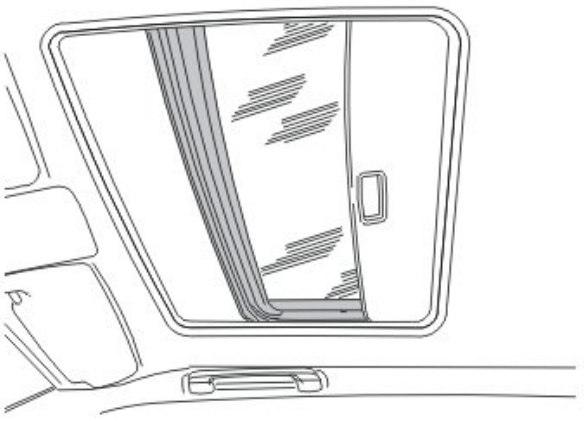
FAULT FOUND - Fault Found

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information UEM-0005

Condition



The upper electronic module (UEM) receives information from the sun roof.
If the sun roof does not respond to repeated requests from the upper electronic module (UEM), the control module interprets it as a communication fault and the diagnostic trouble code (DTC) is stored.
The diagnostic trouble code (DTC) can be detected 20 seconds after the control module has been initialized.

Substitute value
- None.

Possible source
- Open-circuit in UEM_K3 (the serial cable between the upper electronic module (UEM), siren and sun roof)
- Short-circuit to ground in UEM_K3
- Short-circuit to supply voltage in UEM_K3

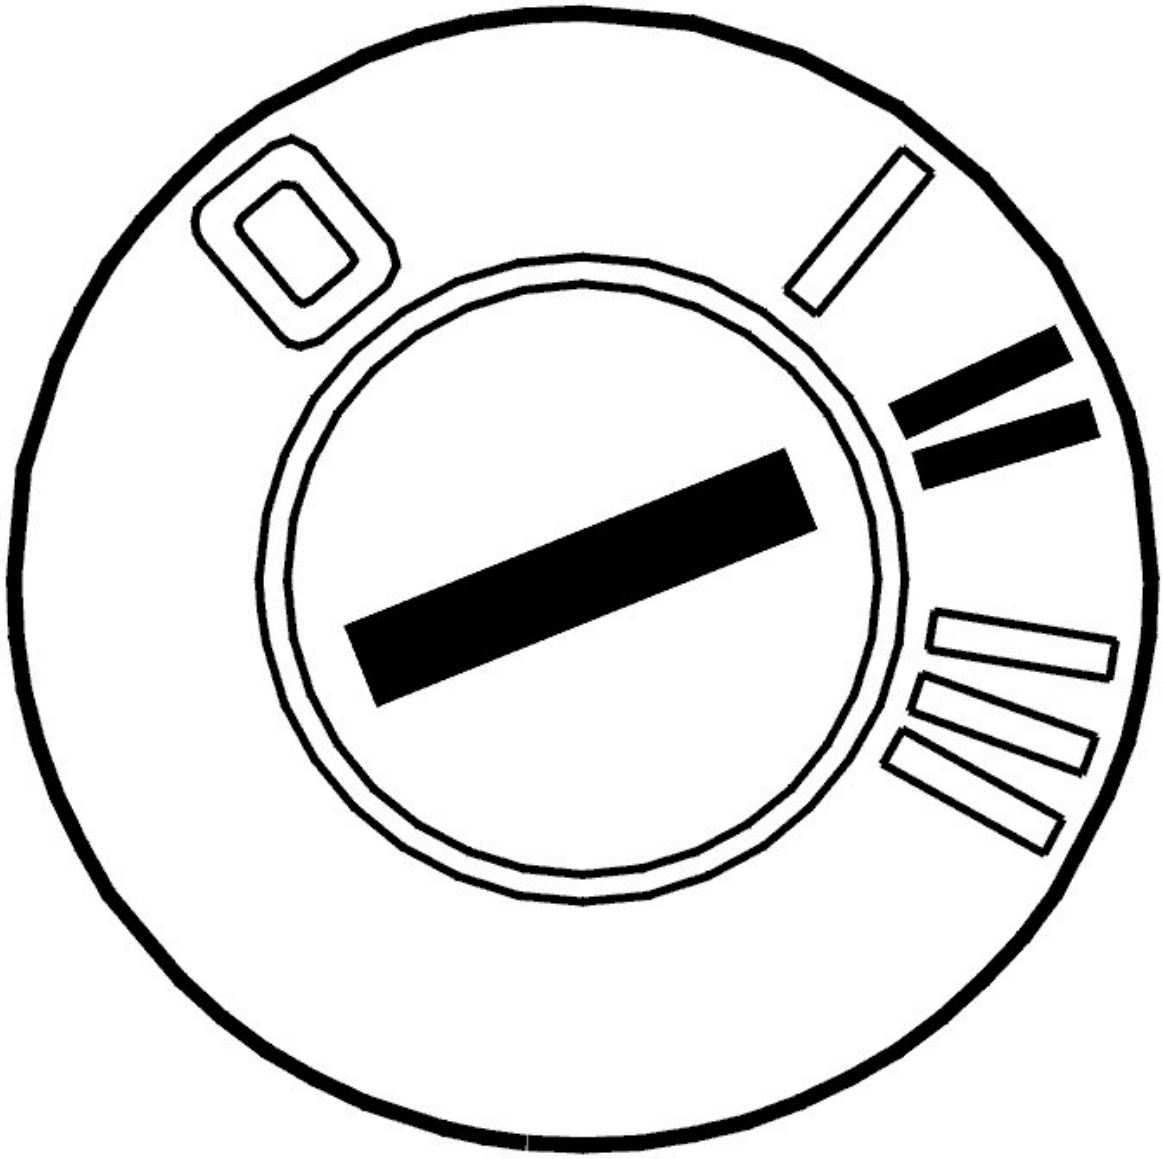
- Damaged Sun roof module (SRM).

Fault symptom[s]
- The power sun roof does not operate.

Communication Fault

Communication fault

Checking for permanent or intermittent faults



- Ignition on.

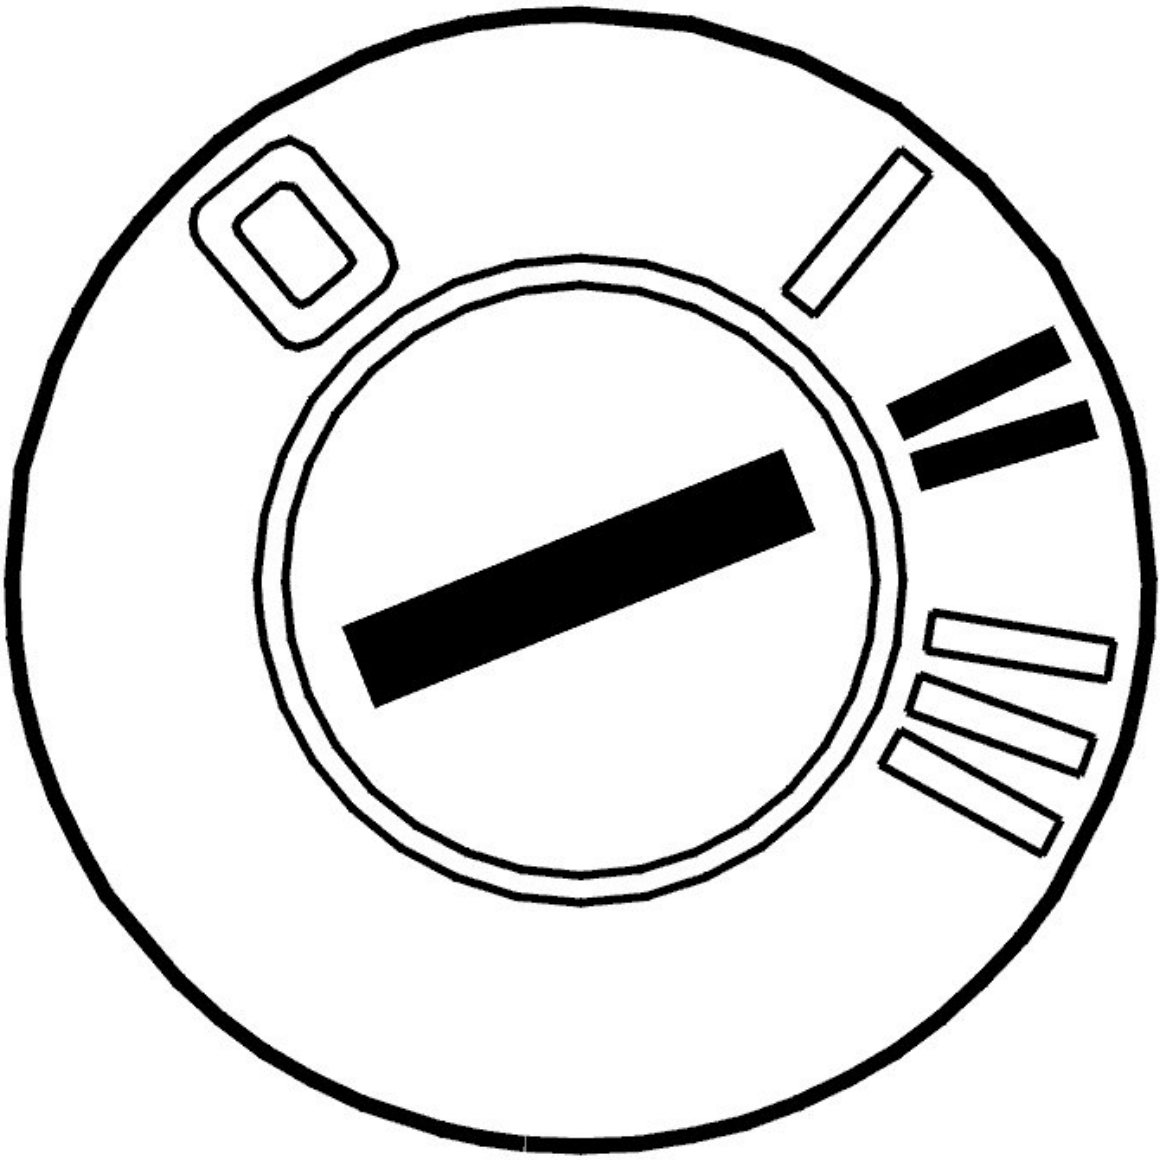
Attempt to operate the sun roof.

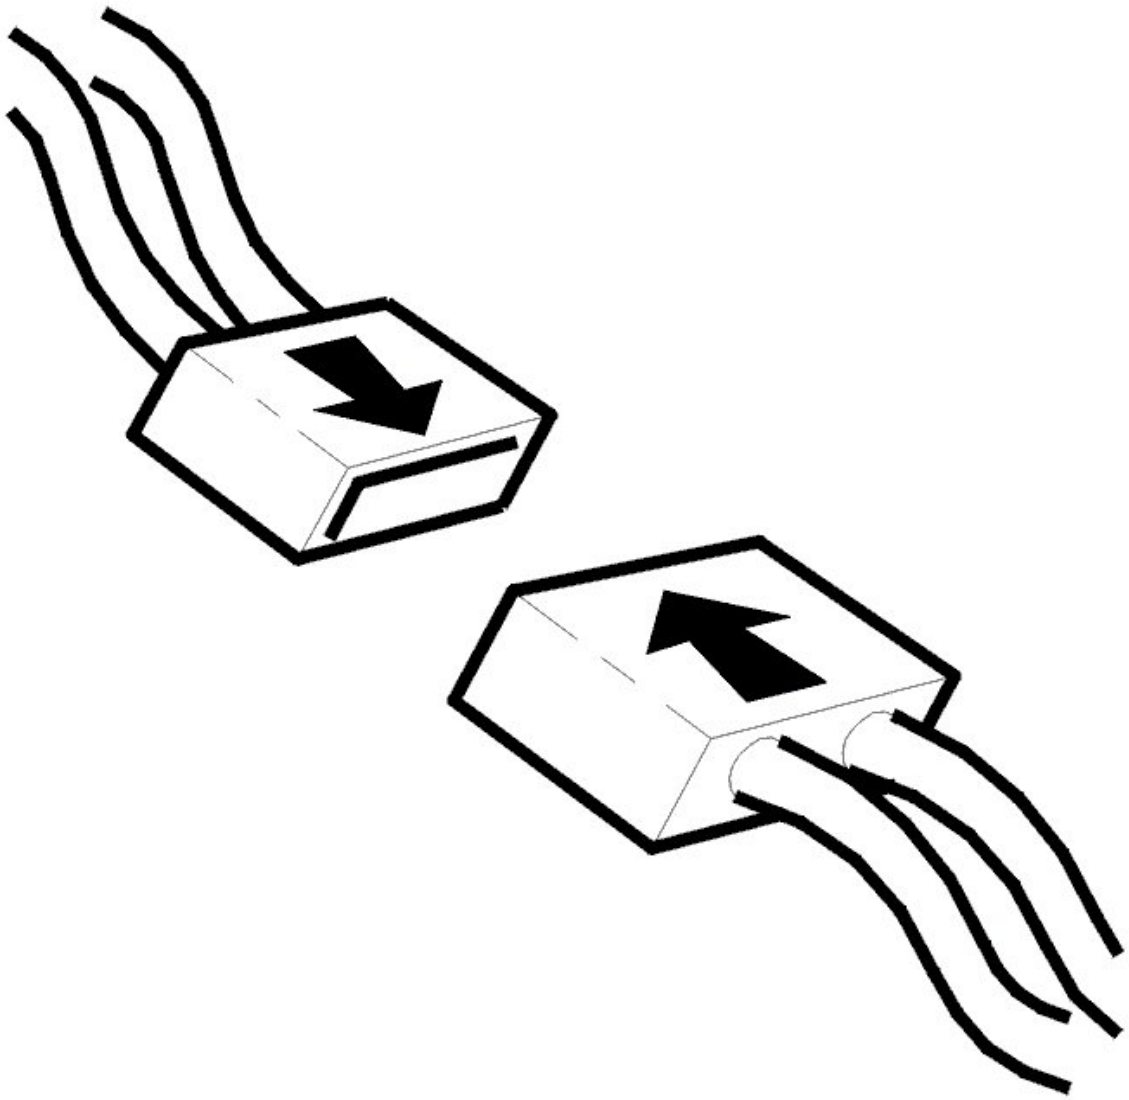
Can the sun roof be operated?

Yes - Intermittent fault

No - Checking the connectors

Checking the connectors





- Ignition off
- Remedy the connectors for the cable harness, sun roof control module and upper electronic module (UEM) for contact resistance and oxidation.

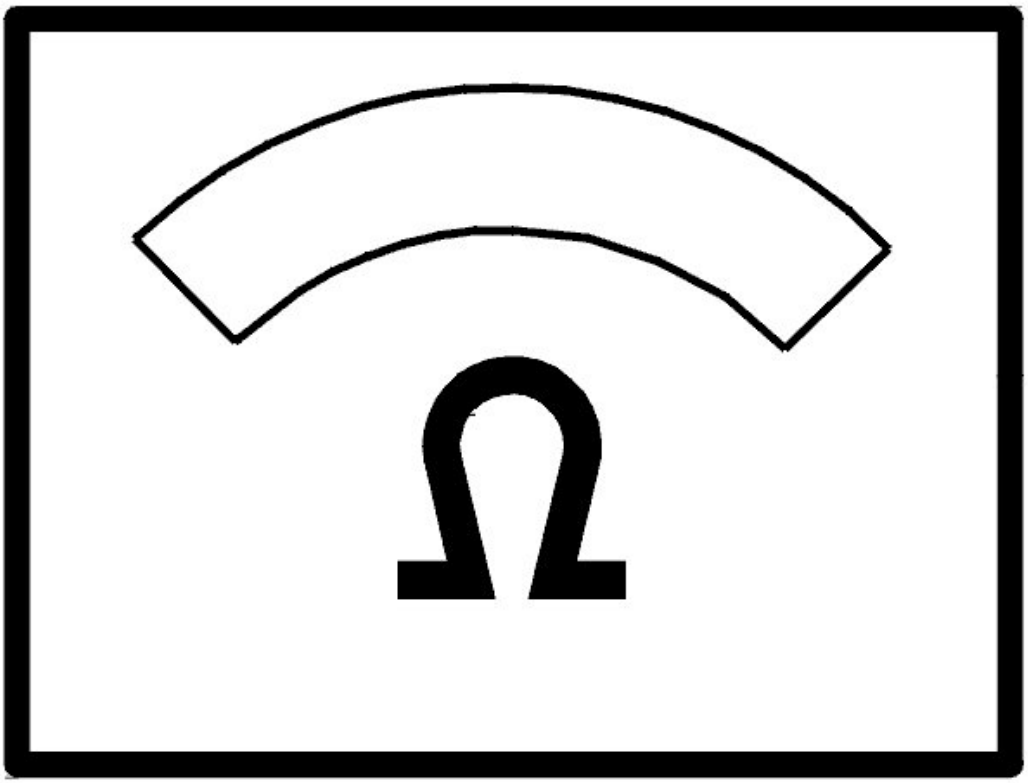
In particular, check for any damage

- Reinstall the components, reconnect the connectors etc.
- Ignition on.

Operate the sun roof.

Other information:

- To access the connector for the upper electronic module (UEM), see Upper electronic module (UEM) rear view / door mirror, replacing See: Body Control Module/Service and Repair
- To access the sun roof connector, see Sun roof module (SRM), replacing See: Body and Frame/Relays and Modules - Body and Frame/Sunroof / Moonroof Module/Service and Repair
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals.



Do the sun roof controls operate?

Yes - Verification

No - Checking for open-circuits and short-circuits

Checking for open-circuits and short-circuits

Check the cable between the upper electronic module (UEM) terminal #21 and the sun roof module (SRM) terminal #4. Check for a short-circuit to ground. Check for an open-circuit. Check for a short-circuit to supply voltage.
Remedy as necessary.

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information UEM-0013

Condition

Diagnostic trouble code (DTC) UEM-0013 is stored if diagnostic trouble codes (DTCs) UEM-000A, UEM-000B, UEM-000C, UEM-0011 and UEM-0012 are not stored and the upper electronic module (UEM) registers an internal fault in the movement sensor or registers that there is an open-circuit or high signal in the movement sensor communication cable when the alarm is active.
In XC90 the diagnostic trouble code (DTC) means that a fault has been detected in the rear movement sensor.
Diagnostic trouble code (DTC) UEM-0013 can be diagnosed when the car is locked from the outside using the remote control.

Substitute value
- None.

Possible source
- Contact fault on the sensor and/or control module sides
- Open-circuit in the sensor communication cable
- Short-circuit to supply voltage in the sensor communication cable
- Defective sensor.

Fault symptom[s]
- Does not alarm the sensor.

Internal Fault

Internal fault

Checking wiring and connectors

(For XC90 the fault-tracing refers to the rear movement sensor.)
Check the signal cable between the upper electronic module (UEM) connector terminal #22 (22) and movement sensor terminal connector terminal #3. Check for an open-circuit. Check for an intermittent open-circuit.
Also check the relevant connectors. Check for oxidation.

Was a fault detected?

Yes - Verification

No - Checking wiring and connectors

Checking wiring and connectors

(For XC90 the fault-tracing refers to the rear movement sensor.)
Check the ground lead between movement sensor connector terminal #5 and the ground terminal 31/83. Check for an open-circuit. Check for an intermittent open-circuit.
Check in particular intermediate connector (54/13:20) in the cable harness.
If no fault was found, try a new sensor.

Other information:

- To connect the breakout box: Connecting the breakout box See: Body and Frame/Body Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box
- For information about upper electronic module (UEM) signals: Signal specification See: Body and Frame/Body Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Description / Specification/Signal Specification, Upper Electronic Module (UEM)
- Movement sensor/Volume sensor/ Mass movement sensor (MMS), replace See: Accessories and Optional Equipment/Antitheft and Alarm Systems/Ultrasonic Sensor/Service and Repair

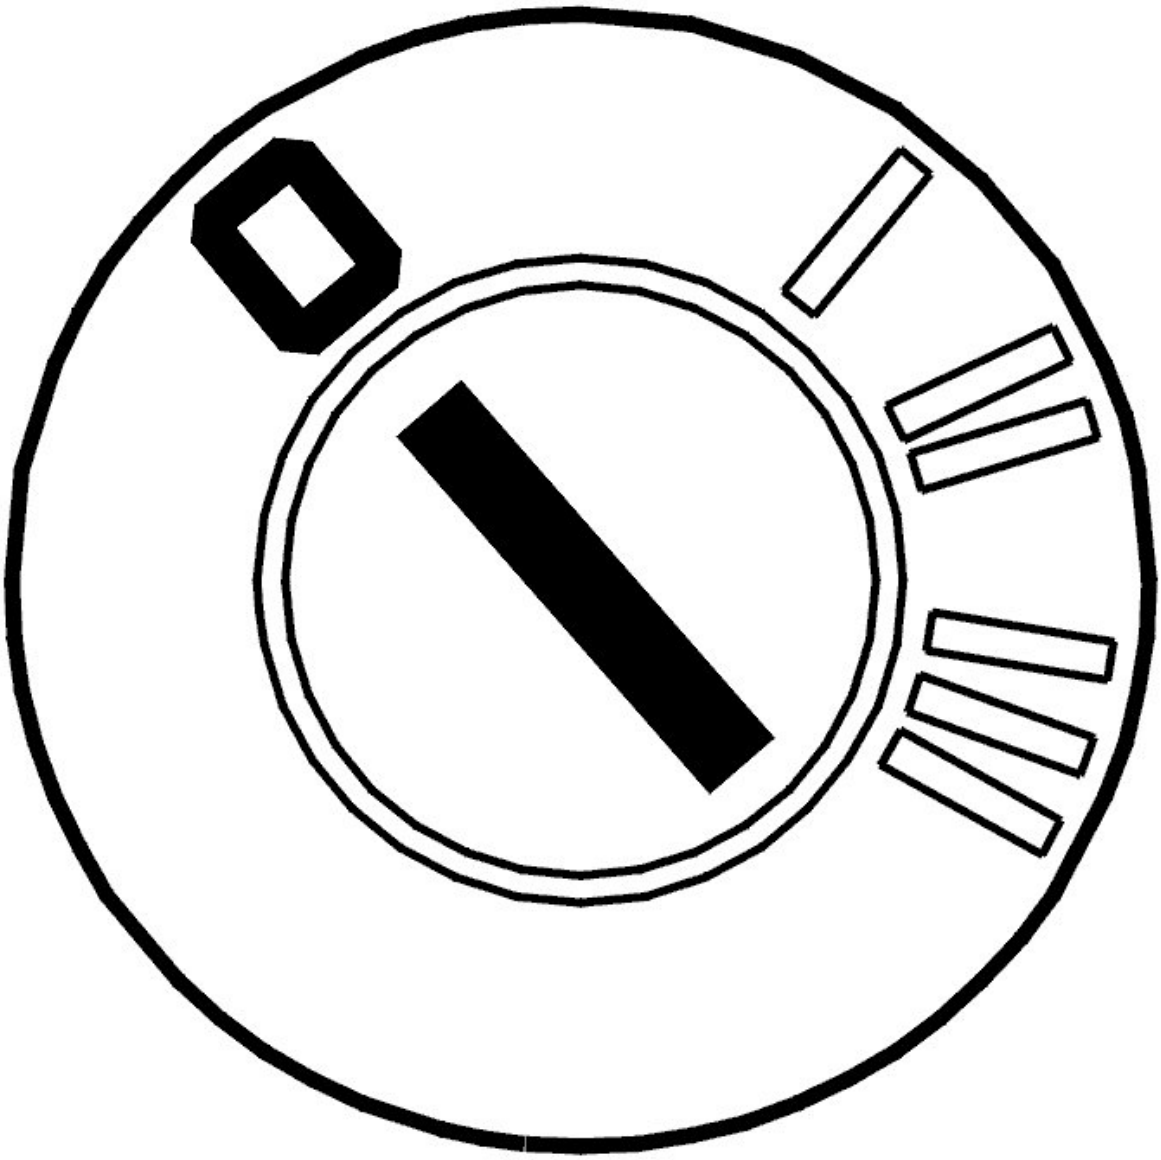
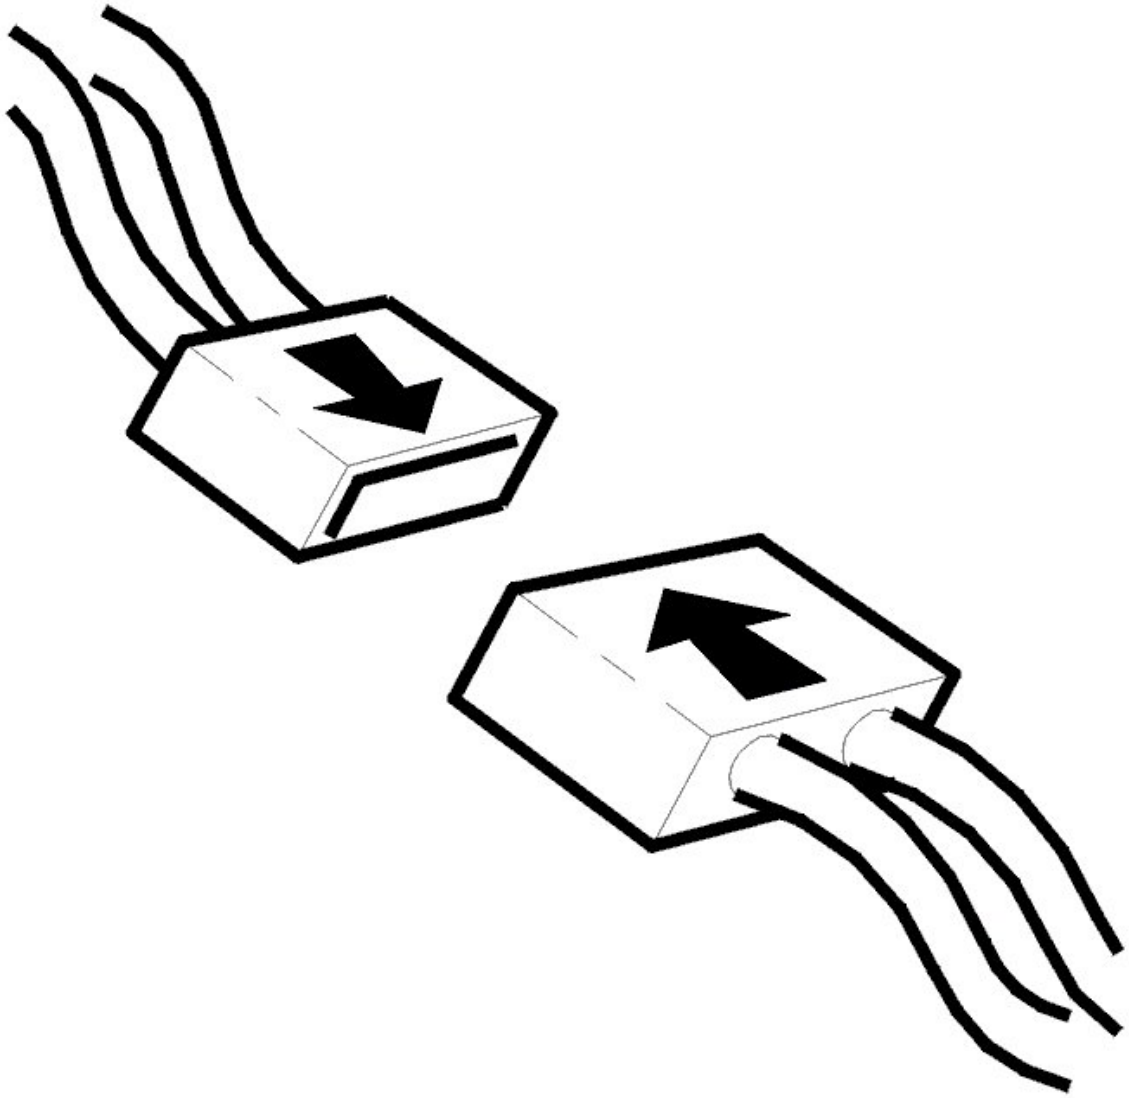
Verification

Verification

Verification

Hint: After carrying out the repair, check that the fault has been remedied.





- Ignition off
- Reinstall the connectors, components etc.

To check the mass movement sensor (MMS) in the S60/S80/V70/XC70

- Check that the function for reduced alarm is not activated (button on 7 in row).
- Open the driver's window, close all doors and hatches. Lock the vehicle using the remote control.
- Wait 25 seconds until the alarm is active. Then trigger the alarm by waving your arm inside the vehicle. The siren or horn must sound and the hazard warning lamps flash. Reset the alarm by pressing the unlocking button on the remote control.
- Check that the mass movement sensor (MMS) has triggered the alarm via the read out of the alarm cause in Vehicle communication.

To check the mass movement sensor (MMS) in the XC90

- Check that the function for reduced alarm is not activated (button on 7 in row).
- Open the driver's window and the rear window on the driver's side. Lock the vehicle using the remote control.
- Wait 25 seconds until the alarm is active. Then trigger the alarm by waving your arm through the driver's door window, inside the vehicle above the front seats. The siren or horn must sound and the hazard warning lamps flash.
- Reset the alarm by pressing the unlocking button on the remote control. Lock the vehicle again.
- Wait 25 seconds until the alarm is active. Then trigger the alarm by waving you arm, through the rear door window on the driver's side, inside the vehicle above the cargo compartment. The siren or horn must sound and the hazard warning lamps flash. Reset the alarm by pressing the unlocking button on the remote control.
- Check that the front and rear mass movement sensor (MMS) has triggered the alarm the last two times via the read out of the alarm cause in Vehicle communication.

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code information

Condition

If the control unit detects that the general courtesy lighting switch has been pressed down for more than 3 minutes, a diagnostic trouble code is displayed. The test is done when the ignition is on or off.

Substitute value
- Nothing.

Possible source
- The general courtesy lighting switch has stuck
- CFL (front left reading lamp switch signal) and CFR (front right reading lamp switch signal) short circuited to voltage supply.

Fault symptom[s]
- Courtesy lighting does not work.

Faulty Signal

Faulty signal

Checking for permanent or intermittent faults

Unlock the car using the key or remote control from outside.

Does the general interior lighting come on?

Yes - Intermittent fault

No - Checking for a short-circuit

Checking for a short-circuit

Check that the button has not jammed in its depressed position.
Check the cable between control module terminal #16 and roof lamp module terminal #7A. Check for a short-circuit to supply voltage.

Check the cable between control module terminal #4 and roof lamp module terminal #8A. Check for a short-circuit to supply voltage. Replace the cable if a fault is found.

Other information:

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition

Diagnostic trouble code (DTC) UEM-0020 is stored if the control module registers that the actual value for rear view mirror anti-dazzle is different from the desired value.

Substitute value
- None.

Possible source
- Defective circuit in the rear view mirror.

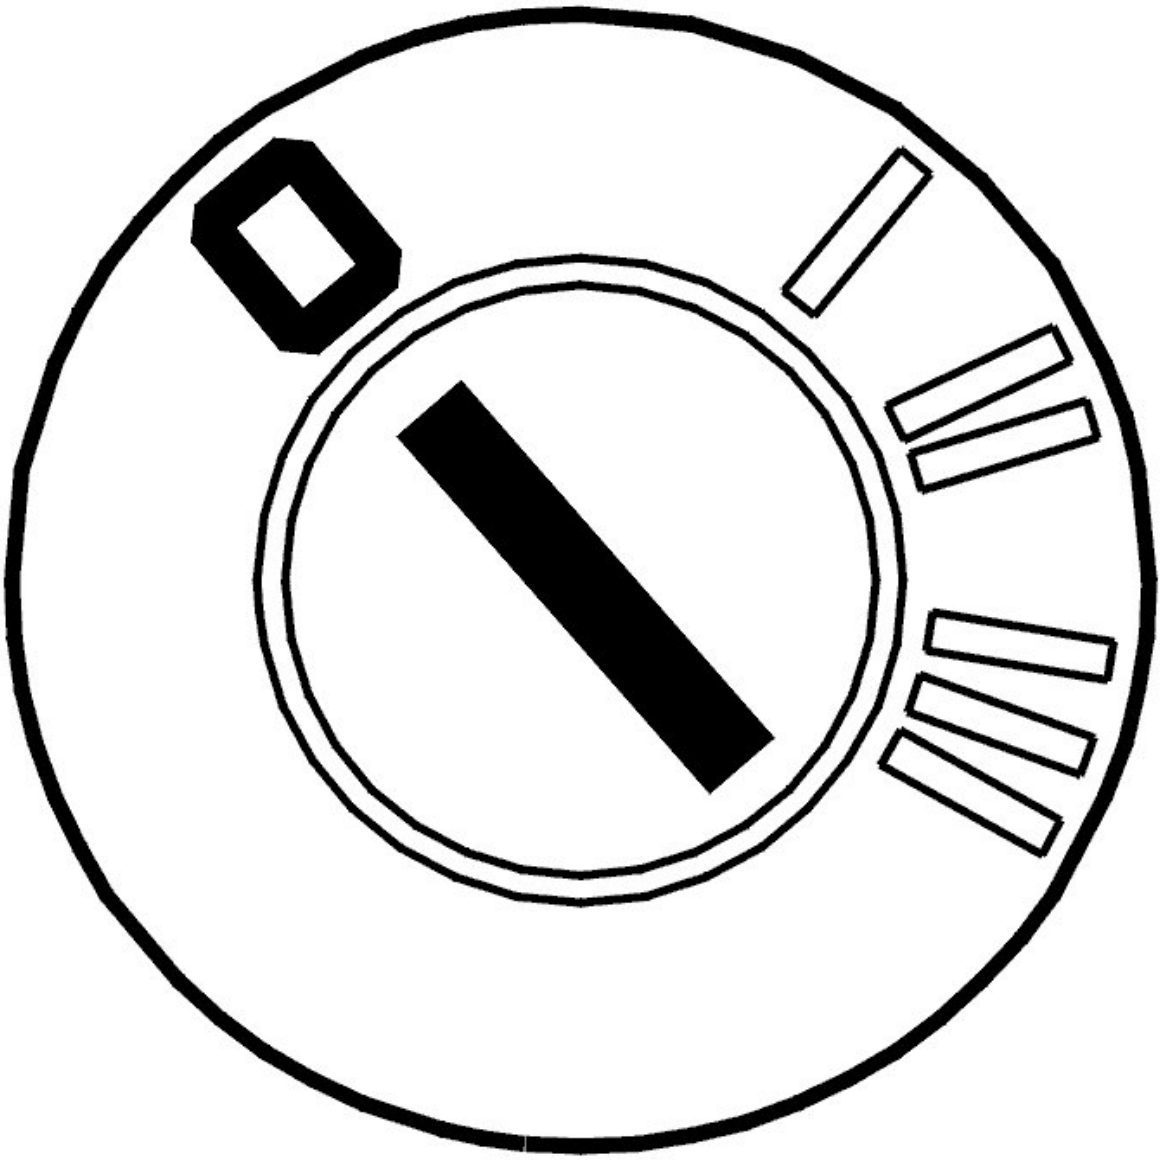
Fault symptom[s]
- No anti-dazzle function
- Poor anti-dazzle function.

Signal Missing

Signal missing

Replacing the control module and programming

Note! If possible, read off the programmed data from the control module before it is replaced.



- Ignition off.

The upper electronic module has registered an internal fault.
As a result of the fault, the control module must be replaced.

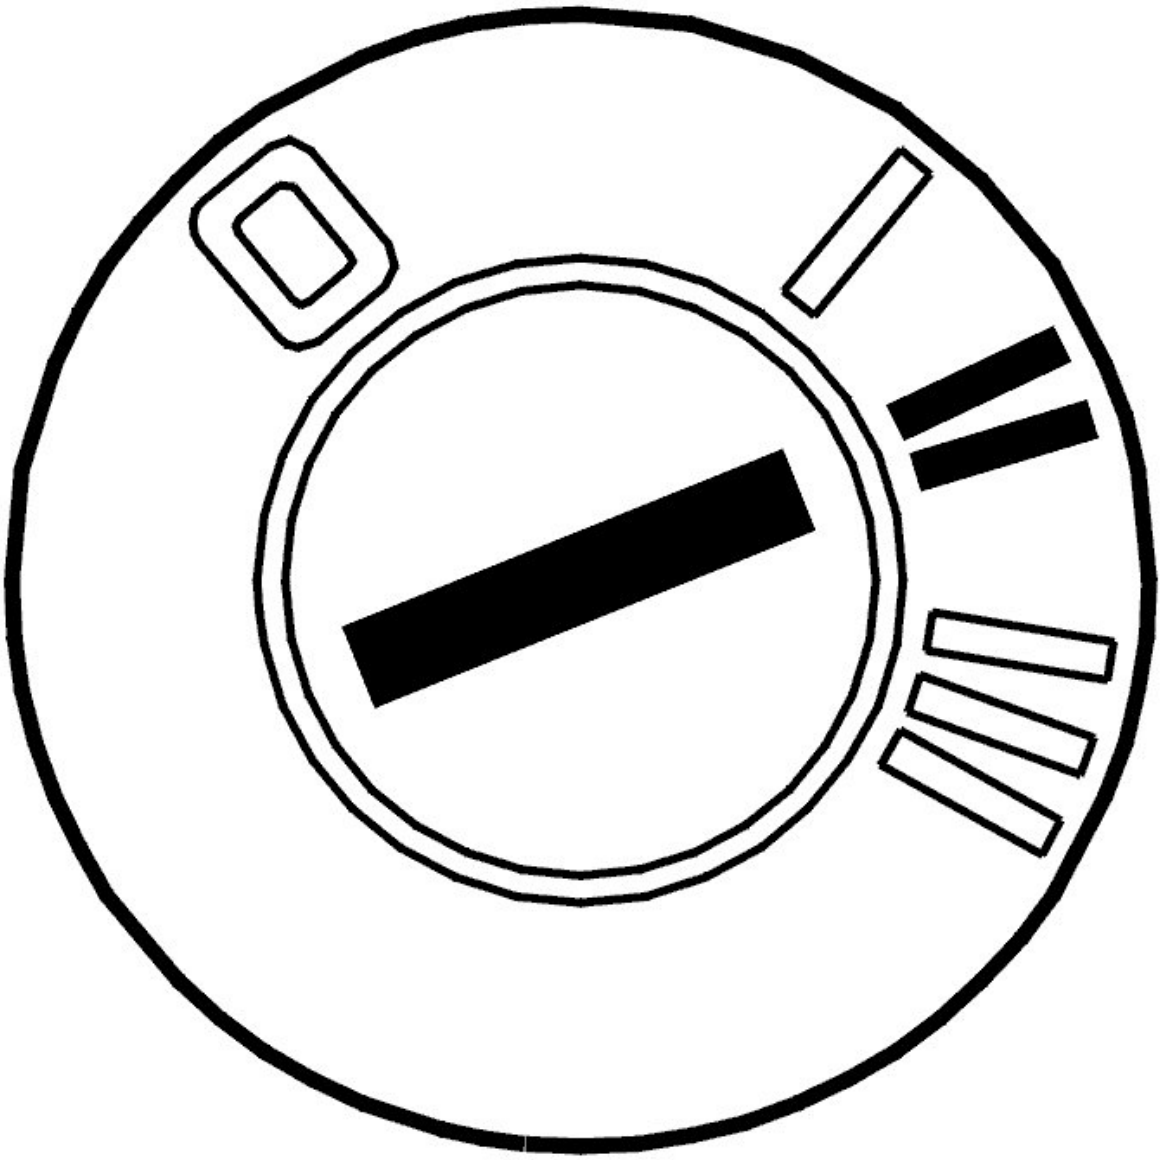
Continue - Replacing the control module

Replacing the control module

Replacing the control module

Reading off the programmed values

Note! Read off the programmed values from the upper electronic module (UEM) before replacing the control module.



- Ignition on
- Click on the symbol for VCT2000 to read off the programmed values.

The retained values are programmed customer parameters in the upper electronic module (UEM). The retained values should be noted for later use.

Other information

- For information about programming the customer parameters, see Diagnostic functions See: Body and Frame/Body Control Systems/Description and Operation/Upper Electronic Module (UEM)/Diagnostic Functions.

Continue - Replacing control modules and downloading software

---

Replacing control modules and downloading software

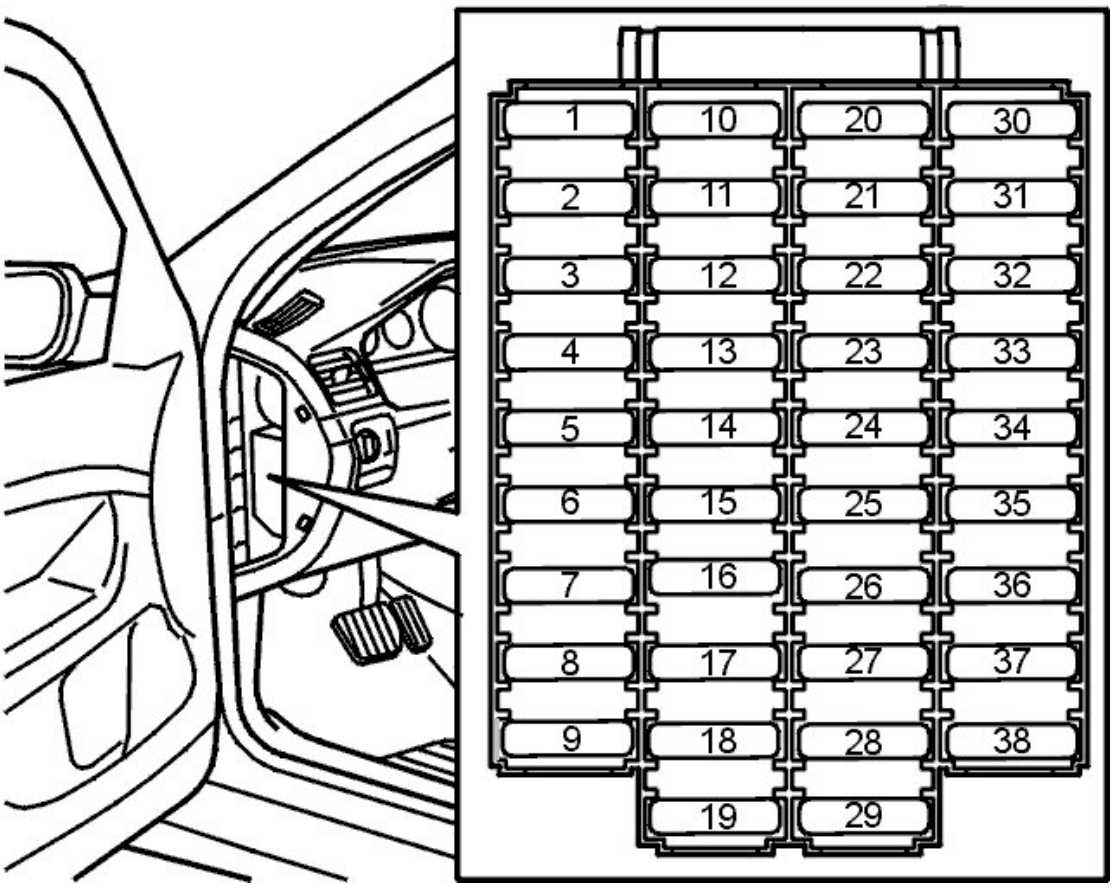
Caution! A new control module is delivered without software. In order for the control module to function new software must be programmed into the control module after it has been replaced.

Replace the control module and download the new software. See Upper electronic module (UEM) rear view / door mirror, replacing See: Body Control Module/Service and Repair.

Hint: When diagnostic trouble code (DTC) E001 is stored, communication with the control module cannot be established. This can be remedied in two ways.

1. Press the remote control button for local lighting

2. Remove fuse 11C/28 from the fusebox in the passenger compartment. Reinstall the fuse again.



Continue - Checking the interior lighting

Checking the interior lighting

Checking the interior lighting (2)

Checking the interior lighting

Two times can be programmed for the interior lighting:

1. Short

- The period from when the door is unlocked, or the engine stops, to when the interior lighting goes out can be changed if it is too long or too short.

2. Long

- The period from when the door is opened, or a lamp is lit with a switch, to when the lamp goes out can be changed if it is too long or too short.

To program a long interior lighting period you must step ("click") through the short interior lighting period programming.

Continue - Programming a short interior lighting period

Programming a short interior lighting period

The general lighting and rear reading lamps light and remain lit for 30 seconds when:

- The door has been unlocked from outside with a key or the remote control.
- The engine has been stopped and the ignition key turned to 0.

The default period is 30 seconds. This can be changed to between 5 and 255 seconds.
Read off the programmed values.
To change the time, mark the desired value in the scrolling list and start programming.

Do you want to program any more parameters?

Yes - Programming a long interior lighting period

No - **Fault Found**

Programming a long interior lighting period

The general lighting and rear reading lamps light and remain lit for 10 minutes when:
- A door is opened after being unlocked.
- The lamp is lit with a switch.

The default period is 10 minutes. This can be changed to between 0 and 255 minutes at 10 minute intervals.
Read off the programmed values.
To change the time, mark the desired value in the scrolling list and start programming.

Continue - **Fault Found**

FAULT FOUND - Checking the anti-dazzle function in the rear view mirror

---

Checking the anti-dazzle function in the rear view mirror

Checking the anti-dazzle function in the rear view mirror

Checking the anti-dazzle function

Note! If the upper electronic module (UEM) has been replaced software, specially developed for downloading after replacing the control module, must be downloaded to the control module before the anti-dazzle function is changed. See Upper electronic module (UEM) rear view / door mirror, replacing See: Body Control Module/Service and Repair.

The rear view mirror anti-dazzle function can be adjusted:
- If the rear view mirror anti-dazzle function is too powerful or too weak, it can be adjusted.

Specific software for setting the anti-dazzle function must be installed in the car to do this.
Order the software. See9499432.
Install the software. See9499432.

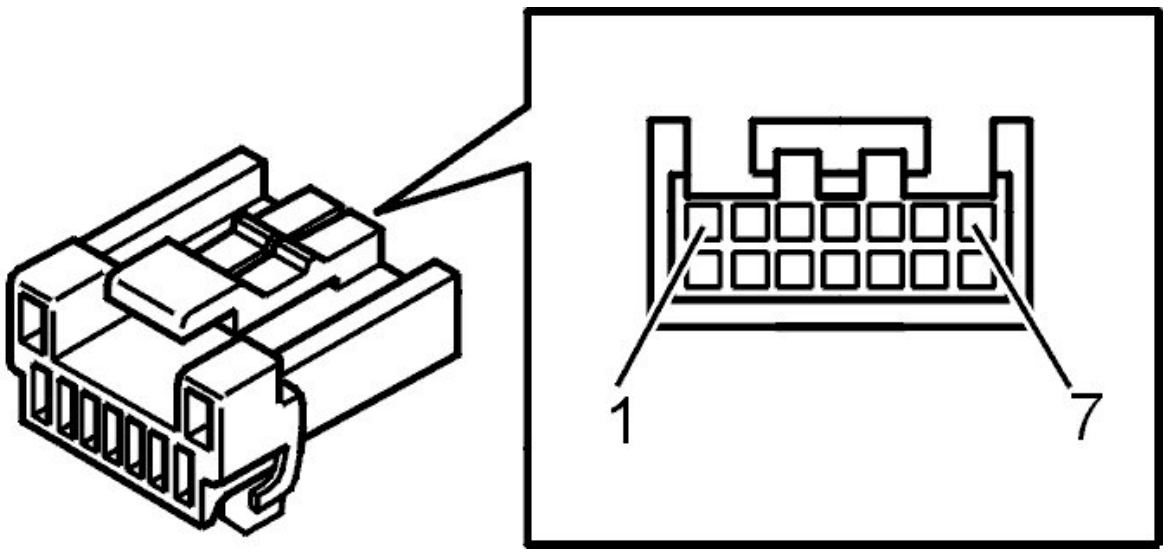
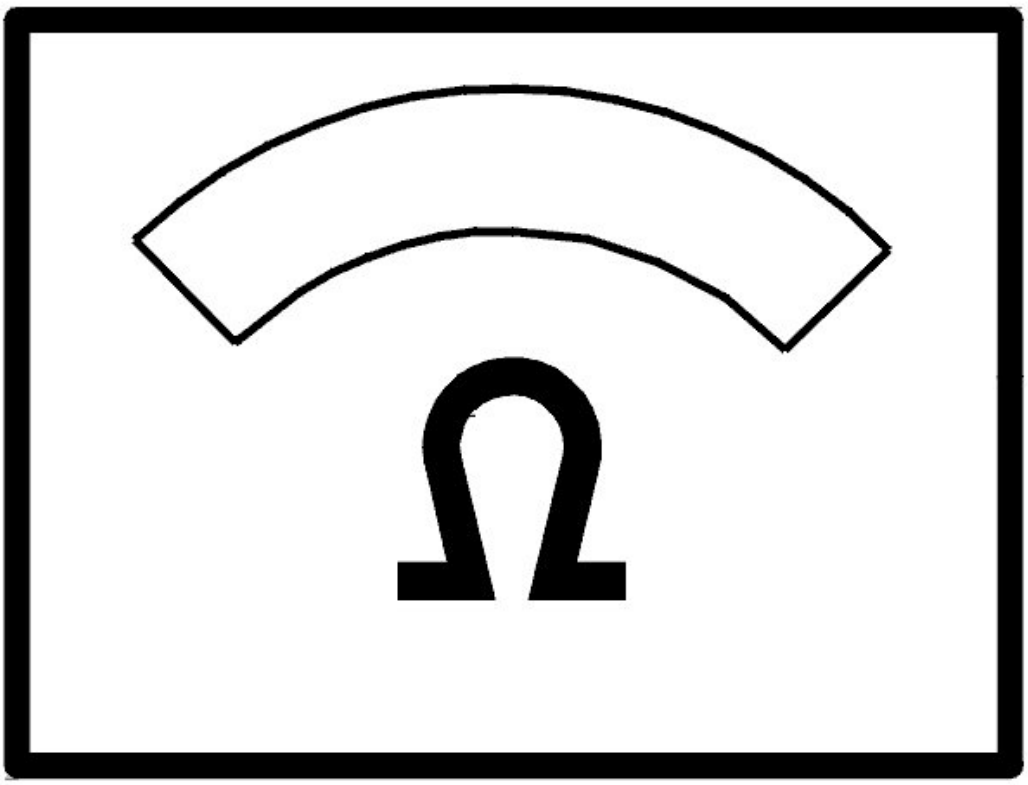
Signal missing

Checking the connectors

Check that the bulb is intact.
Check the connectors on the upper electronic module and rear reading lamp unit for contact resistance and oxidation as described in Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault , and a loose contact as described in Checking wiring and terminals. Intermittent faults See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Intermittent Faults.
Do the necessary corrective action.

Additional information:
- To access/replace the lamp, see Bulb, reading lamp, rear, replacing See: Lighting and Horns/Dome Lamp/Dome Lamp Bulb/Service and Repair.





Is there a fault?

Yes - Verification

No - Checking for open circuits and short circuits

Checking for open circuits and short circuits

Check the wire between the upper electronic module and rear reading lamp unit for an open circuit as described in Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault , and a short circuit to voltage supply as described in Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault.

UEM-0031 Rear left reading lamp
Control unit #7 and reading lamp unit #1.

UEM-0033 Rear right reading lamp
Control unit #17 and reading lamp unit #7.

Additional information:

- For information on signals and additional values, see Signal specification See: Body and Frame/Body Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Description / Specification/Signal Specification, Upper Electronic Module (UEM).
- To connect the test box, see Connecting the breakout box See: Body and Frame/Body Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box.

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code information

Condition

If the control unit detects that the front left reading lamp is on when the rear left reading lamp is off, a faulty control signal from the lamp circuit displays the diagnostic trouble code.

Substitute value
- The lamp goes off.

Possible source
- The signal wire for the front left reading lamp is short circuited to ground
- Intermittent open circuit on signal wire.

Fault symptom[s]
- Courtesy lighting does not work.

Signal Too Low

Signal too low

Checking the connectors

Check the control module and roof lamp module connectors. Check for contact resistance and oxidation. Check for loose connections.

Other information:
- For further information about signals and other values, see Signal specification See: Body and Frame/Body Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Description / Specification/Signal Specification, Upper Electronic Module (UEM)

Diagnostic Trouble Code (DTC) Information

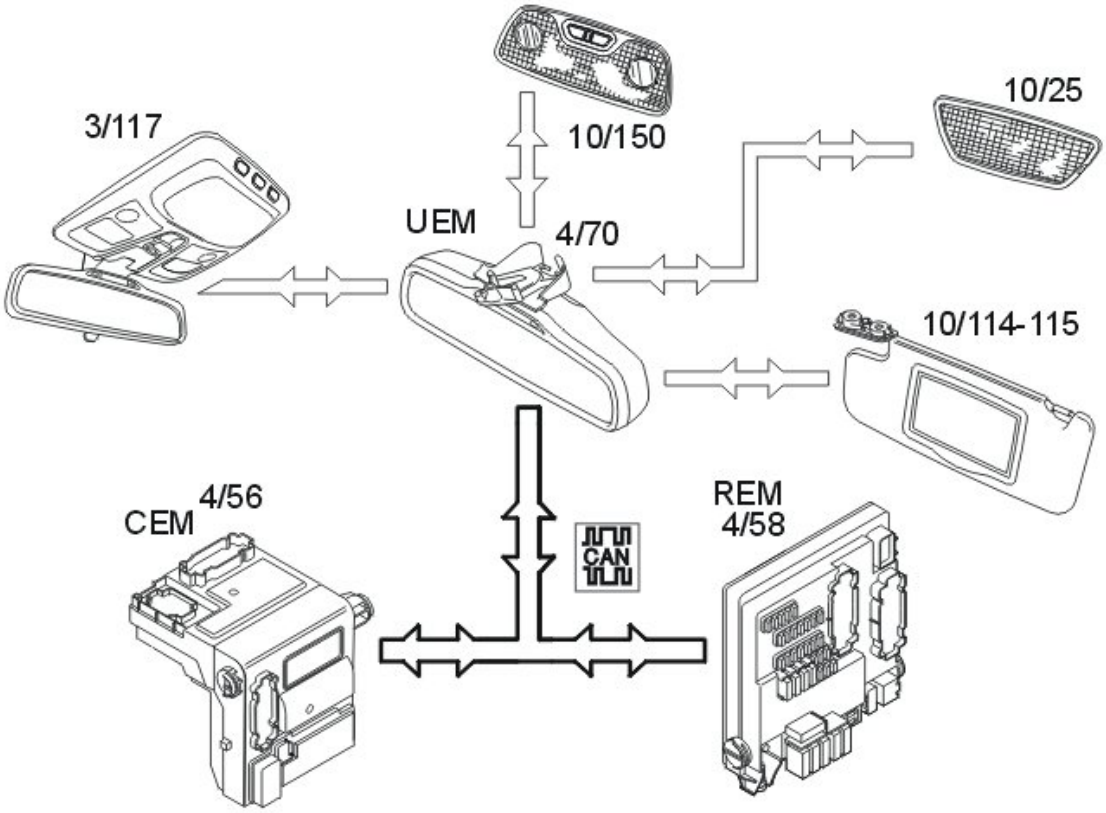
Diagnostic trouble code (DTC) information UEM-0038

Condition



The upper electronic module (UEM) checks the interior lighting. The diagnostic trouble code (DTC) is stored if the control module registers that there is an on signal for the interior lighting in the headlining when the control signal for the general lighting is low.
The diagnostic trouble code (DTC) can be diagnosed when the conditions are met for the interior lighting to be switched on at the same time as the lighting in the cargo compartment is off.

Substitute value
- The lamp goes out.

Possible source
- Short-circuit to ground in the signal cable for the general lighting.

Fault symptom[s]
- The interior lighting does not work.

Signal Too Low

Signal too low

Checking the connectors

Check the control module and roof lamp module connectors. Check for contact resistance and oxidation.

FAULT-TRACING FAILED - No Fault Found

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information UEM-003A

Condition

The upper electronic module (UEM) supplies power to a number of functions in the car via Extended X-supply (EXT_X). These functions include the sun roof logic, mirror lamps in the sun visor, rain sensor, buttons for the headlining lighting and certain button lighting.
Diagnostic trouble code (DTC) UEM-003A is stored if the upper electronic module (UEM) registers too low a level for power supply Extended X-supply (EXT_X).
Diagnostic trouble code (DTC) UEM-003A can be diagnosed in ignition positions I or II.

Substitute value
- Sun roof, mirror lamps in the sun visor, buttons for the headlining lighting and certain button lighting are switched off.

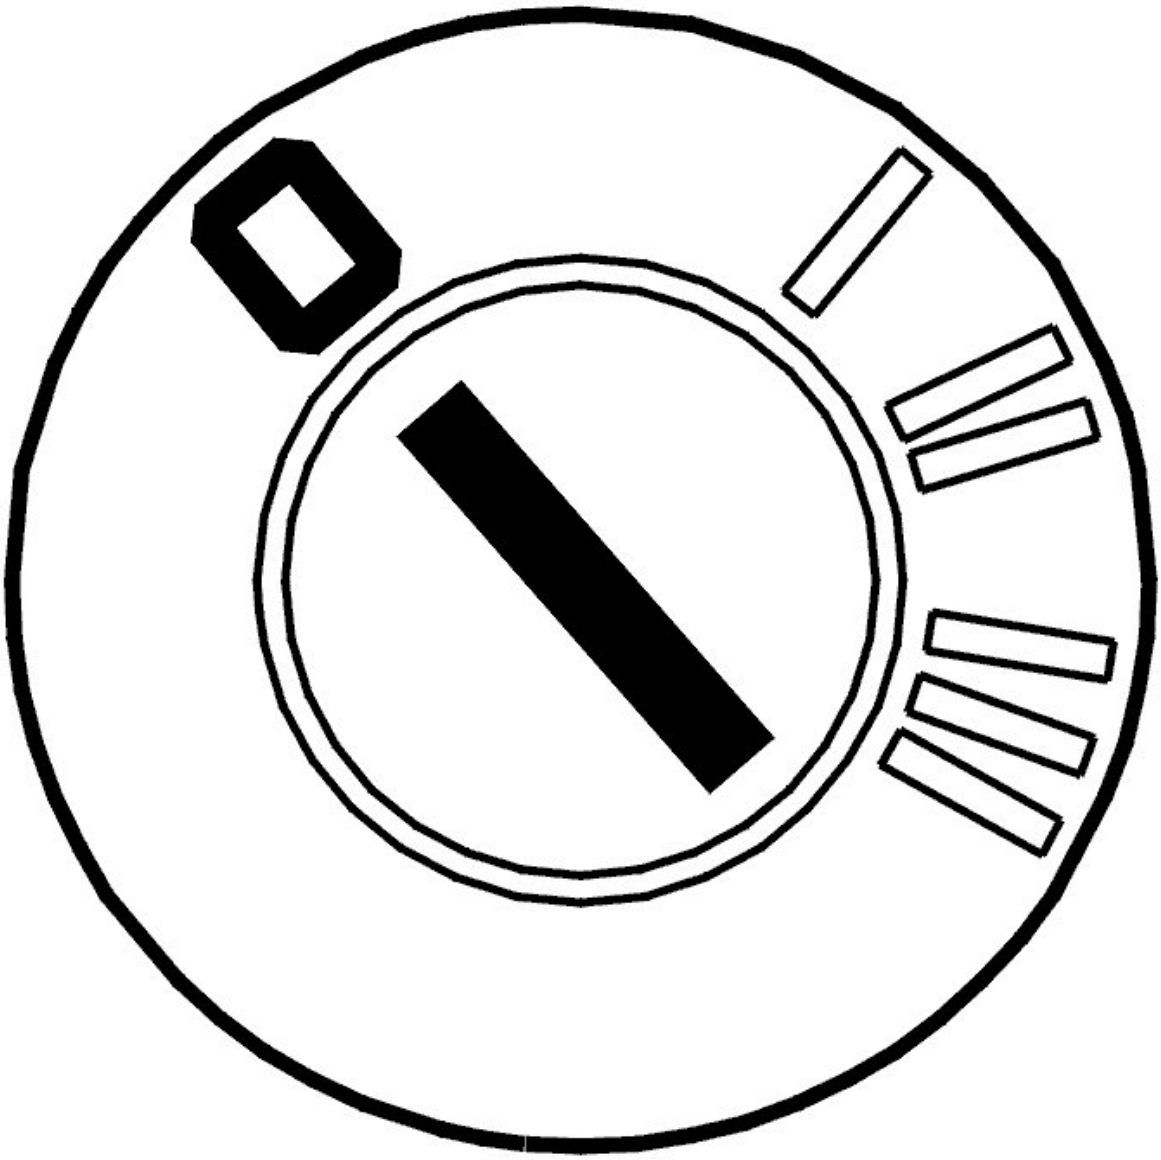
Possible source
- The power supply to the sun roof, mirror lamps in the sun visor, rain sensor, buttons for the headlining lighting and certain button lighting functions is short-circuited to ground.

Fault symptom[s]
- The power sun roof does not operate
- The interior lighting does not operate
- No rain sensor function.

Signal Too Low

Signal too low

Checking for a short-circuit



- Ignition off.

If all the functions that are supplied with power from the upper electronic module (UEM) via Extended X-supply (EXT_X) are not working (i.e. sun roof logic, mirror lamps in the sun visor, rain sensor or interior lighting), it can be assumed that either the cable between the upper electronic module (UEM) and the junction point 53/505 is short-circuited to ground or the wiring from the junction point to each component is short-circuited to ground.
First check the power supply cable between the upper electronic module (UEM) and each component. If the cable is short-circuited to ground, 0 ohms will be measured.
For mirror lamps in the sun visor, check the cable between the mirror lamp connector terminal #1 and the connector for the upper electronic module (UEM) terminal #A8. Check for a short-circuit to ground.
For sun roof and interior lighting, take readings on the cable between the connector for roof lamps terminal #A2 (and the sun roof module) and the connector for the upper electronic module (UEM) #A8. Check for a short-circuit to ground.
For rain sensor, take readings on the cable between the rain sensor connector terminal #A3 and the connector for the upper electronic module (UEM) terminal #A8. Check for a short-circuit to ground.
If all the readings result in a short-circuit to ground, it can be assumed that the fault is between the upper electronic module (UEM) #A8 and junction point 53/505.
Remedy as necessary.

Other information:

- To connect the breakout box, see Connecting the breakout box See: Body and Frame/Body Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information UEM-003C

Condition

The upper electronic module (UEM) uses the same power stages and outputs for interior lighting in several different models. Diagnostic trouble code (DTC) UEM-003C indicates faults in various units, depending on whether the car is a V70, XC70 or an XC90. In the V70 and XC70, faults are indicated by the control signal from the cargo compartment lighting. In the XC90, faults are indicated by the control signal from the 3rd row reading lamps.
Diagnostic trouble code (DTC) UEM-003C is stored if the control module registers that the control signal from the cargo compartment lighting/third row reading lamps is too low.
Diagnostic trouble code (DTC) UEM-003C can be diagnosed when the general roof lighting is lit and the cargo compartment lighting/third row reading lighting is not lit.

Substitute value
- Cargo compartment lighting/3rd row reading lamps switched off.

Possible source
- The cable for power supply to the cargo compartment lighting/third row reading lamps is short-circuited to ground
- Loose connections in the cable for power supply to cargo compartment lighting/third row reading lamps.

Fault symptom[s]
- The cargo compartment lighting is not working
- The interior lighting does not work.

Signal Too Low

Signal too low

Checking the connectors and components

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information UEM-003D

Condition

The upper electronic module (UEM) uses the same power stages and outputs for interior lighting in several different models. Diagnostic trouble code (DTC) UEM-003D indicates faults in various units, depending on whether the car is a V70, XC70 or an XC90. In the V70 and XC70, faults are indicated by the control signal from the cargo compartment lighting. In the XC90, faults are indicated by the control signal from the 3rd row reading lamps.
Diagnostic trouble code (DTC) UEM-003D is stored if the control module registers that the control signal to the cargo compartment lighting/third row reading lamps is too high.
Diagnostic trouble code (DTC) UEM-003D can be diagnosed in ignition position II and when the general roof lighting is lit and the cargo compartment lighting/third row reading lighting is not lit.

Substitute value
- Cargo compartment lighting/third row reading lamps switched off.

Possible source
- The cable for power supply to the cargo compartment lighting/third row reading lamps is short-circuited to supply voltage
- Open-circuit in the cable for power supply to cargo compartment lighting/third row reading lamps.

Fault symptom[s]
- The cargo compartment lighting is not working
- The interior lighting does not work.

Faulty Signal

Faulty signal

Checking the connectors and components

Attempt New Test - Checking the connectors and components

FAULT-TRACING FAILED - No Fault Found

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code information

Condition

If the control unit tries to store data in its memory and the data becomes corrupted, the diagnostic trouble code is displayed.

Substitute value
- Nothing.

Possible source
- Fault in EEPROM.

Fault symptom[s]
- Courtesy lighting does not work
- Alarm does not work.

Internal Fault

Internal fault

Checking for permanent or intermittent faults

Check whether any customer symptoms persist.

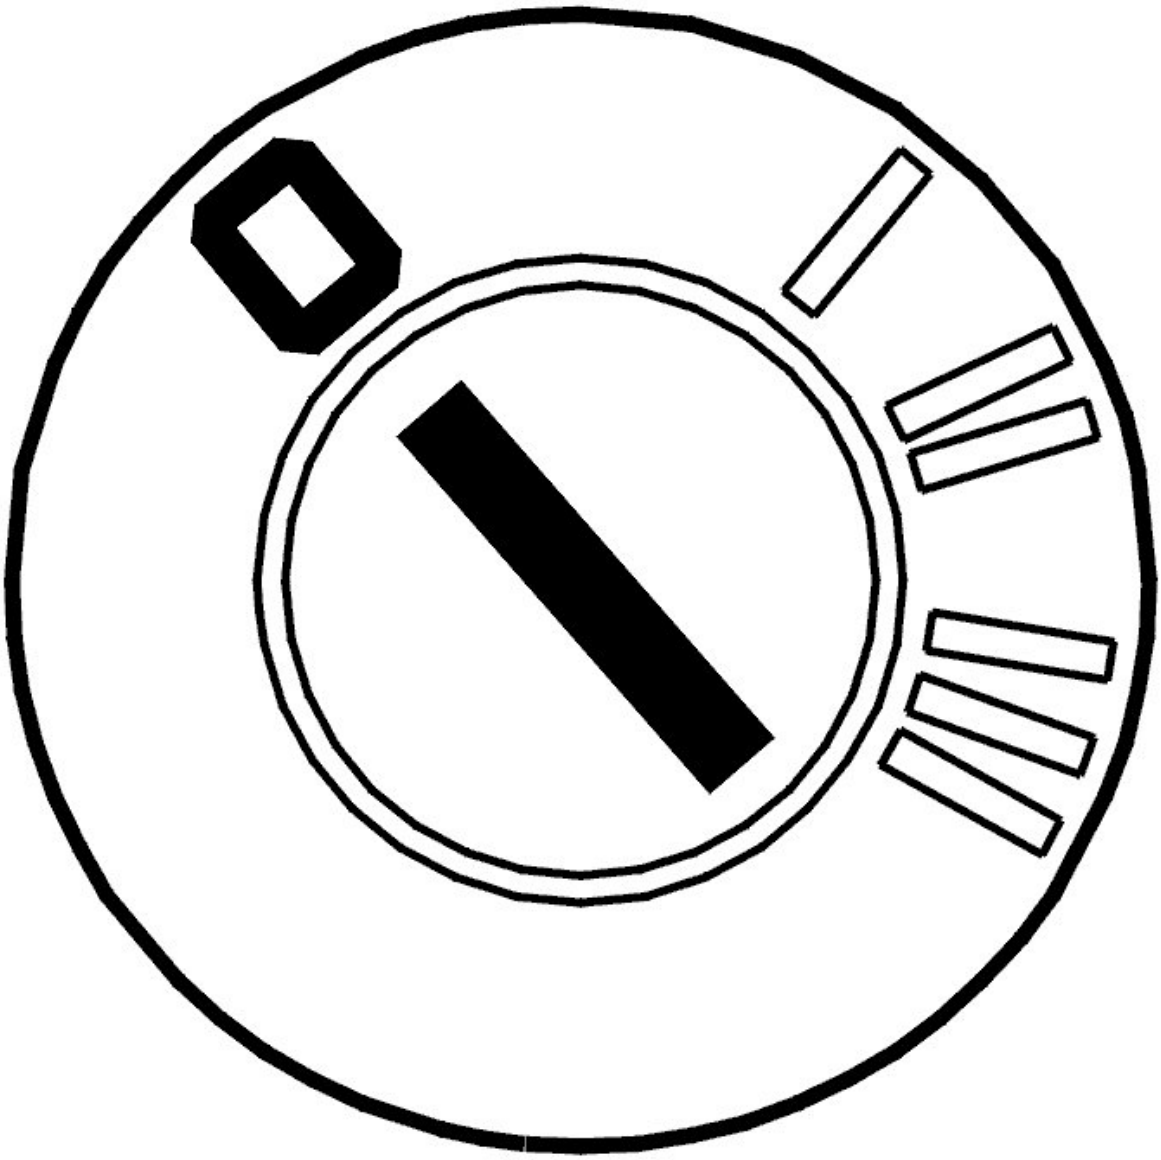
Do any symptoms persist?

Yes - Replacement of control unit and programming

No - Intermittent fault

Replacement of control unit and programming

Note! Before replacing the control unit all the program data should be read from the control unit if possible.



- Ignition off.

The upper electronic module has registered an internal fault.
There is a design fault and the control unit should be replaced.

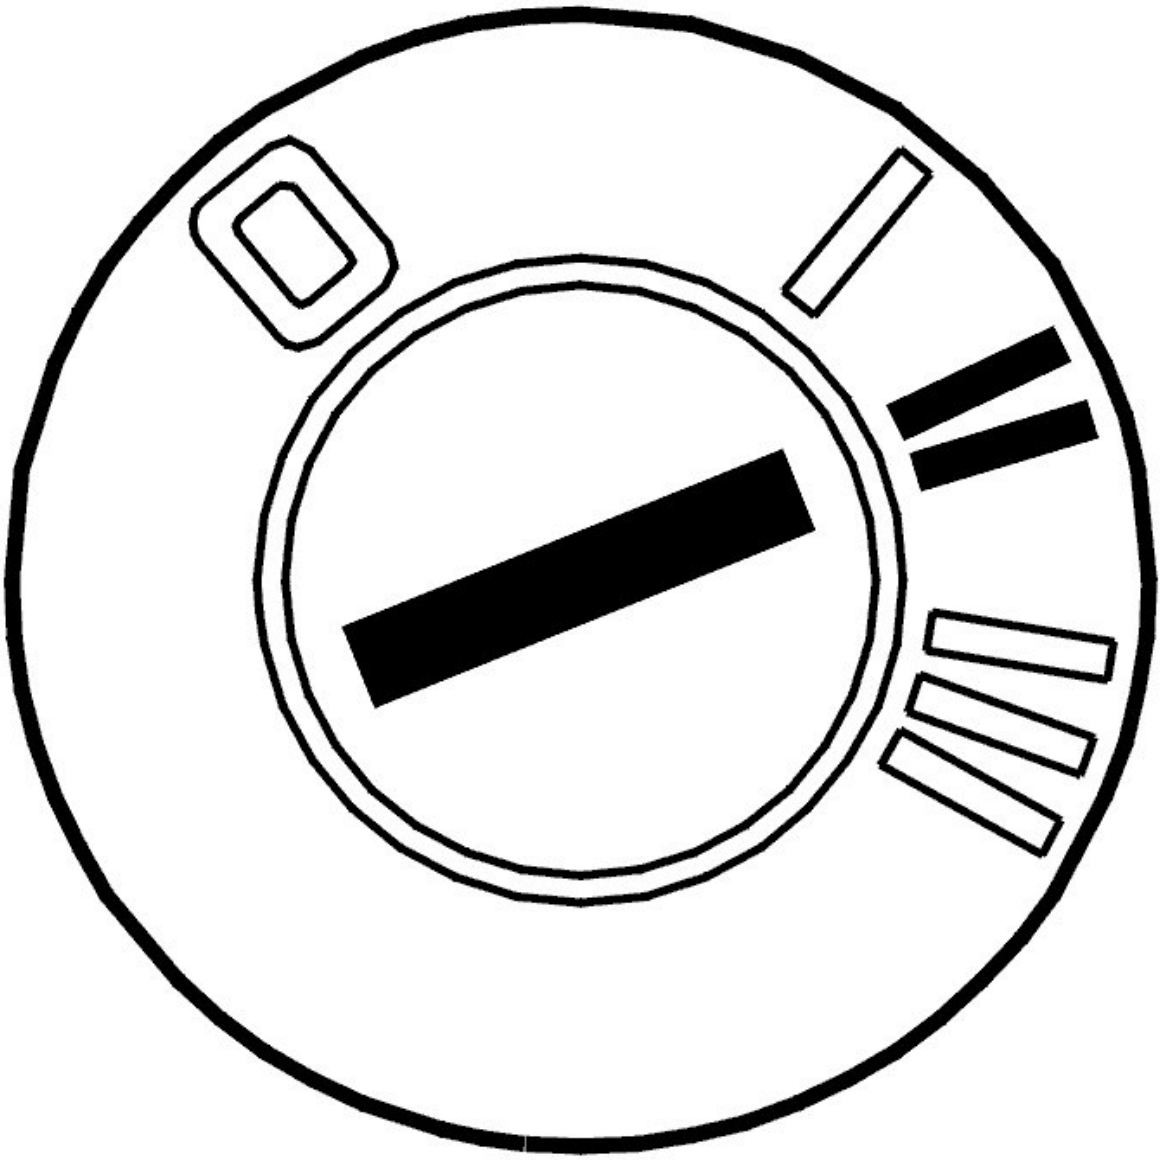
Continue - Replacement of the control unit

Replacement of the control unit

Replacing the control module

Reading off the programmed values

Note! Read off the programmed values from the upper electronic module (UEM) before replacing the control module.



- Ignition on
- Click on the symbol for VCT2000 to read off the programmed values.

The retained values are programmed customer parameters in the upper electronic module (UEM). The retained values should be noted for later use.

Other information

- For information about programming the customer parameters, see Diagnostic functions See: Body and Frame/Body Control Systems/Description and Operation/Upper Electronic Module (UEM)/Diagnostic Functions.

Continue - Replacing control modules and downloading software

---

Replacing control modules and downloading software

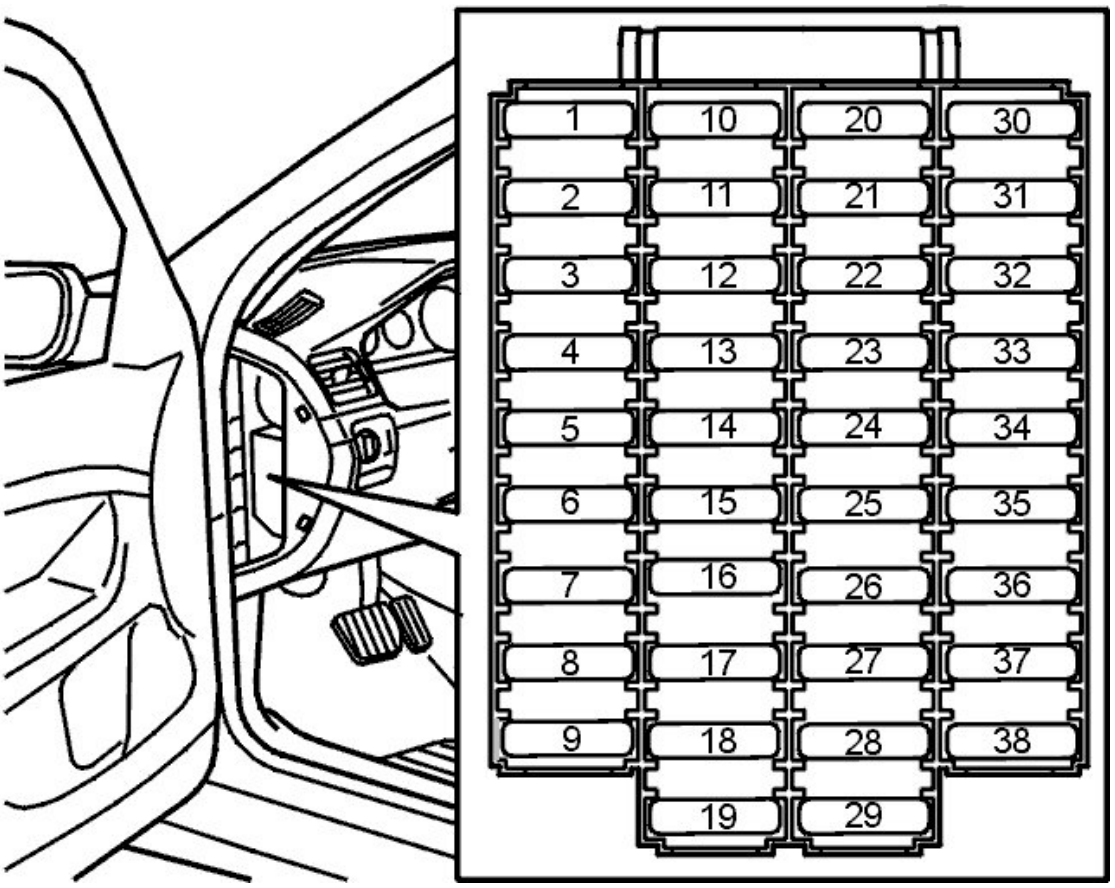
Caution! A new control module is delivered without software. In order for the control module to function new software must be programmed into the control module after it has been replaced.

Replace the control module and download the new software. See Upper electronic module (UEM) rear view / door mirror, replacing See: Body Control Module/Service and Repair.

Hint: When diagnostic trouble code (DTC) E001 is stored, communication with the control module cannot be established. This can be remedied in two ways.

1. Press the remote control button for local lighting

2. Remove fuse 11C/28 from the fusebox in the passenger compartment. Reinstall the fuse again.



Continue - Checking the interior lighting

Checking the interior lighting

Checking the interior lighting (2)

Checking the interior lighting

Two times can be programmed for the interior lighting:

1. Short

- The period from when the door is unlocked, or the engine stops, to when the interior lighting goes out can be changed if it is too long or too short.

2. Long

- The period from when the door is opened, or a lamp is lit with a switch, to when the lamp goes out can be changed if it is too long or too short.

To program a long interior lighting period you must step ("click") through the short interior lighting period programming.

Continue - Programming a short interior lighting period

Programming a short interior lighting period

The general lighting and rear reading lamps light and remain lit for 30 seconds when:

- The door has been unlocked from outside with a key or the remote control.
- The engine has been stopped and the ignition key turned to 0.

The default period is 30 seconds. This can be changed to between 5 and 255 seconds.
Read off the programmed values.
To change the time, mark the desired value in the scrolling list and start programming.

Do you want to program any more parameters?

Yes - Programming a long interior lighting period

No - Fault Found

Programming a long interior lighting period

The general lighting and rear reading lamps light and remain lit for 10 minutes when:
- A door is opened after being unlocked.
- The lamp is lit with a switch.

The default period is 10 minutes. This can be changed to between 0 and 255 minutes at 10 minute intervals.
Read off the programmed values.
To change the time, mark the desired value in the scrolling list and start programming.

Continue - Fault Found

FAULT FOUND - Checking the anti-dazzle function in the rear view mirror

---

Checking the anti-dazzle function in the rear view mirror

Checking the anti-dazzle function in the rear view mirror

Checking the anti-dazzle function

Note! If the upper electronic module (UEM) has been replaced software, specially developed for downloading after replacing the control module, must be downloaded to the control module before the anti-dazzle function is changed. See Upper electronic module (UEM) rear view / door mirror, replacing See: Body Control Module/Service and Repair.

The rear view mirror anti-dazzle function can be adjusted:
- If the rear view mirror anti-dazzle function is too powerful or too weak, it can be adjusted.

Specific software for setting the anti-dazzle function must be installed in the car to do this.
Order the software. See9499432.
Install the software. See9499432.

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code information

Condition

If the control unit registers an internal fault in the sunroof module (SRM), the diagnostic trouble code is displayed.

Substitute value
- Nothing.

Possible source
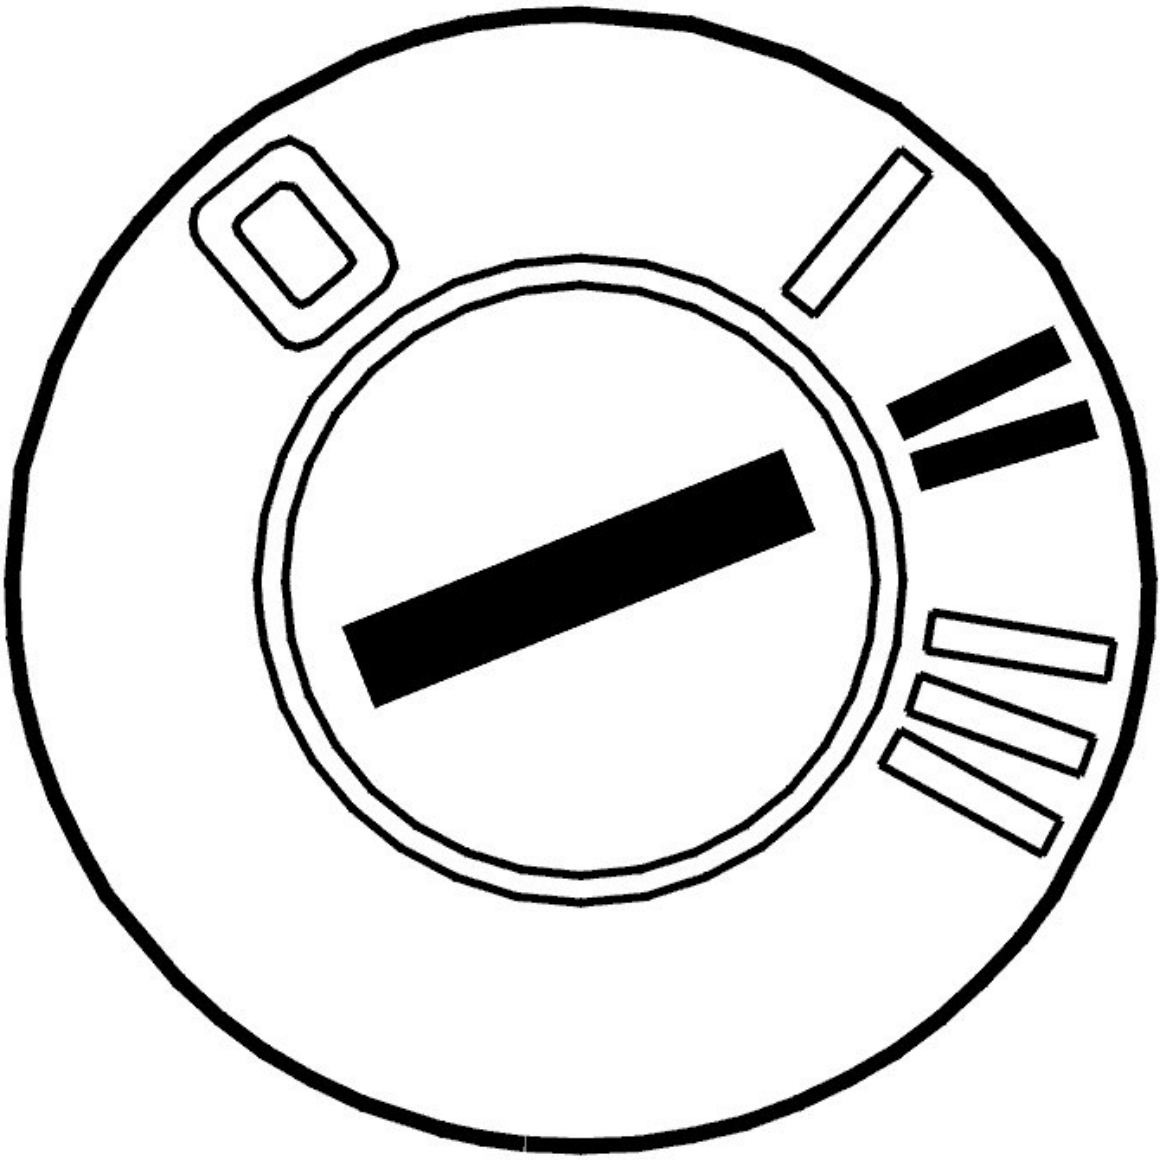
- The signals for AUTO and TILT occur at the same time.

Fault symptom[s]
- Electric sunroof does not work.

Faulty Signal

Faulty signal

Checking for permanent or intermittent faults



- Ignition on.

Check that the sun roof can be moved to its limit positions.

Can the sun roof be operated?

Yes - Intermittent fault

No - Checking for a short-circuit

Checking for a short-circuit

Check the cable between the sun roof module (SRM) and the roof lamp module. Check for a short-circuit to supply voltage.

UEM-0070 Sun roof. Faulty signal

The sun roof module (SRM) terminal #3A and roof lamp module terminal #2B.

UEM-0070 Sun roof. Faulty signal

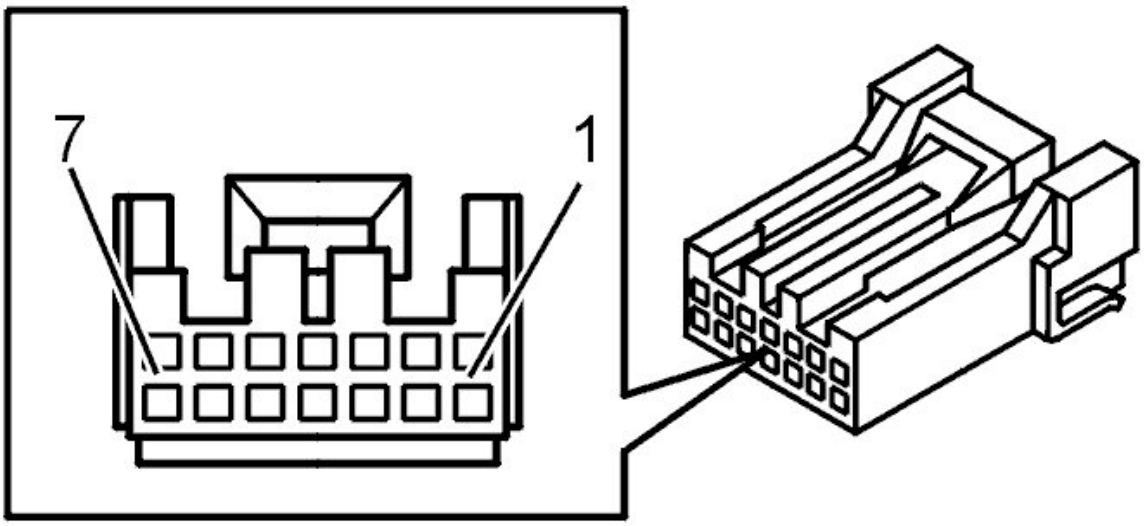
The sun roof module (SRM) terminal #7A and roof lamp module terminal #1B.
Replace the cable if a fault is found.

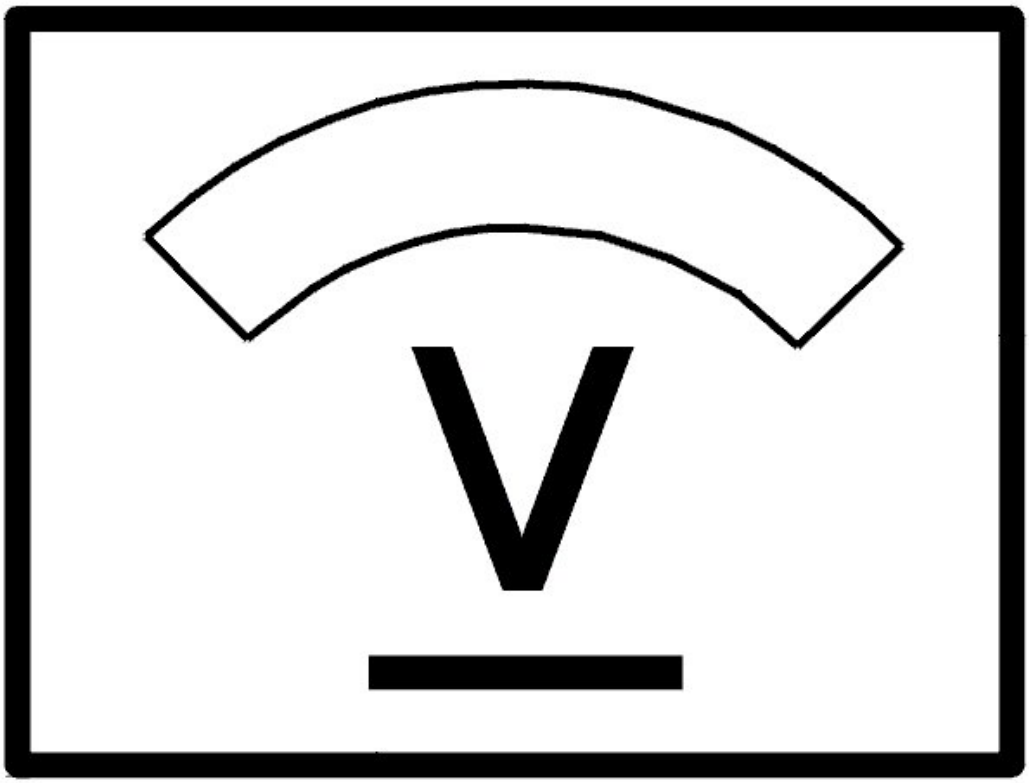
Other information:

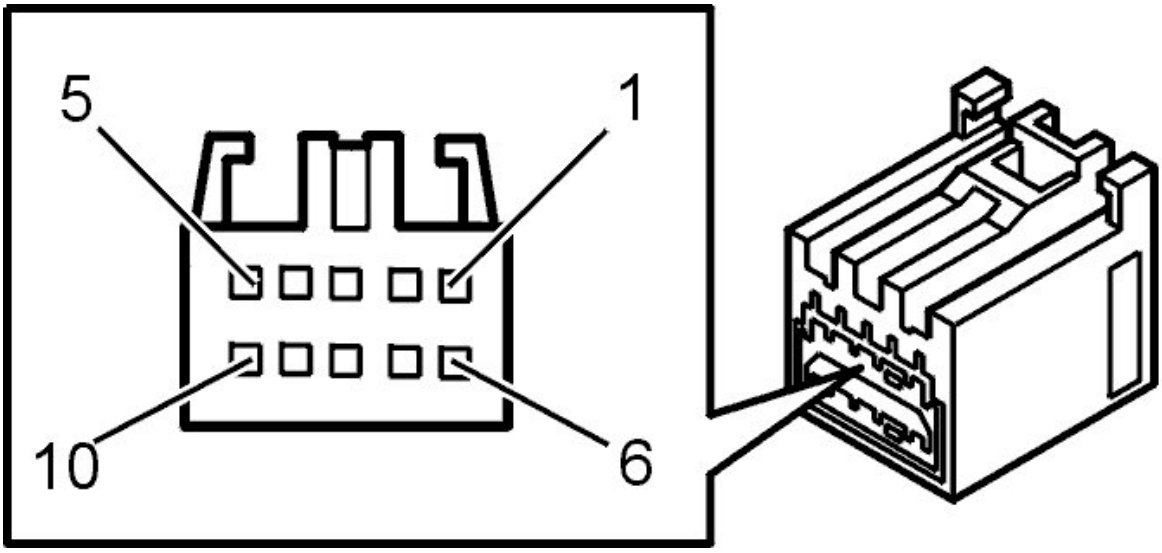
- For further information about signals and other values, see Signal specification See: Body and Frame/Body Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Description / Specification/Signal Specification, Upper Electronic Module (UEM)
- To access the roof lamp module connector, see Replacing interior lighting See: Lighting and Horns/Dome Lamp/Service and Repair
- To access the sun roof module (SRM) connector, see Sun roof module (SRM), replacing See: Body and Frame/Relays and Modules - Body

and Frame/Sunroof / Moonroof Module/Service and Repair

- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals.







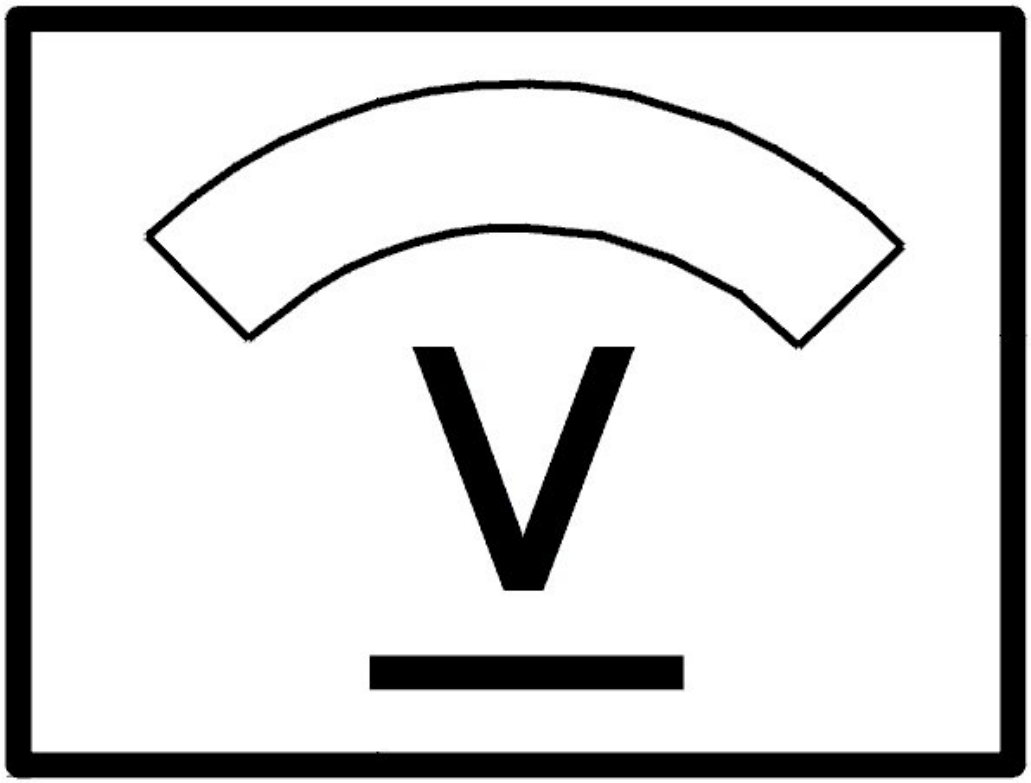
Continue - Checking the cable

Checking the cable

Check the wiring between the sun roof switch and the roof lamp module. Check for a short-circuit to supply voltage.

Other information:

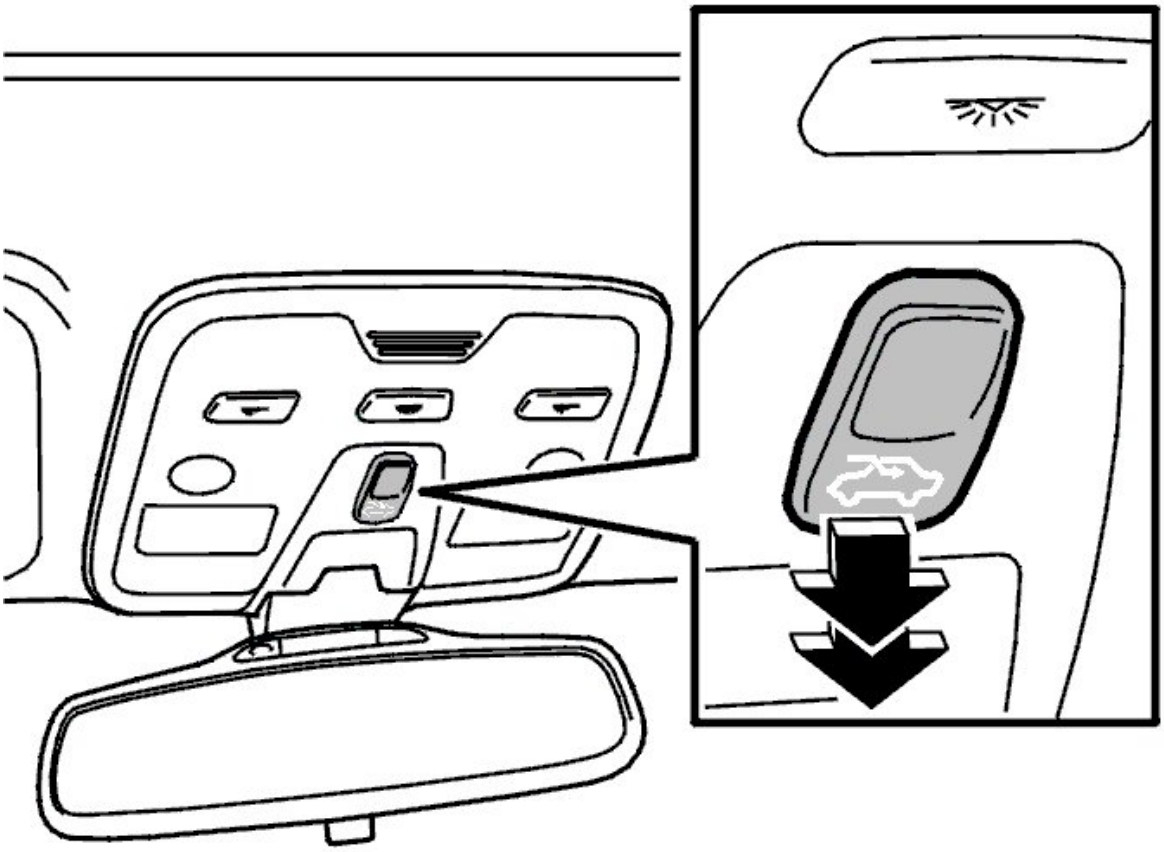
- For further information about signals and other values, see Signal specification See: Body and Frame/Body Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Description / Specification/Signal Specification, Upper Electronic Module (UEM)
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals.



Continue - Replacing the component

Replacing the component

Visually check for damage to the roof lamp module and its switches.
If no fault is found replace the sun roof switch. See Switch sun roof, replacing See: Body and Frame/Roof and Associated Components/Sunroof / Moonroof/Sunroof / Moonroof Switch/Service and Repair.



Continue - Verification

Intermittent fault

Check the connector on the sun roof module (SRM) and the connector on the roof lamp module. Check for contact resistance and oxidation. Check for loose connections.
Check the cable between the sun roof module (SRM) and the roof lamp module. Check for an intermittent short-circuit to supply voltage. Check for an intermittent open-circuit.

UEM-0070 Sun roof. Faulty signal

The sun roof module (SRM) terminal #3A and roof lamp module terminal #2B.

UEM-0070 Sun roof. Faulty signal

The sun roof module (SRM) terminal #7A and roof lamp module terminal #1B.
Check the wiring between sun roof switch and RCM. Check for an intermittent short-circuit to supply voltage.
If no fault is found replace the sun roof switch. See Switch sun roof, replacing See: Body and Frame/Roof and Associated Components/Sunroof / Moonroof/Sunroof / Moonroof Switch/Service and Repair.

Other information:

- For further information about signals and other values, see Signal specification See: Body and Frame/Body Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Description / Specification/Signal Specification, Upper Electronic Module (UEM)

Diagnostic Trouble Code (DTC) Information

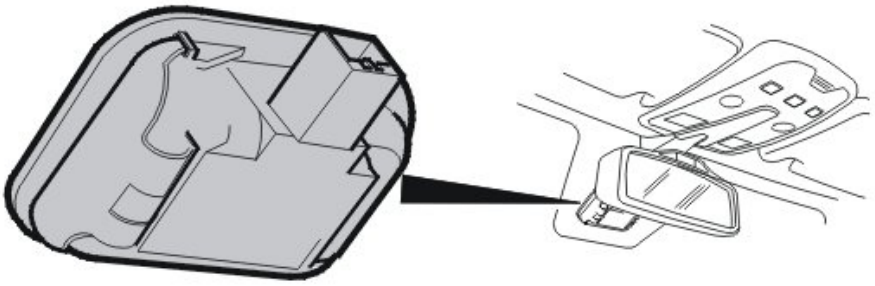
Diagnostic trouble code (DTC) information UEM-0080

Condition



The upper electronic module (UEM) regularly checks the communication with the rain sensor module (RSM).
A diagnostic trouble code (DTC) is stored If the rain sensor module (RSM) does not respond to a request from the upper electronic module (UEM).
The diagnostic trouble code (DTC) can be diagnosed 20 seconds after the ignition is switched on. Diagnostic trouble code (DTC) UEM-0080 is not stored if UEM-0081 or UEM-0082 is stored.

Substitute value
- Intermittent windshield wipers
- The windshield wipers operate at high speed.

Possible source
- Open-circuit in the power supply cable for the rain sensor
- Short-circuit to ground in the power supply cable for the rain sensor
- Open-circuit, short-circuit to ground or supply voltage in the data cable for the rain sensor
- Open-circuit or short-circuit to supply in the ground lead for the rain sensor
- Contact fault on the sensor side and/or control module side
- Defective rain sensor
- Defective control module.

Fault symptom[s]
- No rain sensor function.

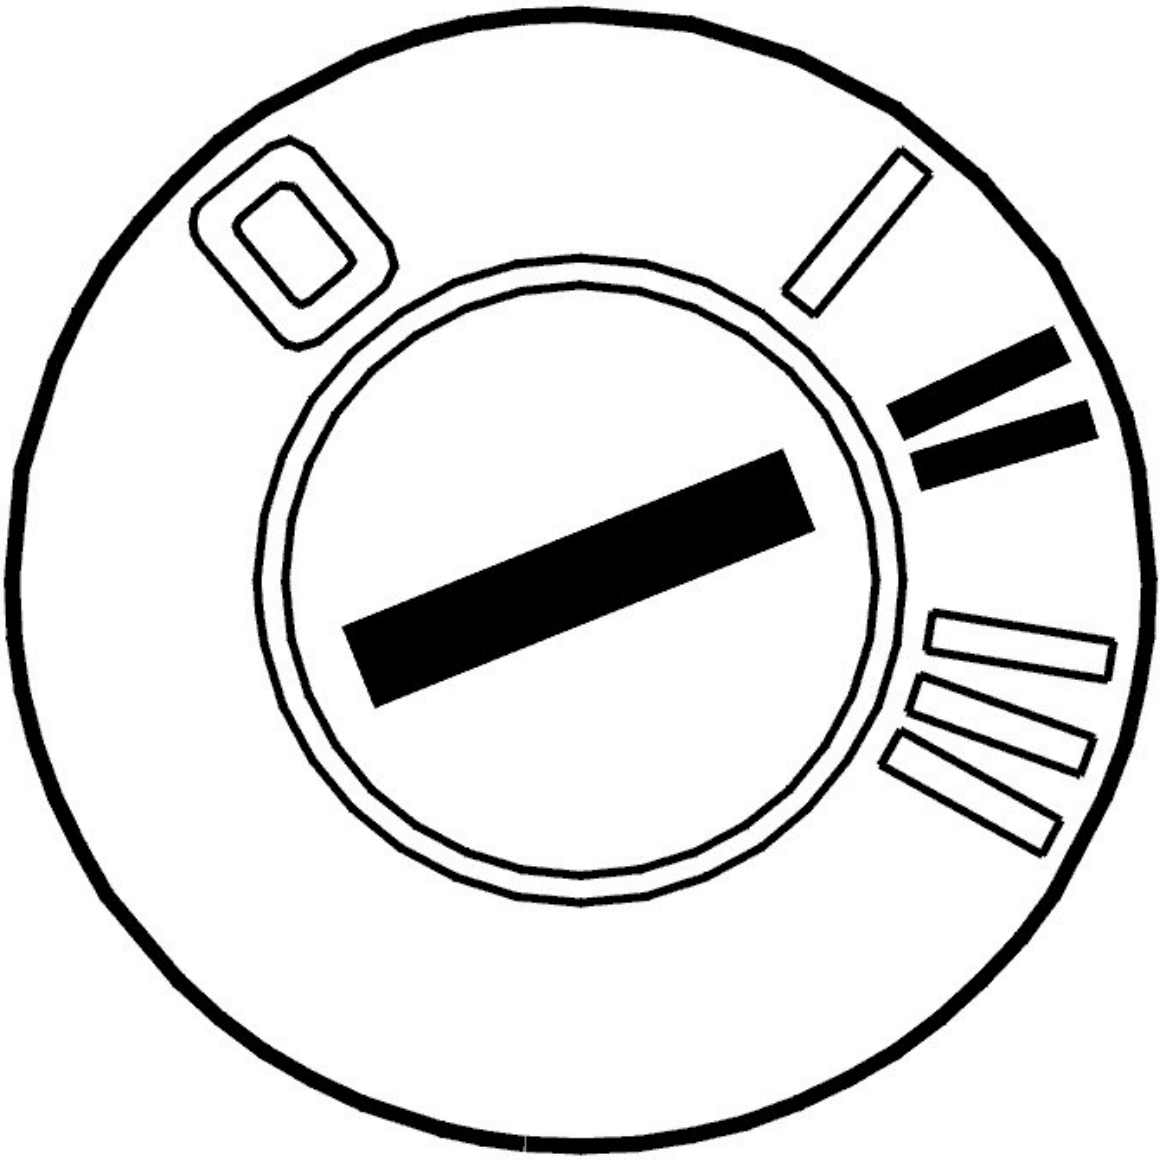
Signal Missing

Signal missing

Checking the function

Checking the rain sensor

Checking the function



- Ignition on
- Activate the rain sensor.

Hint: The wiper blades make a reference stroke to determine the cleanliness and condition of the windshield when the rain sensor is activated. The rain sensor is deactivated when the ignition is switched off. To reactivate the rain sensor with the ignition on, move the stalk to position "0" and then to intermittent wiping.

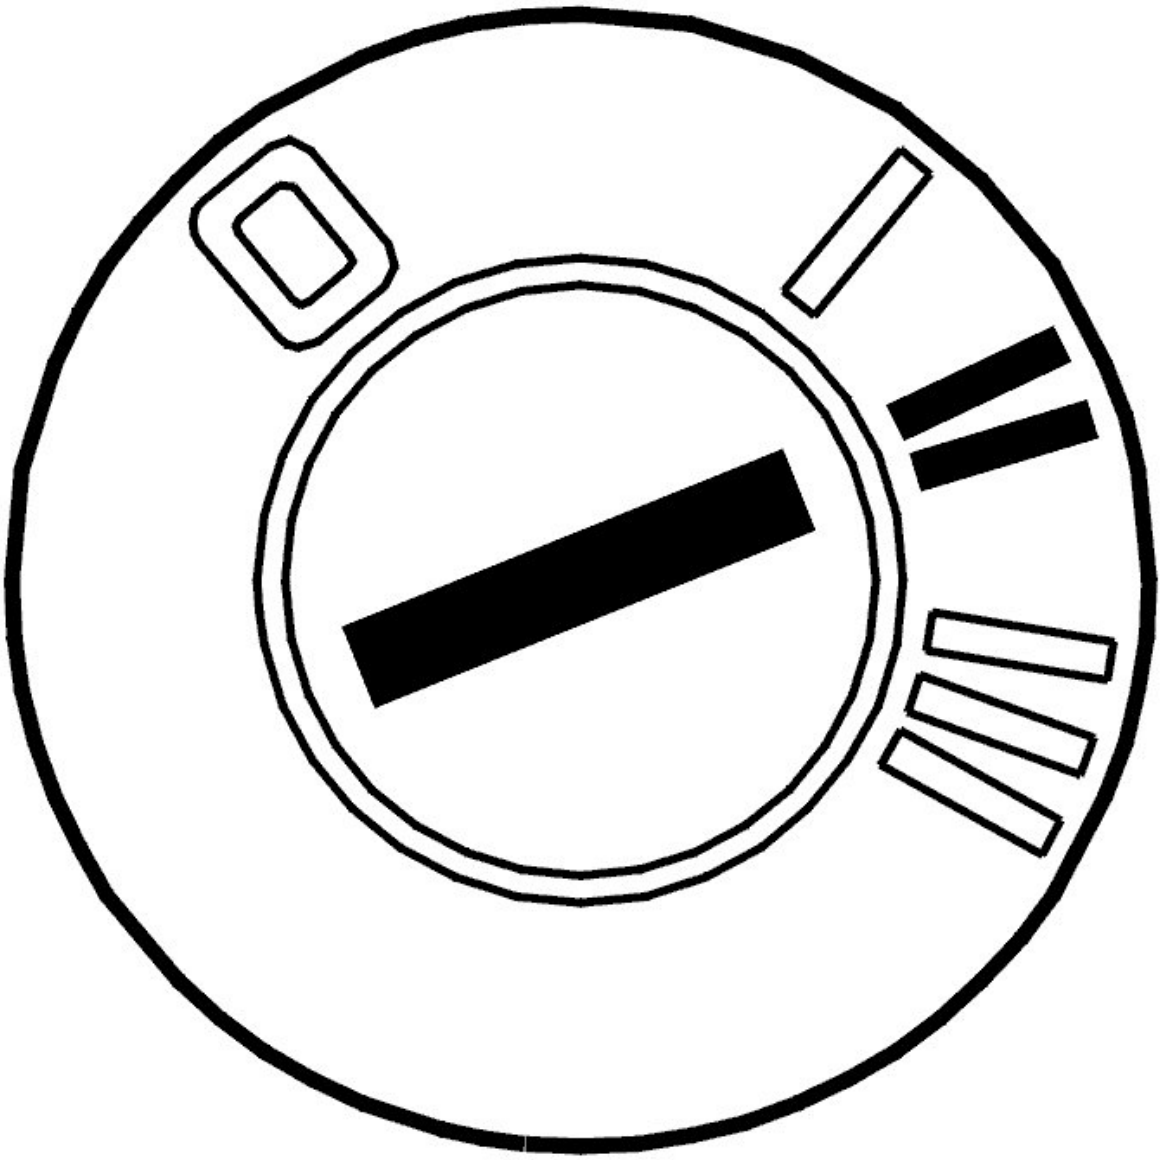
Spray water on the windshield where the rain sensor is positioned.
The wiper blades must now wipe the windshield clean.

Hint: In cars equipped with the rain sensor it replaces the intermittent function. One way of checking the function of the rain sensor is to twist the collar on the lever. This changes the sensitivity of the rain sensor. The windshield wiper should make one stroke. If the intermittent or high speed functions are activated it indicates that the rain sensor function is missing.

Continue - ANOTHER TEST

ANOTHER TEST - Checking the supply to the rain sensor

Checking the supply to the rain sensor



- A number of measurements are required to check the wiring for the rain sensor. Measurements should be carried out on the wiring connector with the rain sensor disconnected. The terminals correspond to ground, voltage and data cables. The data cable is connected to terminal #1 on the rain sensor, terminal #2 is the ground cable and terminal #3 is the power supply for the rain sensor
- Move the windshield wiper stalk to position "0".
- Ignition off
- Disconnect the rain sensor
- Ignition on.

Check the voltage level between the voltage terminal #3 and ground terminal #2 of the wiring.

Hint: The voltage must be 12V.

Other information:

- For further information about signals and other values, see Signal specification See: Body and Frame/Body Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Description / Specification/Signal Specification, Upper Electronic Module (UEM)
- Rain sensor See: Sensors and Switches/Sensors and Switches - Wiper and Washer Systems/Rain Sensor/Service and Repair

Exit fault-tracing for this diagnostic trouble code (DTC) or make another attempt.

Do you want to exit fault-tracing?

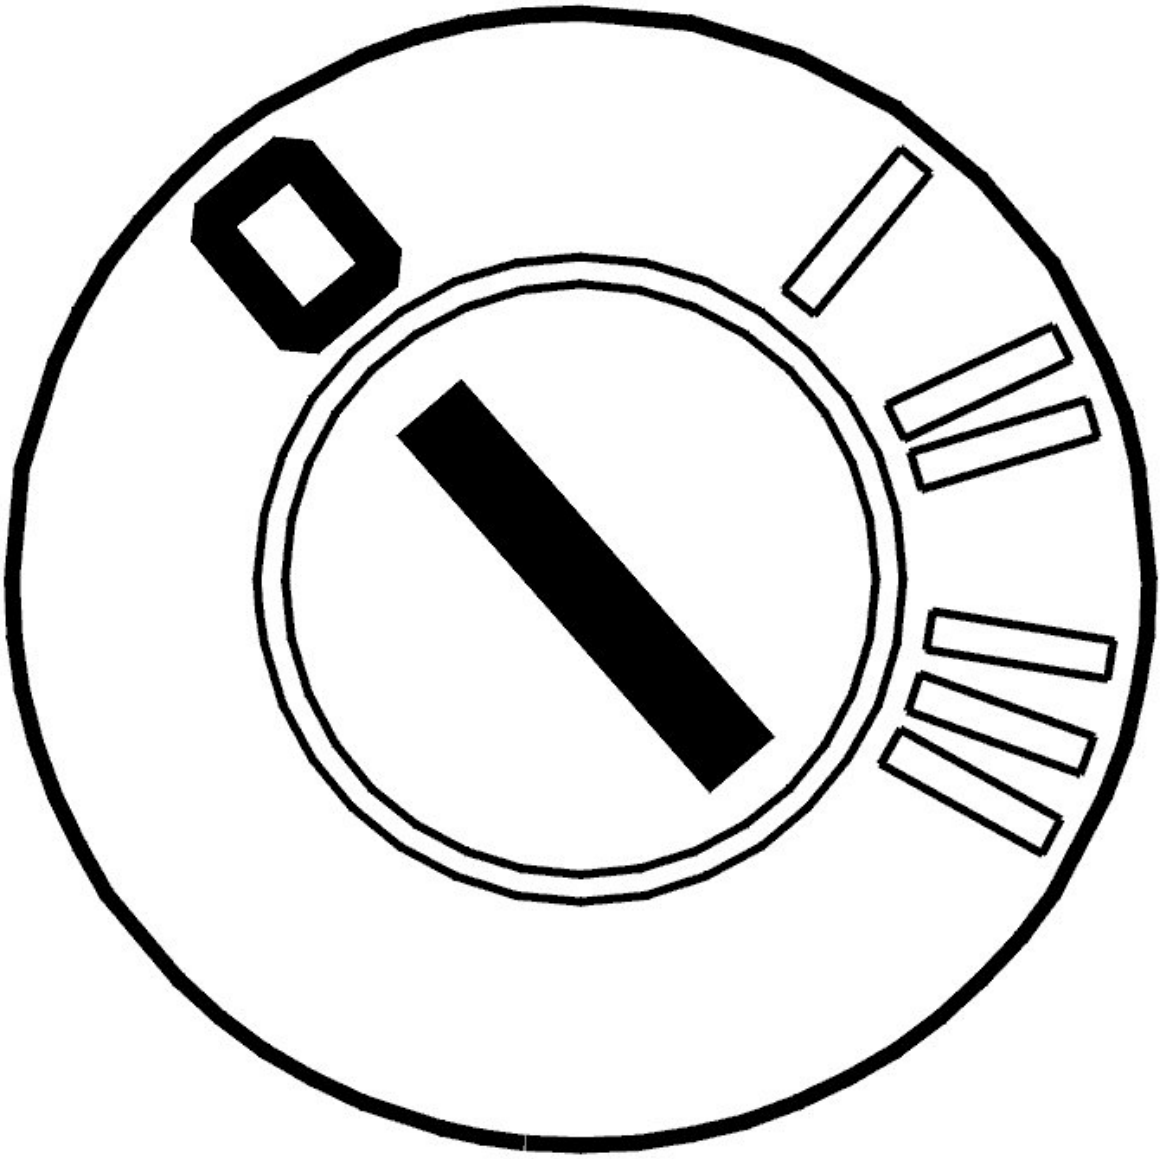
Yes - FAULT-TRACING FAILED

No - Attempt New Test

Attempt New Test - Checking the function

FAULT-TRACING FAILED - No Fault Found

Checking the data cable



Hint: The wiring between upper electronic module (UEM) and the rain sensor consists of two cables.

The upper electronic module (UEM) transmits pulses to the rain sensor using the data cable.
Disconnect the rain sensor.
Check that the data is transmitted on the data cable terminal #1 by checking the voltage level between the data and ground cables for the wiring (that is terminals #1 and #2).

Hint: Use the oscilloscope function and check that a pulsed signal is transmitted. The difference between the high and low values of the pulses is

approximately 12 V. In the event of an open-circuit in the data cable no pulses are transmitted and a continuous voltage is displayed.

If the difference between high and low values of the pulses is between 2 V and 10 V it indicates that the wiring is oxidized or trapped. Replace the wiring between the rain sensor and the roof wiring in the event of a fault.
If no other fault is found try replacing the rain sensor.
Remedy as necessary.

Other information:

- To access or replace the control module, see Upper electronic module (UEM) rear view / door mirror, replacing See: Body Control Module/Service and Repair
- Rain sensor See: Sensors and Switches/Sensors and Switches - Wiper and Washer Systems/Rain Sensor/Service and Repair
- For further information about signals and other values, see Signal specification See: Body and Frame/Body Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Description / Specification/Signal Specification, Upper Electronic Module (UEM)

Diagnostic Trouble Code (DTC) Information

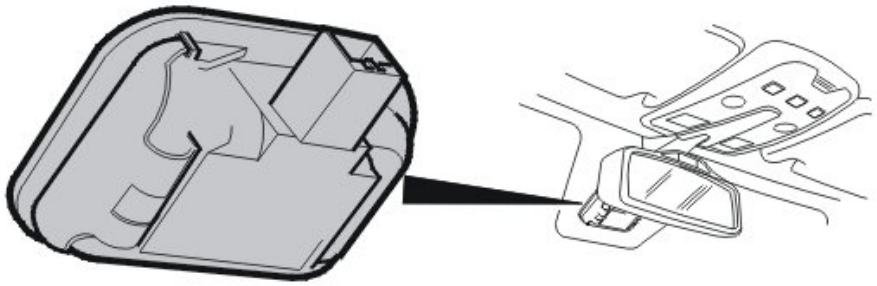
Diagnostic trouble code (DTC) information UEM-0083

Condition



The rain sensor checks itself at start.
The rain sensor checks factors such as reflections on the windshield.
The diagnostic trouble code (DTC) is stored if the rain sensor registers incorrect function.
The diagnostic trouble code (DTC) can be diagnosed with the ignition on and with an outside temperature above + 5 °C (41°F).

Note! On early model years, this diagnostic trouble code (DTC) may be stored if for example there was frost on the window when the check was run. In this case, it does not help to replace any components. Fault-trace the function of the rain sensor before replacing any components.

Substitute value
- Intermittent windshield wipers
- The windshield wipers operate at high speed.

Possible source
- Frost on the windshield during the check
- Crack in the windshield by the rain sensor
- Stone chip on the windshield close to the rain sensor
- The rain sensor is not properly secured to the windshield
- Defective rain sensor.

Fault symptom[s]
- No rain sensor function.

The upper electronic module (UEM) regularly checks communication with the rain sensor.
The diagnostic trouble code (DTC) is generated if the upper electronic module or the rain sensor registers a fault in communication.
The diagnostic trouble code can be diagnosed when the ignition is on.

Substitute value
- Intermittent windshield wiping.
- High speed windshield wiping.

Possible source
- Contact resistance or oxidation on the signal cable.
- Communication disrupted.
- Faulty rain sensor.

Fault symptom[s]
- No rain sensor function.

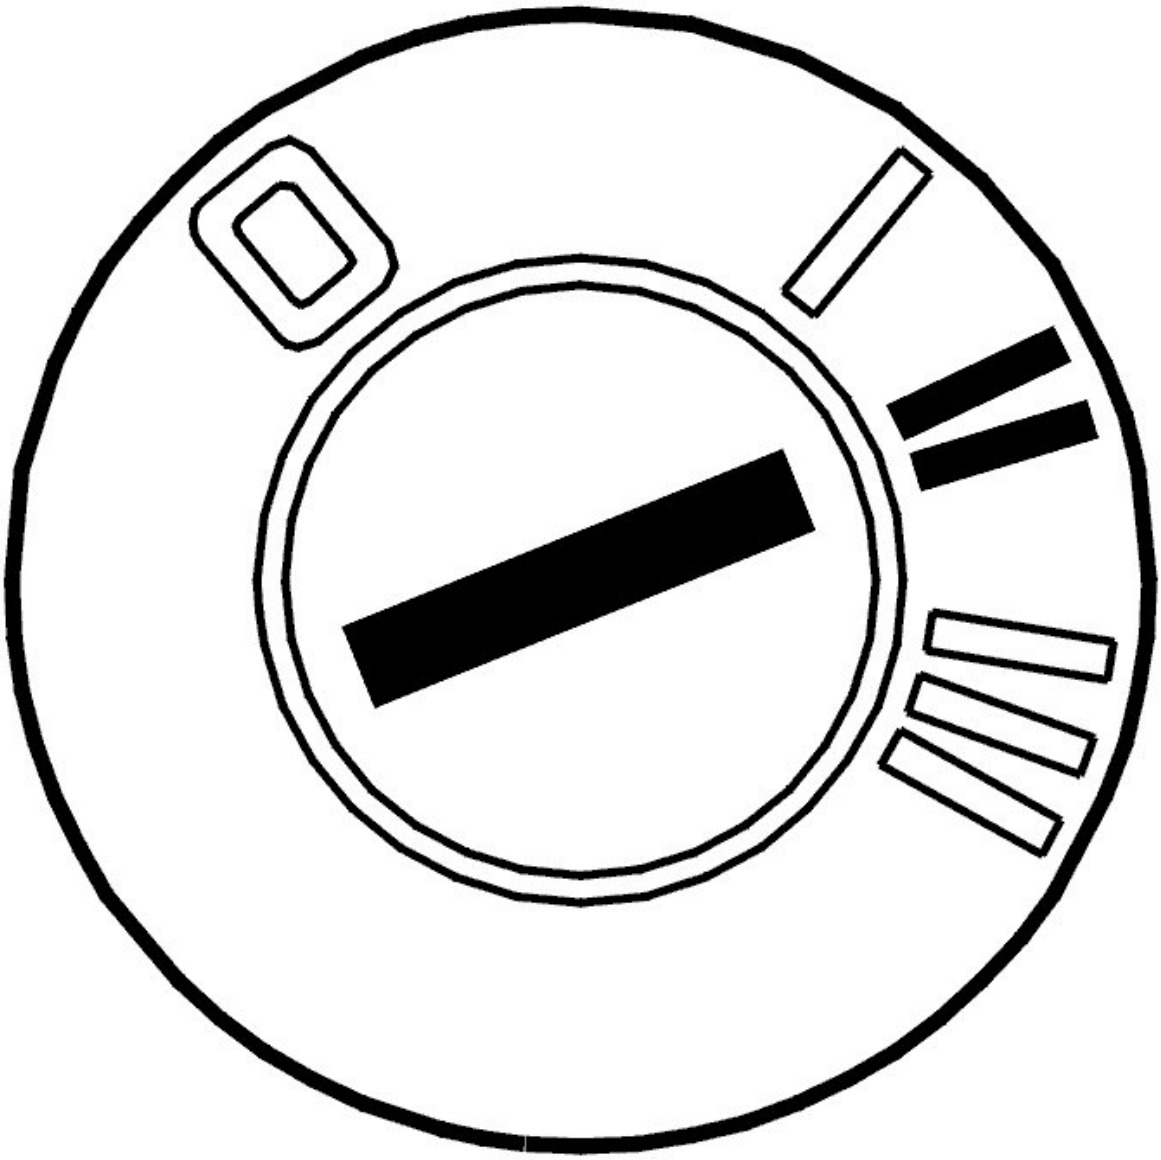
Faulty Signal

Faulty signal

Checking the function

Checking the rain sensor

Checking the function



- Ignition on
- Activate the rain sensor.

Hint: The wiper blades make a reference stroke to determine the cleanliness and condition of the windshield when the rain sensor is activated. The rain sensor is deactivated when the ignition is switched off. To reactivate the rain sensor with the ignition on, move the stalk to position "0" and then to intermittent wiping.

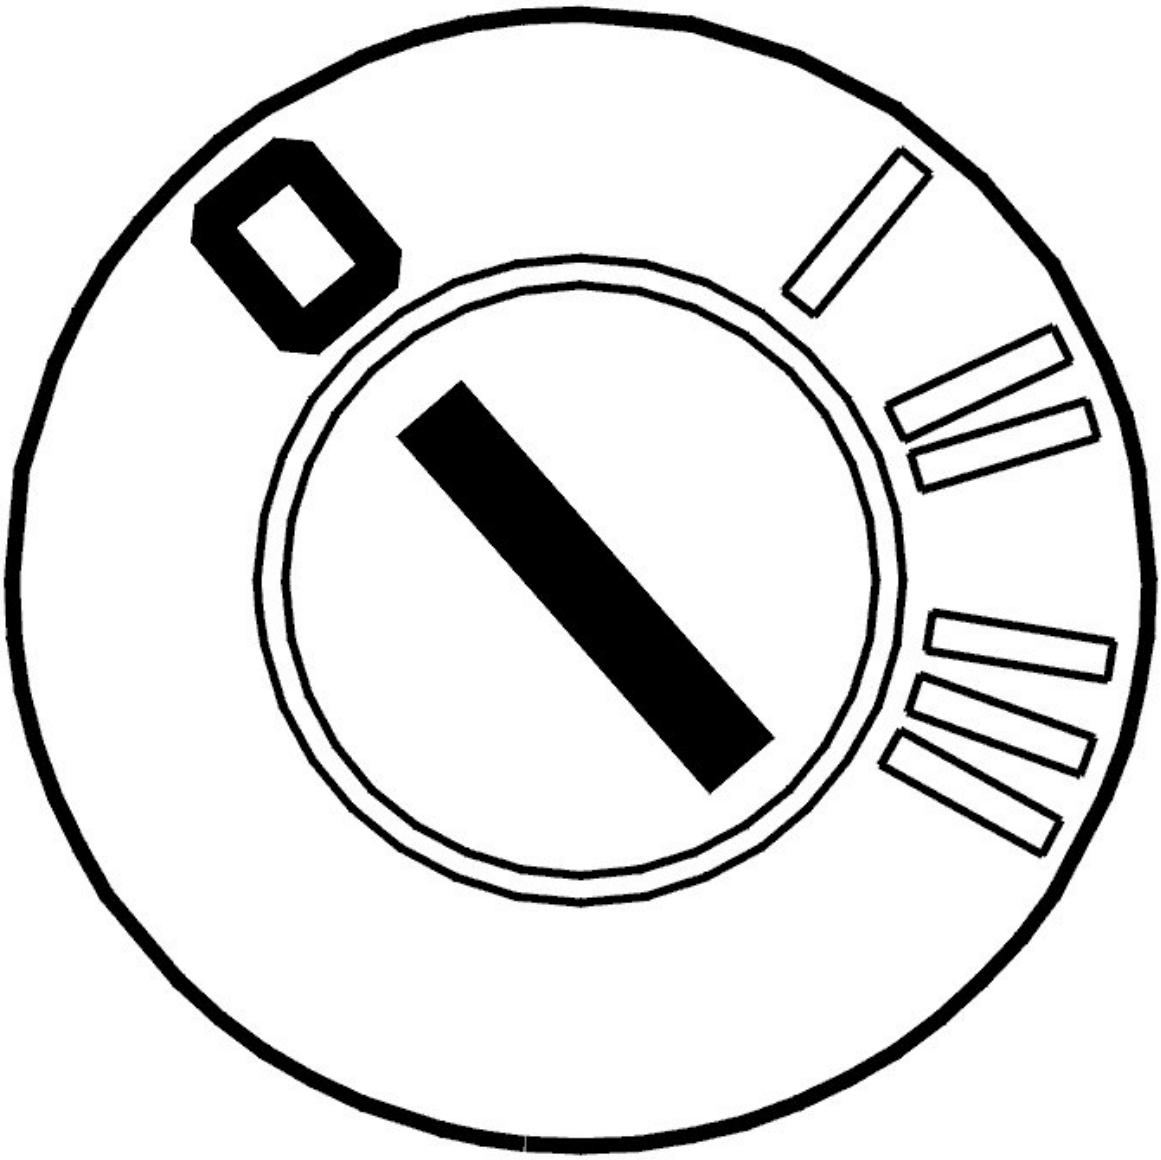
Spray water on the windshield where the rain sensor is positioned.
The wiper blades must now wipe the windshield clean.

Hint: In cars equipped with the rain sensor it replaces the intermittent function. One way of checking the function of the rain sensor is to twist the collar on the lever. This changes the sensitivity of the rain sensor. The windshield wiper should make one stroke. If the intermittent or high speed functions are activated it indicates that the rain sensor function is missing.

Continue - ANOTHER TEST

ANOTHER TEST - Checking the wiring

Checking the wiring



- Ignition off.

Check the connectors for the upper electronic module (UEM) and rain sensor. Check for contact resistance and oxidation.
Also check the rain sensor and GSM antenna wiring (if applicable). Ensure that there are no sources of interference nearby.
Remedy as necessary.

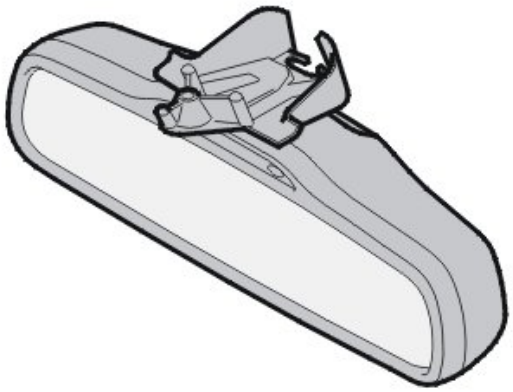
FAULT-TRACING FAILED - No Fault Found

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information UEM-0090

Condition



The upper electronic module (UEM) checks the power supply to the LED for the PAD lamp (Passenger Airbag Deactivated). The LED is integrated in the rear view mirror.
The diagnostic trouble code (DTC) is stored if the upper electronic module (UEM) registers that the power supply signal to the PAD lamp is too low.
The diagnostic trouble code (DTC) can be diagnosed when the LEDs in the rear view mirror are supplied with power, i.e. when the LEDs in the display satisfy conditions for lighting.

Substitute value
- None.

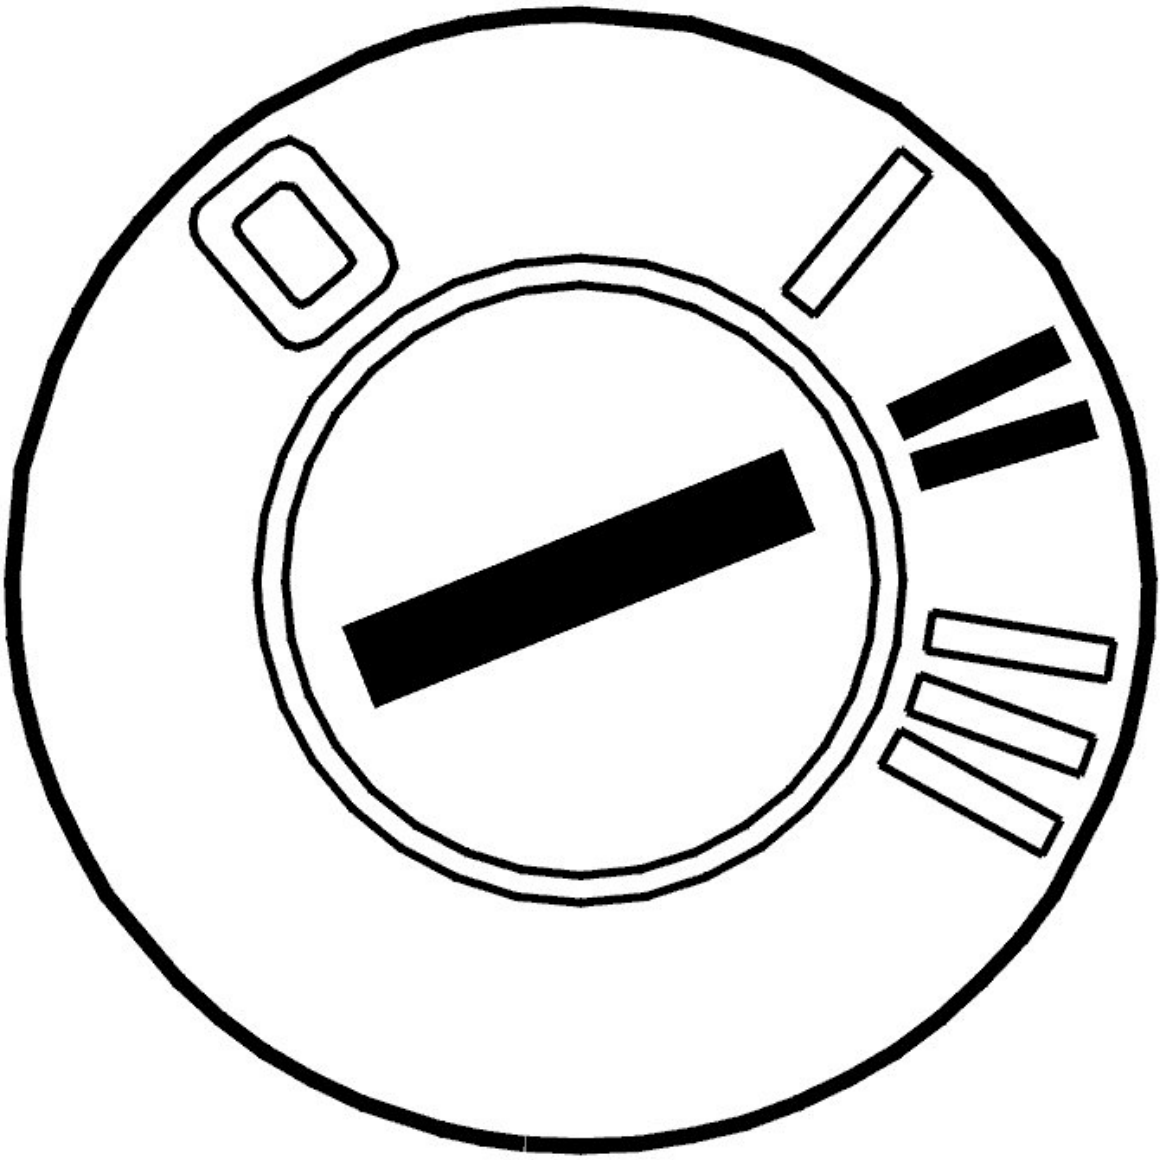
Possible source
- Defective upper electronic module (UEM) (internal fault).

Fault symptom[s]
- The SRS indicator lamp is lit.
- Message in the display.

Signal Too Low

Signal too low

Checking the PAD-light



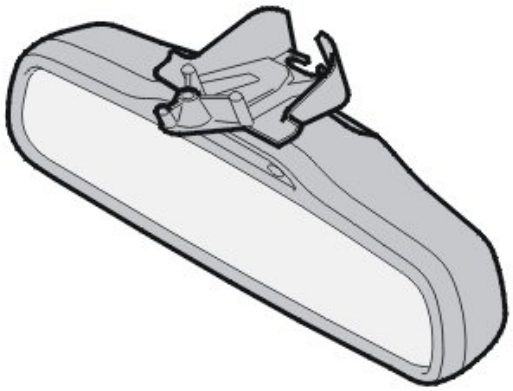
- Ignition off.
- Read off by clicking the VCT2000 symbol.
- Turn the ignition key to position I.
- Check that the requested status from the Supplemental restraint system module (SRS) is ON and that the status of the PAD lamp in the Upper electronic module (UEM) is ON when the lamp is lit. Also check if the Passenger airbag warning lamp (PAD) comes on after the ignition is switched on.

If the requested status from the Supplemental restraint system module (SRS) is ON, the Upper electronic module (UEM) has activated the lamp (status is ON) but the lamp does not come on, the lamp is probably broken. Replace the upper electronic module (UEM). Check that new hardware has the correct P/N.

If the requested status from the Supplemental restraint system module (SRS) is ON, but the Upper electronic module (UEM) has not activated the lamp (status is OFF), check DTCs for errors in CAN communication in the Central electronic module (CEM). Also check the CAN cables between the Upper electronic module (UEM) and the Supplemental restraint system module (SRS). Remedy as necessary.

Other information

- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

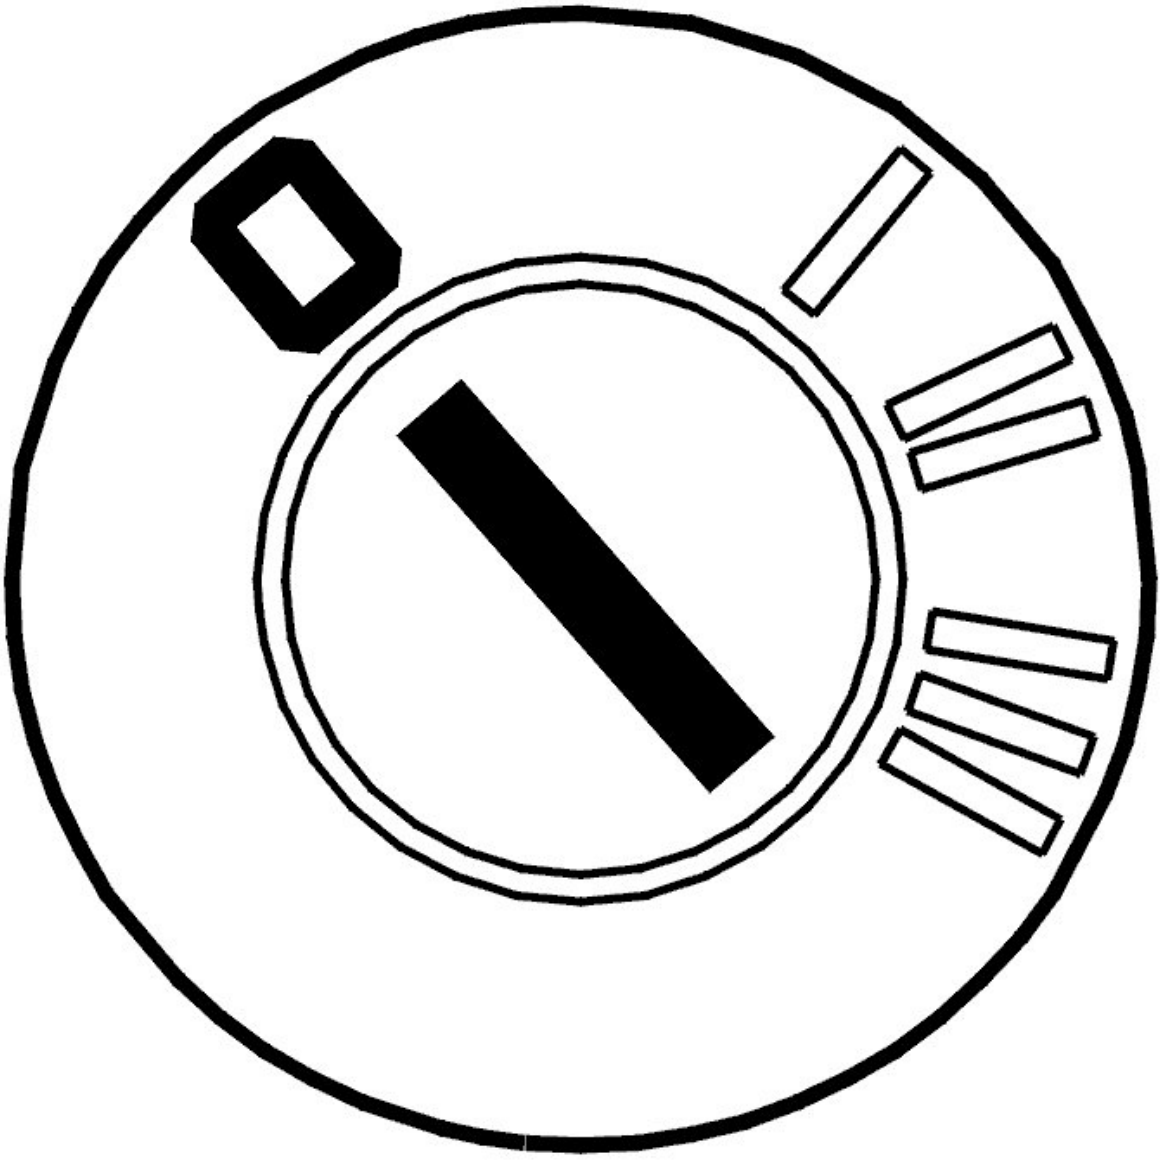


Is the function OK?

Yes - No Fault Found

No - Replacing control module and programming

Replacing control module and programming



- Ignition off.

The LED for the PAD lamp is mounted internally in the rear view mirror and cannot be replaced. Check there are no indications that the power supply to the upper electronic module (UEM) is faulty. Check that the fault in the LED remains after the power is switched off and on again. If the fault remains, the upper electronic module (UEM) must be replaced.

Note! If possible, read off the programmed data from the control module before it is replaced. This should be done as this information is not stored in Volvo's central database. Switch off the ignition before replacing the control module.

Continue - Replacing the control module

Diagnostic Trouble Code (DTC) Information

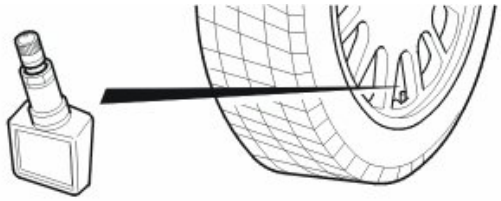
Diagnostic trouble code (DTC) information UEM-00A0

Condition



The upper electronic module (UEM) receives information transmitted by the tire pressure sensors in the wheels, irrespective of the car. The sensors which are registered in the vehicle can be checked by running a statistical selection. A list can then be stored internally in the upper electronic module (UEM).
The diagnostic trouble code (DTC) is stored if the upper electronic module (UEM) registers that the signal from the first of the four accepted sensors disappears whilst the vehicle is being driven.
The diagnostic trouble code (DTC) can be diagnosed after 10 minutes when the tire pressure warning system is active (vehicle speed is above 40 km/h (25 mph)).

Substitute value
- None.

Possible source
- Defective tire pressure sensor
- The receiver is not functioning.

Fault symptom[s]
- Message in the display.
- Warning lights and chimes/Tire pressure monitoring indication/no indication

Signal Missing

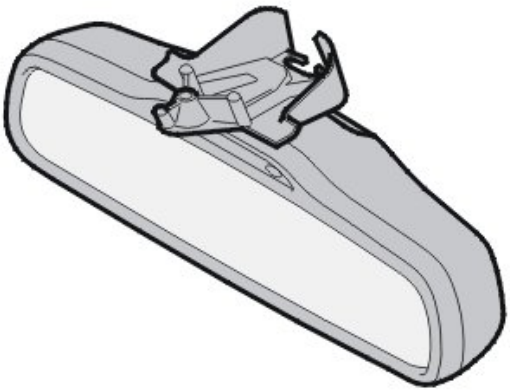
Signal missing

Checking the remote receiver

The remote receiver is located in the inner rear view mirror, and receives signals from both the remote control and the tire pressure sensors. The function of the remote receiver can be checked using the remote control.
Check that the remote receiver works by pressing the lock and unlock button on the remote control. The vehicle should be locked and unlocked.

Note! Fault-trace the symptoms first, if the remote control and receiver are not working.

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

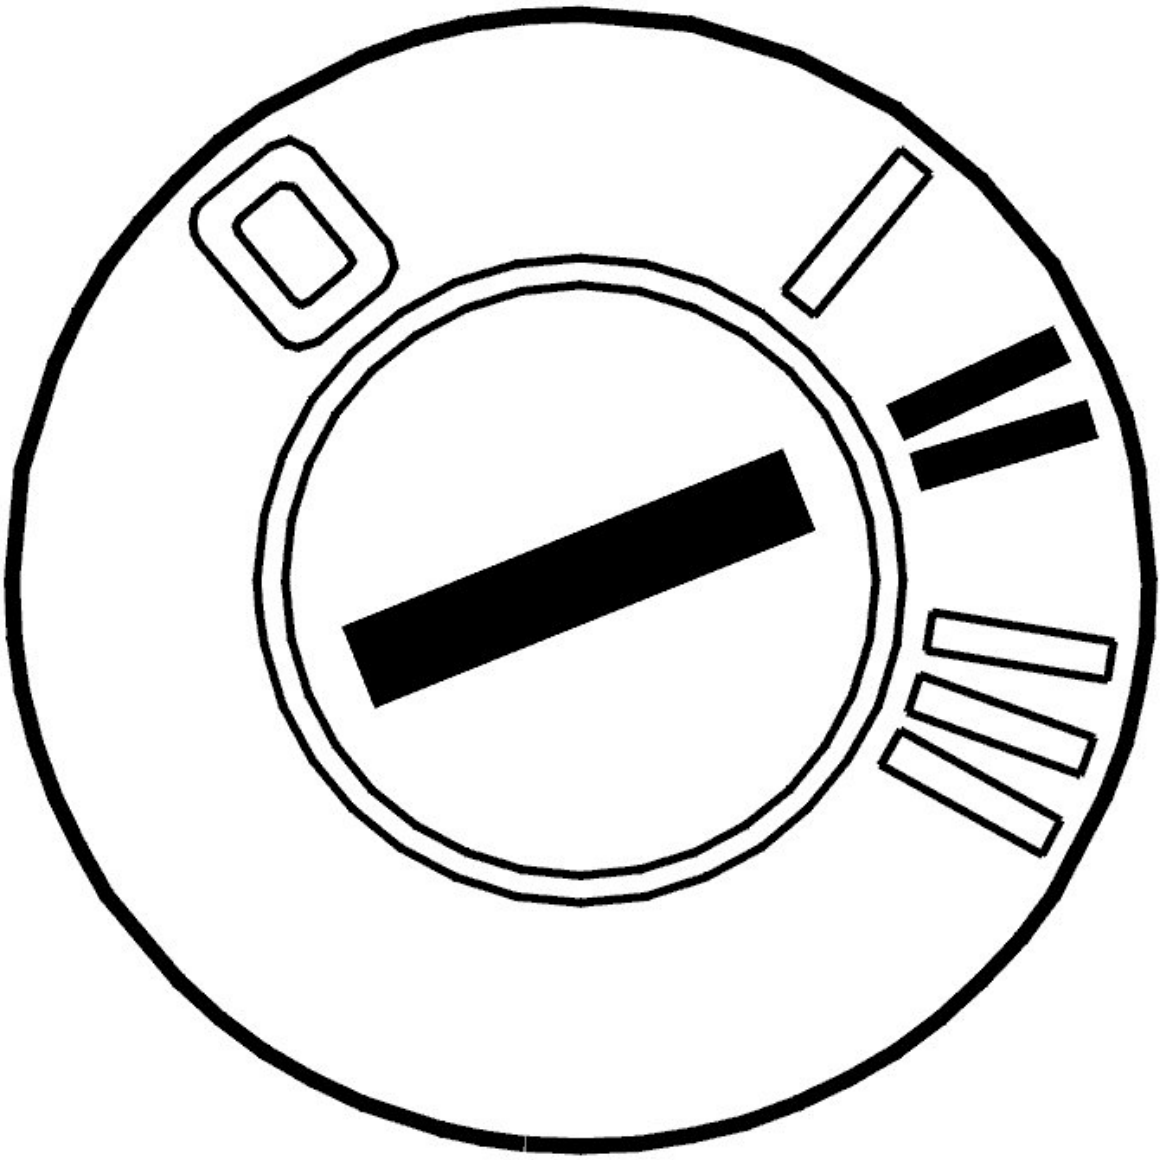


Does the remote control and remote receiver work?

Yes - Checking tire pressure sensors

No - DONE

Checking tire pressure sensors



- Ignition on.

Each tire pressure sensor has its own ID number and battery voltage status, which are sent to and stored in the Upper electronic module (UEM)
Read out the ID numbers for the tyre pressure sensors by clicking on the VCT2000 symbol.
Use the following special tools to activate the sensor.

- 951 2963 See: Tools and Equipment/951 2963

The special tool activates the sensor, which then starts to send information to the Upper Electronic Module (UEM). After activating a sensor, press the "Show data" button for the relevant wheel. Repeat activation for all wheels. Different ID numbers should appear. If the same ID number is displayed as for the previous wheel, activation has failed. Then activate the relevant wheel again and press the "Show data" button again.

Note! Do not forget to press the correct button after each wheel has been activated.

Note! Make sure no special tools lie under the edge of the rim against the tire where the sensor is installed. Activation will not happen if the tool is placed next to the rim. The tool must then be kept in position for 5 seconds for the signals to be received correctly. Use only one special tool at a time in the vicinity of the vehicle.

Note! Avoid positioning the vehicle close to other moving vehicles, the receiver may then receive signals from the sensors of these vehicles. The incorrect ID number may then appear.

Then read off the ID number that is stored for the relevant diagnostic trouble code, by clicking on the diagnostic trouble code in the list. The ID number is then displayed in the window above the list.
Compare the read-out ID number for the relevant wheel with the ID number that is stored with the DTC.

If a sensor does not respond during the test:

- Replace the tyre pressure sensor for the relevant wheel. It is probably the sensor that caused the DTC to be stored.

If all sensors respond:

- The sensor that caused the diagnostic trouble code to be stored has probably had an intermittent malfunction. Replace the tyre pressure sensor for the relevant wheel.

Other information

- Tire pressure sensor, replacement

Fault-tracing information

The fault should have been detected and remedied. As this is not the case fault-tracing has failed.
Exit fault-tracing for this diagnostic trouble code (DTC) or make another attempt.

Do you want to exit fault-tracing?

Yes - FAULT-TRACING FAILED

No - Attempt New Test

FAULT-TRACING FAILED - FAULT-TRACING FAILED

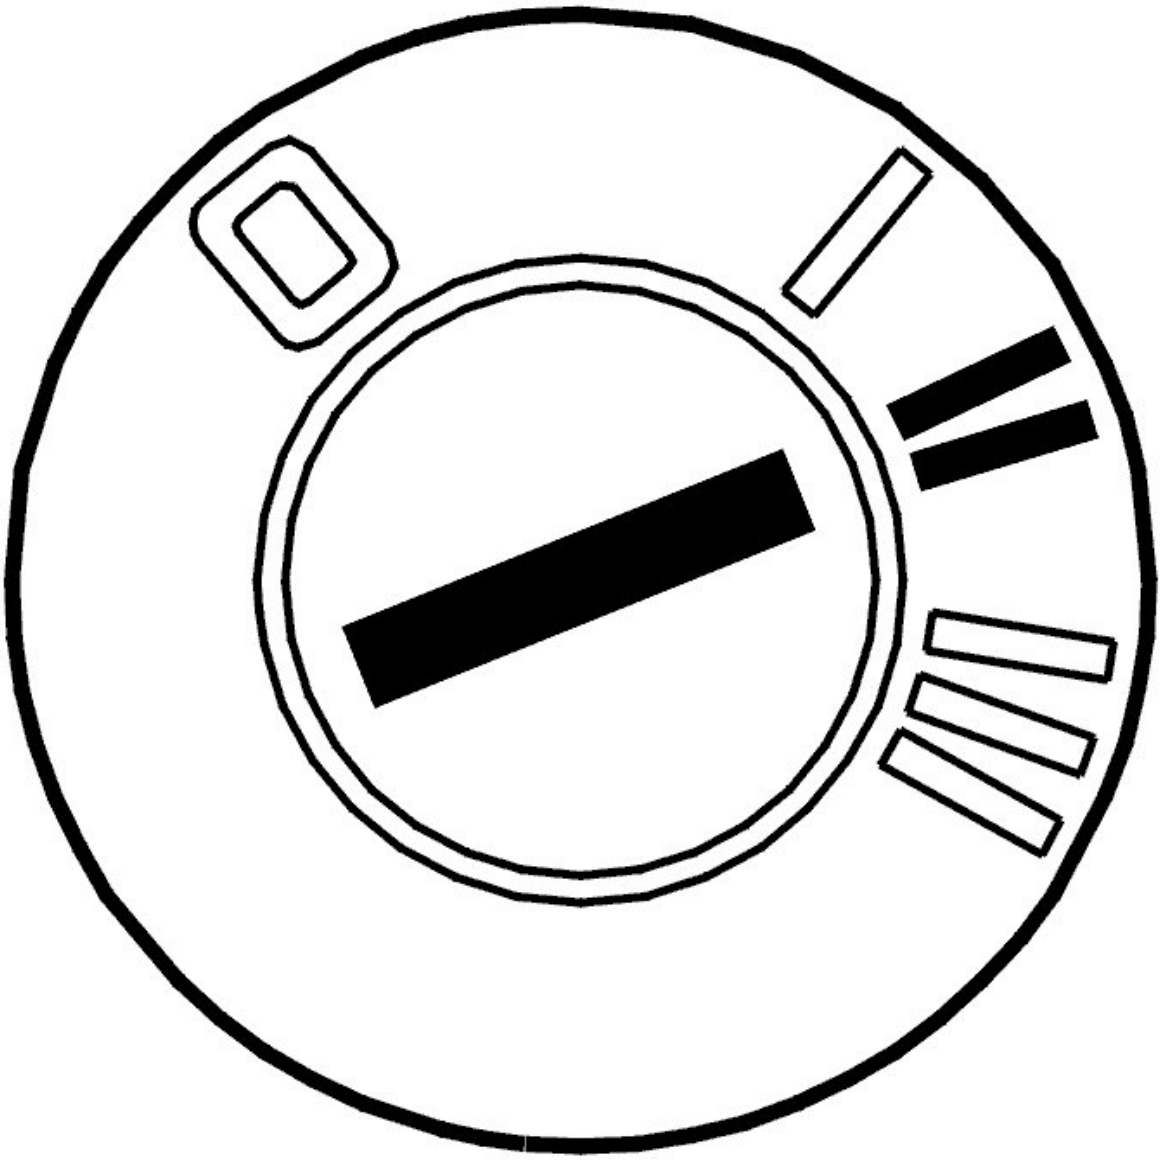
Attempt New Test - Checking the remote receiver

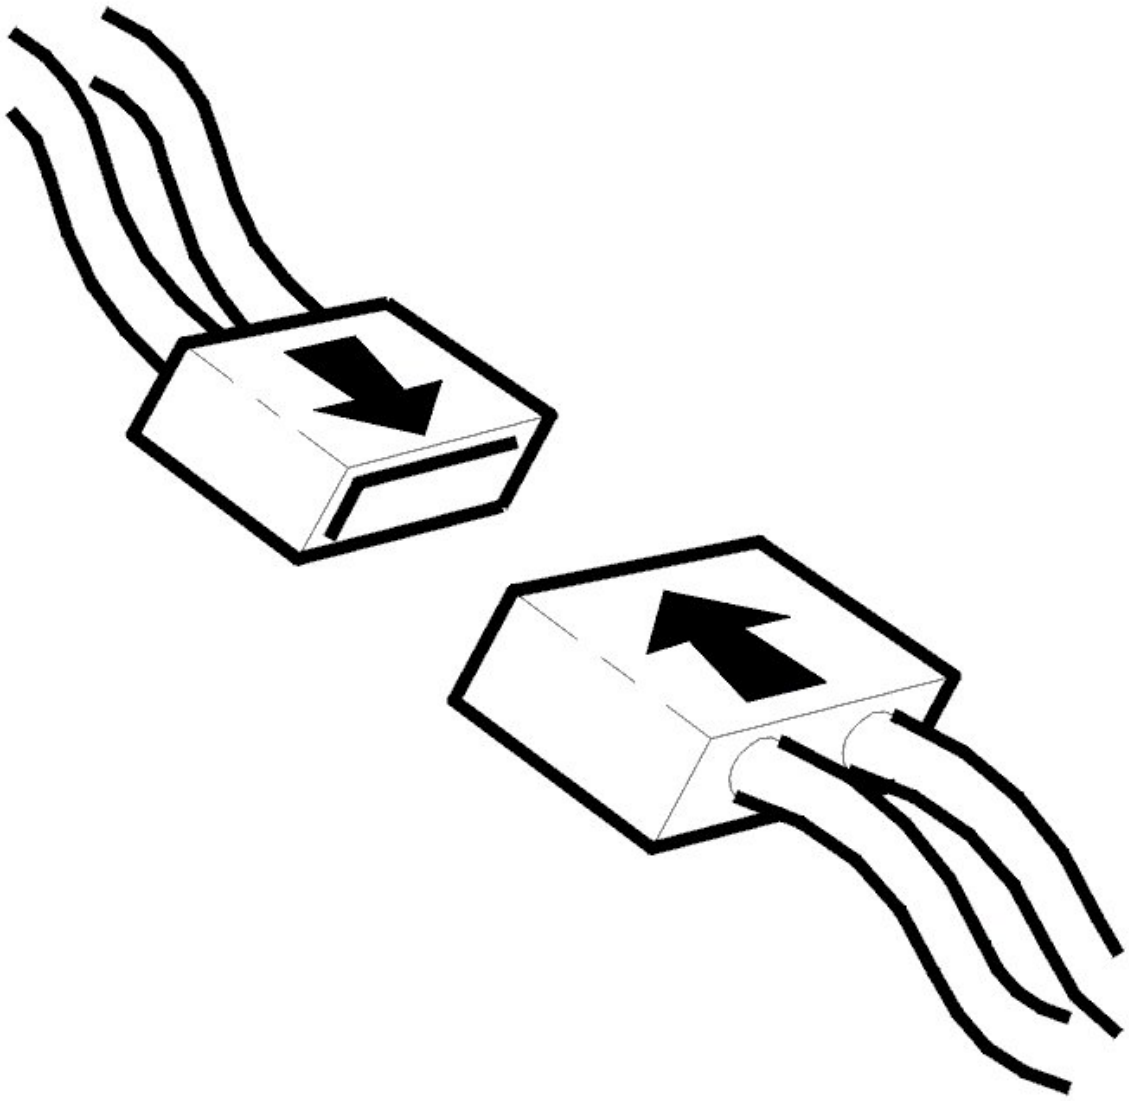
Verification

Verification

Verification

Hint: After carrying out the repair, check that the fault has been remedied.





- Ignition off
- Reinstall the connectors, components etc.
- Ignition on.

Read out the ID numbers for the tyre pressure sensors by clicking on the VCT2000 symbol.
Use the following special tools to activate the sensor.

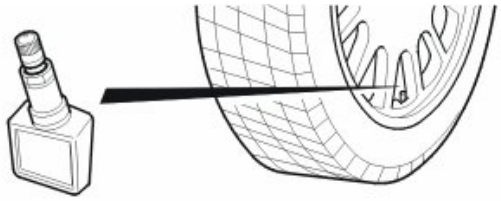
- 951 2963 See: Tools and Equipment/951 2963

The special tool activates the sensor, which then starts to send information to the Upper Electronic Module (UEM). After activating a sensor, press the "Show data" button for the relevant wheel. Repeat activation for all wheels. Different ID numbers should appear.

Note! Ensure that the special tool is positioned under the edge of the rim against the tire where the sensor is installed. The sensor will not be activated if the tool is against the rim. The sensor must then be held in place for approximately 5 seconds for the signals to be correctly received.Use only one special tool at a time in the vicinity of the car.

Note! Carry out the above in an area away from where other cars are being driven. The receiver can pick up signals from sensors on other cars. An incorrect ID number would then be displayed.

Check that the relevant sensor(s) respond. Test different wheels to ensure that different ID numbers are displayed.



Is the sensor OK?

Yes - VERIFIED

No - VERIFICATION FAILED

VERIFIED - Fault Found

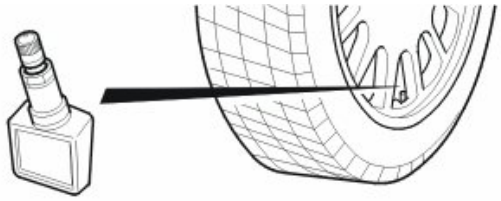
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information UEM-00A1

Condition



The upper electronic module (UEM) receives information transmitted by the tire pressure sensors in the wheels, irrespective of the car. The sensors which are registered in the vehicle can be checked by running a statistical selection. A list can then be stored internally in the upper electronic module (UEM).
The diagnostic trouble code (DTC) is stored if the upper electronic module (UEM) registers that the signal from the second of the four accepted sensors disappears whilst the vehicle is being driven.
The diagnostic trouble code (DTC) can be diagnosed after 10 minutes when the tire pressure warning system is active (vehicle speed is above 40 km/h (25 mph)).

Substitute value
- None.

Possible source
- Defective tire pressure sensor
- The receiver is not functioning.

Fault symptom[s]
- Message in the display.
- Warning lights and chimes/Tire pressure monitoring indication/no indication

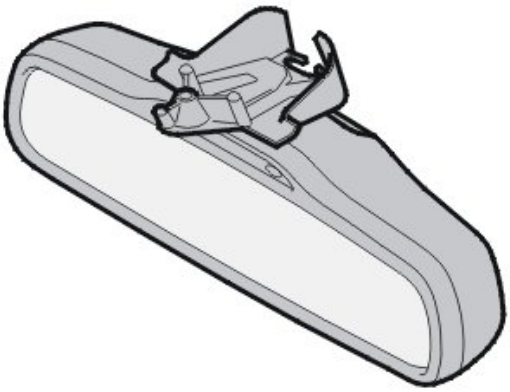
Signal Missing

Signal missing

Checking the remote receiver

The remote receiver is located in the inner rear view mirror, and receives signals from both the remote control and the tire pressure sensors. The function of the remote receiver can be checked using the remote control.
Check that the remote receiver works by pressing the lock and unlock button on the remote control. The vehicle should be locked and unlocked.

Note! Fault-trace the symptoms first, if the remote control and receiver are not working.

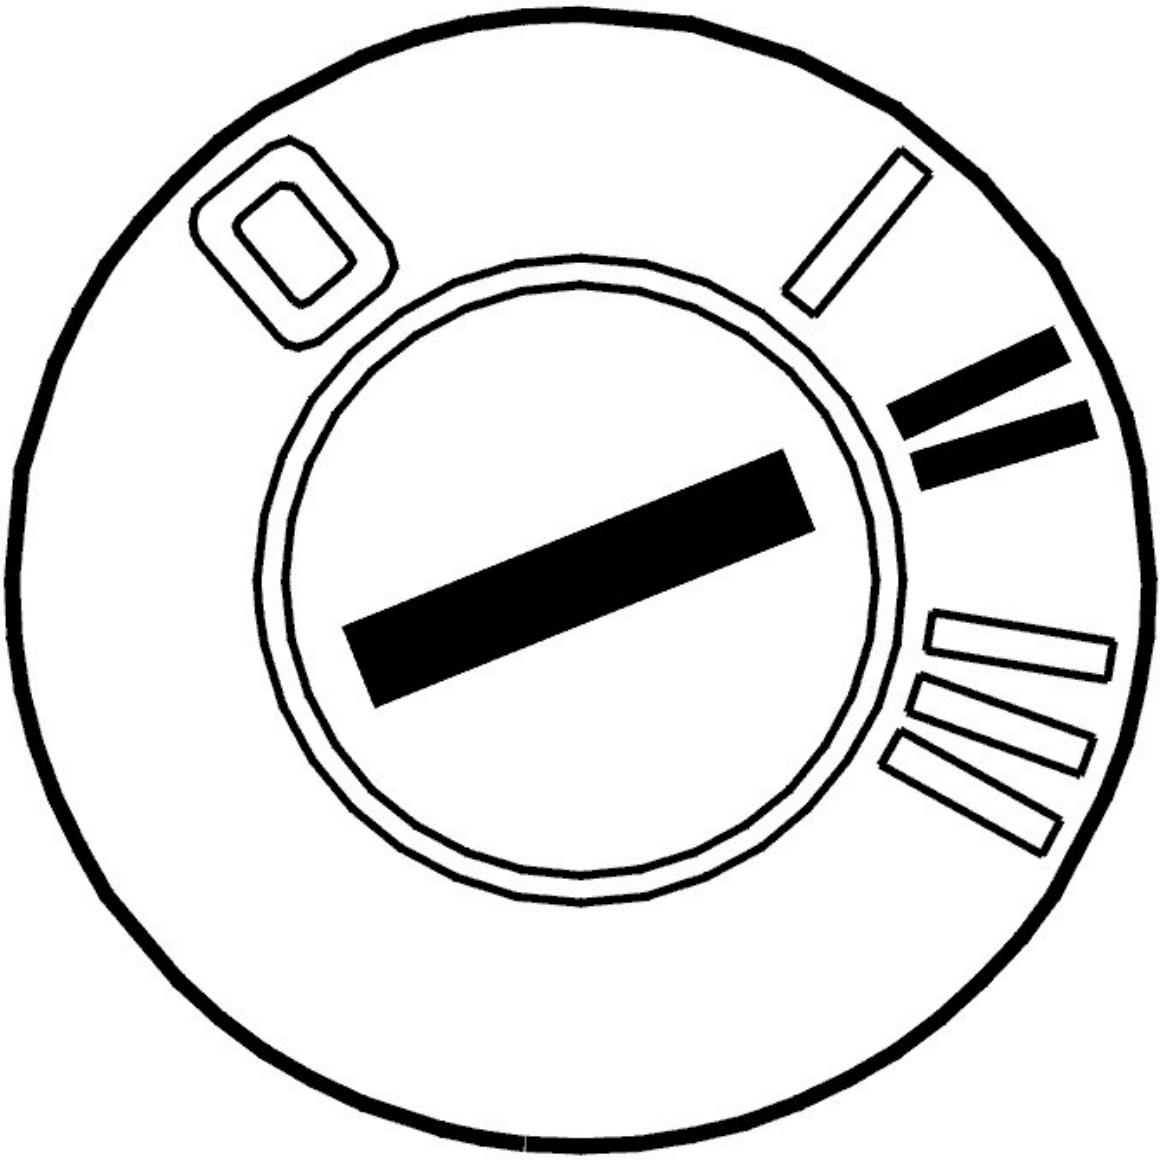


Does the remote control and remote receiver work?

Yes - Checking tire pressure sensors

No - DONE

Checking tire pressure sensors



- Ignition on.

Each tire pressure sensor has its own ID number and battery voltage status, which are sent to and stored in the Upper electronic module (UEM)
Read out the ID numbers for the tyre pressure sensors by clicking on the VCT2000 symbol.
Use the following special tools to activate the sensor.

- 951 2963 See: Tools and Equipment/951 2963

The special tool activates the sensor, which then starts to send information to the Upper Electronic Module (UEM). After activating a sensor, press the "Show data" button for the relevant wheel. Repeat activation for all wheels. Different ID numbers should appear. If the same ID number is displayed as for the previous wheel, activation has failed. Then activate the relevant wheel again and press the "Show data" button again.

Note! Do not forget to press the correct button after each wheel has been activated.

Note! Make sure no special tools lie under the edge of the rim against the tire where the sensor is installed. Activation will not happen if the tool is placed next to the rim. The tool must then be kept in position for 5 seconds for the signals to be received correctly. Use only one special tool at a time in the vicinity of the vehicle.

Note! Avoid positioning the vehicle close to other moving vehicles, the receiver may then receive signals from the sensors of these vehicles. The incorrect ID number may then appear.

Then read off the ID number that is stored for the relevant diagnostic trouble code, by clicking on the diagnostic trouble code in the list. The ID number is then displayed in the window above the list.
Compare the read-out ID number for the relevant wheel with the ID number that is stored with the DTC.

If a sensor does not respond during the test:

- Replace the tyre pressure sensor for the relevant wheel. It is probably the sensor that caused the DTC to be stored.

If all sensors respond:

- The sensor that caused the diagnostic trouble code to be stored has probably had an intermittent malfunction. Replace the tyre pressure sensor for the relevant wheel.

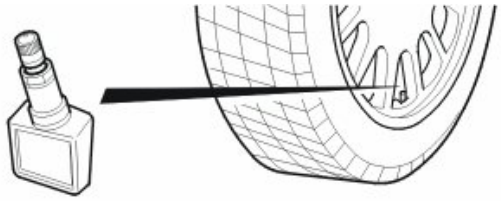
The special tool activates the sensor, which then starts to send information to the Upper Electronic Module (UEM). After activating a sensor, press the "Show data" button for the relevant wheel. Repeat activation for all wheels. Different ID numbers should appear.

Note! Ensure that the special tool is positioned under the edge of the rim against the tire where the sensor is installed. The sensor will not be activated if the tool is against the rim. The sensor must then be held in place for approximately 5 seconds for the signals to be correctly received.Use only one special tool at a time in the vicinity of the car.

Note! Carry out the above in an area away from where other cars are being driven. The receiver can pick up signals from sensors on other cars. An incorrect ID number would then be displayed.

Check that the relevant sensor(s) respond. Test different wheels to ensure that different ID numbers are displayed.



Is the sensor OK?

Yes - VERIFIED

No - VERIFICATION FAILED

VERIFIED - Fault Found

VERIFICATION FAILED - Fault-tracing information

Diagnostic Trouble Code (DTC) Information

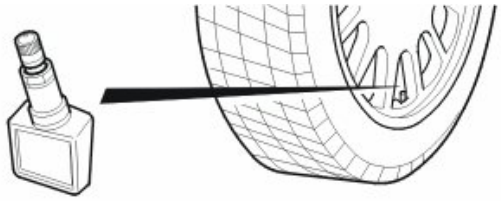
Diagnostic trouble code (DTC) information UEM-00A7

Condition



The upper electronic module (UEM) receives information transmitted by the tire pressure sensors in the wheels, irrespective of the car. The sensors which are registered in the vehicle can be checked by running a statistical selection. A list can then be stored internally in the upper electronic module (UEM). The messages transmitted by the sensors contain information such as the voltage of the internal battery in the sensor.
The diagnostic trouble code (DTC) is stored if the upper electronic module (UEM) receives a message from the fourth of the four accepted sensors indicating low battery voltage.
The diagnostic trouble code (DTC) can be diagnosed after 10 minutes when the tire pressure warning system is active (vehicle speed is above 40 km/h (25 mph)).

Substitute value
- None.

Possible source
- Low battery voltage in the tire pressure sensor.

Fault symptom[s]
- Message in the display.
- Warning lights and chimes/Tire pressure monitoring indication/no indication

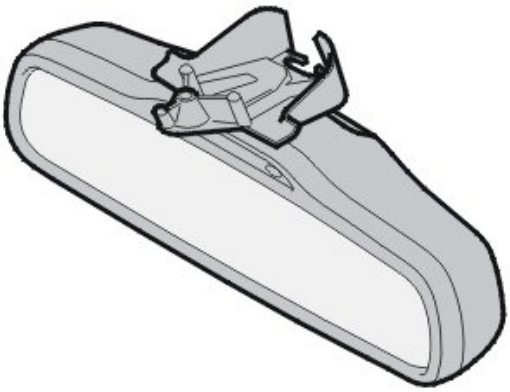
Low Battery

Low battery

Checking the remote receiver

The remote receiver is located in the inner rear view mirror, and receives signals from both the remote control and the tire pressure sensors. The function of the remote receiver can be checked using the remote control.
Check that the remote receiver works by pressing the lock and unlock button on the remote control. The vehicle should be locked and unlocked.

Note! Fault-trace the symptoms first, if the remote control and receiver are not working.

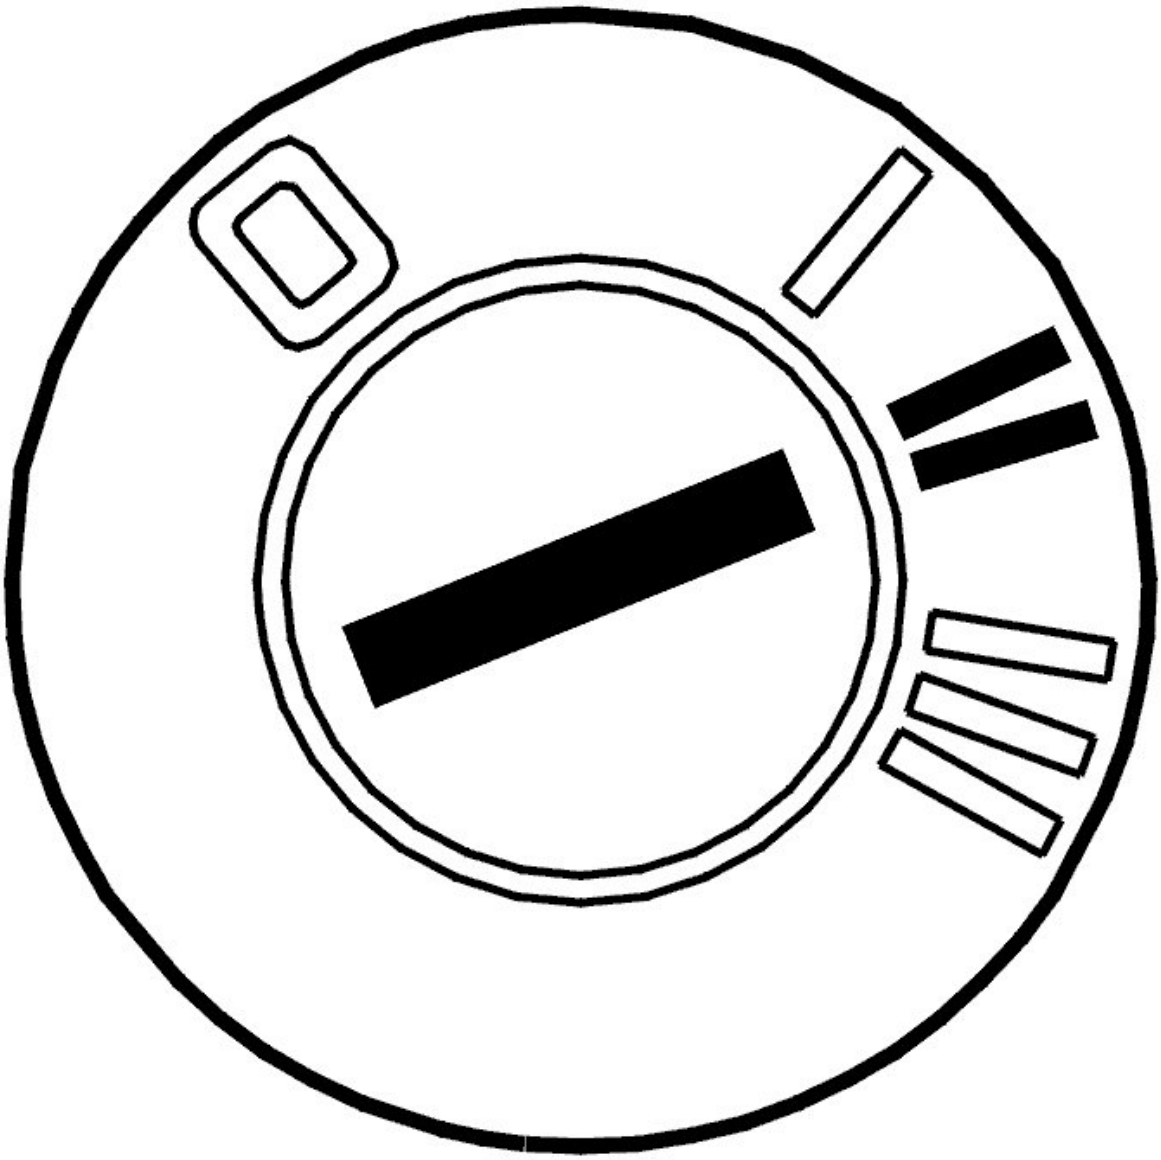


Does the remote control and remote receiver work?

Yes - Checking tire pressure sensors

No - DONE

Checking tire pressure sensors



- Ignition on.

Each tire pressure sensor has its own ID number and battery voltage status, which are sent to and stored in the Upper electronic module (UEM)
Read out the ID numbers for the tyre pressure sensors by clicking on the VCT2000 symbol.
Use the following special tools to activate the sensor.

- 951 2963 See: Tools and Equipment/951 2963

The special tool activates the sensor, which then starts to send information to the Upper Electronic Module (UEM). After activating a sensor, press the "Show data" button for the relevant wheel. Repeat activation for all wheels. Different ID numbers should appear. If the same ID number is displayed as for the previous wheel, activation has failed. Then activate the relevant wheel again and press the "Show data" button again. If the sensor does not respond, the battery has probably been discharged or the sensor does not work. Replace the sensor for the relevant wheel.

Note! Do not forget to press the correct button after each wheel has been activated.

Note! Make sure no special tools lie under the edge of the rim against the tire where the sensor is installed. Activation will not happen if the tool is placed next to the rim. The tool must then be kept in position for 5 seconds for the signals to be received correctly. Use only one special tool at a time in the vicinity of the vehicle.

Note! Avoid positioning the vehicle close to other moving vehicles, the receiver may then receive signals from the sensors of these vehicles. The incorrect ID number may then appear.

Then read off the ID number that is stored for the relevant diagnostic trouble code, by clicking on the diagnostic trouble code in the list. The ID number is then displayed in the window above the list.
Compare the read-out ID number for the relevant wheel with the ID number that is stored with the DTC.
Replace the tyre pressure sensor for the relevant wheel.

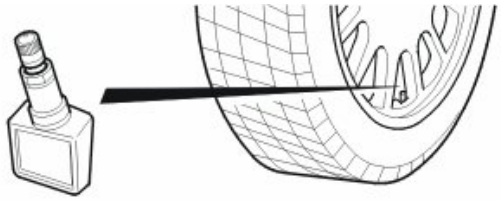
VERIFICATION FAILED - Fault-tracing information

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information UEM-00A8

Condition



The upper electronic module (UEM) receives information transmitted by the tire pressure sensors in the wheels, irrespective of the car. The sensors which are registered in the vehicle can be checked by running a statistical selection. A list can then be stored internally in the upper electronic module (UEM).
The diagnostic trouble code (DTC) is stored if the upper electronic module (UEM) registers that the signal from fewer than four of the accepted sensors has been received during an operating cycle.
The diagnostic trouble code (DTC) can be diagnosed after 10 minutes when the tire pressure warning system is active (vehicle speed is above 40 km/h (25 mph)).

Substitute value
- None.

Possible source
- A rim without a tire pressure sensor has been installed
- A rim with a tire pressure sensor not intended for this model has been installed (the sensor is unable to communicate with the receiver)
- Defective tire pressure sensor
- The receiver is not functioning.

Fault symptom[s]

- Message in the display.
- Warning lights and chimes/Tire pressure monitoring indication/no indication

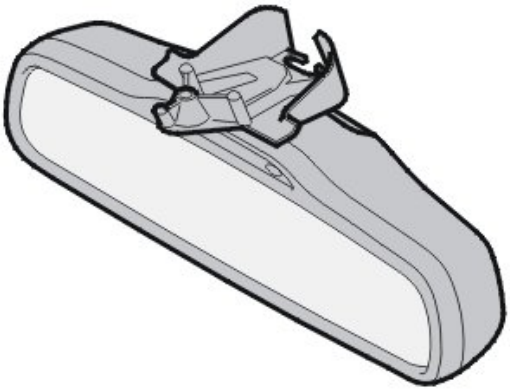
Sensor Missing

Sensor missing

Checking the receiver

The receiver is in the rear view mirror. It receives signals from both the remote control and tire pressure sensors. The remote control can be used to check that the receiver is working.
Check the function of the receiver by pressing the locking and unlocking button on the remote control. The vehicle must lock and unlock.

Note! Fault-trace the symptoms if the remote control and receiver are not working.

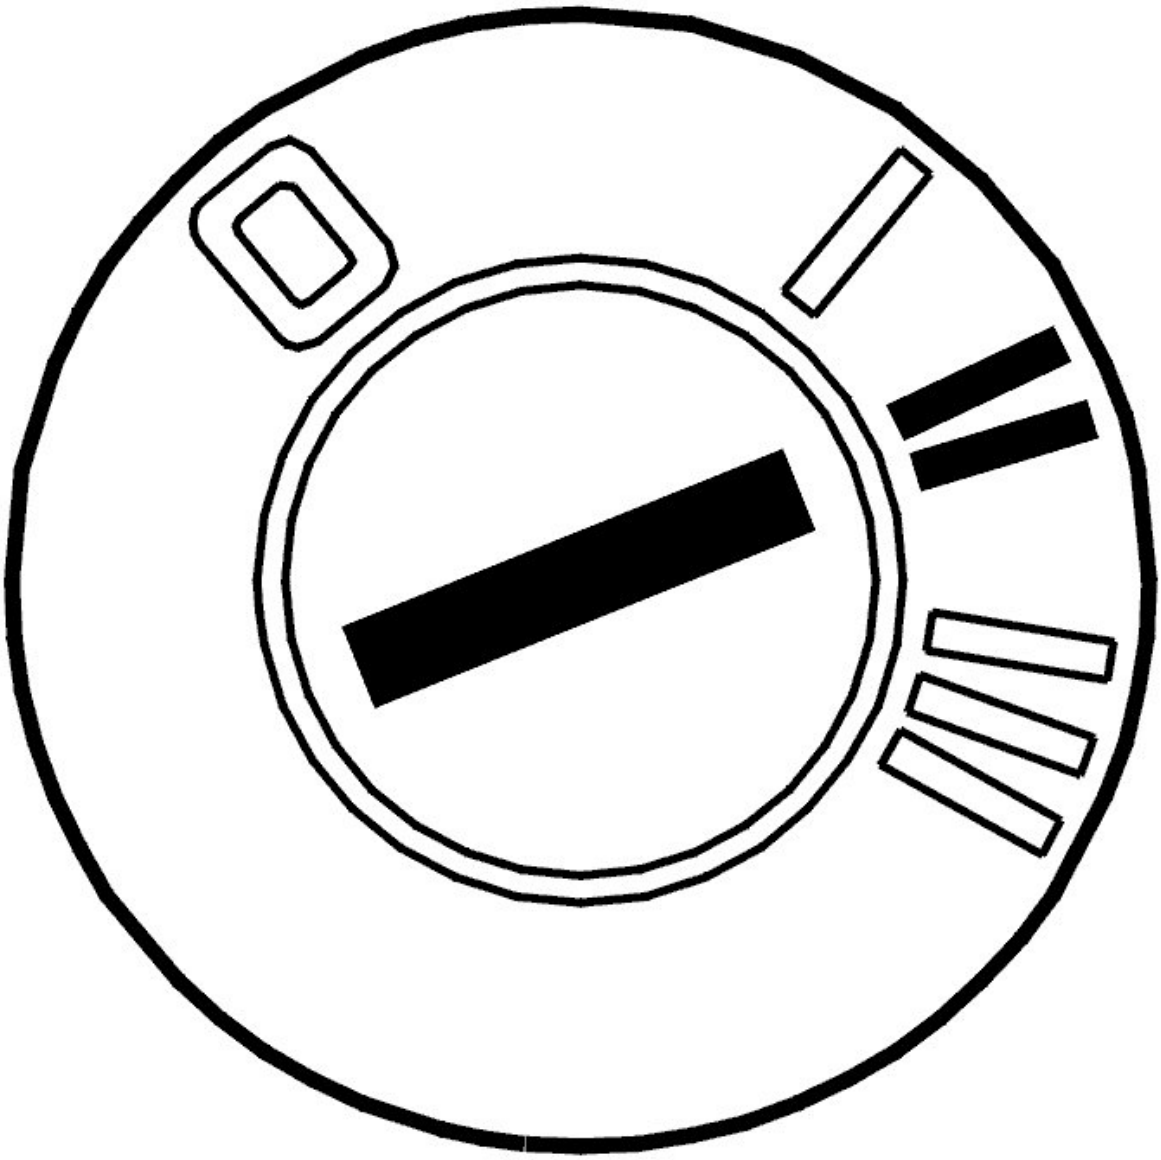


Are the remote control and receiver working?

Yes - Checking the tire pressure sensors

No - DONE

Checking the tire pressure sensors



- Ignition on.

Each tire pressure sensor has its own ID number which is transmitted to and stored in the upper electronic module (UEM). Read off the last stored ID number by clicking on the VCT2000 symbol. The last stored ID number is displayed until a new ID number is received and stored.

Note! The last stored value is erased when the ignition is switched off and on again.

Use special tool951 2963 See: Tools and Equipment/951 2963 to activate one of the sensors. The special tool activates the sensor which then starts to transmit information to the upper electronic module (UEM). The ID number of the sensor can then be read in the display.

Note! Ensure that the special tool is positioned under the edge of the rim against the tire where the sensor is installed. The sensor will not be activated if the tool is against the rim. The sensor must then be held in place for approximately 5 seconds for the signals to be correctly received.Use only one special tool at a time in the vicinity of the car.

Note! Carry out the above in an area away from where other cars are being driven. The receiver can pick up signals from sensors on other cars. An incorrect ID number would then be displayed.

Repeat this procedure for each wheel. Different ID numbers must be displayed.

If a sensor does not respond during the test:

Check that a tire pressure sensor is installed on the rim. Install a new sensor if there is no sensor installed. If the sensor is installed but is still not working, it may be defective or be a sensor intended for another make or model. Replace the tire pressure sensor.

If all sensors respond:

Intermittent fault. The control module has previously detected that one or more sensors are not communicating. This may be because the vehicle previously had a wheel mounted without a functioning sensor.

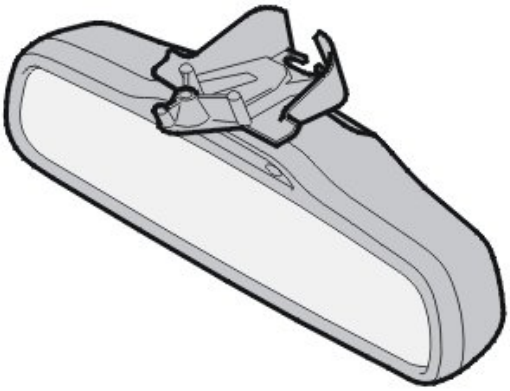
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information UEM-00A9

Condition



The upper electronic module (UEM) has a configuration file which controls certain internal settings. The upper electronic module (UEM) checks that the configuration file is correct.
The diagnostic trouble code (DTC) is stored if the upper electronic module (UEM) registers that the configuration file is incorrect or missing.
The diagnostic trouble code (DTC) can be detected when the control module is initialized after being reset or when diagnostic trouble codes (DTCs) are erased.

Substitute value
- Factory settings are used.

Possible source
- Incorrect or missing configuration file.

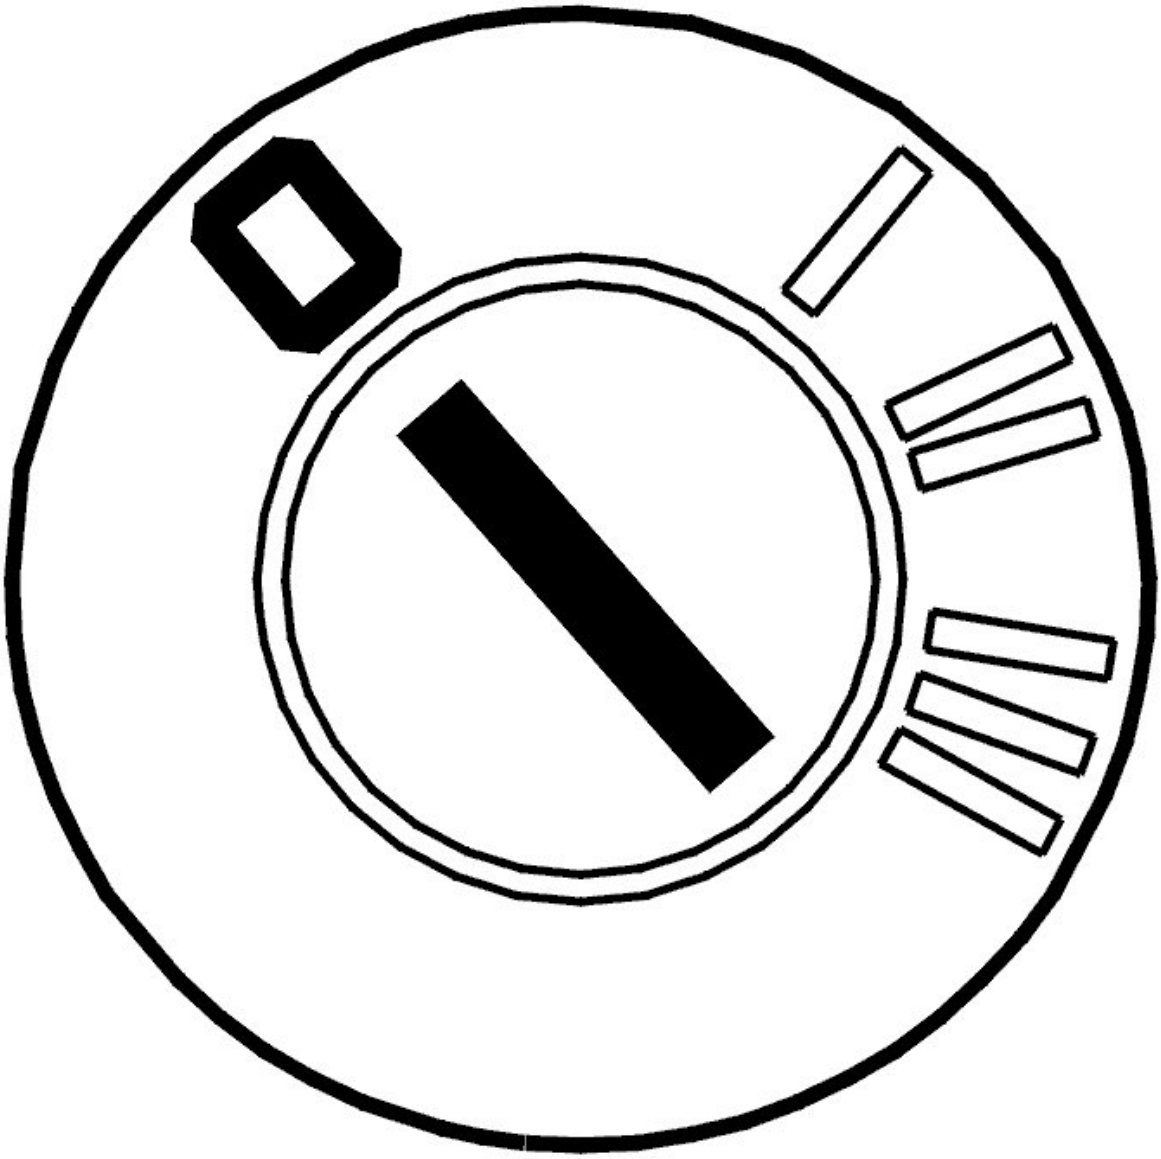
Fault symptom[s]
- None.

Configuration Fault

Configuration fault

Replacing software

Note! If possible, read off the programmed data before replacing software.



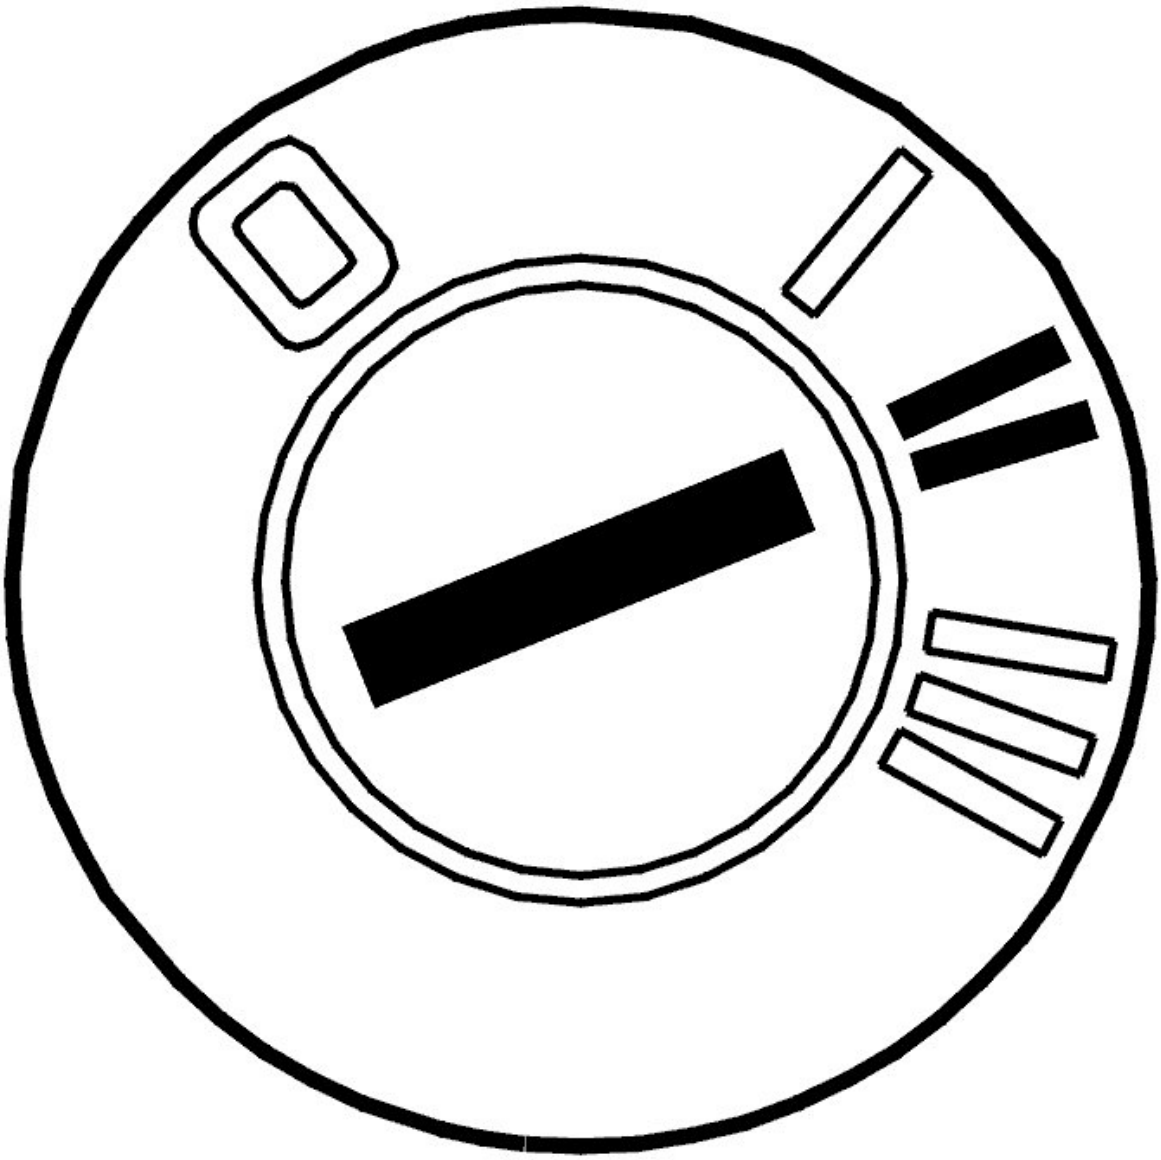
- Ignition off.

The upper electronic module (UEM) has registered a fault in the configuration file.
The fault may be due to a program fault. The software must be replaced.

Continue - Reading off programmed values

Reading off programmed values

Note! Read off the programmed values from the upper electronic module (UEM) before re-programming.



- Ignition on
- Click on the symbol for VCT2000 to read off the programmed values.

The obtained values are programmed customer parameters in the upper electronic module (UEM). These values should be noted for later use.

Other information

- For information about programming the customer parameters, see Diagnostic functions See: Body and Frame/Body Control Systems/Description and Operation/Upper Electronic Module (UEM)/Diagnostic Functions.

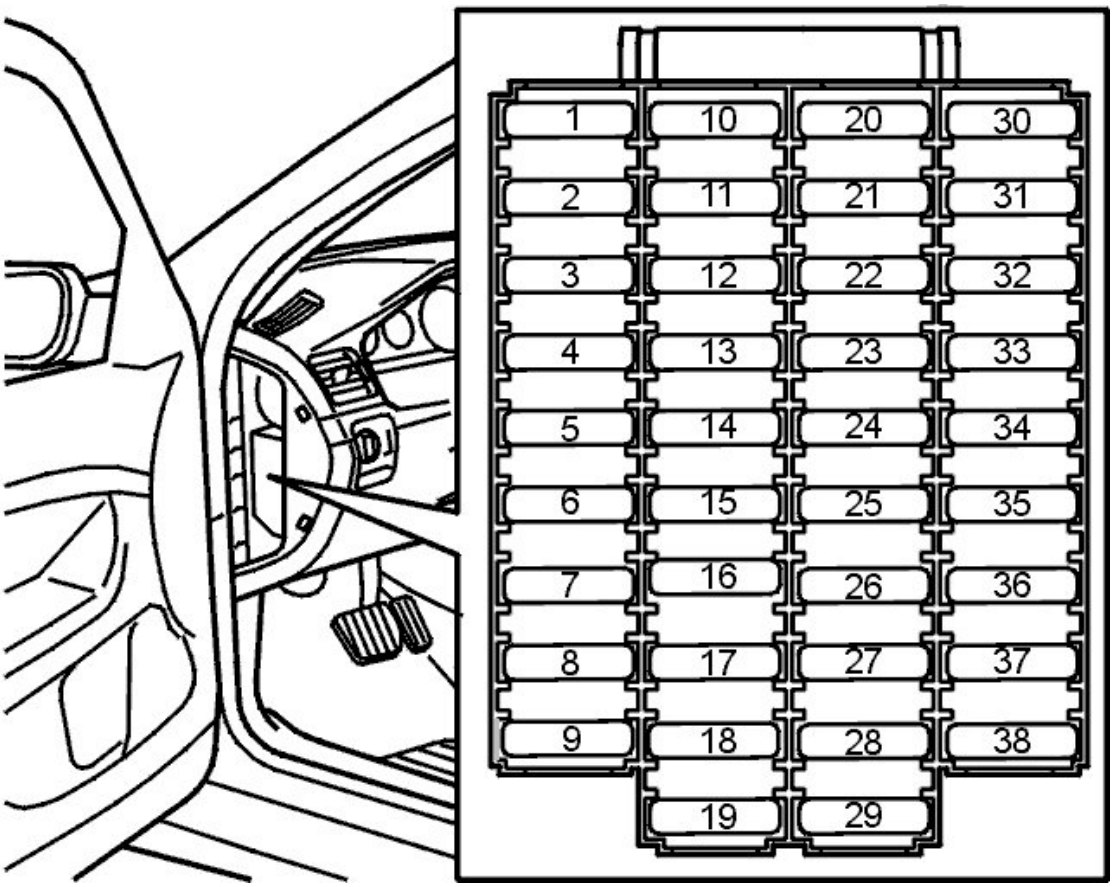
Continue - Downloading software

Downloading software

Download new software. See Upper electronic module (UEM) rear view / door mirror, replacing See: Body Control Module/Service and Repair. Do not replace the control module.

Hint: If diagnostic trouble code (DTC) UEM-E001 is stored, communication with the control module cannot be established. This can be remedied in two ways.

1. Press the remote control button for local lighting
2. Remove fuse 11C/28 from the fusebox in the passenger compartment. Reinstall the fuse again.



Continue - Checking interior lighting

Checking interior lighting

Checking the interior lighting (2)

Checking the interior lighting

Two times can be programmed for the interior lighting:

1. Short
- The period from when the door is unlocked, or the engine stops, to when the interior lighting goes out can be changed if it is too long or too short.

2. Long
- The period from when the door is opened, or a lamp is lit with a switch, to when the lamp goes out can be changed if it is too long or too short.

To program a long interior lighting period you must step ("click") through the short interior lighting period programming.

Continue - Programming a short interior lighting period

Programming a short interior lighting period

The general lighting and rear reading lamps light and remain lit for 30 seconds when:
- The door has been unlocked from outside with a key or the remote control.
- The engine has been stopped and the ignition key turned to 0.

The default period is 30 seconds. This can be changed to between 5 and 255 seconds.
Read off the programmed values.
To change the time, mark the desired value in the scrolling list and start programming.

Do you want to program any more parameters?

Yes - Programming a long interior lighting period

No - Fault Found

Programming a long interior lighting period

The general lighting and rear reading lamps light and remain lit for 10 minutes when:
- A door is opened after being unlocked.
- The lamp is lit with a switch.

The default period is 10 minutes. This can be changed to between 0 and 255 minutes at 10 minute intervals.
Read off the programmed values.
To change the time, mark the desired value in the scrolling list and start programming.

FAULT FOUND - Checking anti-dazzle function in rear view mirror

---

Checking anti-dazzle function in rear view mirror

Checking the anti-dazzle function in the rear view mirror

Checking the anti-dazzle function

Note! If the upper electronic module (UEM) has been replaced software, specially developed for downloading after replacing the control module, must be downloaded to the control module before the anti-dazzle function is changed. See Upper electronic module (UEM) rear view / door mirror, replacing See: Body Control Module/Service and Repair.

The rear view mirror anti-dazzle function can be adjusted:
- If the rear view mirror anti-dazzle function is too powerful or too weak, it can be adjusted.

Specific software for setting the anti-dazzle function must be installed in the car to do this.
Order the software. See9499432.
Install the software. See9499432.

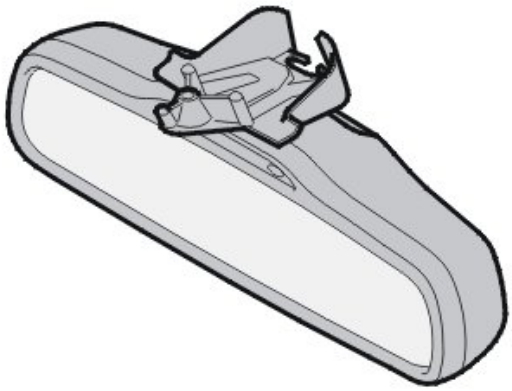
Continue - DONE

DONE - Fault Found

UEM-E001

Diagnostic trouble code (DTC) information UEM-E001

Condition



The control modules transmit and receive information via a standardized serial communication method - CAN (Controller Area Network). The diagnostic trouble code (DTC) is stored if the control module registers serious interference (CAN communication blocked).

Note! In the event of system communication problems, it is not possible to communicate with the control module. Therefore it will only be possible to read off the fault if it is intermittent.

Substitute value
- The control module shuts itself off ("bus-off").

  Hint: The control module will remain shut off until the power supply is broken (15, 30, X). When the power supply is connected the control module will make a new attempt to communicate.

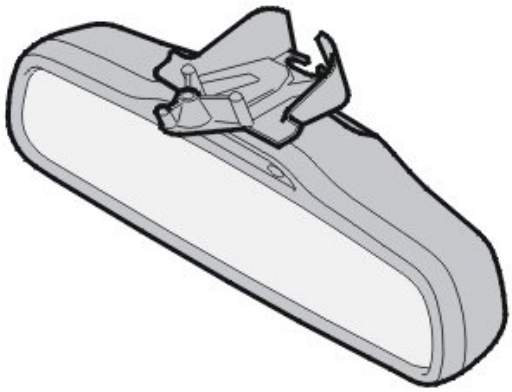
Possible source
- Short-circuit between the control area network (CAN) wiring
- Open-circuit in the control area network (CAN) wiring
- Internal fault in the control module
- Internal fault in another control module in the same part of the control area network (CAN).

Fault symptom[s]
- Cannot be controlled with the remote control
- The interior lighting does not operate
- The power sun roof does not operate
- The alarm does not function at all
- No rain sensor function.

UEM-E003

Diagnostic trouble code (DTC) information UEM-E003

Condition



The control module compares its configuration ID with the signal configuration transmitted on the control area network (CAN) by the central electronic module (CEM). If the configuration IDs do not correspond the fault code is stored. The diagnostic trouble code (DTC) is also stored if the communication between the control module and the central electronic module (CEM) is interrupted.

Note! In the event of open-circuit in both the control area network (CAN) cables, it is not possible to communicate with the control module. Therefore it will only be possible to read off the diagnostic trouble code (DTC) if this type of fault is intermittent. When the diagnostic trouble code (DTC) is stored, the control module responds to the diagnostic command, however normal control area network (CAN) communication does not work. ("Expulsion mode")

Substitute value
- None.

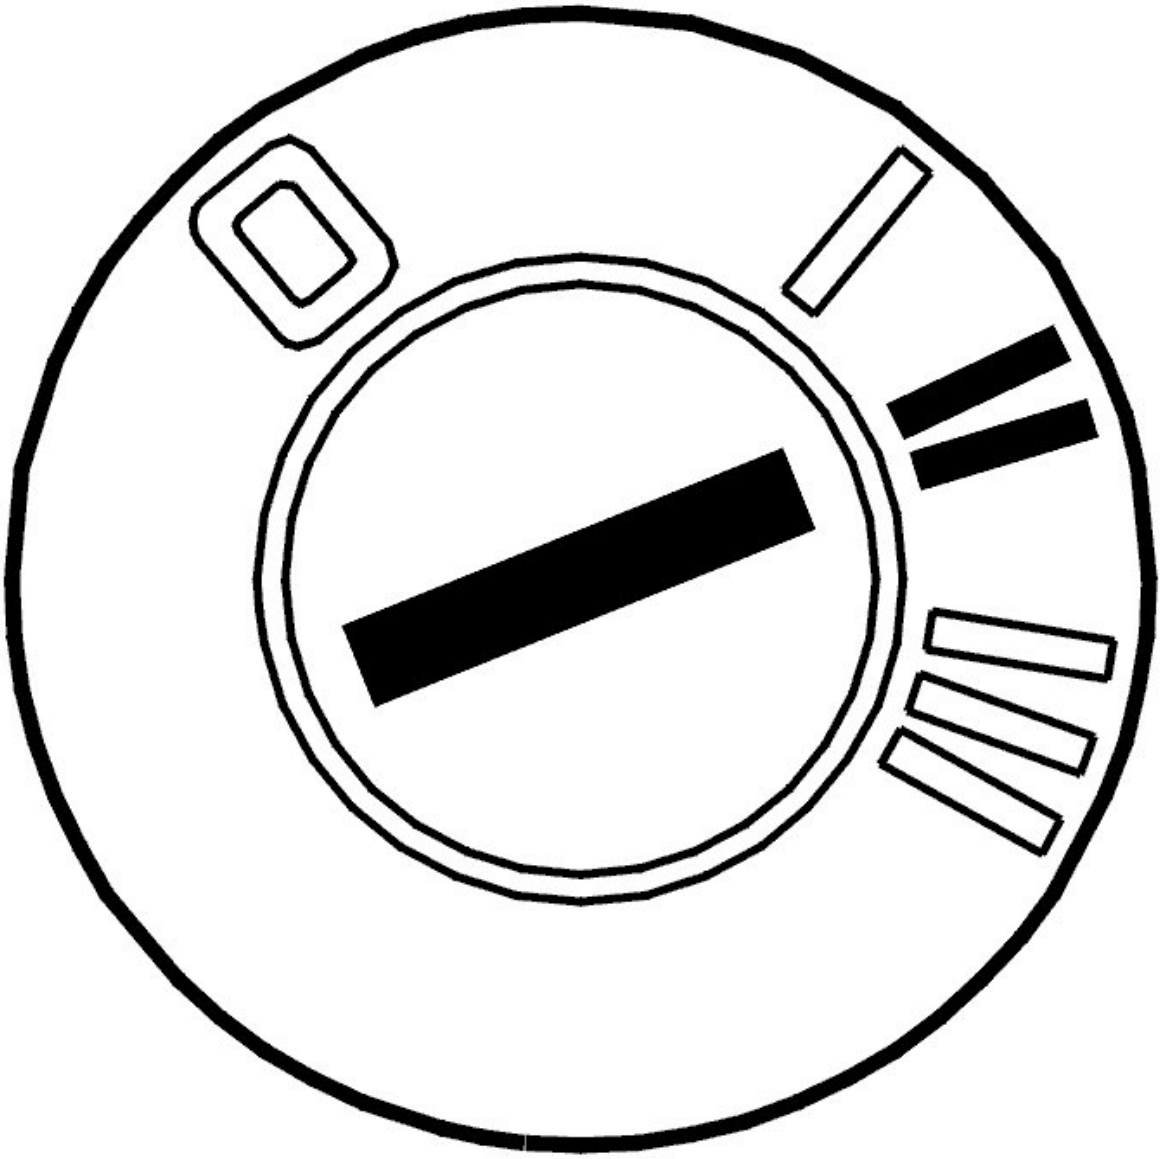
Possible source
- Faulty control area network (CAN) configuration ID. (The node is not intended for this car, for example a used control module with different software/hardware.)
- Open-circuit in the control area network (CAN) wiring between the control module and the central electrical module (CEM).

Fault symptom[s]
- Cannot be controlled with the remote control
- The interior lighting does not operate
- The power sun roof does not operate
- The alarm does not function at all
- No rain sensor function.

UEM-XXXX

Unknown diagnostic trouble code (DTC) for the current control module version

Reading off diagnostic trouble codes (DTCs)



- Ignition on.

Read off the diagnostic trouble code (DTC) that is stored in the car.
Make a note of the code. Report the code to VIDA customer support.

Continue - DONE

VIDA (Vehicle Information & Diagnostics For Aftersales)

VIDA (Vehicle Information & Diagnostics for Aftersales)

During the second half of 2004, VADIS (Volvo Aftersales Diagnostic and Information System) was phased out and replaced by VIDA (Vehicle Information & Diagnostics for Aftersales). The purpose of VIDA is to support service providers in repairing and servicing Volvo vehicles. VIDA provides Service and Parts information, as well as diagnostic fault tracing, and software downloads. As in VADIS, these areas are integrated into one single application. All functionality that could be found in VADIS will be found in VIDA. However, in some particular areas, e.g., the diagnostic work flow, search functionality, and the Parts catalogue, VIDA contains considerable enhancements when compared to VADIS.

Volvo's VIDA (Vehicle Information & Diagnostics for Aftersales) system ties together service and repair data, parts data, service bulletins, software (firmware) downloads, fault tracing and on-board diagnostic as well as other related information to decrease service time.

Much of the diagnostic information provided here is presented in a manner that assumes the technician is using the web-based Volvo diagnostic system (VIDA) to diagnose the vehicle. Volvo does not provide any information based on performing diagnosis with a third party diagnostic tool aside from a conversion from P Codes to Volvo ECM Codes. See: Diagnostic Trouble Code Descriptions

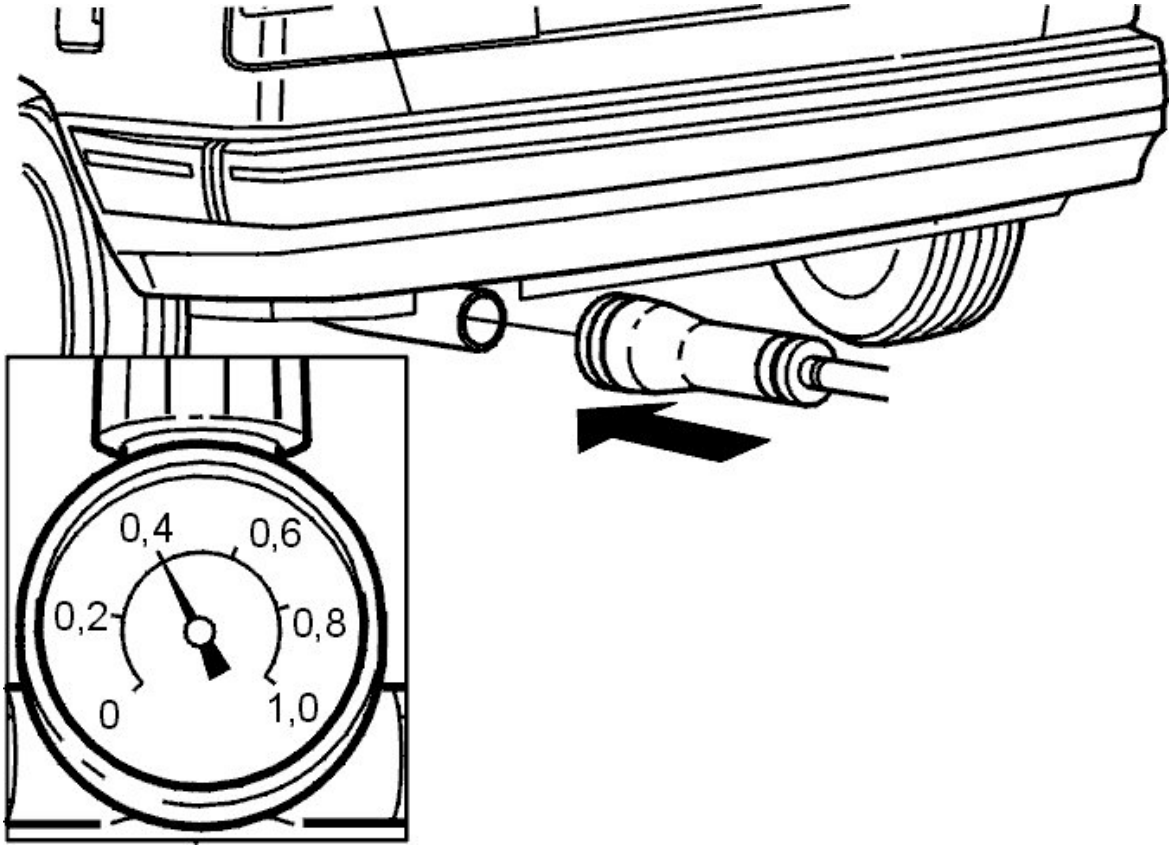
Air Leakage Exhaust System, Check

Checking for air leakage in the exhaust system

Special tools:

999 5544 REGULATOR See: Tools and Equipment/999 5544 Regulator
999 5546 ADAPTOR See: Tools and Equipment/999 5546 Adaptor

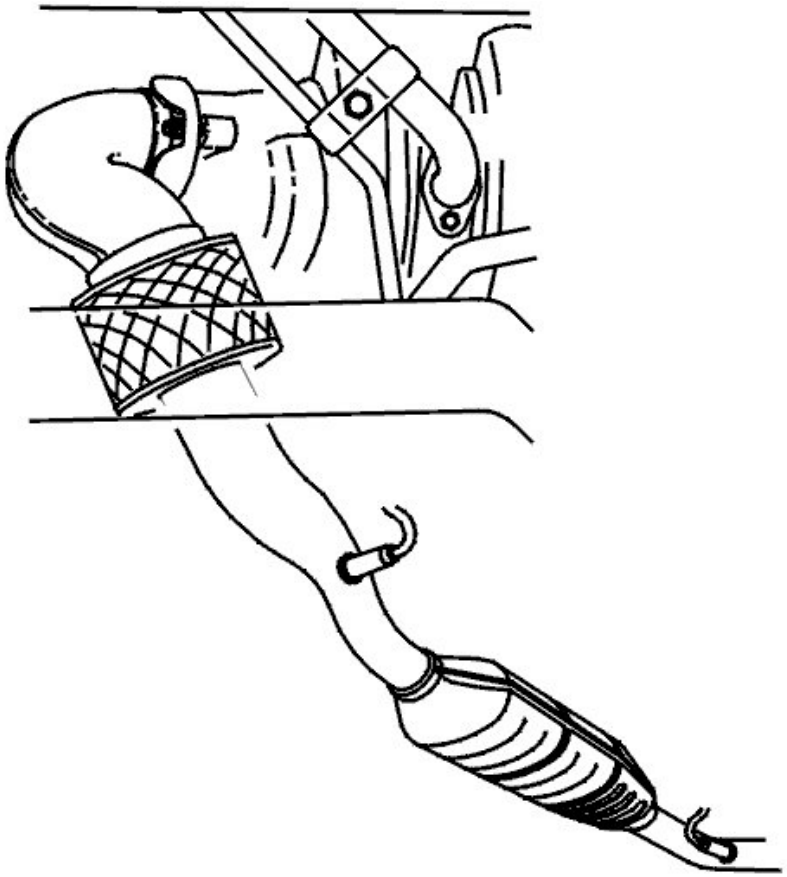
Connecting



Caution! If the car has been driven recently the exhaust system can be very hot, let it cool down a little. Otherwise the special tool may get burnt.

Remove the exhaust tail pipe.
Install tool999 5546 ADAPTOR See: Tools and Equipment/999 5546 Adaptor with pressure regulator999 5544 REGULATOR See: Tools and Equipment/999 5544 Regulator on the exhaust system.
Adjust the pressure to**0.4 bar**. Depending on the condition of the exhaust system a**lower**pressure may be necessary.

Check



Check exhaust system by spraying a soap solution on all joints and connections between cylinder head and rear heated oxygen sensor (HO2S).
Only very small and slow bubbles are permissible.
Install tail pipe on exhaust system after check.

Air Leaks in the Intake System, Checking

Air leaks in the intake system, checking

Special tools:

999 5545 ADAPTOR See: Tools and Equipment/999 5545 Adaptor
999 5544 REGULATOR See: Tools and Equipment/999 5544 Regulator

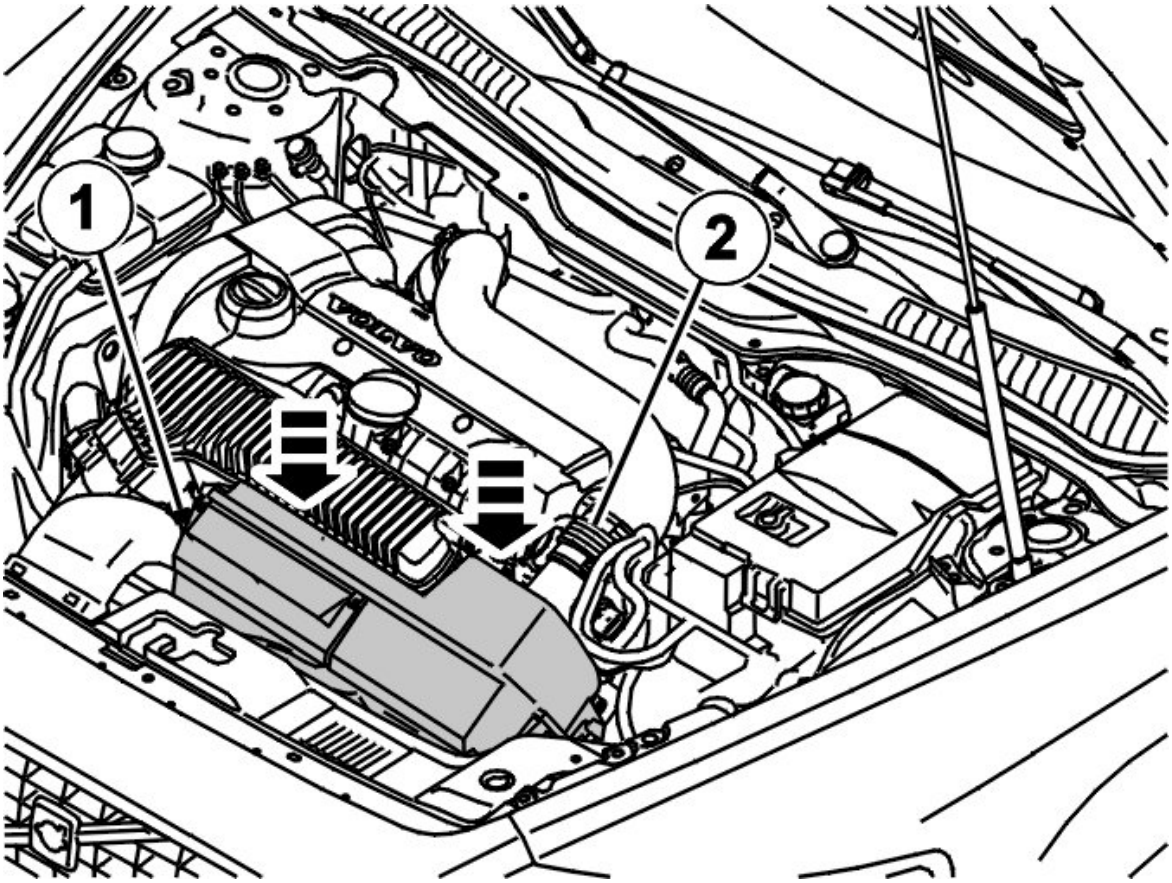
Note! The illustrations in this service information are used for different model years and/or models. Some variation may occur. However, the essential information in the illustrations is always correct.

Removal

Preparations

Check that all hoses are undamaged. Check that all hoses are in place with their hose clips tightened.

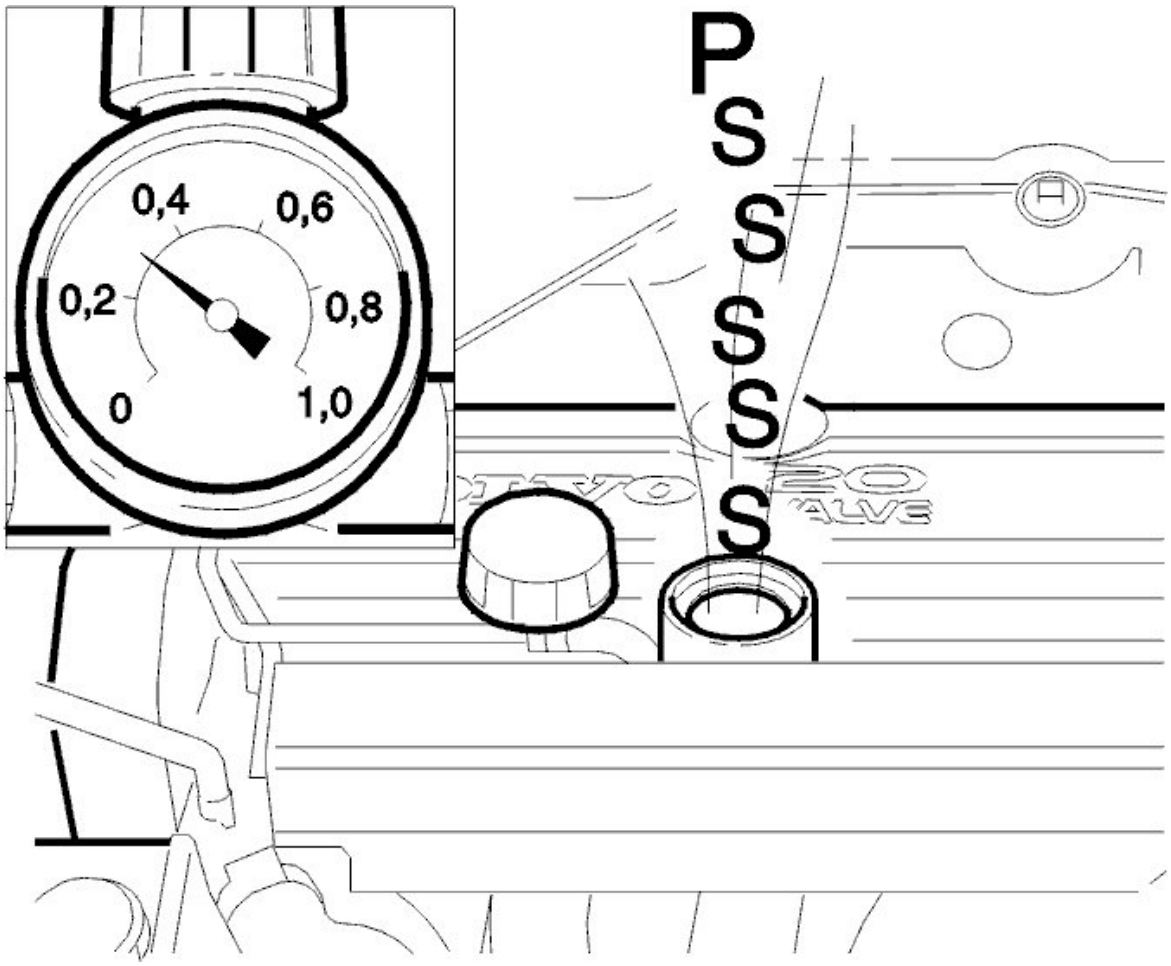
Connect the test pressurization equipment



Remove:

- the hose clamp (2) between the mass air flow (MAF) sensor and the intake manifold for the turbocharger (TC)
- the screws for the intake manifold. Fold the pipe up. Connect tool999 5545 ADAPTOR See: Tools and Equipment/999 5545 Adaptor and pressure regulator999 5544 REGULATOR See: Tools and Equipment/999 5544 Regulator to the intake manifold. Tighten the hose clamp.

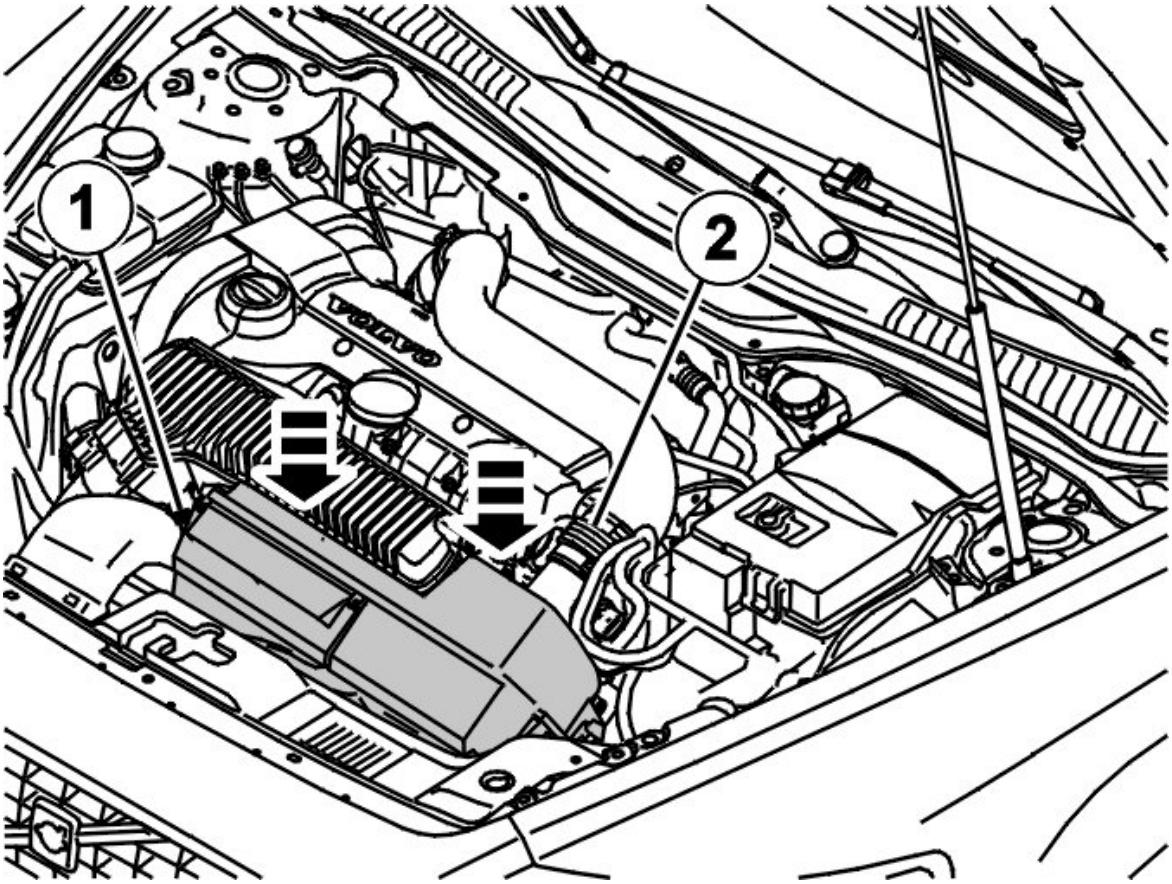
Check



Remove the oil filler cap. Connect the compressed air hose. Adjust the regulator to obtain a maximum pressure of**0.3 bar**.
There may be a gentle hissing sound from the oil filler opening. This is due to the opening of an intake valve and the leakage of cylinder pressure past the piston rings. If a leak is suspected, spray a soap solution onto the area. Remedy any leakage.

Installation

Installing components



Install:
- the intake manifold between the mass air flow (MAF) sensor and the turbocharger (TC)
- the screws for the intake manifold. Tighten
- the hose clamp (2) at the mass air flow (MAF) sensor.

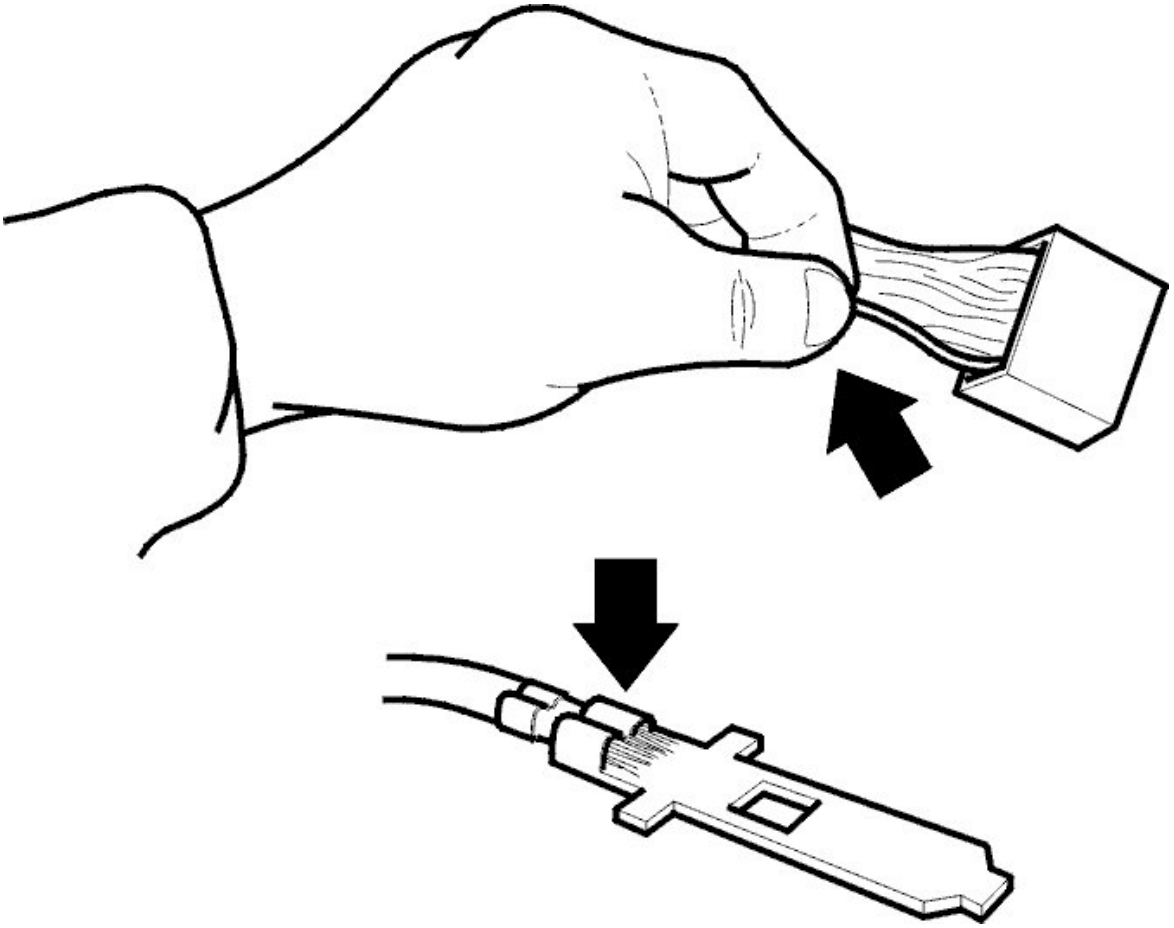
Checking Wiring And Terminals

Checking wiring and terminals

Contents

Select appropriate fault-tracing on wiring and connectors.
- Inspect terminals visually
- Open-circuit
- Short-circuit to ground
- Short-circuit to supply voltage
- Loose connections (terminals)
- Contact resistance and oxidation
- Intermittent fault-tracing See: Testing and Inspection/Component Tests and General Diagnostics/Intermittent Fault-Tracing

Inspect terminals visually



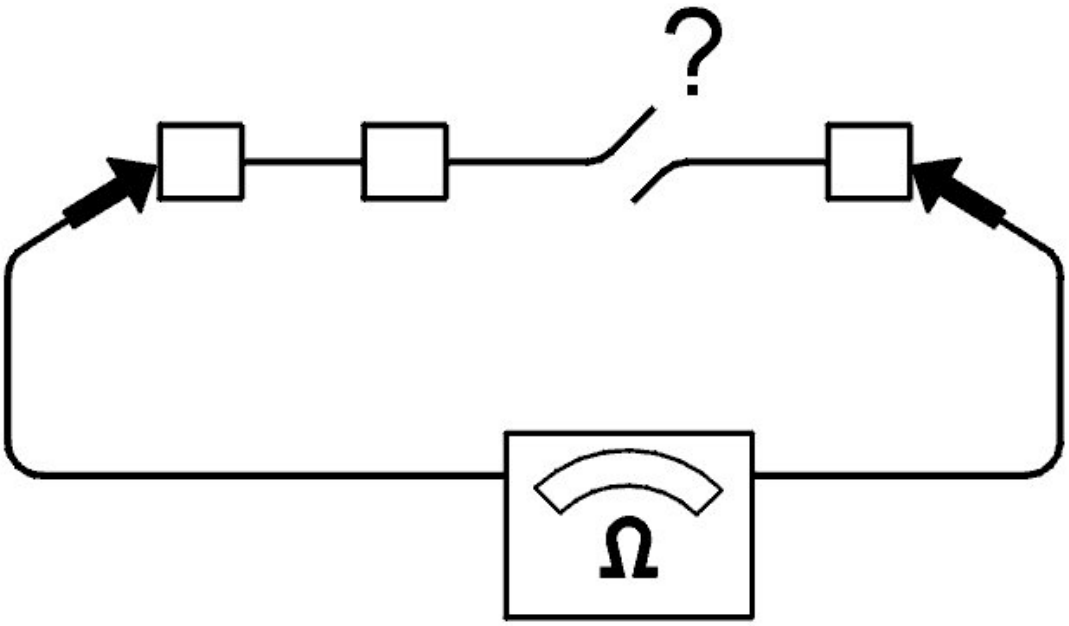
Note! When checking the engine control module (ECM), do not remove the control module from the car before the main relay has interrupted the power supply. This may take up to 4 minutes after the ignition has been switched off and the engine cooling fan (FC) has stopped running.

Inspect the terminals visually when checking, or taking readings from, opened connectors.
For repair of wiring and terminals, see VIDA/REPAIR/CLEANING, CHECKING AND ADJUSTMENT/3 Electrical system/37 Wiring and fuses/371 Wiring.

Checks:

- Check for oxidation. This can cause poor connections in the terminals
- Check for damage to pins and terminals. Check that they are properly inserted into the connector. Check that the cable is properly connected to the pin or terminal. Check pins and terminals particularly carefully
- Using a loose male connector, test to see if the female connector provides a good contact and that the pin remains in place when the male connector is pulled lightly
- Shake the cable lightly and pull on connectors during measurement to locate damage.

Open-circuit



Caution! Avoid touching control module connector pins and corresponding cable harness connectors. There is a risk of electrostatic discharge, which could damage the control module. Relieve any charge on yourself and the tools to be used by holding the metal part of the tool and touching part of the body just before starting work.

An open-circuit in a cable will be indicated by the loss of a function (or functions).
Chafed and broken leads are common causes of faults.
For repair of wiring and terminals, see VIDA/REPAIR/CLEANING, CHECKING AND ADJUSTMENT/3 Electrical system/37 Wiring and fuses/371 Wiring.

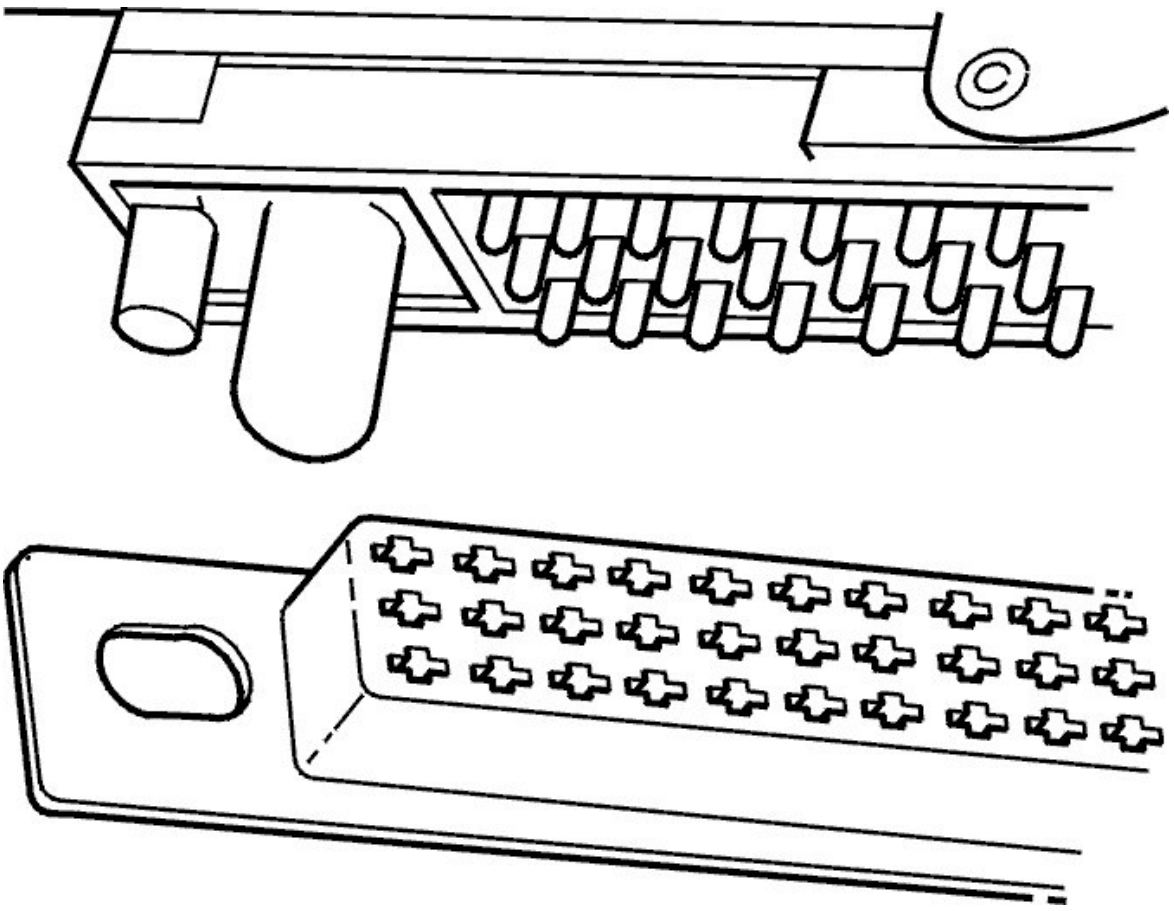
Checks:

- Disconnect the connectors at both ends of the cable.

Check the cables visually according to Inspect terminals visually.
Connect an ohmmeter between the ends of the cable.
The ohmmeter should read approximately 0ohms if there is no open-circuit in the cable.

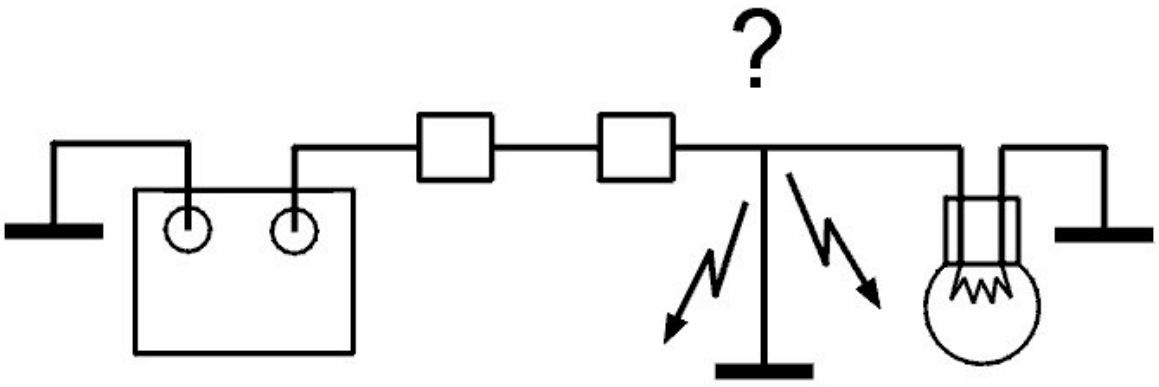
Note! When taking readings from the female connector it is important to position a replacement part between the female connector and the measuring instrument. The replacement part consists of a piece of cable with a cable terminal at one end. Never insert an object into the female connector. There is a risk of damaging the female connector.

Shake the cable lightly and pull on connectors during measurement to locate the damage.
If the reading is not correct. Replace the cable and / or continue according to Contact resistance and oxidation.



Always check the control module and control module box connectors to ensure that their pins and sockets are not bent or damaged, this may cause faults.
Check pins and terminals particularly carefully.

Short-circuit to ground



Caution! Avoid touching control module connector pins and corresponding cable harness connectors. There is a risk of electrostatic discharge, which could damage the control module. Relieve any charge on yourself and the tools to be used by holding the metal part of the tool and touching part of the body just before starting work.

A short-circuit between a live cable and ground is often indicated by the loss of a function or a fuse blowing when a current is passed through the cable.
For repair of wiring and terminals, see VIDA/REPAIR/CLEANING, CHECKING AND ADJUSTMENT/3 Electrical system/37 Wiring and fuses/371 Wiring.

Checks:

- Check the cables visually according to Inspect terminals visually.

Activate all switches and sensors in the circuit. Check whether the fuse blows

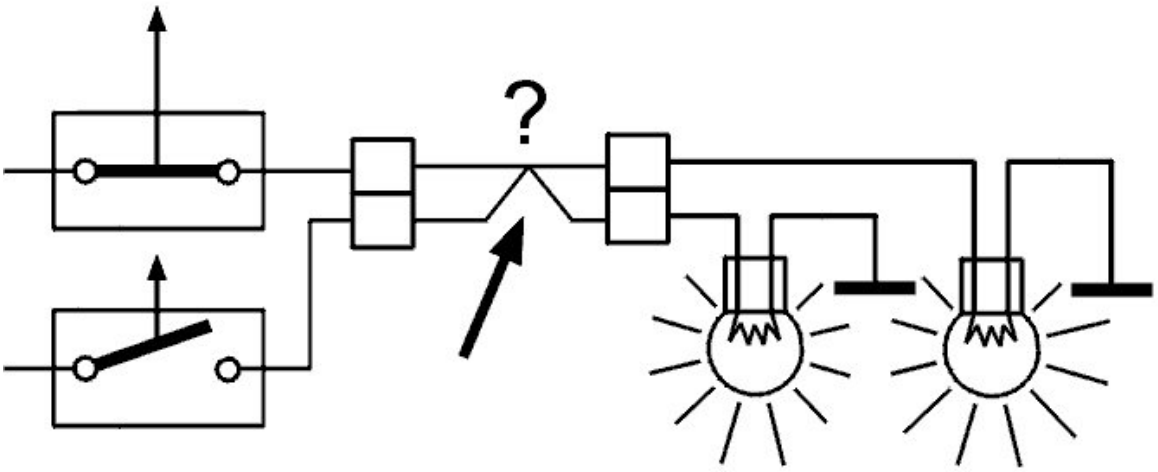
- Disconnect the connectors in the circuit to ensure that they do not affect readings.

Connect an ohmmeter between cable and ground.
The ohmmeter should read infinite resistance if no components are connected.

Note! When taking readings from the female connector it is important to position a replacement part between the female connector and the measuring instrument. The replacement part consists of a piece of cable with a cable terminal at one end. Never insert an object into the female connector. There is a risk of damaging the female connector.

Shake the cable lightly and pull on connectors during measurement to locate the damage.
If the reading is not correct, replace the cable and / or continue according to Contact resistance and oxidation.

Short-circuit to supply voltage



Caution! Avoid touching control module connector pins and corresponding cable harness connectors. There is a risk of electrostatic discharge, which could damage the control module. Relieve any charge on yourself and the tools to be used by holding the metal part of the tool and touching part of the body just before starting work.

A short-circuit between a cable and supply voltage is often indicated by the loss of a function or a fuse blowing when a current is passed through the cable.
For repair of wiring and terminals, see VIDA/REPAIR/CLEANING, CHECKING AND ADJUSTMENT/3 Electrical system/37 Wiring and fuses/371 Wiring.

Checks:

- Check the cables visually according to Inspect terminals visually.

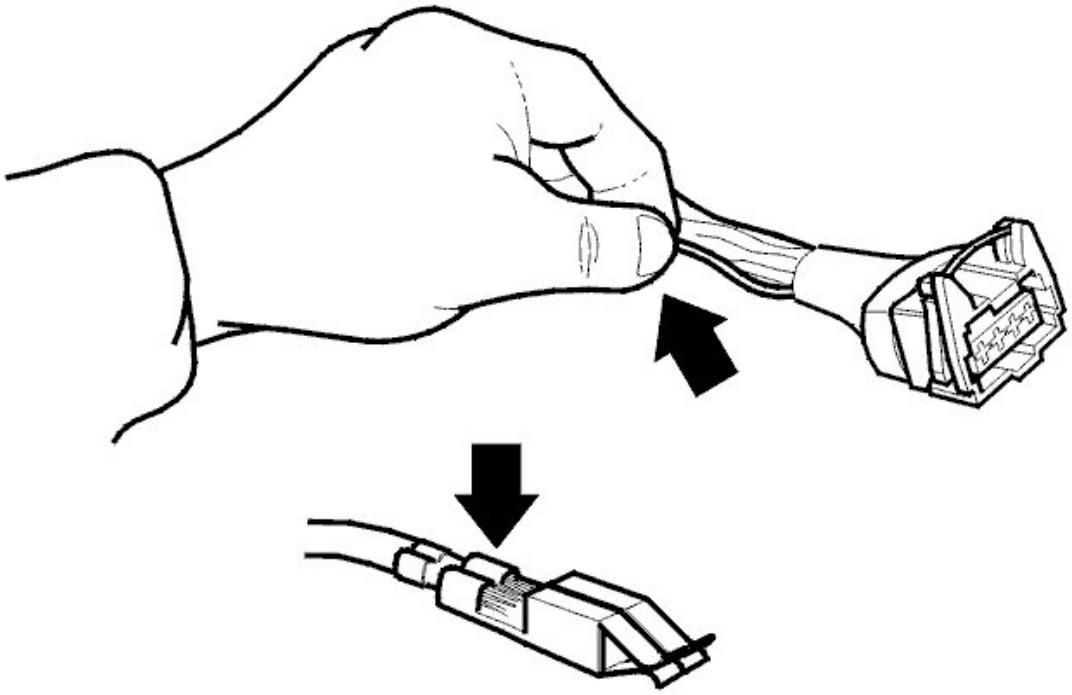
Use a voltmeter to take readings at various points in the circuit while operating switches and sensors.
The voltmeter reading depends on the circuit being tested and the positions of switches and sensors. Use the wiring diagram to determine the correct voltage in the circuit.
Use an ohmmeter between the suspect cables to detect short-circuits between them.
The ohmmeter should read infinite resistance between cables not connected to each other in the circuit.

Note! When taking readings from the female connector it is important to position a replacement part between the female connector and

the measuring instrument. The replacement part consists of a piece of cable with a cable terminal at one end. Never insert an object into the female connector. There is a risk of damaging the female connector.

Shake the cable lightly and pull on connectors during measurement to locate the damage.
If the reading is not correct. Replace the cable and / or continue according to Contact resistance and oxidation.

Loose connections (terminals)



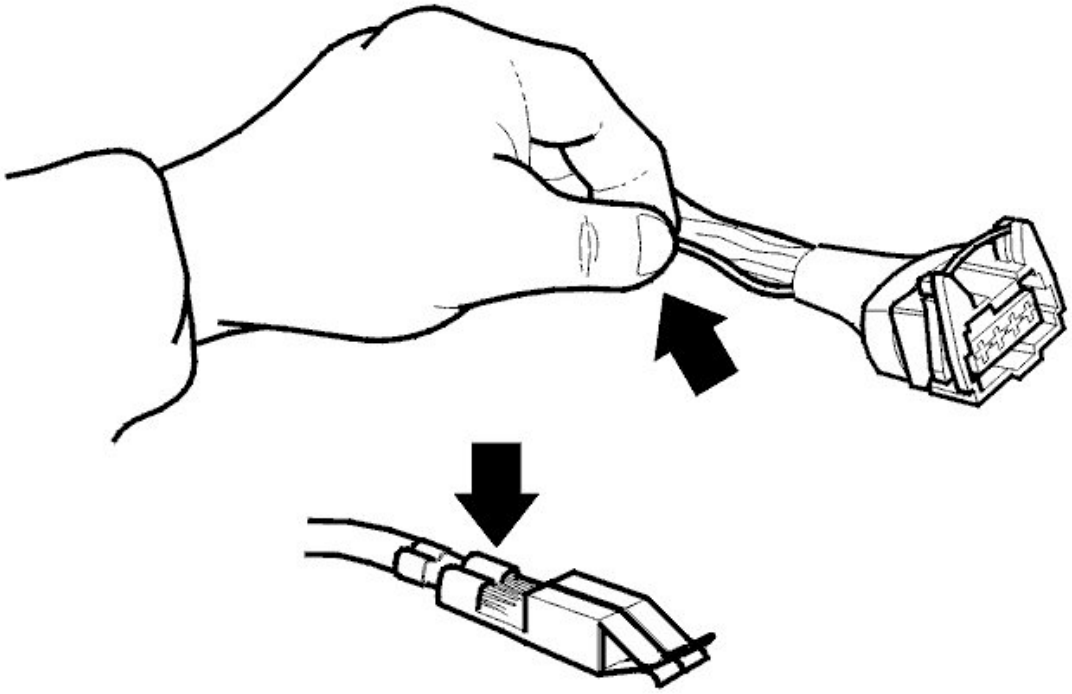
For repair of wiring and terminals, see VIDA/REPAIR/CLEANING, CHECKING AND ADJUSTMENT/3 Electrical system/37 Wiring and fuses/371 Wiring.
Loose connections in terminals may be caused by oxidation of the pins and sockets, or by a faulty connection of a cable to its cable terminal. Loose connections produce the same faults as an intermittent open-circuit in a cable.

Checks:

- Inspect terminals visually according to Inspect terminals visually.

Continue according to Contact resistance and oxidation.

Contact resistance and oxidation

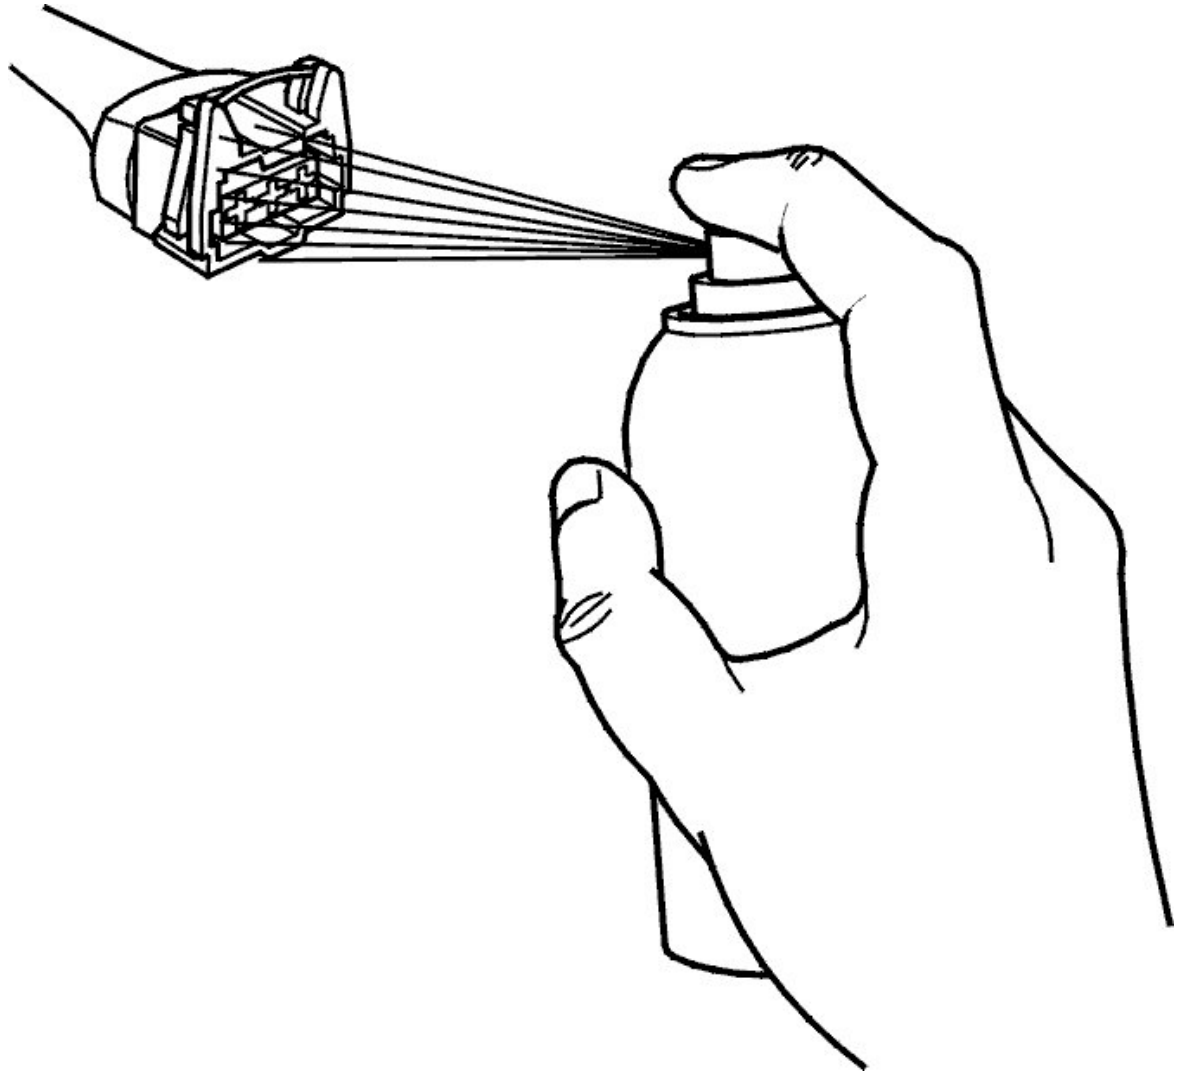


Caution! Avoid touching control module connector pins and corresponding cable harness connectors. There is a risk of electrostatic discharge, which could damage the control module. Relieve any charge on yourself and the tools to be used by holding the metal part of the tool and touching part of the body just before starting work.

The resistance in switches, cables and terminals should be 0 ohms. There is sometimes some resistance in connections due to oxidation.
If resistance is too great there will be function problems. The magnitude of the resistance before it causes a malfunction depends on the circuit load. A guideline would be a few ohms.

Note! When taking readings from the female connector it is important to position a replacement part between the female connector and the measuring instrument. The replacement part consists of a piece of cable with a cable terminal at one end. Never insert an object into the female connector. There is a risk of damaging the female connector.

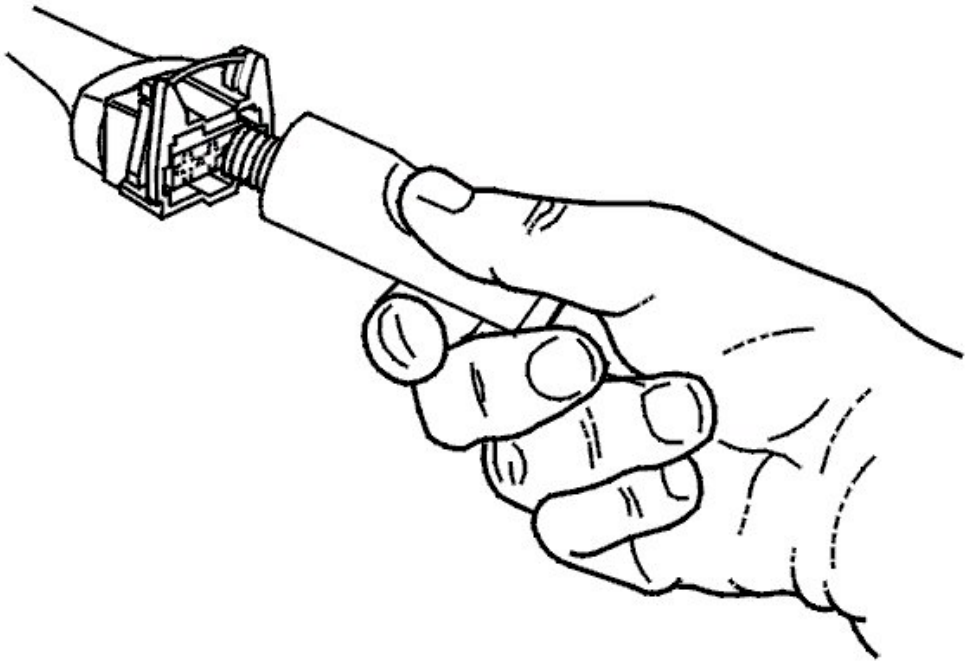
Cleaning female socket terminals and male pin terminals



Note! Do not apply rust solvent spray or grease to the catalyst monitor sensor or instrument cluster connectors.

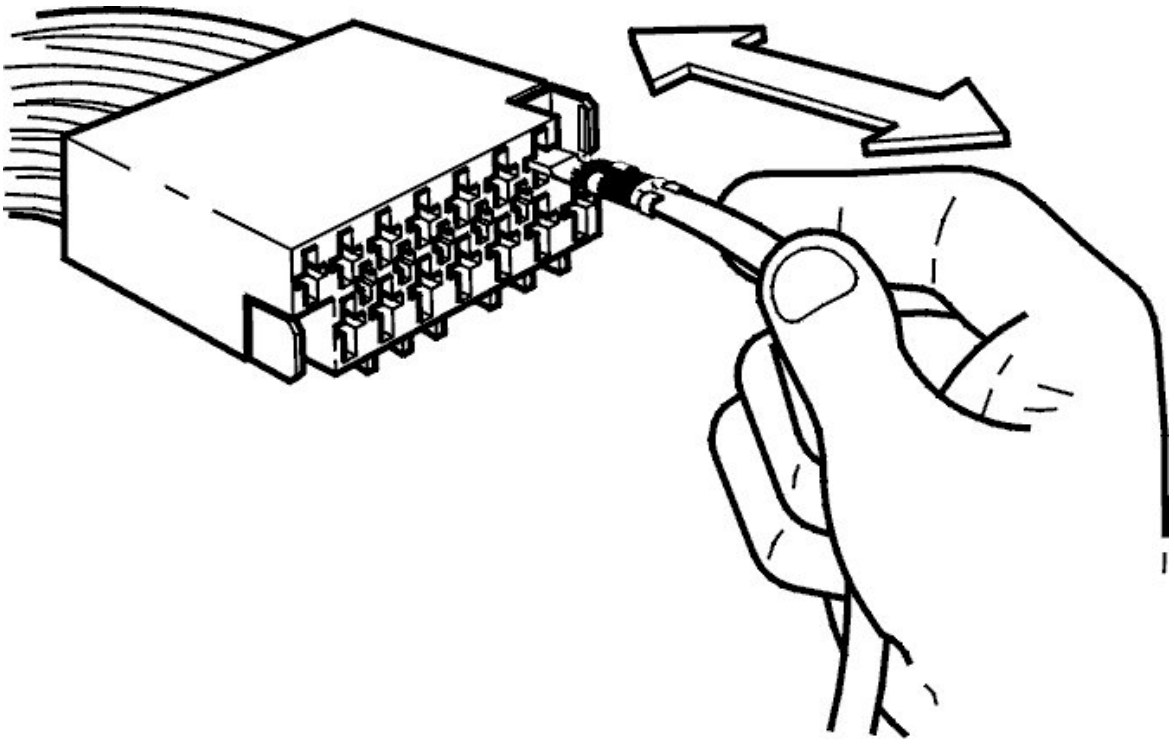
- Ignition off
- Disconnect the battery negative terminal
- Use compressed air to clean the disconnected connector
- Apply rust solvent spray 1161422 to the disconnected connectors
- Blow clean using compressed air.

Greasing female terminals



Note! Do not fill the protective cover with grease.

- Press grease, P/N 1161417-9, into the terminals directly from the tube
- Check that all the cavities in the connectors are filled
- Use a loose male pin to ensure that contact in sockets is good. The pin should remain in position when pulled gently.



Intermittent fault-tracing

General

The reason the car is in the workshop is because the customer has experienced abnormalities with the car. The symptoms experienced by the customer does not always coincide with a permanent fault. The fault might not occur when the customer arrives at the workshop but occurs on a single occasion.
In order to deduce the fault type is important to check the symptoms reported by the customer:

- How does the car behave? Is the car difficult to start, are the gears hard to shift, does the tachometer flicker etc.

- What are the circumstances when the fault occurs? under heavy load, is it dependent on the weather, outside temperature, on uneven roads, when making sharp turns, only when the engine is cold, under hard braking etc.

It is important to interview the customer about the surrounding circumstances in the event of a fault.
It may be an advantage to simulate the driving conditions for when the symptom occurs and carry out an analysis and deduce the fault. By deducing the fault, the symptom can be remedied so that the fault does not recur.
When a diagnostic trouble code (DTC) has been stored the freeze frames are also stored. These can be used to recreate the driving conditions for the diagnostic trouble code (DTC).
Tools:

- Reading off freeze frames, read off the freeze frame data for the relevant diagnostic trouble code (DTC)
- Status identifier, read off the status of the selected diagnostic trouble code (DTC)
- The counter indicates, amongst other things, how many fault free cycles have been carried out since the diagnostic trouble code (DTC) was stored.

Intermittent electrical fault

An intermittent electrical fault can be caused by faults in the wiring, components or connectors.
Possible fault causes for intermittent electrical faults are:

- Damaged terminal pins in the connector
- Loose connections in the connectors
- Poor ground connection (oxidation)
- Moisture, poor connections in the connector
- Defects, cracking, damage on the components
- Strong magnetic or other interference that has affected the control modules.

Intermittent functional faults

Intermittent functional faults could be caused by mechanical defects in the components.

- Cracked or blocked hoses
- Incorrect oils, fluids
- Incorrect fuel
- Sticking mechanical components.

Intermittent internal faults

Intermittent internal faults could be due to:

- Electromechanical interference
- Power supply too low
- Oxidized ground terminal for the control module
- Defective internal components.

Intermittent communication problems

Intermittent communication problems could be due to:

- Electromechanical interference
- Oxidation / loose connections in the connectors
- Defective signal cables.

Simulating fault causes

A large amount of input data is a required to recreate and simulate fault occurring circumstances.
Certain cases can be difficult to recreate. High speed driving and stalling to achieve high loads is not recommended.
In order to achieve high loads accelerate hard in quick succession a number of time instead.
Cases that are possible to simulate:

- high load
- moisture
- heat
- cold
- loose connections.

High load

High load can be simulated by accelerating hard repeatedly.

Moisture

Moisture can be simulated by spraying water on the suspected faulty component or connector using a spray bottle or hose.

Heat

Heat can be simulated by using a hot air gun or similar to heat up a suspected faulty component or connector.

In order to achieve a high engine temperature allow the engine to idle at a high load with the hood down to prevent air flowing through the engine compartment. Run the engine in hot conditions. Read off the engine coolant temperature (ECT) using VIDA, the temperature gauge in the combined instrument panel is progressive.

Cold

Cold can be simulated by cooling down the suspected faulty component or connector using a freeze spray.

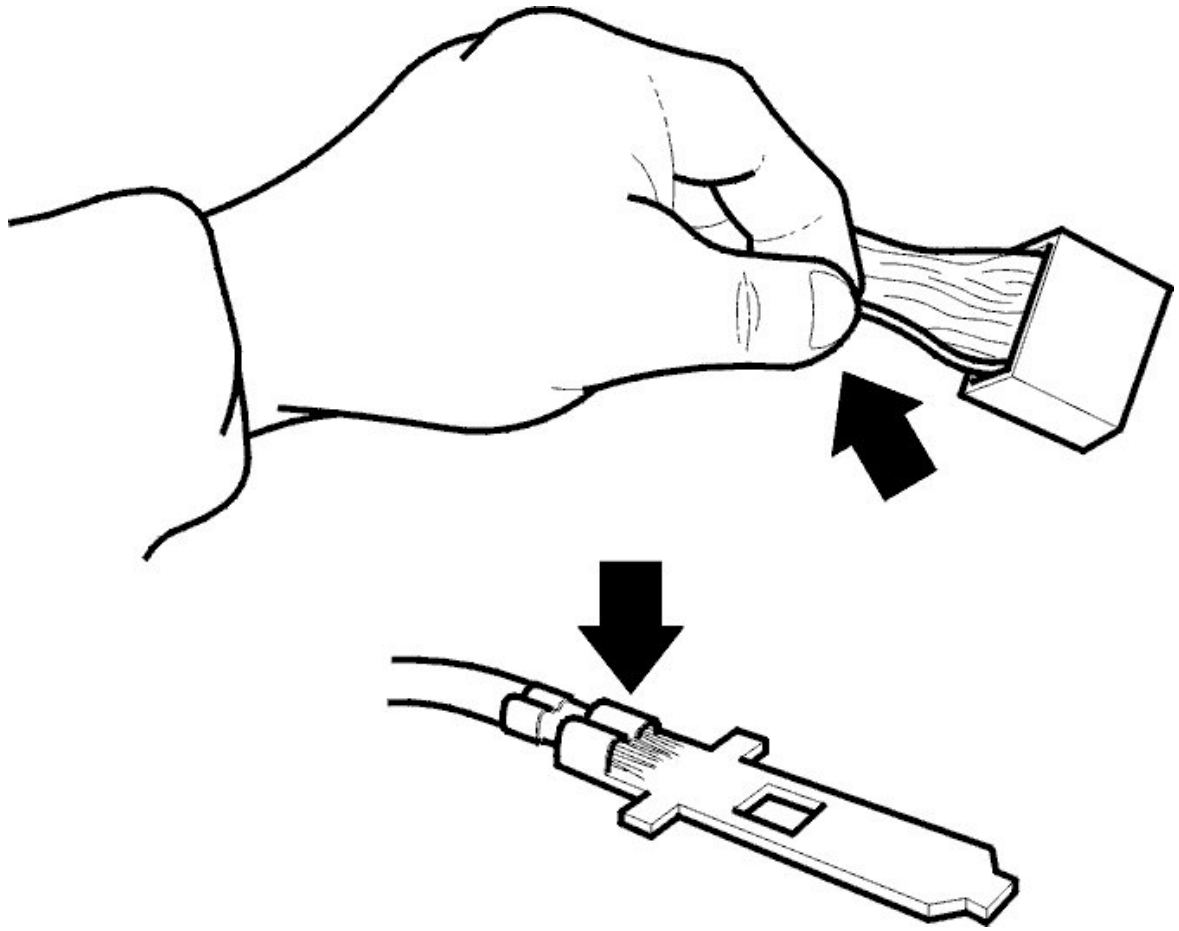
Loose connections

Loose connections can be simulated by twisting and shaking the connector whilst the function is activated.

Checking Wiring and Terminals - Intermittent Faults

Checking wiring and terminals. Intermittent faults

Inspect terminals visually



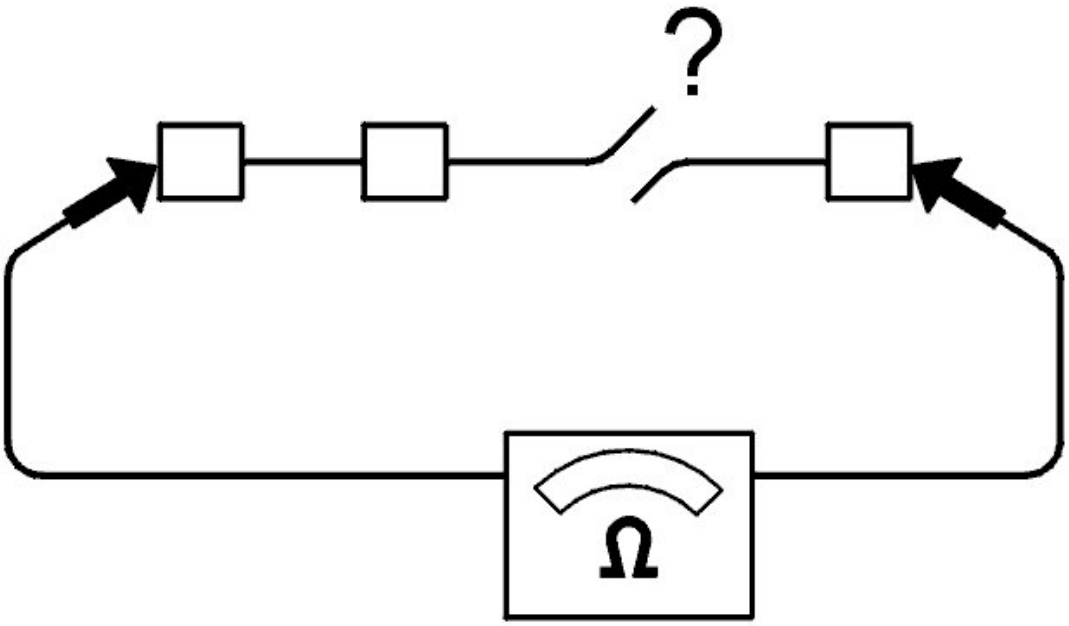
Note! When checking the engine control module (ECM), do not remove the control module from the car before the main relay has interrupted the power supply. This may take up to 4 minutes after the ignition has been switched off and the engine cooling fan (FC) has stopped running.

Inspect the terminals visually when checking, or taking readings from, opened connectors.
For repair of wiring and terminals, see VIDA/REPAIR/CLEANING, CHECKING AND ADJUSTMENT/3 Electrical system/37 Wiring and fuses/371 Wiring.

Checks:

- Check for oxidation. This can cause poor connections in the terminals
- Check for damage to pins and terminals. Check that they are properly inserted into the connector. Check that the cable is properly connected to the pin or terminal. Check pins and terminals particularly carefully
- Using a loose male connector, test to see if the female connector provides a good contact and that the pin remains in place when the male connector is pulled lightly
- Shake the cable lightly and pull on connectors during measurement to locate damage.

Open-circuit, intermittent faults

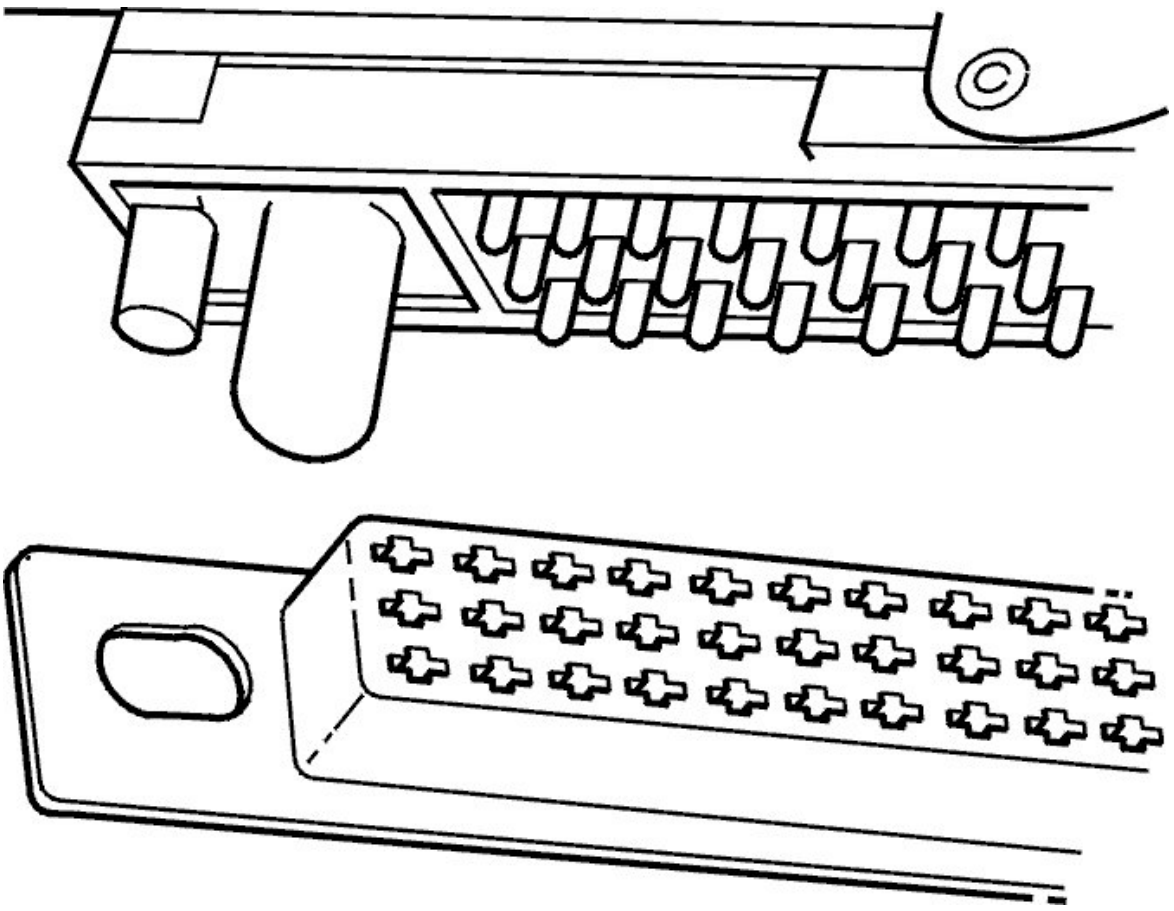


An open-circuit in a cable will be indicated by the loss of a function (or functions).
Chafed and broken leads are common causes of faults.
For repair of wiring and terminals, see VIDA/REPAIR/CLEANING, CHECKING AND ADJUSTMENT/3 Electrical system/37 Wiring and fuses/371 Wiring.

Checks:

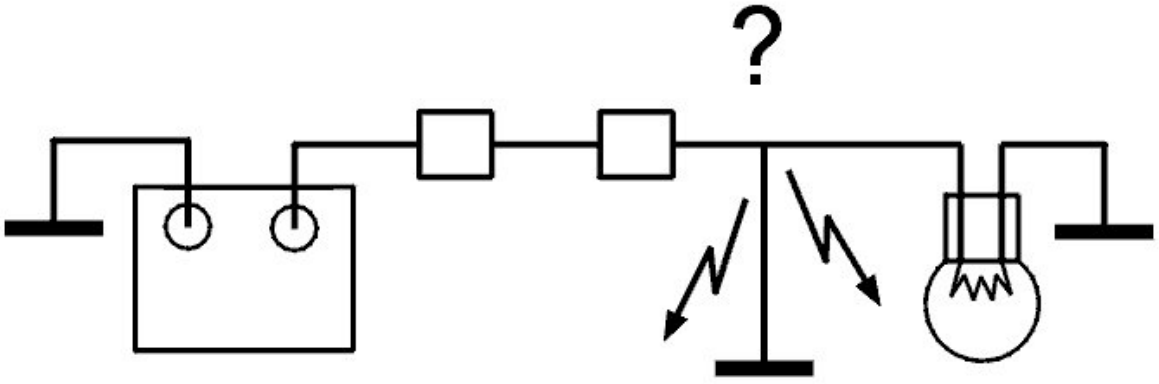
- Disconnect the connectors at both ends of the cable.

Check the cables visually according to Inspect terminals visually.
Connect an ohmmeter between the ends of the cable.
The ohmmeter should read approximately 0ohms if there is no open-circuit in the cable.
Shake the cable lightly and pull on connectors during measurement to locate the damage.
If the reading is not correct. Replace the cable and / or continue according to Contact resistance and oxidation.



Always check the control module and control module box connectors to ensure that their pins and sockets are not bent or damaged, this may cause faults.
Check pins and terminals particularly carefully.

Short-circuit to ground, intermittent faults



A short-circuit between a live cable and ground is often indicated by the loss of a function or a fuse blowing when a current is passed through the cable.
For repair of wiring and terminals, see VIDA/REPAIR/CLEANING, CHECKING AND ADJUSTMENT/3 Electrical system/37 Wiring and

fuses/371 Wiring.

Checks:

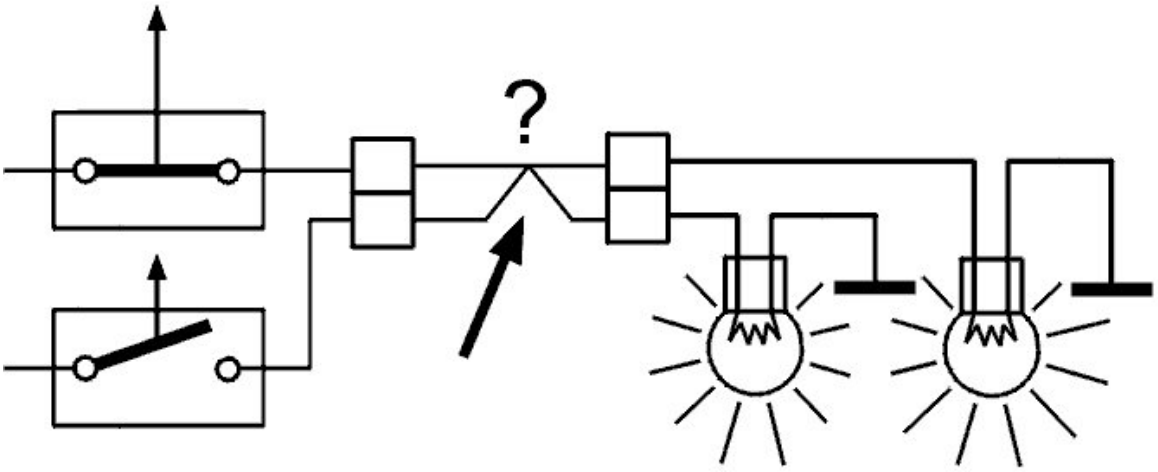
- Check the cables visually according to Inspect terminals visually.

Activate all switches and sensors in the circuit. Check whether the fuse blows

- Disconnect the connectors in the circuit to ensure that they do not affect readings.

Connect an ohmmeter between cable and ground.
The ohmmeter should read infinite resistance if no components are connected.
Shake the cable lightly and pull on connectors during measurement to locate the damage.
If the reading is not correct, replace the cable and / or continue according to Contact resistance and oxidation.

Short-circuit to supply voltage, intermittent faults



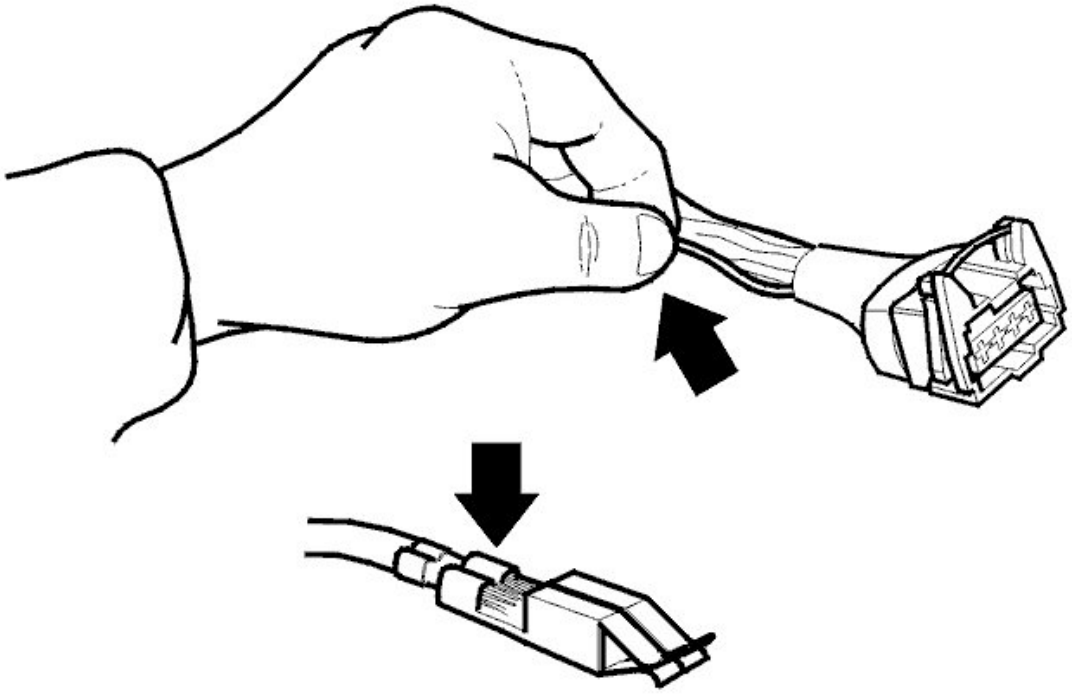
A short-circuit between a cable and supply voltage is often indicated by the loss of a function or a fuse blowing when a current is passed through the cable.
For repair of wiring and terminals, see VIDA/REPAIR/CLEANING, CHECKING AND ADJUSTMENT/3 Electrical system/37 Wiring and fuses/371 Wiring.

Checks:

- Check the cables visually according to Inspect terminals visually.

Use a voltmeter to take readings at various points in the circuit while operating switches and sensors.
The voltmeter reading depends on the circuit being tested and the positions of switches and sensors. Use the wiring diagram to determine the correct voltage in the circuit.
Use an ohmmeter between the suspect cables to detect short-circuits between them.
The ohmmeter should read infinite resistance between cables not connected to each other in the circuit.
Shake the cable lightly and pull on connectors during measurement to locate the damage.
If the reading is not correct. Replace the cable and / or continue according to Contact resistance and oxidation.

Loose connections (terminals)



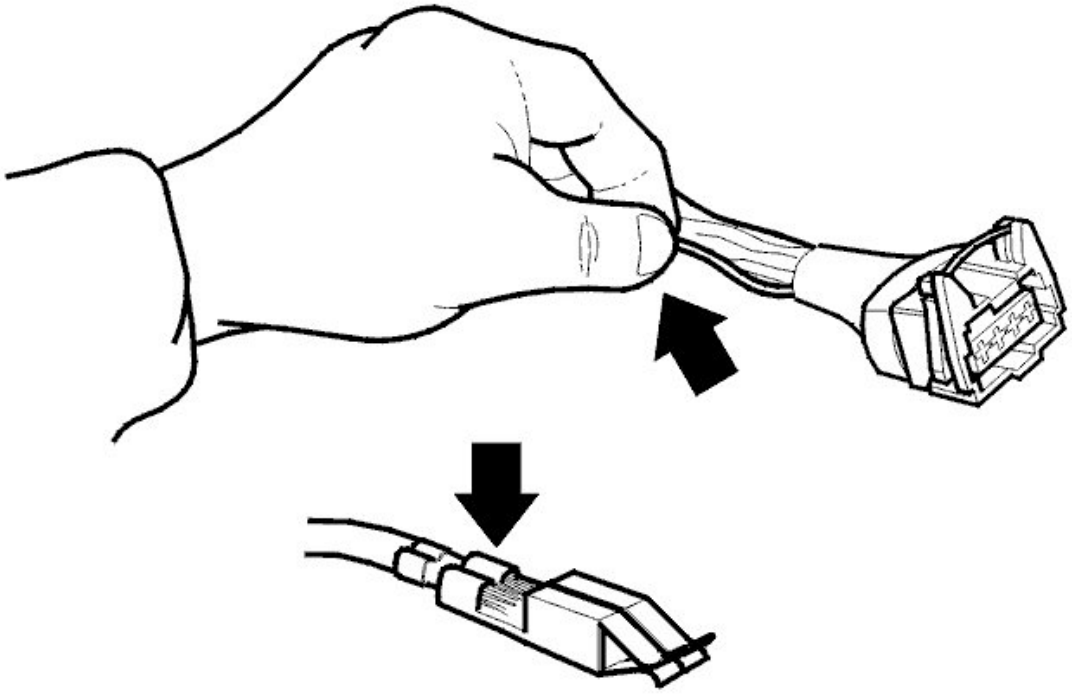
For repair of wiring and terminals, see VIDA/REPAIR/CLEANING, CHECKING AND ADJUSTMENT/3 Electrical system/37 Wiring and fuses/371 Wiring.
Loose connections in terminals may be caused by oxidation of the pins and sockets, or by a faulty connection of a cable to its cable terminal. Loose connections produce the same faults as an intermittent open-circuit in a cable.

Checks:

- Inspect terminals visually according to Inspect terminals visually.

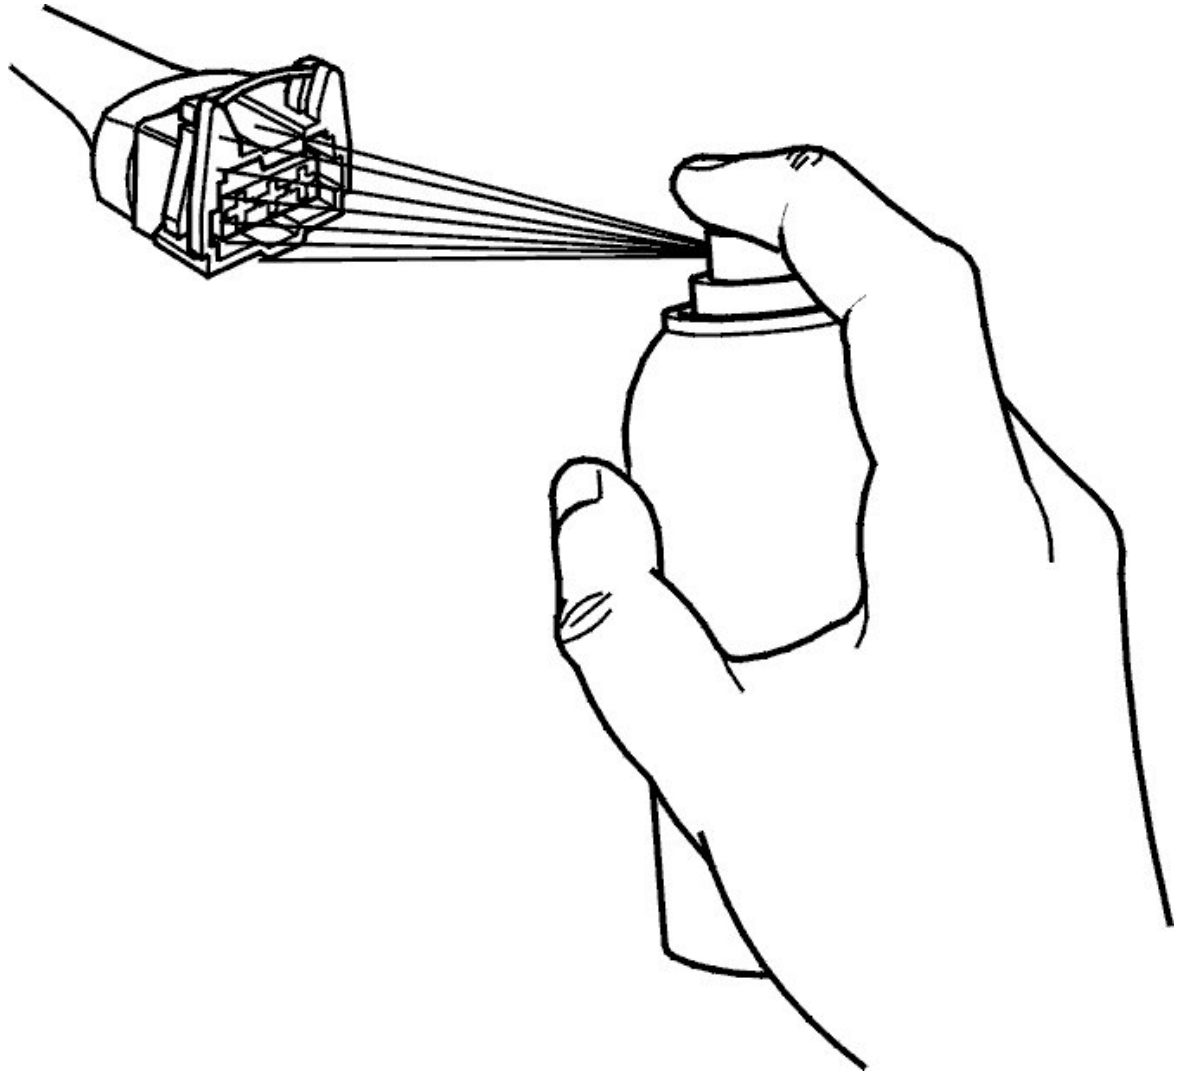
Continue according to Contact resistance and oxidation.

Contact resistance and oxidation



In theory, the resistance across contacts, leads and terminals should be 0 ohms. However, there is always some resistance due to terminal oxidation. If resistance is too great there will be function problems. The magnitude of the resistance before it causes a malfunction depends on the circuit load. A guideline would be a few ohms.

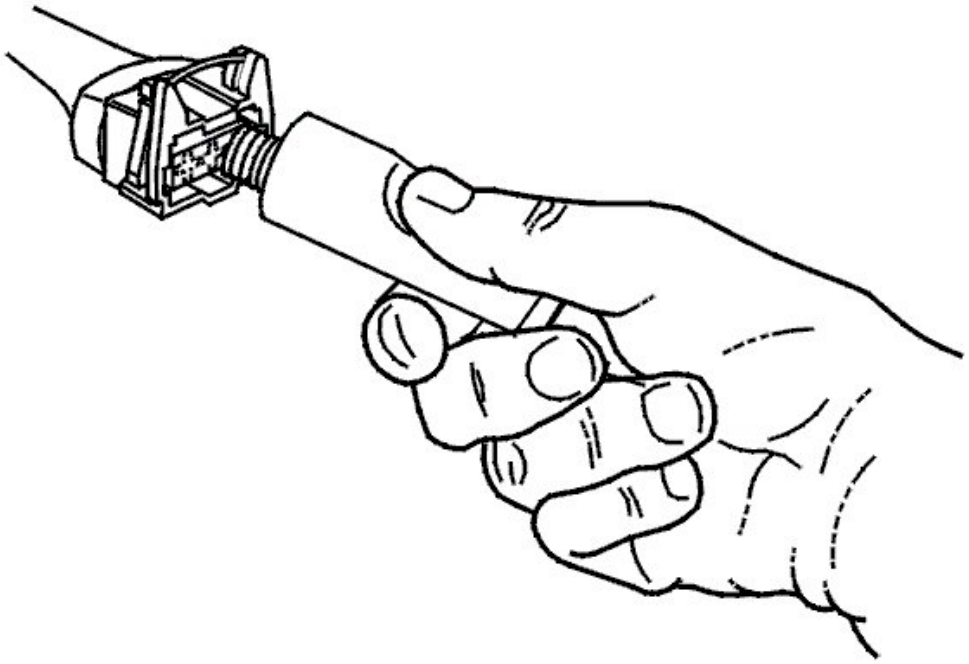
Cleaning female socket terminals and male pin terminals



Note! Do not apply rust solvent spray or grease to the catalyst monitor sensor or instrument cluster connectors.

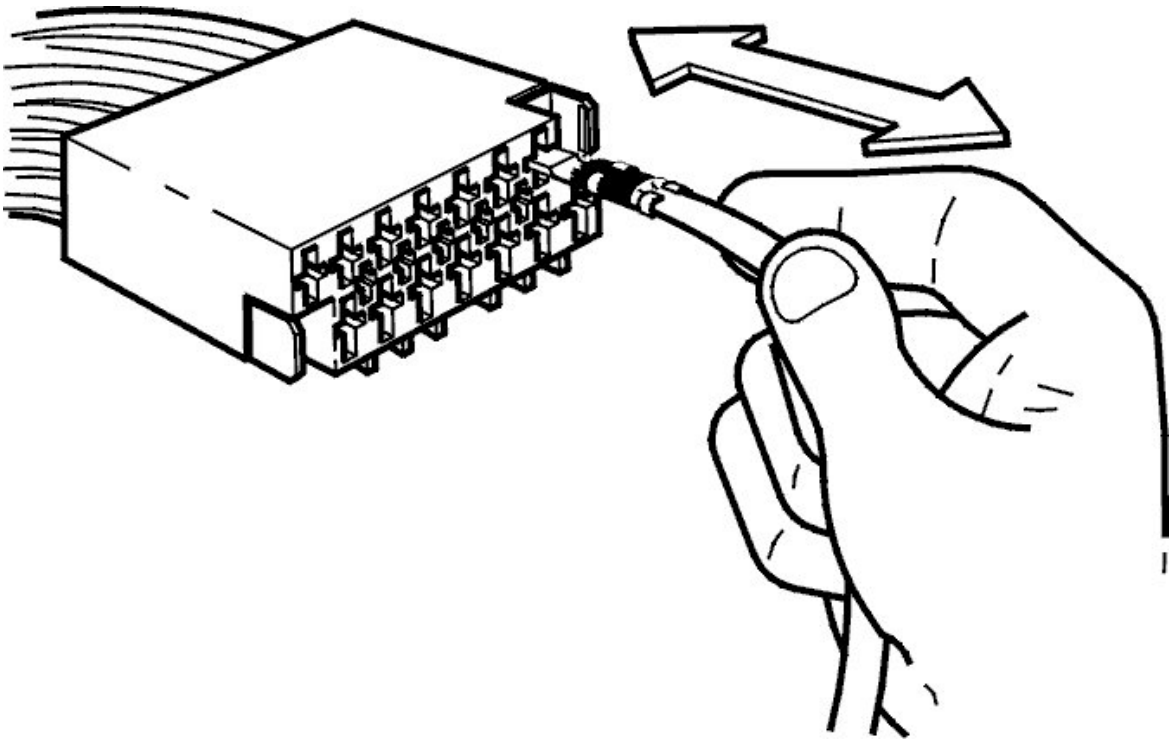
- Ignition off
- Disconnect the battery negative terminal
- Use compressed air to clean the disconnected connector
- Apply rust solvent spray 1161422 to the disconnected connectors
- Blow clean using compressed air.

Greasing female terminals



Note! Do not fill the protective cover with grease.

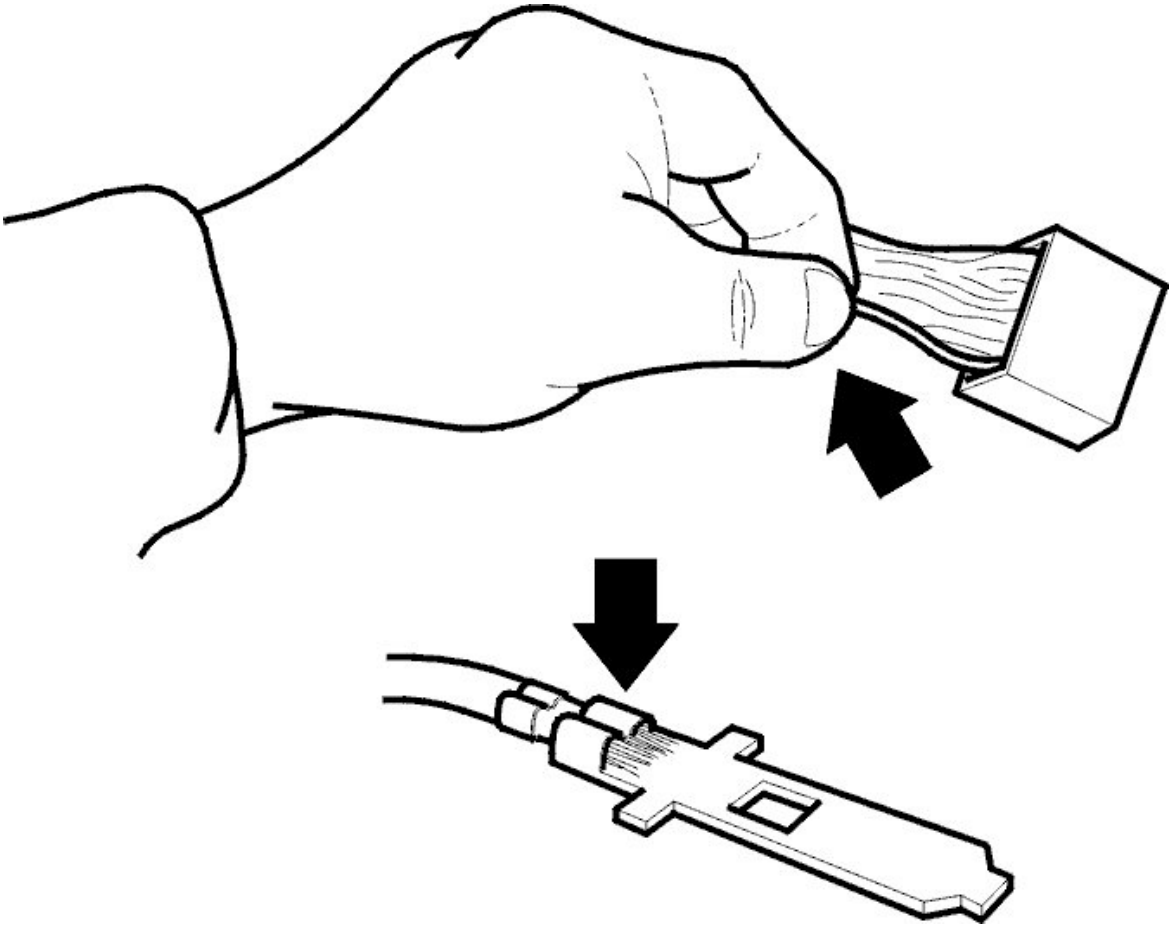
- Press grease, P/N 1161417-9, into the terminals directly from the tube
- Check that all the cavities in the connectors are filled
- Use a loose male pin to ensure that contact in sockets is good. The pin should remain in position when pulled gently.



Checking Wiring and Terminals - Permanent Faults

Checking wiring and terminals. Permanent fault

Check terminals visually



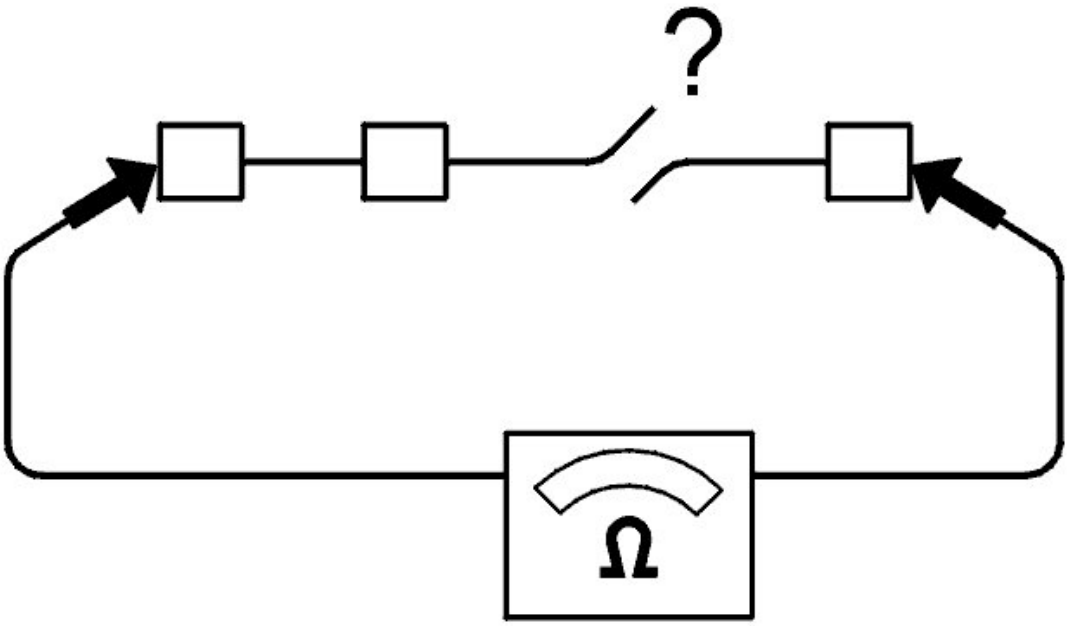
Note! When checking the engine control module (ECM), do not remove the control module from the car before the main relay has interrupted the power supply. This may take up to 4 minutes after the ignition has been switched off and the engine cooling fan (FC) has stopped running.

Inspect the terminals visually when checking, or taking readings from, opened connectors.
For repair of wiring and terminals, see VIDA/REPAIR/CLEANING, CHECKING AND ADJUSTMENT/3 Electrical system/37 Wiring and fuses/371 Wiring.

Checks:

- Check for oxidation. This can cause poor connections in the terminals
- Check for damage to pins and terminals. Check that they are properly inserted into the connector. Check that the cable is properly connected to the pin or terminal. Check pins and terminals particularly carefully
- Use a separate male terminal to check the female terminal. Check that they are secure: Pull on the pin.

Open-circuit, permanent faults

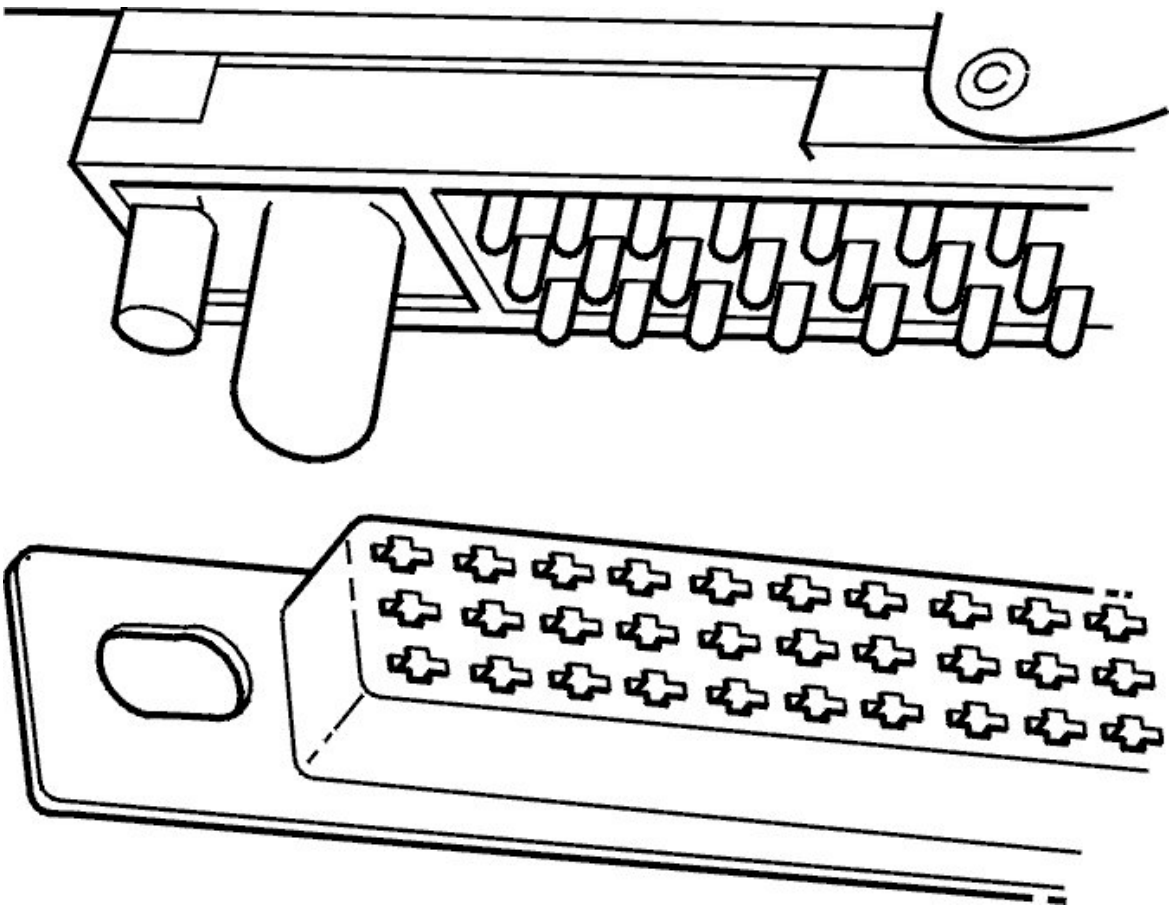


An open-circuit in a cable is indicated by a loss of one or more functions.
Chafed and broken cables or terminals that have come loose are common causes of faults in electrical systems.
For repair of wiring and terminals, see VIDA/REPAIR/CLEANING, CHECKING AND ADJUSTMENT/3 Electrical system/37 Wiring and fuses/371 Wiring.

Checks:

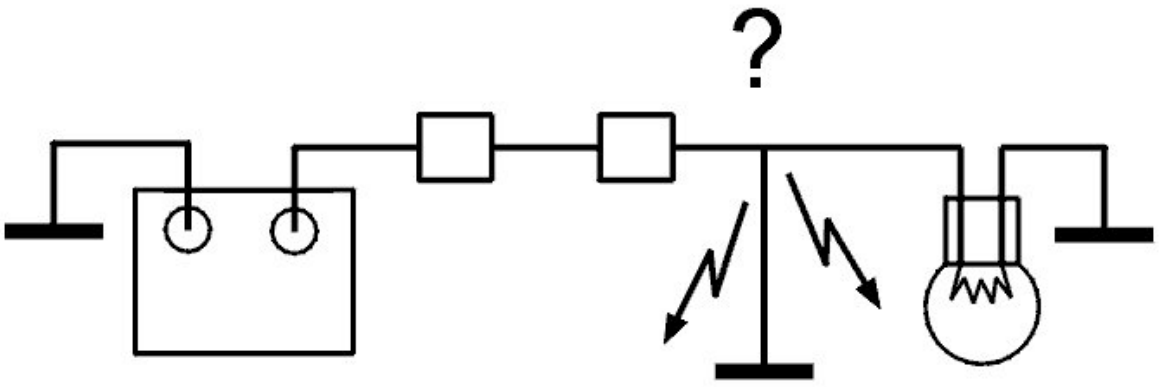
- Disconnect the connectors at both ends of the cable.

Connect an ohmmeter between the ends of the cable.
The ohmmeter should read approximately 0 ohms if there is no open-circuit in the cable.



Always check the control module and control module box connectors to ensure that their pins and sockets are not bent or damaged, as this can cause faults.
Check pins and terminals particularly for this fault. See Check terminals visually.

Short-circuit to ground, permanent faults



A short-circuit between a live cable and ground is often indicated by the loss of a function or a fuse blowing when a current is passed through the cable.
For repair of wiring and terminals, see VIDA/REPAIR/CLEANING, CHECKING AND ADJUSTMENT/3 Electrical system/37 Wiring and

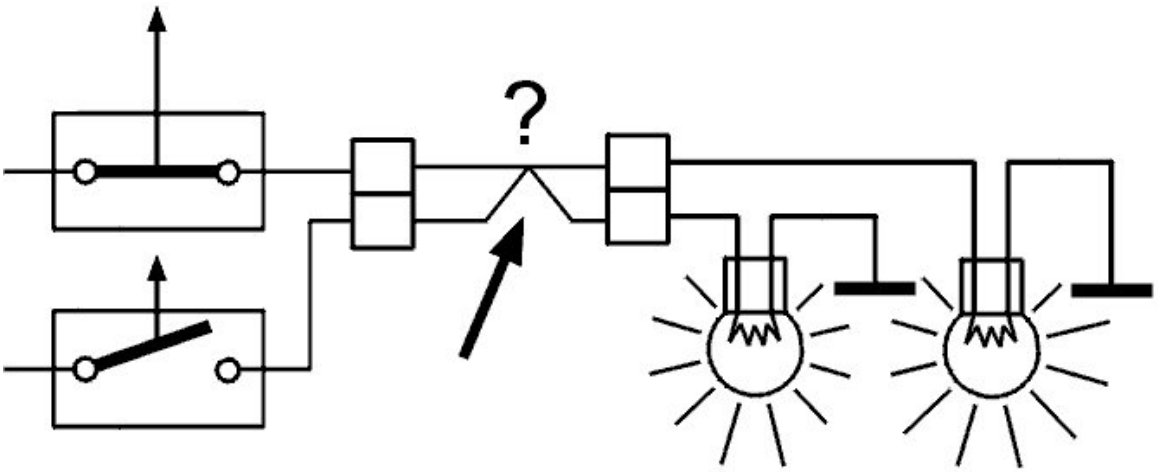
fuses/371 Wiring.

Checks:

- Activate all switches and sensors in the circuit. Check whether the fuse blows
- Disconnect the connectors in the circuit to ensure that they do not affect readings.

Use an ohmmeter to take a resistance reading between the cable and ground.
The ohmmeter should read infinite resistance if no components are connected.
Check pins and terminals particularly for this fault. See Check terminals visually.

Short-circuit to supply voltage. Permanent faults



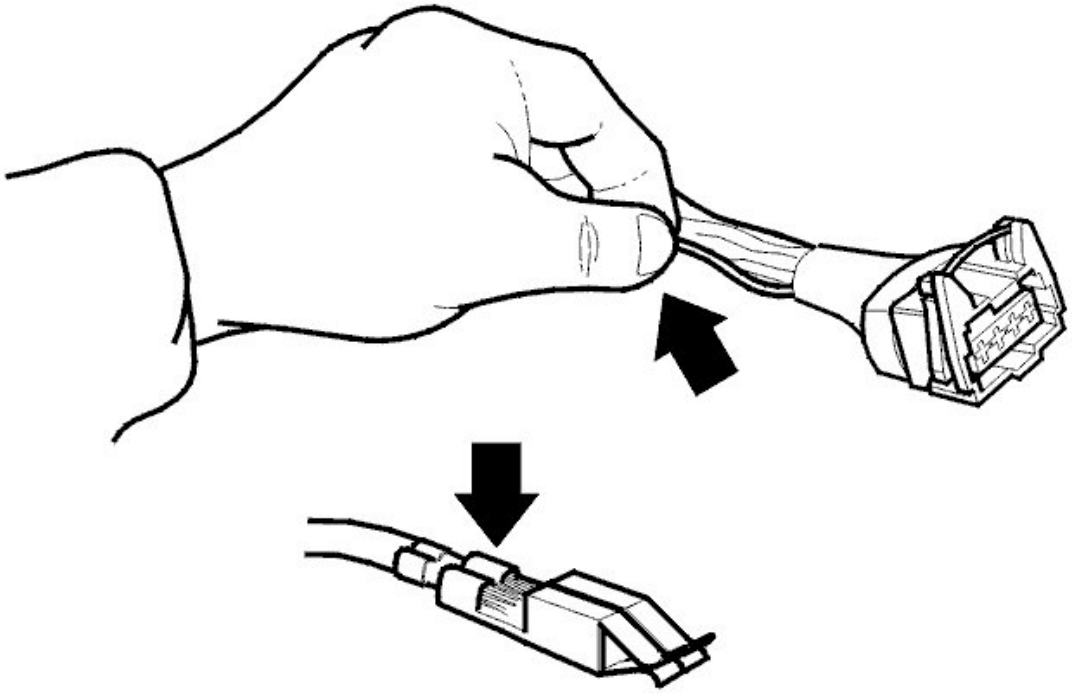
A short-circuit between a cable and supply voltage is often indicated by the loss of a function or a fuse blowing when voltage is passed through the cable.
For repair of wiring and terminals, see VIDA/REPAIR/CLEANING, CHECKING AND ADJUSTMENT/3 Electrical system/37 Wiring and fuses/371 Wiring.

Checks:

- Use a voltmeter to take readings at various points in the circuit while operating switches and sensors.

Voltmeter readings will depend on which circuit is tested and the status of switches and sensors. Use the wiring diagram to determine the correct voltage in the circuit.
Use an ohmmeter between the suspect cables to detect short-circuits between them.
The ohmmeter should read infinite resistance between cables not connected to each other in the circuit.
Check pins and terminals particularly for this fault. See Check terminals visually.

Contact resistance and oxidation

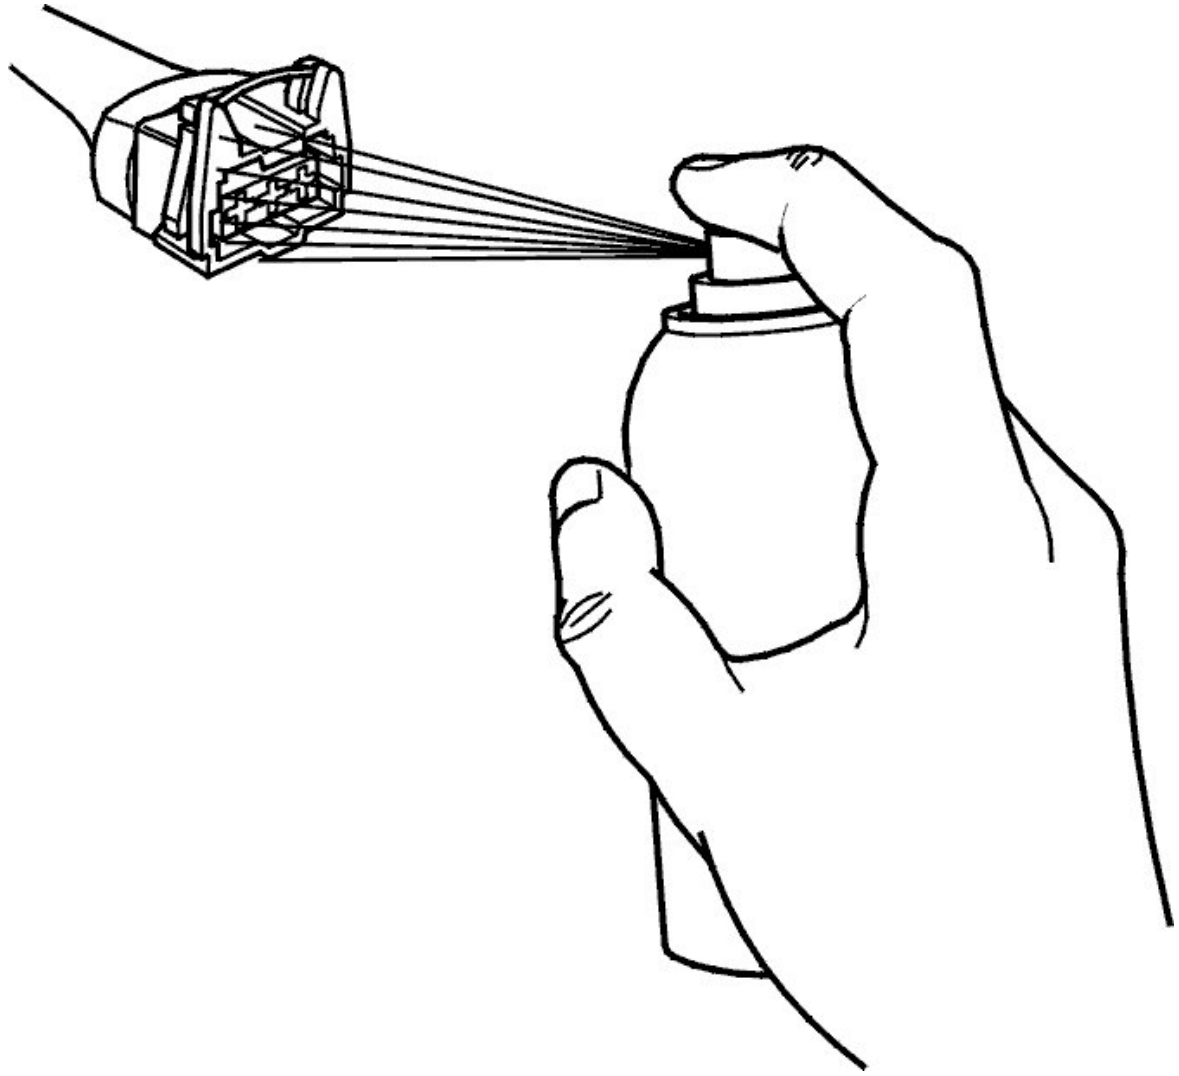


For repair of wiring and terminals, see VIDA/REPAIR/CLEANING, CHECKING AND ADJUSTMENT/3 Electrical system/37 Wiring and fuses/371 Wiring.
In theory, the resistance across contacts, leads and terminals should be 0 ohms. However, there is always some resistance due to terminal oxidation. If this resistance becomes too great the result will be a malfunction. The magnitude of the resistance before it causes a malfunction depends on the circuit load.

Checks:

- Check the cables visually according to Check terminals visually.

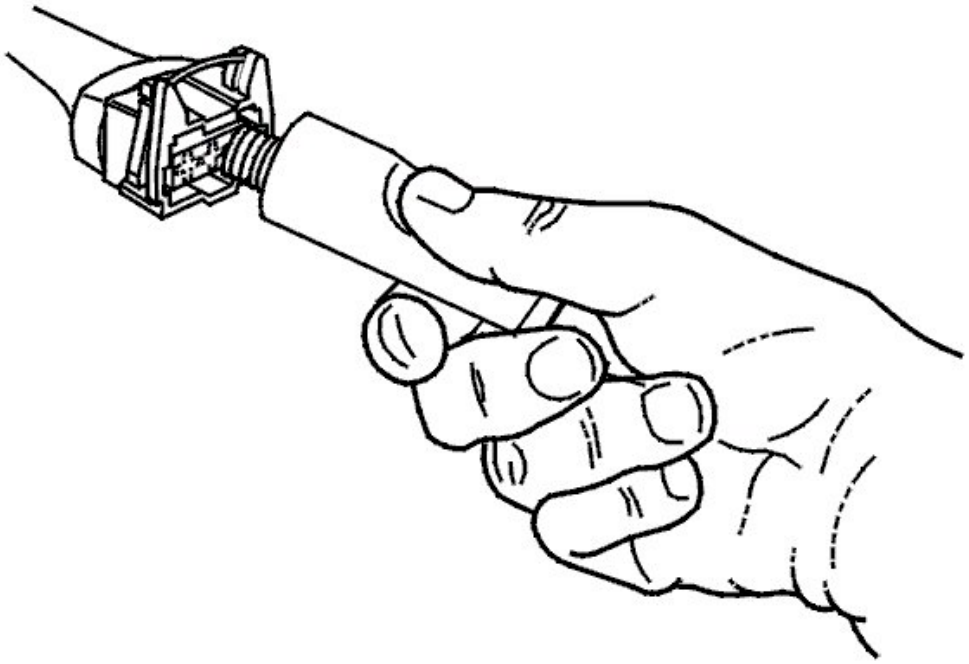
Cleaning female socket terminals and male pin terminals



Note! Do not apply rust solvent spray or grease to the catalyst monitor sensor or instrument cluster connectors.

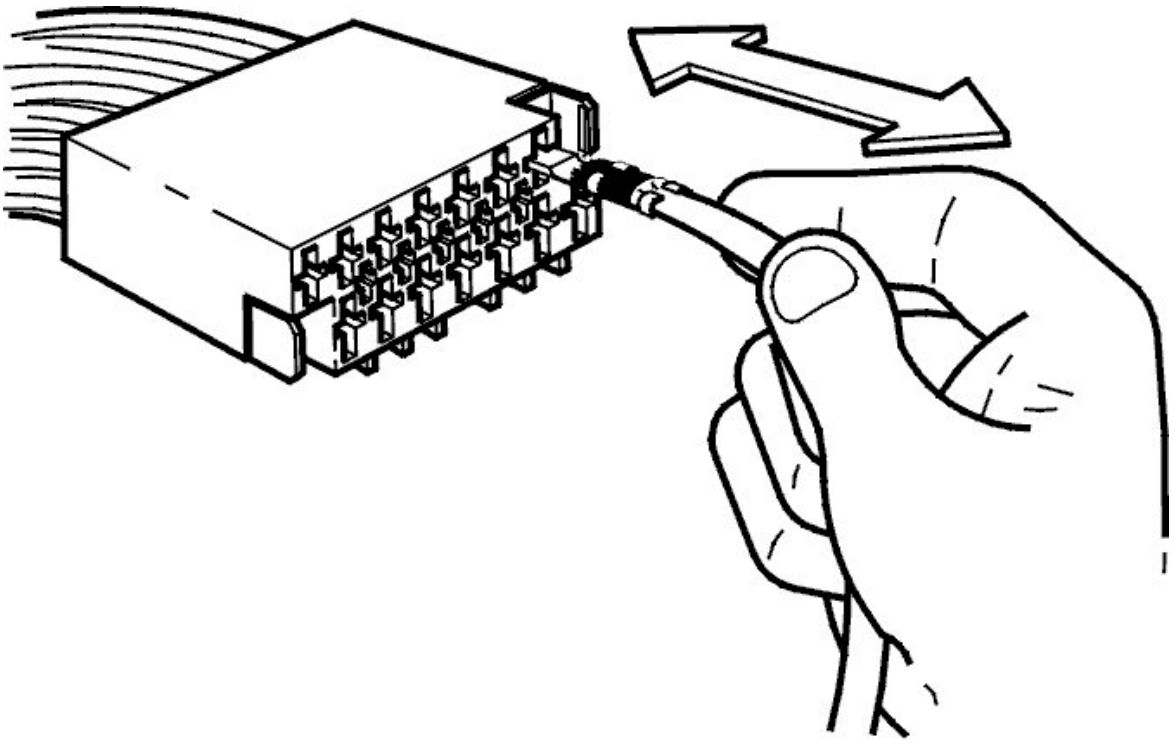
- Ignition off
- Disconnect the battery negative terminal
- Use compressed air to clean the disconnected connector
- Apply rust solvent spray 1161422 to the disconnected connectors
- Blow clean using compressed air.

Greasing female terminals



Note! Note! Do not fill the protective cover with grease.

- Press grease, P/N 1161417-9, into the female sockets directly from tube
- Check that all the terminal cavities are filled
- Use a loose male pin to ensure that the connection in the sockets is good. The pin should remain in position when pulled gently.



Component Specifications

Component specifications

The component specification gives the value of the component when the connector is disconnected. Where no value is given, it is not possible to measure a relevant value at the component.

The figure within the brackets indicates the terminal pin on the component to which the value refers.

Designation	Type	Supply voltage	Value	Other
Air conditioning (A/C) relay	Mechanical relay	12V (#1)	Approximately 96 Ω (coil)	
A/C pressure sensor	Absolute manifold absolute pressure (MAP) sensor	5 V (#3)	-	
Stop lamp switch	Position switch	12 V (#1)	The switch is closed when the pedal is depressed (terminals #1-#5)	
Fuel pump (FP) relay	Mechanical relay	-	Approximately 96 Ω (coil)	The relay is controlled by the central electronic module (CEM)
Fuel temperature sensor	NTC resistor	5V (#3)	5896 Ω at 0°C 3792 Ω at 10°C 2500Ω at 20°C 1707Ω at 30°C 1175 Ω at 40°C (#1-#2)	Integrated in the fuel pressure sensor
Fuel pressure sensor	Piezo resistive pressure sensor	5V (#3)	-	
Engine cooling fan (FC) control module	-	12 V (#2)	-	
Canister purge (CP) valve	Electromagnetic valve	12 V (#1)	17-24 Ω at 20°C (terminals #1-#2)	
Accelerator pedal (AP) position sensor	Electronic pedal sensor with two output signals, PWM and a linear analog signal	12 V (terminal #1) 5 V (terminal #6) Power supply analog position sensors	-	
Throttle unit	Electronic throttle control module with two integrated potentiometers and a damper motor	5 V (#3)	1.2-3.5 Ω (terminals #1-#4 motor winding). 1000-1500 Ω (terminals #2-#3 Parallel connection of potentiometers 1 and 2).	-

Designation	Type	Supply voltage	Value	Other
			Approximately 820 Ω when the throttle is closed. Approximately 1580 Ω at wide open throttle (terminals #2-#6 potentiometer 1). Approximately 1480 Ω when the throttle is closed. Approximately 500 Ω at wide open throttle (terminals #2-#5 potentiometer 2)	
Injector	Electromagnetic injector valve	12 V (#1)	Approximately 12 Ω at 20°C (terminal #1-#2)	
Camshaft sensor	Magneto-resistive sensor	5 V (#1)	-	
Knock sensor (KS)	Piezo electric component	-	Greater than 1 MΩ (terminal #1-#2 front knock sensor (KS)). Greater than 1 MΩ (terminals #3-#4 rear knock sensor (KS))	Separate signal ground for the knock sensors (KS)
Clutch pedal sensor	Slide potentiometer	5 V (#2)	Unaffected pedal: 1400-2400 Ω Fully depressed pedal: 200-800 Ω (#2-#4)	
Cooling fan for control modules	Fan motor	12 V (#1)	-	The engine cooling fan (FC) is controlled by the engine control module (ECM)
Coolant level sensor	Position switch	Connected to ground (terminal #2)	Closed when the engine coolant level is normal	
Boost pressure sensor	Absolute manifold absolute pressure (MAP) sensor	5 V (#3)	-	
Preheating, front heated oxygen sensor (HO2S)	PTC resistor	12 V (#3)	2.6-3.4 Ω at 20°C (terminals #3-#4)	
Preheating, rear heated oxygen sensor (HO2S)	PTC resistor	12 V (#1)	Approximately 9 Ω at 20°C (terminal #1-#2)	

Designation	Type	Supply voltage	Value	Other
Mass air flow (MAF) sensor	-	12 V (#2) 5 V (#4)	-	
Air temperature sensor, intake	NTC resistor	5 V (#3)	5886 Ω at 0°C 3791 Ω at 10°C 2510 Ω at 20°C 1715 Ω 30°C (#1-#2)	Integrated in the boost pressure sensor
Leak diagnostic unit	Consists of an air pump, an electromagnetic valve and an internal heating element (PTC resistor)	12 V (#4)	Approximately 118 Ω (terminals #1-#4 pump motor winding) 27.9 -34.1 Ω (terminals #3-#4 Valve coil)	The heating element for heating up the pulsed secondary air injection system (PAIR) pump is controlled by the central electronic module (CEM)
Engine coolant temperature (ECT) sensor	NTC resistor	5 V (#1)	15040 Ω at -20°C 2450 Ω at 20°C 318 Ω at 80°C (#1- #2)	
PTC resistor air preheating	PTC resistor	12 V (#1)	Approximately 10 Ω at 20°C	
Oil level sensor	Electronic sensor with PTC resistor and capacitive measurement element	5 V (#3)	-	
Oil pressure sensor	Pressure switch (Pressostat)	Grounded in the cylinder block	Closed switch when the oil pressure is low	
Camshaft reset valve	Electromagnetic valve	12 V (#1)	3.7-11.1 Ω (#1-#2)	
Flywheel sensor	Engine speed sensor	-	108.5-142.5 Ω at 20°C (terminals #1-#2)	
System relay	Mechanical relay	12V (#1)	Approximately 80 Ω (coil)	
Turbocharger (TC) control valve	Electromagnetic valve (3 way)	12 V (#1)	21.8-24.2 Ω at 20° C (terminals #1-#2)	
Outer temperature sensor	NTC resistor	5 V (#1)	18702 Ω at -20 °C 6318 Ω at 0°C 2424 Ω at 20°C 1034 Ω at 40°C (#1- #3)	

Example of Use of the Frozen Values

Information

Example of use of the frozen values

Faults can be intermittent, which is important to remember when fault-tracing for possible causes. If the fault is not present when the vehicle is in the workshop, a fault cause can be missed as the values can be correct when fault-tracing is carried out. A good indication of when the fault occurred the first time are the frozen values that can be read out using VIDA/Details.

The frozen values are stored immediately after a fault has been detected. Most parameters in the frozen values are the same for all faults and indicates a general status when a fault has been detected, e.g. engine speed, load, coolant temperature, vehicle speed and battery voltage. Some of them have been selected to give a better understanding of the specific fault. Diagnostic Trouble Code (DTC) ECM-903F Throttle position (TP) can be used as an example of how the frozen values can be used (this is only one example and there may be deviations in reality).

One of the checks given in fault-tracing is "voltage supply to throttle unit" and continues with a suggestion to check the battery and charging system. However, the battery's condition, with the vehicle in the workshop, does not show the battery voltage when the fault was detected. The best information is in the frozen values, i.e. the voltage that the Engine control module (ECM) detected, when the Electronic throttle module (ETM) indicated the fault.

However, remember that this is not an indication of the voltage supply to the Electronic throttle module (ETM), but to the Engine control module (ECM). If the Engine control module (ECM), according to the frozen values, had a good voltage, the battery worked. The voltage supply to the

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

Electronic throttle module (ETM) should therefore be checked separately.

Frozen values for ECM-903F
- Status, lambda control bank 1 = LR: Closed circuit with two sensors
- Status, lambda control bank 2 = LR: Closed circuit with two sensors
- Calculated load = 4.71%
- Engine coolant temperature = 87°C
- Fuel trim, quick adjustment, bank 1 = 15.63%
- Fuel trim, slow adjustment, bank 1 = -0.78%
- Fuel trim, quick adjustment, bank 2 = 23.44%
- Fuel trim, slow adjustment, bank 2 = -0.78%
- Engine speed = 760 rpm
- Vehicle speed = 0 km/h
- Boost pressure = 30%
- Battery voltage = 12.50 V
- Throttle angle, desired value = 14.84%
- Air mass = 23.8 kg/h Outdoor temperature = 33°C

In this case, we assume that the vehicle had a low battery voltage in the workshop. As seen in the frozen values however, the battery voltage was correct when the fault occurred, and this was therefore probably not the cause.

This is an example of how the frozen values can be used, to make fault-tracing more efficient and prevent taking too much time fault-tracing incorrectly. This prevents fault-tracing and correcting a fault that was not actually the cause of the problem, which was originally to be solved.

The odometer setting (km) is included among the frozen values in the Engine control module (ECM). This makes a fast comparison with the odometer counter possible, so that one can determine if the fault occurred as part of the fault-tracing and can be ignored.

For example, the CAN related diagnostic Trouble Codes (DTCs) can be detected when the battery voltage drops when working on the vehicle, by the passenger compartment lighting and other loads draining the battery. The frozen values indicate the odometer setting in km. Multiplying this value by 0.62 gives the distance in miles. The current distance in miles and km can be read out using VIDA.

The following should be taken into account when using frozen values for fault-tracing. The frozen values, that should be used with care, are those that have been stored for CAN and are related to Diagnostic Trouble Codes (DTCs) for the Electronic throttle module (ETM).

If the Electronic throttle module (ETM) detects that the communication to the Engine control module (ECM) is interrupted, error flags are stored in the Electronic throttle module (ETM). These error flags are sent to the Engine control module (ECM) as soon as communication on the CAN is working again. This means that the Engine control module (ECM) stores the Diagnostic Trouble Codes (DTCs) as soon as the Electronic throttle module (ETM) supplies them. This, in turn means that it is at this time that the frozen values are stored. For the Electronic throttle module (ETM) this means that the frozen values occur from a point in time after the fault first occurred.

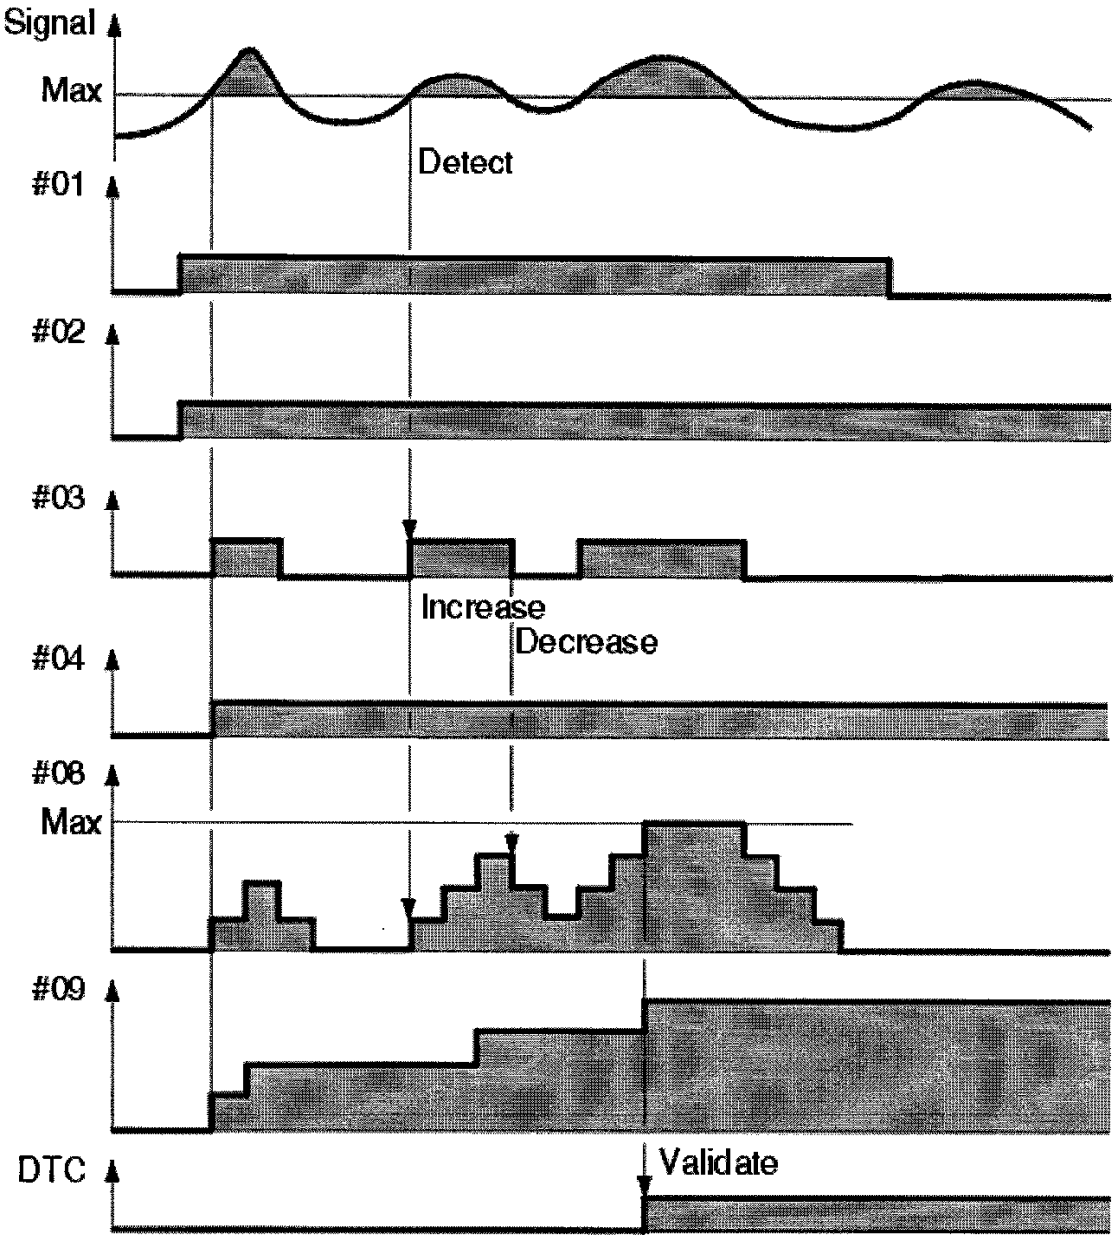
Description of Status Identifier

Status identifier	
There are different status identifiers that can be read off for each diagnostic trouble code (DTC). The control module tests each terminal almost continuously. By reading off the diagnostic trouble code (DTC) and the associated status identifier (which detects the fault and stores the DTC), information about the test is obtained. Not all status identifiers need to be implemented in one control module. This varies from system to system. All status identifiers are reset and start counting again each time the control module is powered up and when erasing diagnostic trouble codes (DTCs). The possible status identifiers are described below.	
Status identifier	**Explanation**
Upper graph	When the signal value is above or below a maximum or minimum value that is considered to be a fault by the control module, an instantaneous fault is registered (i.e. a fault is active). The value may vary depending on the specific diagnostic trouble code (DTC). Examples of this are U > 11.5 V, U < 2 V or f < 10 Hz.
SI#01 (see the graph)	The test is active. The control module can only detect faults and store diagnostic trouble codes (DTC) when the test is running.
SI#02 (see the graph)	The test has been active. Indicates whether the control module was able to detect faults and store diagnostic trouble codes (DTC).
SI#03 (see the graph)	The control module detects an instantaneous fault. This information is used by the control module to determine if or when a diagnostic trouble code (DTC) should be stored. As soon as a signal exceeds the permitted value (compare with the upper graph), there is an instantaneous fault.
SI#04 (see the graph)	The control module has detected an instantaneous fault. An instantaneous fault has been detected at some stage.
SI#05	Lamp lighting / Text message. Information about whether the diagnostic trouble code (DTC) activates a warning lamp or text message in the combined instrument panel.
SI#06	The test is disabled because another fault has occurred. The diagnostic trouble code (DTC) is stored at the point of the base fault. If this leads to further faults, related diagnostic trouble codes (DTCs) are not stored.
SI#08 (see the graph)	Counter for instantaneous faults. When an instantaneous fault is detected by the control module, a counter counts up for as long as the fault exists. When the fault is no longer present, the counter counts down again. The diagnostic trouble code (DTC) is stored in the car if the counter reaches a certain maximum value. The maximum value varies between different diagnostic trouble codes (DTCs). The speed of the count depends on how long the fault can persist before it results in customer symptoms.
SI#09 (see the graph)	Maximum value of counter SI#08. There are a variety of ways that the counter value for instantaneous faults can be read off depending on how often the diagnostic has been run.
Lower graph	Validating diagnostic trouble codes (DTCs). The diagnostic trouble code

Status Identifier, Description

	(DTC) is stored when the counter for instantaneous faults has reached its maximum value.

Status Identifier, Description (Continued)



Graphs

Description of Counters

COUNTERS, DESCRIPTION

Counter

A useful fault-tracing tool is the Diagnostic Trouble Code (DTC) counter. The control module stores 6 different counters for each Diagnostic Trouble Code (DTC), which describes the occurrence. The counters can be used to determine when and how often a fault has been detected. Using the counters for the Diagnostic Trouble Code (DTC) it is possible to see if the fault has only been registered during the current operating cycle or whether it has been detected previously.

If a fault is intermittent it is possible to determine how intermittent the fault is by studying the values of the different counters.

Example:

- Counter 1 = 15 Counts the number of operating cycles since the fault was last validated.
- Counter 3 = 69 Counts the number of operating cycles since the fault was first validated.
- Counter 4 = 1 Counts how many times the fault has occurred since the first time the fault was first validated.
- Counter 5 = 91764 The counter adds the time in seconds for which the control module has been operating since the fault was first validated and the diagnostic trouble code (DTC) was stored.
- Counter 6 = 0 The counter adds the time in seconds for which the test, the diagnostic, has run since the fault was first validated and the diagnostic trouble code (DTC) was stored.
- Counter 7 = 0 The counter adds the time in seconds for which the fault has been validated since the fault was first validated and the diagnostic trouble code (DTC) was stored.

In the examples given above, counter 1 gives the number of operating cycles where the diagnostic was run without a fault being detected. Counting takes place from when the fault was last detected. Counter 3 is the total number of operating cycles regardless of whether the

diagnostic was run or not. Counter 4 shows the number of operating cycles where the diagnostic detected a fault. Counters 3 and 4 start to count from the first operating cycle after the operating cycle when the fault was first detected.

In the example, counter 4 = 1, which means that the fault was detected twice. One can see that no fault was detected during the relevant operating cycle. Depending on the number of operating cycles and the customer1s driving pattern, it can assist in ruling out this control module from the customer's current problems. The counters can help us understand how intermittent the fault can be. If the counters 1 = 0, 3 = 0 and 4 = 0 it indicates that there have not been any operating cycles since the fault was detected and that the fault was probably generated in the workshop.

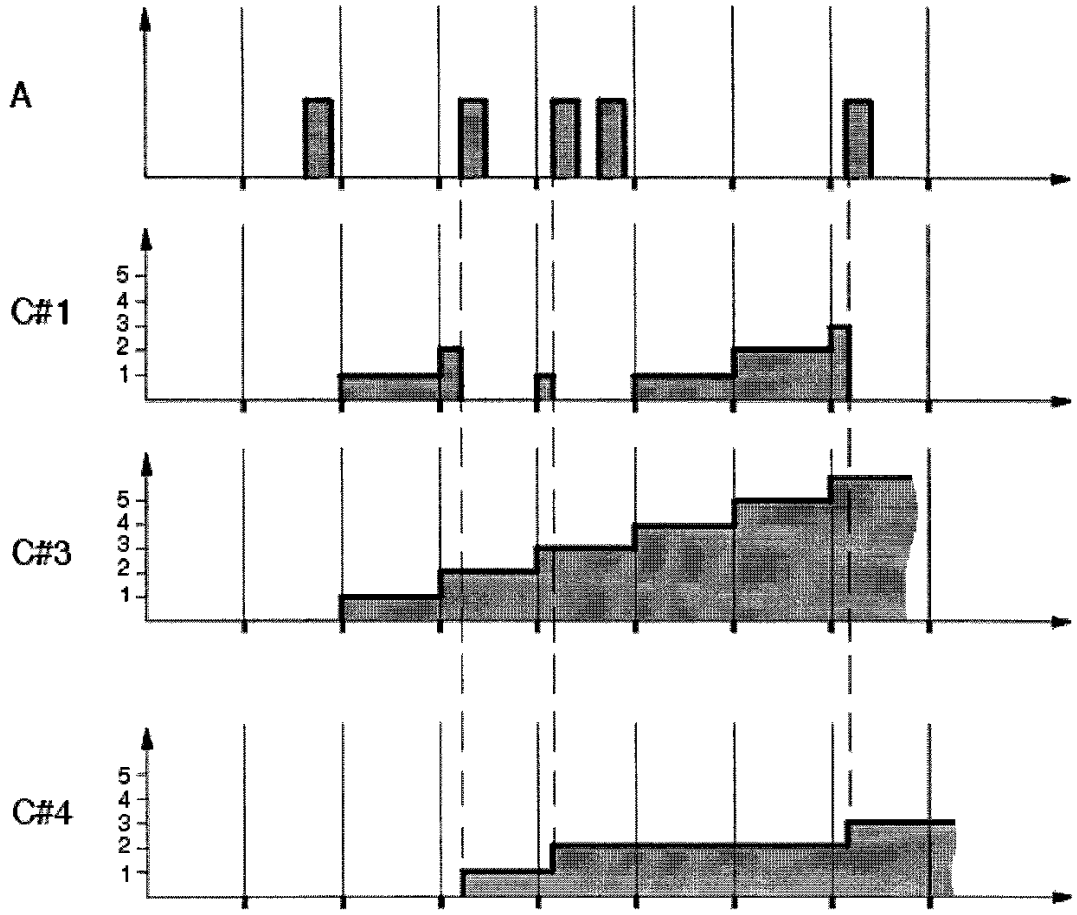
For an operating cycle to be recognized certain requirements may be necessary, for example, increasing the engine coolant temperature. In certain cases ignition on, ignition off and ignition on again are counted as an operating cycle.

Counter 5 can be useful if the fault was detected in this operating cycle. The time can be used to determine more exactly when the fault occurred.

NOTE: Not all counters need be implemented in a control module, this varies from system to system. The possible counters are described below.

Counter	Function
A (see the graph) Counter 1	The graph illustrates the time at which a fault occurs. In the illustration the control module has detected a fault in the second cycle. This fault has then occurred a total of 5 times. The counter can be read off for each diagnostic trouble code (DTC) in the control module in which this is implemented. Operating cycles are marked with vertical lines. An operating cycle usually begins at ignition on and finishes when the ignition is switched off.
C#1 (see the graph) Counter 2	Counts the number of operating cycles since the fault was *last* validated. This information can be used to determine whether the fault is active during the current operating cycle or not. The fault is present now if the value is zero. This counter is also used for most systems to give "Permanent fault" and " Intermittent fault" text messages in VIDA when reading off a diagnostic trouble code (DTC).
C#3 (see the graph) Counter 3	Counts the number of operating cycles since the fault was *first* validated. When a fault has been validated, the counter will count up by 1 for each subsequent operating cycle. The same as counter C#1 but monitors the number of cycles since the first fault occurred.
C#4 (see the graph) Counter 4	Counts the number of operating cycles in which the fault was validated since it was first validated. Counts the number of times the fault has occurred since the first time.
C#5 Counter 5	The counter assesses the number of seconds the control module has been operating since the fault was first validated and the diagnostic trouble code (DTC) was stored. The time the control module has been operating is only counted when it is active, not in "sleep mode".
C#6 Counter 6	The counter assesses the number of seconds the test (the diagnosis) has been operating since the fault was first validated and the diagnostic trouble code (DTC) was stored.
C#7 Counter 7	The counter assesses the number of seconds the fault has been valid since it was first validated and the diagnostic trouble code (DTC) was stored.

Counters, Description



Graphs

Description of Parameters, Quick Test of the Fuel Tank System

Description of parameters, quick test of the fuel tank system

Conditions

ECU power supply (V)

The value indicates the voltage supply from the system relay to the engine control module (ECM).

Atmospheric pressure (Pa)

The value indicates the ambient pressure. The Engine control module (ECM) receives a signal from the atmospheric pressure sensor.

Hint: The sensor is integrated in the Engine control module (ECM).

Fuel level (l)

The value shows the fuel level in the tank. The Engine control module (ECM) receives a signal from fuel level sensor.

Hint: The sensor is connected to the Central electronic module (CEM) and information is sent to the Engine control module (ECM) via CAN.

°

Ambient temperature (C)

The value indicates the ambient temperature. The Engine control module (ECM) receives a signal from the outside temperature sensor.

Hint: The sensor is connected to the Central electronic module (CEM) and information is sent to the Engine control module (ECM) via CAN.

Test status

Fuel tank system quick test

Shows the current status of the quick test (In progress/Not in progress)

Test phase

Shows the current phase of the leak diagnosis. For more information, see "Test phases, quick test tank system".

Fuel tank pressure (Pa)

The value indicates the calculated tank pressure. The Engine control module (ECM) calculates the average pressure with the help of the measured power consumption on the leak diagnostic unit's pump. The pressure will rise from 0 Pa to approx. 4500 Pa during the test.

Hint: The calculated pressure can differ from the measured pressure by ±15 %. This is normal.

Test result

DMTL, test result

Shows the test result on the leak diagnostic unit (DMTL).
If "Fault found" is shown, the Engine control module (ECM) has generated a diagnostic trouble code (DTC) for the fault. Fault tracing should be started/continued.

Tank system, test result

Shows the test result for the fuel tank system.
If "Minor leak found" or "Major leak found" is shown the Engine control module (ECM) has generated a diagnostic trouble code (DTC) for the fault. Fault tracing should be started/continued.

Estimated leak (mm)

The value shows the diameter of the leak. The Engine control module (ECM) calculates the diameter with the help of measurements made during testing.

Hint: The parameter should be used to get an understanding of how close to the diagnostic trouble code limit the system is. If the estimated size of the leak is very close to the diagnostic trouble code limit, fault tracing should probably be carried out despite the test result for the tank system showing "No leakage found", especially if the diagnostic trouble code (DTC) for leakage was initially generated.

Fault-Tracing Information - Intermittent Fault

Fault-Tracing Information
If the fault is intermittent, do not verify fault-tracing if the fault does not recur.

It is possible to view the information again, or leave fault-tracing for this diagnostic trouble code (DTC).

Do you want to view the information again?

YES: Repeat Procedure.
NO: Refer to Trouble code Descriptions. See: Diagnostic Trouble Code Descriptions

Fault-Tracing Information - Interrupted Fault

Fault-Tracing Information
Fault-tracing is not followed by verification for this fault.

The information can be displayed again or fault-tracing this fault can be interrupted.

Do you want to view the information again?

YES: Repeat Procedure.
NO: Refer to Trouble code Descriptions. See: Diagnostic Trouble Code Descriptions

Fault-Tracing Information - Permanent Fault

Fault-Tracing Information
The fault should have been detected and remedied. As this is not the case fault-tracing has failed.

Exit fault-tracing for this diagnostic trouble code (DTC) or make another attempt.

Do you want to exit fault-tracing?

YES: Refer to Trouble code Descriptions. See: Diagnostic Trouble Code Descriptions
NO: Repeat Procedure.

Fault-Tracing Information - Previously Registered

Fault-Tracing Information
The control module has previously registered a fault. The fault is now no longer present.

Continue: Refer to Fault-Tracing Information - Intermittent Fault. See: Diagnostic Trouble Code Tests and Associated Procedures/Related Tests, Information and Procedures/Fault-Tracing Information/Fault-Tracing Information - Intermittent Fault

Identifying Upgraded Software ECM/ETM

Identifying Upgraded Software ECM/ETM

Upgraded software for the engine control module (ECM) and electronic throttle module (ETM), available during 2006 or later, can be identified. The updated software has the diagnostic number/software number as set out in the table below. The diagnostic number/software number can be read using VIDA/DIAGNOSTICS/NETWORK.

CAUTION! For the USA/Canada market, with turbocharged and 6-cylinder normally aspirated engines the software of the engine control module (ECM) can be identified using the software number or diagnostic number, depending on the version of the software involved.

The differences between the first version, which is identified by the software number, and the second version, which is identified by the diagnostic number, include the following:

- Improved driveability after engine control module (ECM) reset. The start values for some system adaptations are adjusted to facilitate handling of aged/worn systems/components after diagnostic trouble code deletion or when the control module has been without power.
- Increased hardiness to certain combinations of aging/wear in the system. The work areas for some adaptations are adjusted to better match the aging of certain components.
- Supplements as to which faults are to generate a message to the driver.
- Improved serviceability (diagnostic trouble code generation) for some intermittent faults that generate driveability problems.

The diagnostic number (also known as diagnostic version in VIDA) and the software number can be read out via VIDA/DIAGNOSTICS/NETWORK. The electronic throttle module (ETM) is identified solely by the diagnostic number.

If the diagnostic number/software number is within the following series, it is the latest software downloaded:

- **5-cylinder non-turbo engines**, (all markets):
  Engine control module (ECM) diagnostic number 30785129 - 30785132 or 30785667 and electronic throttle module (ETM) 30785387.

- **Turbocharged and 6-cylinder normally aspirated engines** (USA/Canada market):
  First version, engine control module (ECM) software number 30785203 - 30785240 and electronic throttle module (ETM) diagnostic number 30785388.

  Second version, engine control module (ECM) diagnostic number 30785372 - 30785378 and electronic throttle module (ETM) diagnostic number 30785388.

- **Turbo engines and 6-cylinder non-turbo engines**, (all markets except the USA/Canada market):
  Engine control module (ECM) software number 30785372 - 30785378 and electronic throttle module (ETM) diagnostic number 30785388.

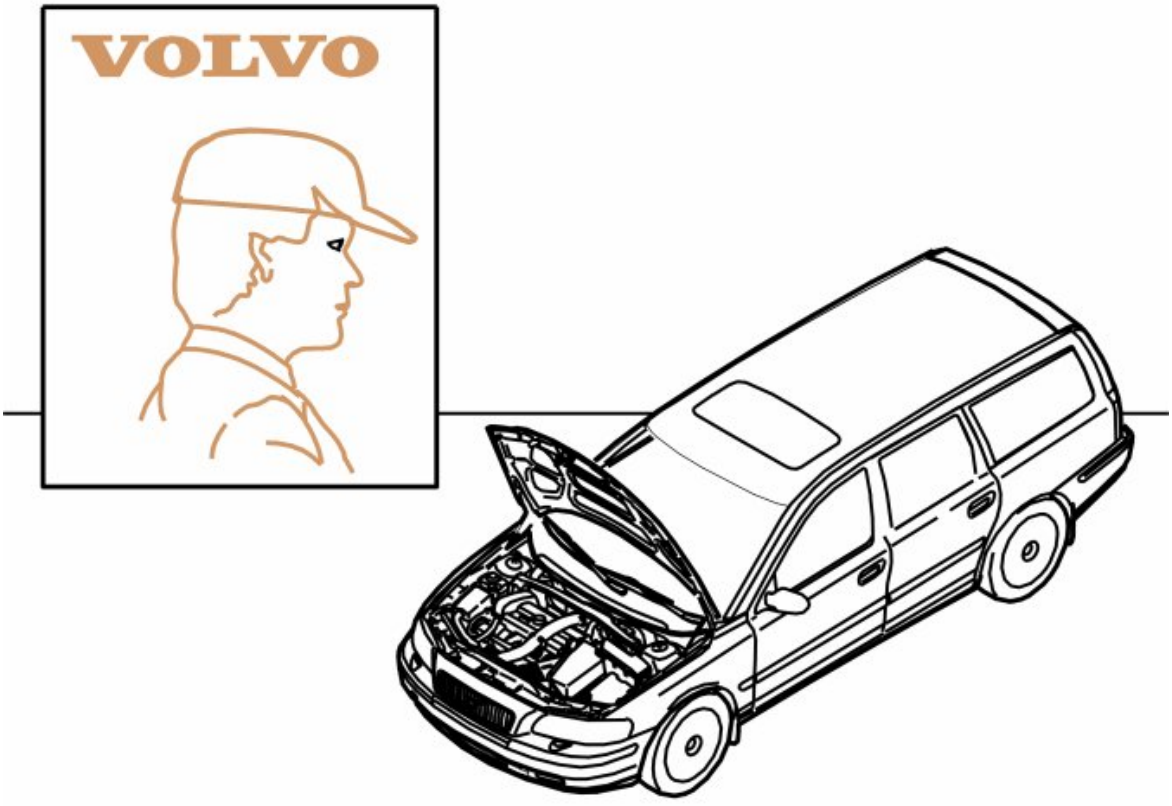
Information

Information

Example of use of the frozen values



Faults can be intermittent, which is important to remember when fault-tracing for possible causes. If the fault is not present when the vehicle is in the workshop, a fault cause can be missed as the values can be correct when fault-tracing is carried out. A good indication of when the fault

occurred the first time are the frozen values that can be read out using VIDA/Details.
The frozen values are stored immediately after a fault has been detected. Most parameters in the frozen values are the same for all faults and indicates a general status when a fault has been detected, e.g. engine speed, load, coolant temperature, vehicle speed and battery voltage. Some of them have been selected to give a better understanding of the specific fault. Diagnostic Trouble Code (DTC) ECM-903F Throttle position (TP) can be used as an example of how the frozen values can be used (this is only one example and there may be deviations in reality).
One of the checks given in fault-tracing is "voltage supply to throttle unit" and continues with a suggestion to check the battery and charging system. However, the battery's condition, with the vehicle in the workshop, does not show the battery voltage when the fault was detected. The best information is in the frozen values, i.e. the voltage that the Engine control module (ECM) detected, when the Electronic throttle module (ETM) indicated the fault.
However, remember that this is not an indication of the voltage supply to the Electronic throttle module (ETM), but to the Engine control module (ECM). If the Engine control module (ECM), according to the frozen values, had a good voltage, the battery worked. The voltage supply to the Electronic throttle module (ETM) should therefore be checked separately.

Frozen values for ECM-903F
Status, lambda control bank 1 = LR: Closed circuit with two sensors
Status, lambda control bank 2 = LR: Closed circuit with two sensors
Calculated load = 4.71 %
Engine coolant temperature = 87 °C
Fuel trim, quick adjustment, bank 1= 15.63%
Fuel trim, slow adjustment, bank 1 = -0.78%
Fuel trim, quick adjustment, bank 2 = 23.44%
Fuel trim, slow adjustment, bank 2 = -0.78%
Engine speed = 760 rpm
Vehicle speed = 0 km/h
Boost pressure = 30%
Battery voltage = 12.50 V
Throttle angle, desired value = 14.84%
Air mass = 23.8 kg/h Outdoor temperature = 33 °C

In this case, we assume that the vehicle had a low battery voltage in the workshop. As seen in the frozen values however, the battery voltage was correct when the fault occurred, and this was therefore probably not the cause. This is an example of how the frozen values can be used, to make fault-tracing more efficient and prevent taking too much time fault-tracing incorrectly. This prevents fault-tracing and correcting a fault that was not actually the cause of the problem, which was originally to be solved.
The odometer setting (km) is included among the frozen values in the Engine control module (ECM). This makes a fast comparison with the odometer counter possible, so that one can determine if the fault occurred as part of the fault-tracing and can be ignored.
For example, the CAN related diagnostic Trouble Codes (DTCs) can be detected when the battery voltage drops when working on the vehicle, by the passenger compartment lighting and other loads draining the battery. The frozen values indicate the odometer setting in km. Multiplying this value by 0.62 gives the distance in miles. The current distance in miles and km can be read out using VIDA.
The following should be taken into account when using frozen values for fault-tracing. The frozen values, that should be used with care, are those that have been stored for CAN and are related to Diagnostic Trouble Codes (DTCs) for the Electronic throttle module (ETM).
If the Electronic throttle module (ETM) detects that the communication to the Engine control module (ECM) is interrupted, error flags are stored in the Electronic throttle module (ETM). These error flags are sent to the Engine control module (ECM) as soon as communication on the CAN is working again. This means that the Engine control module (ECM) stores the Diagnostic Trouble Codes (DTCs) as soon as the Electronic throttle module (ETM) supplies them.
This, in turn means that it is at this time that the frozen values are stored. For the Electronic throttle module (ETM) this means that the frozen values occur from a point in time after the fault first occurred.

Information About Combined Diagnostic Trouble Codes (DTCs)

Information About Combined Diagnostic Trouble Codes (DTCs)

5 Cyl Non Turbo Engines

Combined Diagnostic Trouble Codes (DTCs)

The following table is available to facilitate fault-tracing of ETM related diagnostic trouble codes (DTCs).

NOTE: Probable root diagnostic trouble codes (DTCs) are in bold and listed at the top of each cell.

Example of how to read the table: If the codes **903F** and 980F are generated in a vehicle with a Denso management system, then 903F is the probable root diagnostic trouble code. The diagnostic trouble codes (DTCs) can also be stored individually or together with other diagnostic trouble codes (DTCs) that do not affect ETM.

Ranking Values

Ranking values

There is a ranking value for each diagnostic trouble code (DTC). The ranking value describes the proximity of a real fault in the system. When the ranking value exceeds 128 a diagnostic trouble code (DTC) is stored. Misfire, which counts the number of missed combustions is an exceptions. The smart tool is able to read out the ranking values for the relevant diagnostic trouble codes (DTCs) (those that may have caused a diagnostic trouble codes (DTCs) to be stored). If the ranking value for any of the diagnostic trouble codes (DTCs) is close or over 128 carry out fault-tracing according to the relevant diagnostic trouble code (DTC), even if the diagnostic trouble code (DTC) has not been stored.
The ranking information consists of two values:

- "Latest" contains the ranking value at read off
- "Worst" contains the highest ranking value the diagnostic trouble code (DTC) has had.

These parameters are first set to zero when erasing the relevant diagnostic trouble code (DTC).

Signal Description

Signal description

General

All values given below are between the terminals stated in column 1 and breakout box terminal #B2. Control module terminals #A1-#A60 correspond to terminals #A1-#A60 on the breakout box, terminals #A61-#A70 correspond to terminals #B1-#B10 on the breakout box and terminals #B1-#B50 correspond to terminals #B10-#B60 on the breakout box.

Note! It is important to connect the breakout box and check the ground terminals before taking readings.

Hint: If the numbering of the connector is different from the numbering on the breakout box, the connector number is given first, terminal #A61, followed by the breakout box number in brackets, (terminal #B1). Example: #A61 (#B1).

U=	DC voltage in volts (V)	U A/C =	AC voltage in volts (V)
U bat =	Battery voltage in volts (V)	f =	Frequency in Hertz (Hz)
U low =	Voltage near 0V or 0V	%pulse =	Pulse ratio (%)
t =	Time in milliseconds (ms)

Checking the Fuel Pressure and Residual Pressure in the Workshop

Checking the fuel pressure and residual pressure in the workshop

Choosing a method for taking a reading

Note! For vehicles with demand activated fuel pumps (FP), see VIDA vehicle communication Quick test of fuel pump (FP).

The fuel pressure can be measured with the car stationary or while being driven. Residual pressure is measured with the car stationary.
When the car is being driven, see Taking fuel pressure readings while driving the car See: Fuel Delivery and Air Induction/Fuel Pressure/Testing and Inspection/Taking Fuel Pressure Readings While Driving the Car.

Continue - Measuring the line pressure

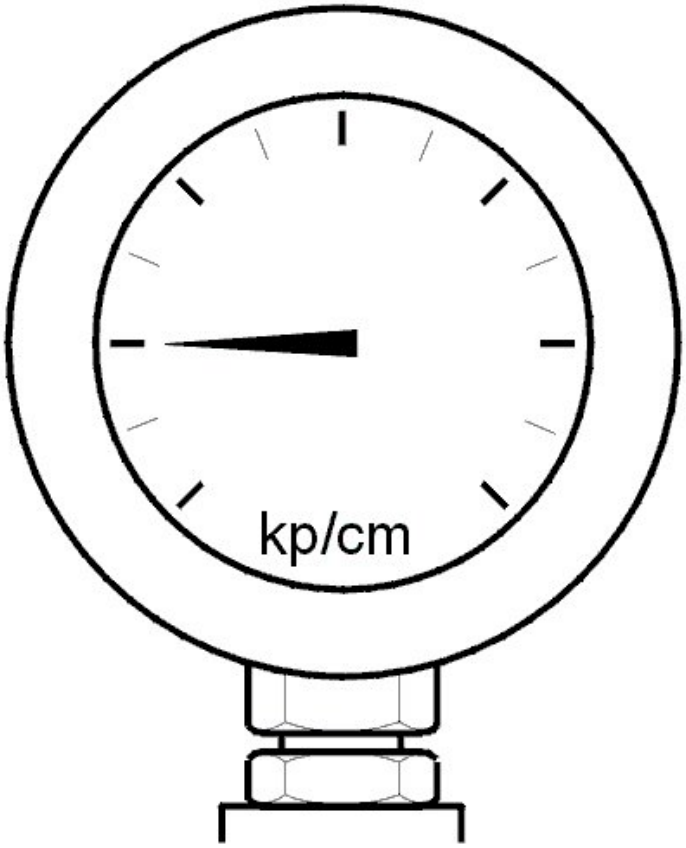
Measuring the line pressure

- Connect the pressure gauge according to Fuel pressure gauge See: Fuel Delivery and Air Induction/Fuel Pressure/Testing and Inspection/Fuel Pressure Gauge
- Remove the soundproofing panel
- Remove the fuel pump (FP) relay (CMI 12 in the passenger compartment)
- Connect a cable to the relay base as illustrated.

Read off the line pressure from the pressure gauge. The line pressure must be 375-395 kPa
Check the residual pressure if the fuel pressure is OK.
Remedy as necessary

Other information

- For the location of and to replace the fuel pump (FP) relay, see Central electronic module (CEM), replacing See: Body Control Module/Service and Repair/Central Electronic Module (CEM), Replacing
- For the location of and to replace the fuel pump (FP), see Right side fuel pump with level sensor See: Fuel Delivery and Air Induction/Fuel Tank/Fuel Gauge Sender/Service and Repair/Right Side Fuel Pump With Level Sensor
- Replacing the fuel filter See: Fuel Delivery and Air Induction/Fuel Filter/Service and Repair
- To disconnect the pressure gauge, see Fuel pressure gauge See: Fuel Delivery and Air Induction/Fuel Pressure/Testing and Inspection/Fuel Pressure Gauge.



Is the rest pressure to be checked?

Yes - Checking the residual pressure

No - DONE

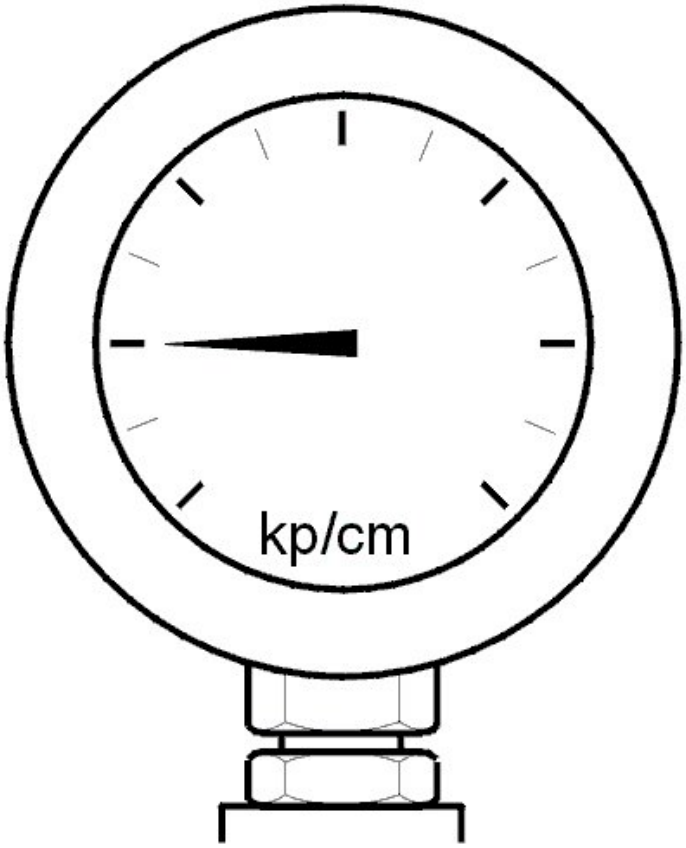
Checking the residual pressure

- Switch off the ignition
- Disconnect the cable between the terminals on the relay base
- Reinstall the fuel pump (FP) relay.

The line pressure must not fall below 200 kPa within 20 minutes of the fuel pump (FP) being shut-off.
Remedy as necessary

Other information

- For the location of and to replace the fuel pump (FP) relay, see Central electronic module (CEM), replacing See: Body Control Module/Service and Repair/Central Electronic Module (CEM), Replacing
- For the location of and to replace the fuel pump (FP), see Right side fuel pump with level sensor See: Fuel Delivery and Air Induction/Fuel Tank/Fuel Gauge Sender/Service and Repair/Right Side Fuel Pump With Level Sensor
- To disconnect the pressure gauge, see Fuel pressure gauge See: Fuel Delivery and Air Induction/Fuel Pressure/Testing and Inspection/Fuel Pressure Gauge.

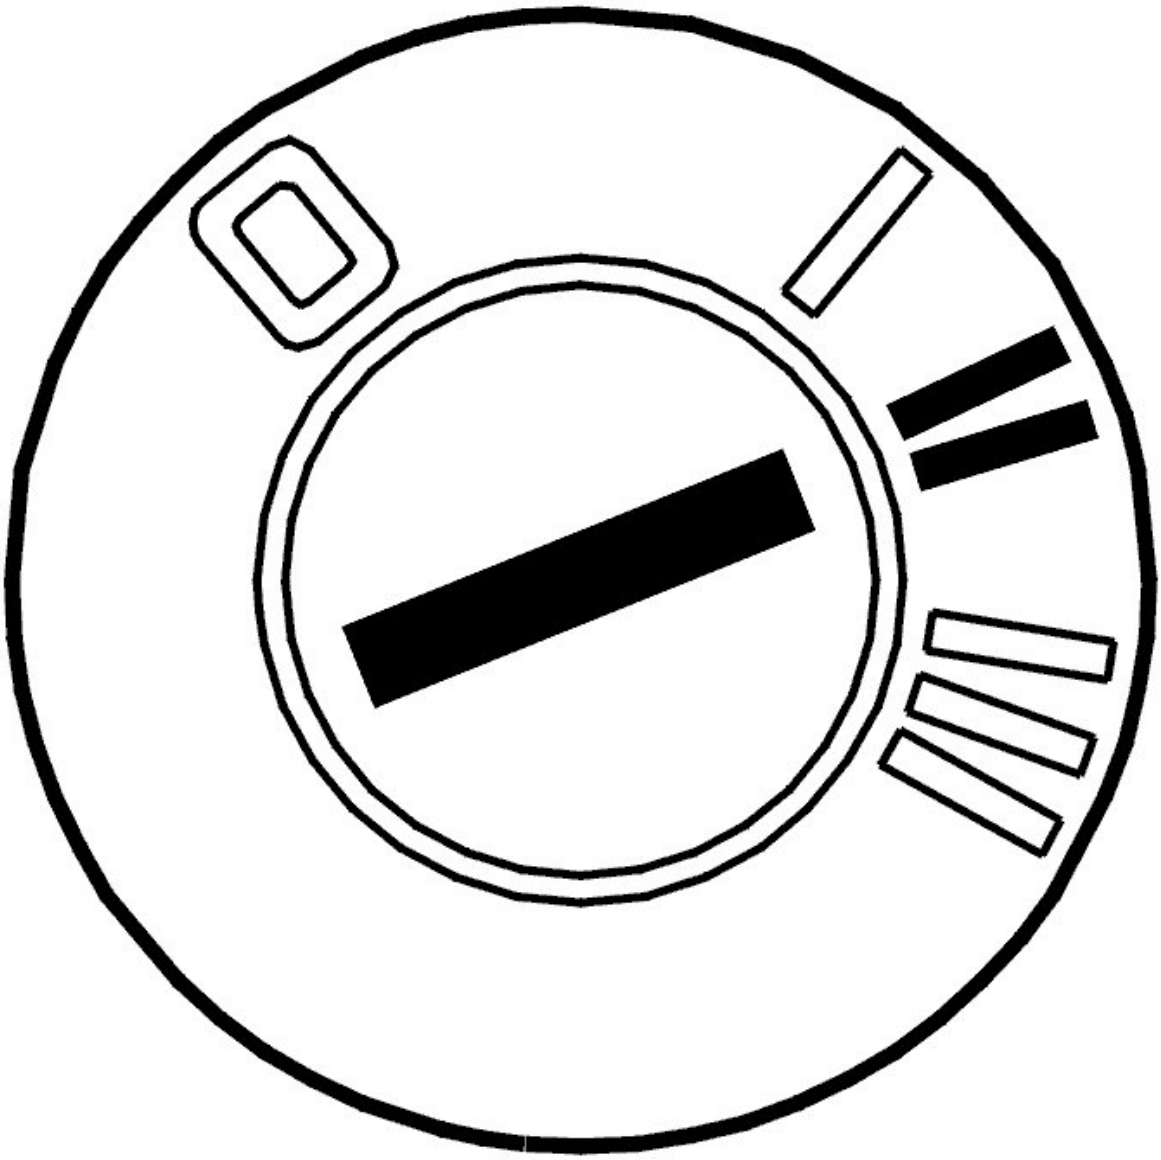


Continue - DONE

Checking the Status of the Pedal Position Sensor

Checking the status of the pedal position sensor

Checking the status of the pedal position sensor



A number conditions must be met for cruise control to be controlled by the engine control module (ECM). Some of these conditions are speed, the clutch and the brake pedal must not be depressed and certain diagnostic trouble codes (DTCs) must not be stored.
The clutch and brake pedal position sensors are checked to determine if they are in a position where the engine control module (ECM) allows cruise control.

Note! On cars with automatic transmissions, the parameter for the brake pedal position sensor displays "Active" (the brake pedal position sensor allows the cruise control to function).

- Ignition on
- Click on the VCT2000 symbol
- Check if the clutch pedal position sensor and the brake pedal position sensor are in the " Active" position when the pedals are in the unaffected positions.

Check that the status changes when the pedals are depressed.
The brake pedal and the clutch pedal must be in the "Active" position for the engine control module (ECM) to allow cruise control.

Continue - DONE

Readiness Code

Readiness Code

Read the readiness code

Read off diagnostic trouble codes (DTCs) and the readiness status.
If readiness is "OK" and no diagnostic trouble codes are stored, two cycles have run, i.e. the system's diagnostic functions have run two times without detecting a fault.

Hint: Readiness is reset (to "NOT OK") when the diagnostic trouble codes are cleared or if power is cut off to the engine control module (ECM).

US government information (US only)

The United States Environmental Protection Agency (EPA) has issued a guidance letter, "Performing Onboard Diagnostic System checks as Part of a Vehicle Inspection and Maintenance Program" (EPA420-R-01-015 June 2001), that incorporates various implementation issues associated with OBD-I/M testing. One being that the EPA has revised the readiness criteria to allow states to not reject MY 1996-2000 vehicles with two or fewer unset readiness codes, or MY 2001 and newer vehicles with no more than one unset readiness code. As mentioned herein this is suggested practice. Each individual state may abide by this guidance or enforce state regulations suited to their individual environmental needs. Please consult your State Department of Motor Vehicle for your current I/M testing regulations and procedures.

Select the appropriate remedy depending on this status:

1. If diagnostic trouble codes (DTCs) are stored
2. If readiness is "NOT OK".
3. If readiness is "OK" and no diagnostic trouble codes (DTCs) are stored.

1 - Diagnostic Trouble Code (DTC) stored

2 - Read the diagnostic status for readiness

3 - **DONE**

Read the diagnostic status for readiness

Read off the status of the diagnostic functions.

Select the appropriate remedy depending on this status:

1. Readiness for probe diagnostics, diagnostics for heated oxygen sensor (HO2S) preheating three-way catalytic converter (TWC) diagnostics "NOT READY".
2. Readiness for leak diagnostics "NOT READY".

Hint: The diagnostic for evaporative emission control is included in readiness for leak diagnostics.

1 - Carry out TRIP

2 - Quick test of the fuel tank system

Carry out TRIP

Perform a TRIP following Verifying repairs See: Monitors, Trips, Drive Cycles and Readiness Codes/Verifying Repairs so that the engine control module (ECM) executes a diagnosis for diagnostic functions.

Continue - Read the readiness code

Quick test of the fuel tank system

Run a quick test of the fuel tank system via the vehicle communication socket.
The engine must be run to operating temperature and then left idling for a few minutes before the diagnostic function for EVAP control can be run.

Select Continue

Continue - DONE

Diagnostic Trouble Code (DTC) stored

Fault-trace and remedy stored diagnostic trouble codes (DTCs).

Continue - ANOTHER TEST

Check For Air Leaks In the Intake System

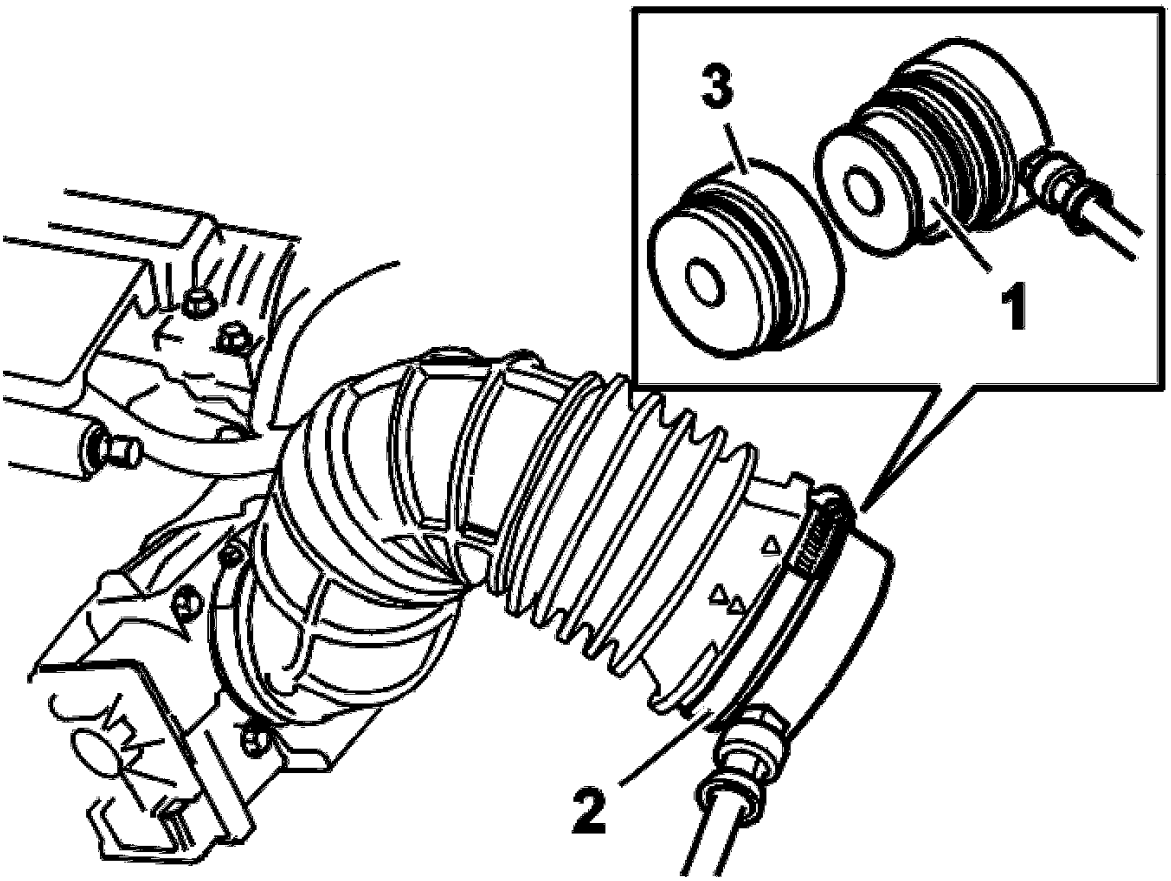
Air Leakage In The Intake System, Checking

Special Tools: 999 5545, 999 5544, 999 7080

NOTE: As the illustrations in this service information are used for different model years and/or models, some variation may occur. However, the essential information is always correct.

Preparations
Check that all hoses are undamaged and are in place with their hose clamps tightened.

Engagement



NOTE: S80 T6 and S60/V70 R use: 999 5545 (1) with 999 7080 (3). Lock 999 7080 on 999 5545.

Remove the fresh air hose from the mass air flow (MAF) sensor.

Install tool 999 5545 (1) and pressure regulator 999 5544 on the fresh air intake. Tighten the hose clamp (2).

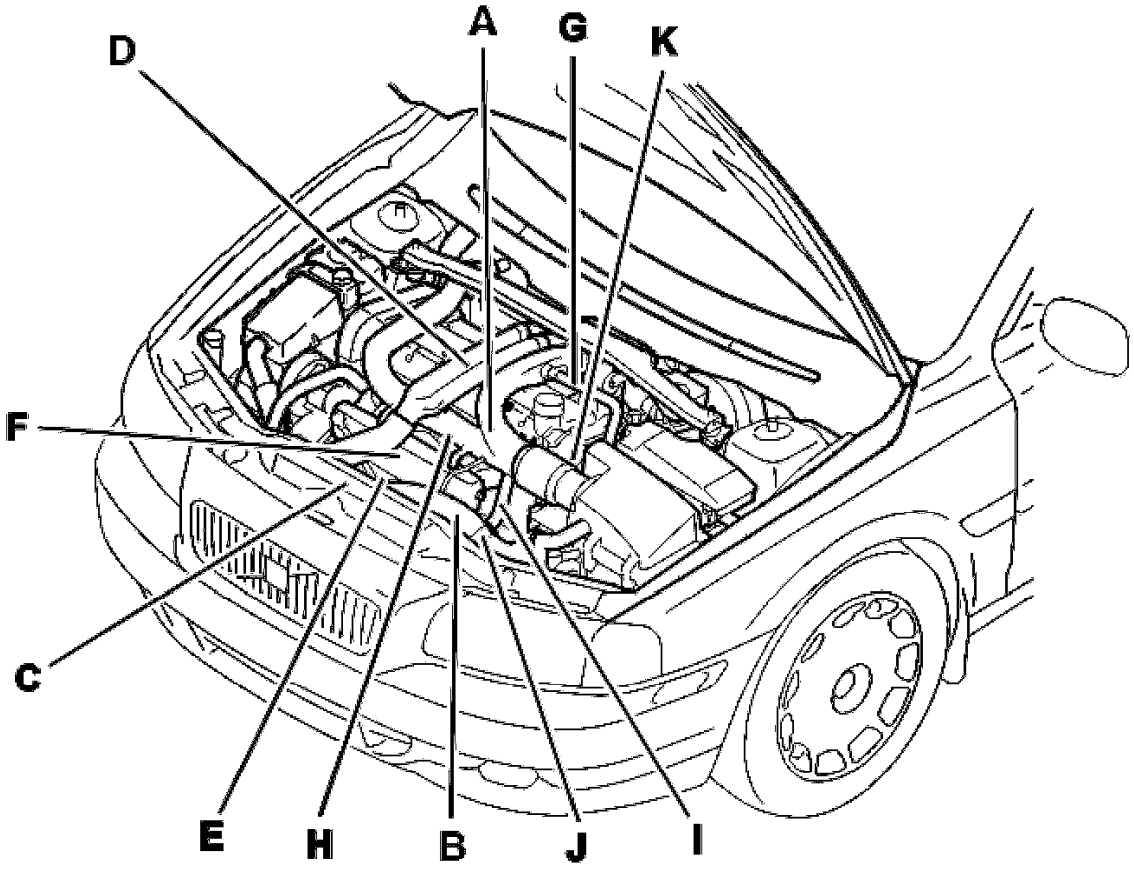
Remove the oil filler cap.

Check
Adjust the regulator to obtain a maximum pressure of **0.3 bar (0.15 psi)**. There may be a gentle hissing sound from the oil filler opening. This is due to the opening of an intake valve and the leakage of cylinder pressure past the piston rings.

Check components and connections.

If a leak is suspected, spray a soap solution onto the area. Check for air leakage from the canister purge (CP) valve. No leakage is permissible.

Checking components



A - fresh air intake
B - lower charge air pipe
C - charge air cooler (CAC)
D - upper charge air pipe
E - throttle body (TB)
F - intake manifold with vacuum hoses and gaskets
G - crankcase ventilation
H - injectors
I - brake servo hose
J - evaporative emission system (EVAP) valve
K - Turbocharger (TC) control valve.

Checking Power and Ground Terminals

Checking power supply and ground terminal, engine control module (ECM)

Checking power supply and ground terminal, engine control module (ECM)

Checking the power supply

- Check the fuse for power supply to engine control module (ECM) terminal #A17 (#A17).

If the fuse is blown, check the circuit for a short-circuit to ground

- Check the fuse for power supply to engine control module (ECM) terminal #B11 (#B21).

If the fuse is blown, check the circuit for a short-circuit to ground

- Check the power supply to engine control module (ECM) terminal #A17 (#A17). The voltage must be approximately battery voltage when the ignition is on.

If the voltage is incorrect, check the cable between ignition switch terminal 30 and system relay terminal #3 and the cable between system relay

terminal #5 and engine control module (ECM) terminal #A17 (#A17). Check for an open-circuit

- Check the power supply to engine control module (ECM) terminal #B11 (#B21). The voltage must be approximately battery voltage when the ignition is on.

If the voltage is incorrect, check the cable between ignition switch terminal 30 and engine control module (ECM) terminal #B11 (#B21). Check for an open-circuit.

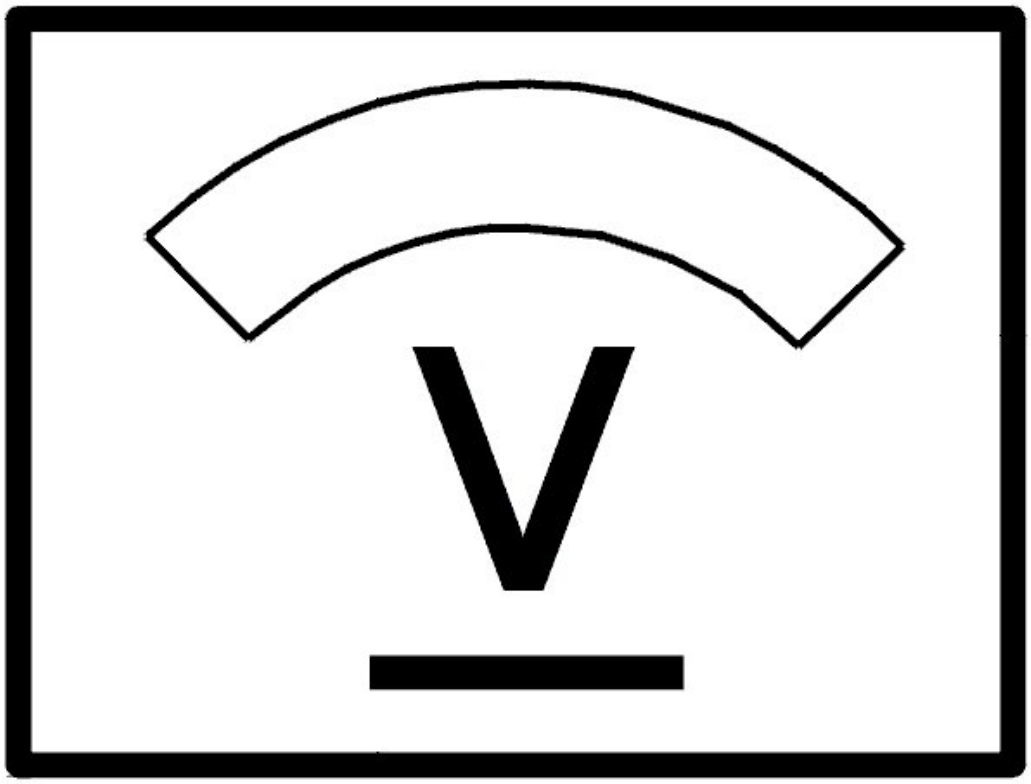
Checking ground terminal

- Check the ground leads between engine control module (ECM) terminals #A53 (#A53), #A54 (#A54), #A63 (#B3) and the common ground terminal in the body for the wiring. Check for an open-circuit
- Check the ground terminal in the body for the engine control module (ECM). Check for contact resistance and oxidation.

Remedy as necessary

Other information

- To connect the breakout box, see Connecting the breakout box, B5244T5, B5254T2 See: Pinout Values and Diagnostic Parameters/Connecting the Breakout Box
- For information about signals on 5 cylinder engines, see Signal specification See: Pinout Values and Diagnostic Parameters/Signal Description / Specification
- For information about signals on 6 cylinder engines, see Signal specification See: Pinout Values and Diagnostic Parameters/Signal Description / Specification
- For further information about the fuses and relays, see the Wiring Diagram
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals



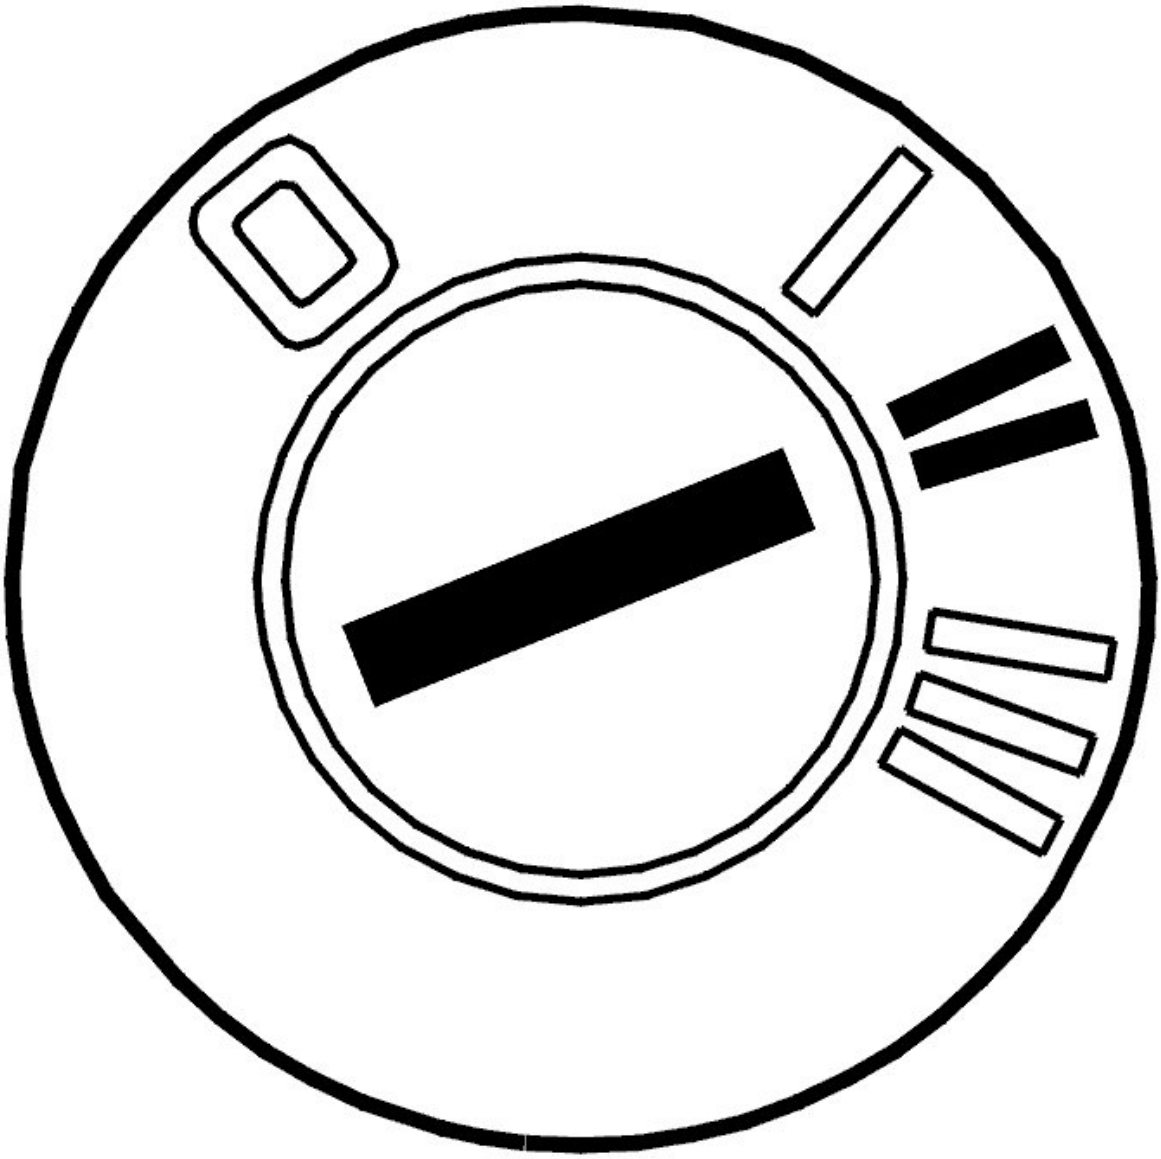
Was a fault detected?

Yes - Fault Found

No - No Fault Found

Activating Components and Functions

Activating components and functions



- Ignition on.

Activate components and/or functions by clicking the VCT2000 symbol.
Description of activation, B5244T5, B5254T2 See: Scan Tool Testing and Procedures/Vehicle Communication Information, Engine Control Module (ECM)/Description of Activations

Continue - DONE

Numeric Result 0 - Communication fault

Communication fault

Communication has been interrupted for one of the following reasons:
- The ignition is switched off
- VCT2000 disconnected from the data link connector (DLC)
- VCT2000 disconnected from the VIDA cart
- Communication problems in VIDA application or in car.

- No voltage in the data link connector (DLC).

Check therefore:
- That the control module power supply and ground terminal are fault-free.
- That the fuse for the data link connector (DLC) is intact.
- that the ignition is on
- that the battery voltage (system voltage) is normal (approximately 12 V).

If necessary a battery charger can be connected during the test.
For information about charge currents and the battery, see: Battery, charging See: Starting and Charging/Battery/Service Precautions/Technician Safety Information/Battery, Charging
- that VCT2000 is correctly connected to the VIDA cart and the data link connector (DLC)
- that VCT2000 and the wiring is fault-free.

Other information
- For information about fuse and terminal numbers, see the relevant Wiring Diagram.

Try to establish communication again or exit reading off diagnostic trouble codes (DTCs). Depending on the communication fault, select one of the following options.
1. Try again
2. Fault-trace more comprehensively for the communication problem that has occurred
3. Exit fault-tracing / Read off from the next system.

Which alternative is requested?

1 - Activating components and functions

2 - Checking communication faults

3 - **FAILED**

Checking communication faults

Checking communication errors

Selecting car model

Select car model to obtain relevant troubleshooting information.

Select one of the following model alternatives
1. S40 (04-) / V50.
2. V70 (00-), V70 XC (01-) / XC70, S60, S80 and XC90.
3. V70 (-00), V70 XC and S70 / C70.
4. S40 (-04)/ V40.

1 - car model S40 (04-) / V50

2 - car model V70 (00-), V70 XC (01-) / XC70, S60, S80 and XC90

3 - car model V70 (-00), V70 XC and S70 / C70

4 - Checking communication errors car model S40 (-04) / V40

Checking communication errors, car model S40 (04-) / V50

Hint: Test the communication with another corresponding vehicle to decide if the malfunction is in the vehicle or in VIDA/VCT/cable harness. If the communication works on another vehicle, the malfunction is in the vehicle.

Hint: For current information about each circuit and signals, see wiring diagram and signal description for each system.

Diagnostic outlet

- Check the voltage feed to diagnostic outlet #16. The voltage shall match battery voltage.
- Check the cable for power ground and signal ground to diagnostic outlet #4 and #5.

Hint: When VCT2000 is connected to the diagnostic outlet (is supplied with voltage), the indicator diode shall be activated with a green light. Then the indicator diode flashes quickly when communication takes place with a control module. In case of certain internal malfunctions on VCT2000 the indicator diode is activated with a red light!

Communication cables

- For communication problems with control units on**the high-speed network**, check communication cables between diagnostic outlet #6/ #14 and central electronic module (CEM) #B11/ #B12 for open circuit, short-circuit to ground and short-circuit to voltage according to references above.
- For communication problems with control units on**the low-speed network**, check communication cables between diagnostic outlet #3/#11 and central electronic module (CEM) #B16/#B15 for open circuit, short-circuit to ground and short-circuit to voltage according to references above.
- Also check the communication cables for the low and high-speed net between the central electronic module (CEM) and the other connected control modules according to troubleshooting above.

Control modules

- Check that the control module's voltage feed and ground connection are trouble-free.

Caution! If none of the above checks help, try reading out diagnostic trouble codes in the central electronic module (CEM). Done via VIDA vehicle communication. A prerequisite for being able to communicate with the control modules in the vehicle is that the central electronic module (CEM) is active and can be communicated with. If communication is not possible with the central electronic module (CEM), check the voltage feed and ground for the central electronic module (CEM).

VCT2000 and cable harness

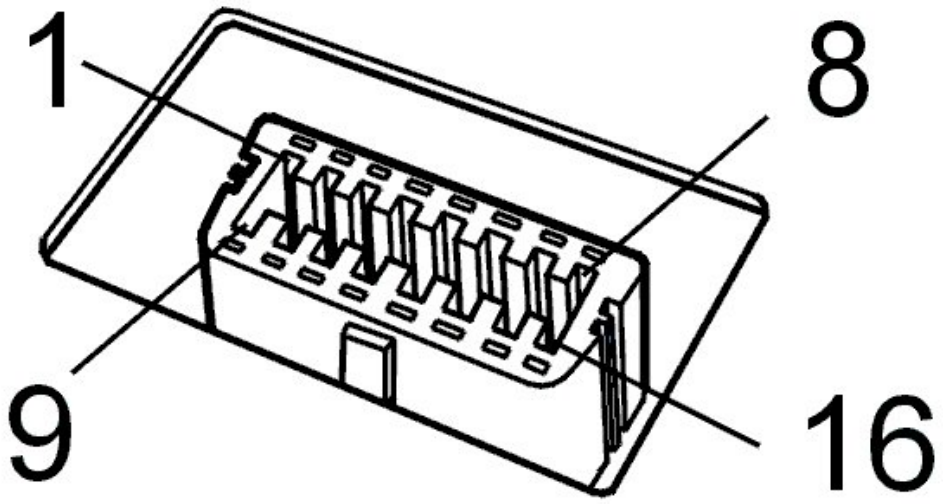
- Connect VCT2000 to the vehicle so that it is supplied with voltage. Test VCT2000 by selecting the system's self-test and VCT Test in the VIDA main menu. If any malfunction is found according to the test, first replace the cable harness then the VCT2000, if the test still indicates a malfunction.
- If no malfunctions were found after troubleshooting according to above, try with a new cable harness and/or new VCT2000.

VIDA

- If no malfunctions were found after troubleshooting according to above, try performing a complete system reset of VIDA.

Other information

- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals



Continue - Fault Found

Checking communication errors, car model V70 (00-), V70 XC (01-) / XC70, S60, S80 and XC90

Hint: Test the communication with another corresponding vehicle to decide if the malfunction is in the vehicle or in VIDA/VCT/cable harness. If the communication works on another vehicle, the malfunction is in the vehicle.

Hint: For current information about each circuit and signals, see wiring diagram and signal description for each system.

Different speed on the CAN-communication can lead to problems

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

Volvo's vehicles have different speed of communication on the high-speed part of the CAN-network (HS-CAN), depending on model year.

- Model year -2004 communicates with 250 kbit/s.
- Model year 2005- communicates with 500 kbit/s.

Due to this, it is very important to specify correct vehicle profile before any communication is started with the vehicle's HS-CAN. This is normally done by pressing on " Retrieve VIN" or by manually specifying vehicle parameters under "Vehicle profile".
If the wrong model year has been selected, it may lead to blocking of the CAN-net, diagnostic trouble codes being stored in several control modules or missing response from control modules at continued communication. The following control modules may be affected by this problem:

- Brake control module (BCM)/(ABS)
- Engine control module (ECM)
- Electronic Throttle Module (ETM)
- Suspension Module (SUM)
- Central electronic module (CEM)
- Transmission control module (TCM)
- Steering wheel angle sensor module (SAS)
- Steering Wheel Module (SWM)
- Electrical Power Steering Module (EPS)

If this happens, take the following action:

- Turn off the ignition and remove the ignition key. Insert the key again in position II.
- If the above does not work, remove the battery cable and connect it again after a minute to reset the control modules.
- Select the correct vehicle profile in VIDA and erase the diagnostic trouble codes. Check that the symptoms have disappeared.

Diagnostic outlet

- Check the voltage feed to diagnostic outlet #16. The voltage shall match battery voltage.
- Check the cable for power ground and signal ground to diagnostic outlet #4 and #5.

Hint: When VCT2000 is connected to the diagnostic outlet (is supplied with voltage), the indicator diode shall be activated with a green light. Then the indicator diode flashes quickly when communication takes place with a control module. In case of certain internal malfunctions on VCT2000 the indicator diode is activated with a red light!

Communication cables

- Check the communication cable (k-line) between diagnostic outlet #7 and central electronic module (CEM) #D6 and other connected control modules for open circuit, short-circuit to ground and short-circuit to voltage.

Caution! In case of malfunction on this communication cable, communication cannot be established on either the low or high-speed network. First when communication takes place on this cable, the low and high-speed cables between the diagnostic outlet and central electronic module (CEM) are connected to the rest of the network in the vehicle. This is controlled via a relay in the central electronic module (CEM). This relay is only found on vehicles of model year -2004.

- For communication problems with control units on**the high-speed network**, check communication cables between diagnostic outlet #6/ #14 and central electronic module (CEM) #B7/ #B8 for open circuit, short-circuit to ground and short-circuit to voltage according to references above.
- For communication problems with control units on**the low-speed network**, check communication cables between diagnostic outlet #3/#11 and central electronic module (CEM) #B19/#B20 for open circuit, short-circuit to ground and short-circuit to voltage according to references above.
- Also check the communication cables for the low and high-speed net between the central electronic module (CEM) and the other connected control modules according to troubleshooting above.

Control modules

- Check that the control module's voltage feed and ground connection are trouble-free.

Caution! If none of the above checks help, try reading out diagnostic trouble codes in the central electronic module (CEM). Done via VIDA vehicle communication. A prerequisite for being able to communicate with the control modules in the car is that the central electronic module (CEM) is active and can be communicated with. If communication is not possible with the central electronic module (CEM), check the voltage feed and ground for the central electronic module (CEM).

VCT2000 and cable harness

- Connect VCT2000 to the vehicle so that it is supplied with voltage. Test VCT2000 by selecting the system's self-test and VCT Test in the VIDA main menu. If any malfunction is found according to the test, first replace the cable harness then the VCT2000, if the test still indicates a malfunction.
- If no malfunctions were found after troubleshooting according to above, try with a new cable harness and/or new VCT2000.

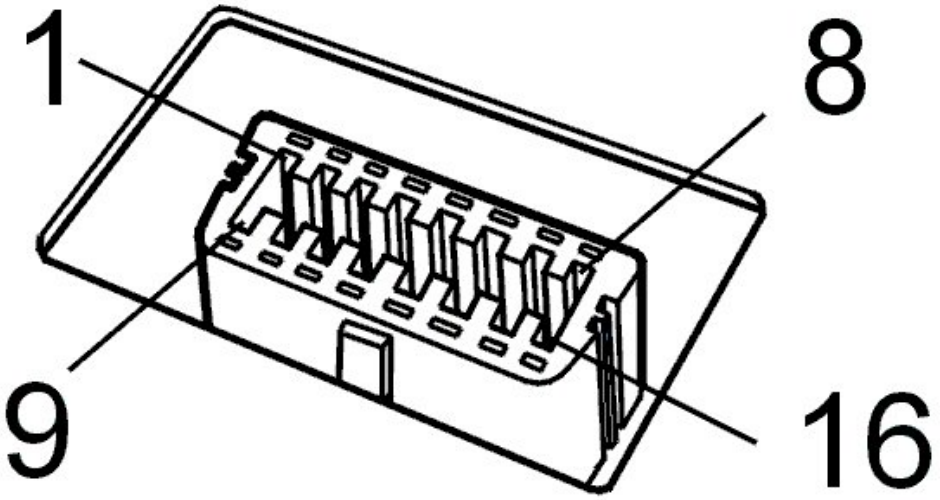
VIDA

- If no malfunctions were found after troubleshooting according to above, try performing a complete system reset of VIDA.

Other information

- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2



Continue - Fault Found

Checking communication errors, car model V70 (-00), V70 XC and S70/C70

Hint: Test the communication with another corresponding vehicle to decide if the malfunction is in the vehicle or in VIDA/VCT/cable harness. If the communication works on another vehicle, the malfunction is in the vehicle.

Hint: For current information about each circuit and signals, see wiring diagram and signal description for each system.

Diagnostic outlet
- Check the voltage feed to diagnostic outlet #16. The voltage shall match battery voltage.
- Check the cable for power ground and signal ground to diagnostic outlet #4 and #5.

Hint: When VCT2000 is connected to the diagnostic outlet (is supplied with voltage), the indicator diode shall be activated with a green light. Then the indicator diode flashes quickly when communication takes place with a control module. In case of certain internal malfunctions on VCT2000 the indicator diode is activated with a red light!

Communication cables
- Check the communication cable (k-line) between diagnostic outlet #7 and the driver information module (DIM) #B4 and other connected control modules for open circuit, short-circuit to ground and short-circuit to voltage.

Caution! In case of malfunction on this communication cable, communication cannot be established on the high-speed network. First when communication takes place on this cable, the high-speed cables between the diagnostic outlet and driver information module (DIM) are connected to the high-speed network in the vehicle. This is controlled via a relay in the driver information module (DIM).

- Check communication cables between diagnostic outlet #6/#14 and the driver information module (DIM) #A19/#A20 for open circuit, short-circuit to ground and short-circuit to voltage according to references above.
- Also check the communication cables for the**high-speed network**between the driver information module (DIM) and the other connected control modules according to troubleshooting above.

Communication cable for cruise control as own system (not integrated)
- Check the communication cable between diagnostic outlet #13 and cruise control for open circuit, short-circuit to ground and short-circuit to voltage according to references above.

Communication cable for engine management system Fenix 5.2
- Check the communication cable between diagnostic outlet #3 and engine control module (ECM) for open circuit, short-circuit to ground and short-circuit to voltage according to references above.

Control modules
- Check that the control module's voltage feed and ground connection are trouble-free.

Caution! Model year 99- and control modules on the CAN-network. If none of the above checks help, try reading out diagnostic trouble codes in the driver information module (DIM). Done via VIDA vehicle communication. A prerequisite for being able to communicate with the control modules in the vehicle is that the driver information module (DIM) is active and can be communicated with. If communication is not possible with the driver information module (DIM), check the voltage feed and ground for the control module.

VCT2000 and cable harness
- Connect VCT2000 to the vehicle so that it is supplied with voltage. Test VCT2000 by selecting the system's self-test and VCT Test in the VIDA main menu. If any malfunction is found according to the test, first replace the cable harness then the VCT2000, if the test still indicates

a malfunction.

- If no malfunctions were found after troubleshooting according to above, try with a new cable harness and/or new VCT2000.

VIDA

- If no malfunctions were found after troubleshooting according to above, try performing a complete system reset of VIDA.

- Check the communication cables between diagnostic outlet #7 and connected control modules for open circuit, short-circuit to ground and short-circuit to voltage.

Communication cable for cruise control as own system (not integrated)
- Check the communication cable between diagnostic outlet #13 and cruise control for open circuit, short-circuit to ground and short-circuit to voltage according to references above.

Communication cable for engine management system Fenix 5.1 and diesel (not Lucas)
- Check the communication cables between diagnostic outlet #11/#15 and engine control module (ECM) for open circuit, short-circuit to ground and short-circuit to voltage according to references above.

Control modules
- Check that the control module's voltage feed and ground connection are trouble-free.

VCT2000 and cable harness
- Connect VCT2000 to the vehicle so that it is supplied with voltage. Test VCT2000 by selecting the system's self-test and VCT Test in the VIDA main menu. If any malfunction is found according to the test, first replace the cable harness then the VCT2000, if the test still indicates a malfunction.
- If no malfunctions were found after troubleshooting according to above, try with a new cable harness and/or new VCT2000.

VIDA
- If no malfunctions were found after troubleshooting according to above, try performing a complete system reset of VIDA.

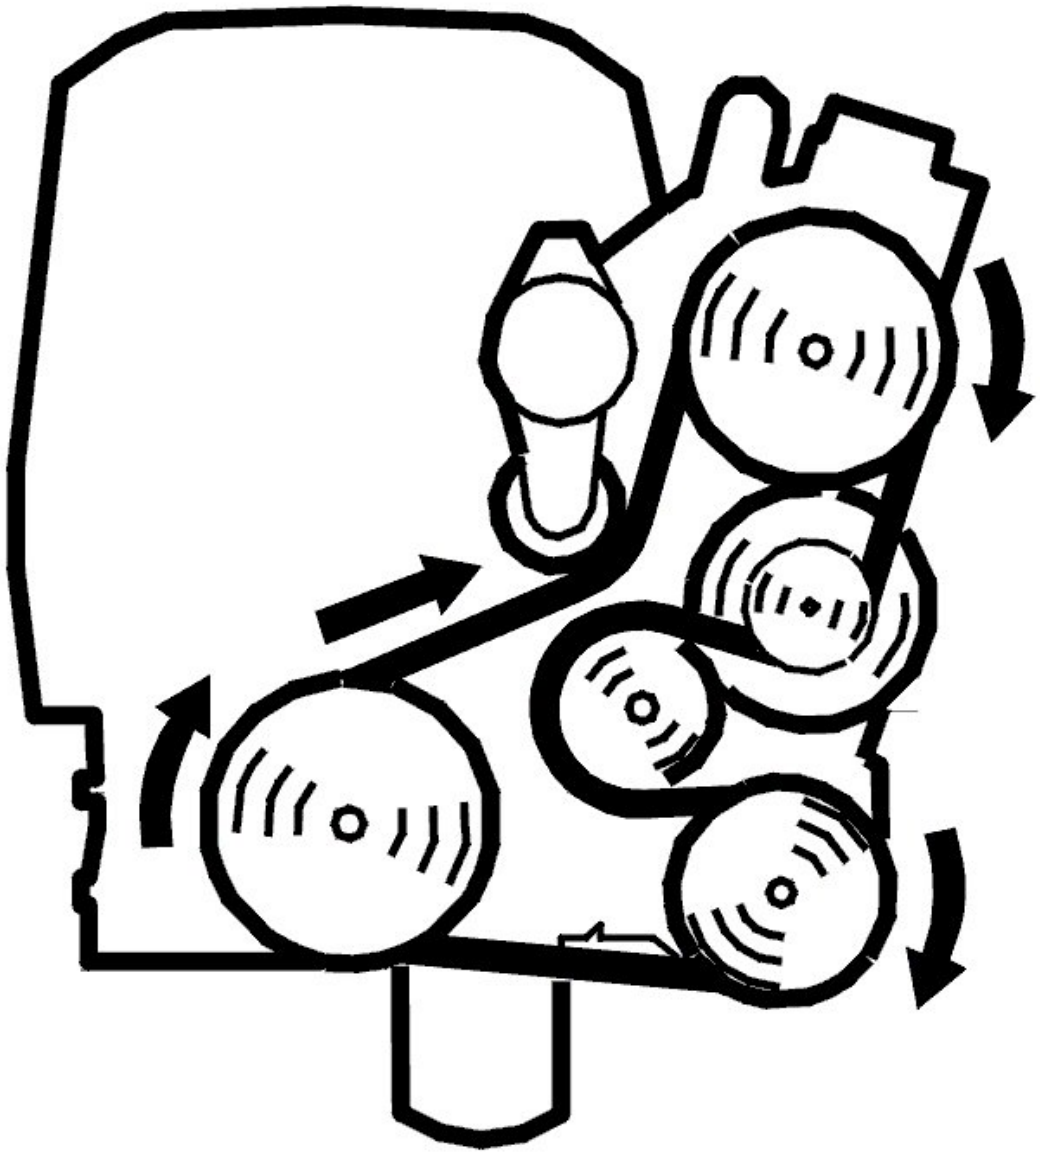
Quick Test of Exhaust Camshaft Control

Quick test of exhaust camshaft control

Quick test of exhaust camshaft control



- Start the engine
- Read off the value for the camshaft shift angle and the desired value for the camshaft shift angle
- Active the quick test of camshaft control by clicking the start button
- Increase the engine speed (RPM) to approximately 2500 rpm and keep the engine running at this speed.

When the engine speed (RPM) increases, the control module will start the quick test to control the shift angle of the camshaft for the different target values.
During the quick test, check that the shift angle of the camshaft (actual value) corresponds to the target values to an accuracy of ±10°.
Deviation between the values can be read off in the lower display.
Carry out the check for approximately 15 seconds at an engine speed (RPM) of 2500 rpm. The test is completed when the shift angle of the camshaft returns to 0°. To restart the test, let the engine return to idle speed, then increase the engine speed to approximately 2500 rpm.

Hint: A diagnostic trouble code (DTC) is stored in the control module if the control module detects a fault during the test.

Note! The test is active until the ignition is switched off. Switch off the ignition before delivering the car to the customer.

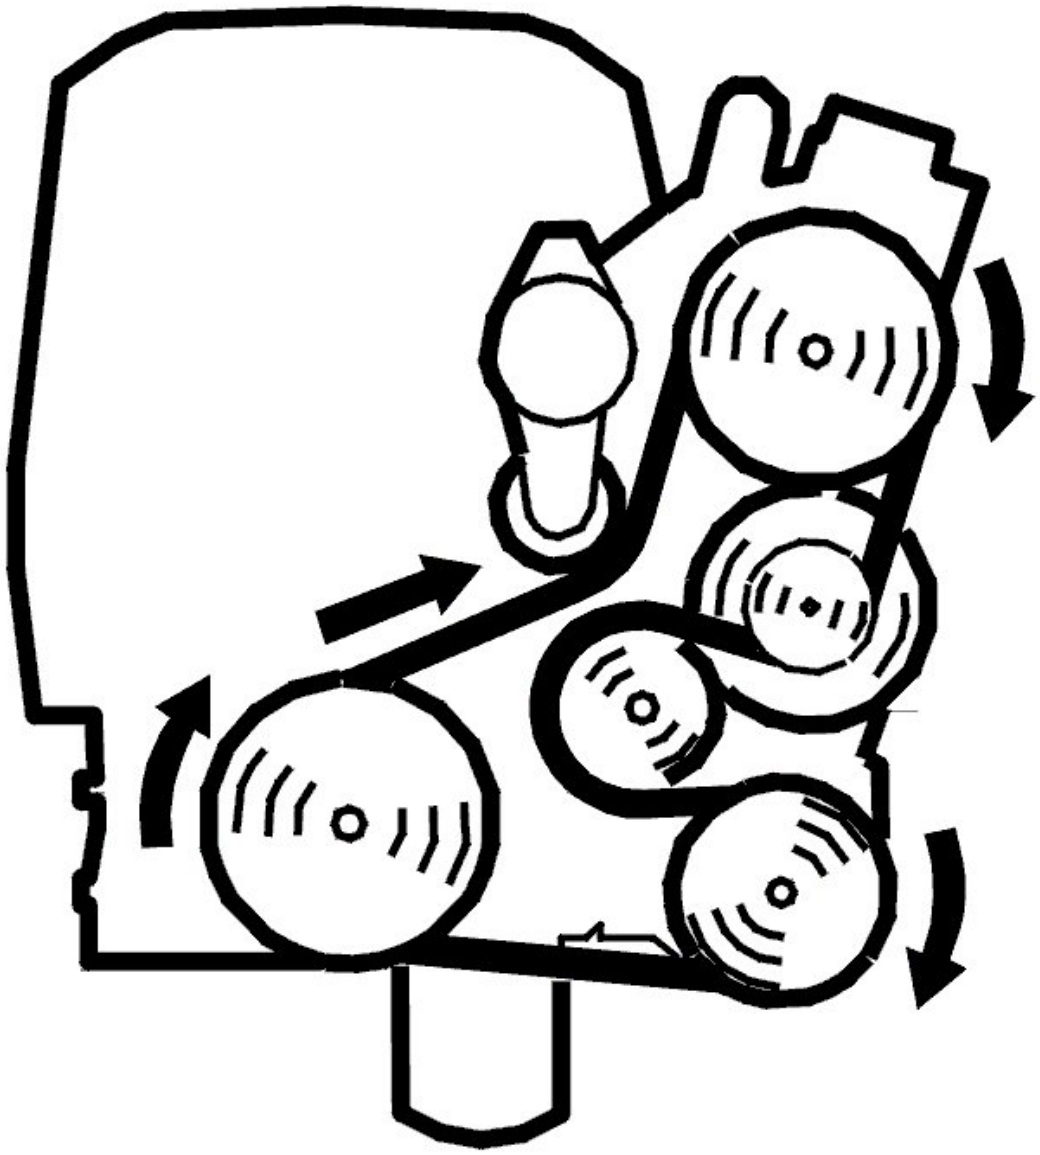
Select "Continue" to exit

Continue - DONE

Quick Test of Intake Camshaft Control

Quick test of intake camshaft control

Quick test of intake camshaft control



- Start the engine
- Read off the value for the camshaft shift angle and the desired value for the camshaft shift angle
- Active the quick test of camshaft control by clicking the start button
- Increase the engine speed (RPM) to approximately 2500 rpm and keep the engine running at this speed.

When the engine speed (RPM) increases, the control module will start the quick test to control the shift angle of the camshaft for the different target values.
During the quick test, check that the shift angle of the camshaft (actual value) corresponds to the target values to an accuracy of ±10°.
Deviation between the values can be read off in the lower display.
Carry out the check for approximately 15 seconds at an engine speed (RPM) of 2500 rpm. The test is completed when the shift angle of the camshaft returns to 0°. To restart the test, let the engine return to idle speed, then increase the engine speed to approximately 2500 rpm.

Hint: A diagnostic trouble code (DTC) is stored in the control module if the control module detects a fault during the test.

Note! The test is active until the ignition is switched off. Switch off the ignition before delivering the car to the customer.

Select "Continue" to exit

Continue - DONE

Quick Test of the Fuel Tank System

Quick test of the fuel tank system (USA/CDN)

Checking diagnostic trouble codes (DTCs), engine control module (ECM)
Note! There must be no diagnostic trouble code(s) (DTC) for the evaporative emission system (EVAP) and valve (ECM-420X, ECM-421X) or leak diagnostic unit (ECM-432X, ECM-433X). These could prevent the leak diagnostic. Check that none of these diagnostic trouble codes (DTCs) are stored.

- Ignition on.

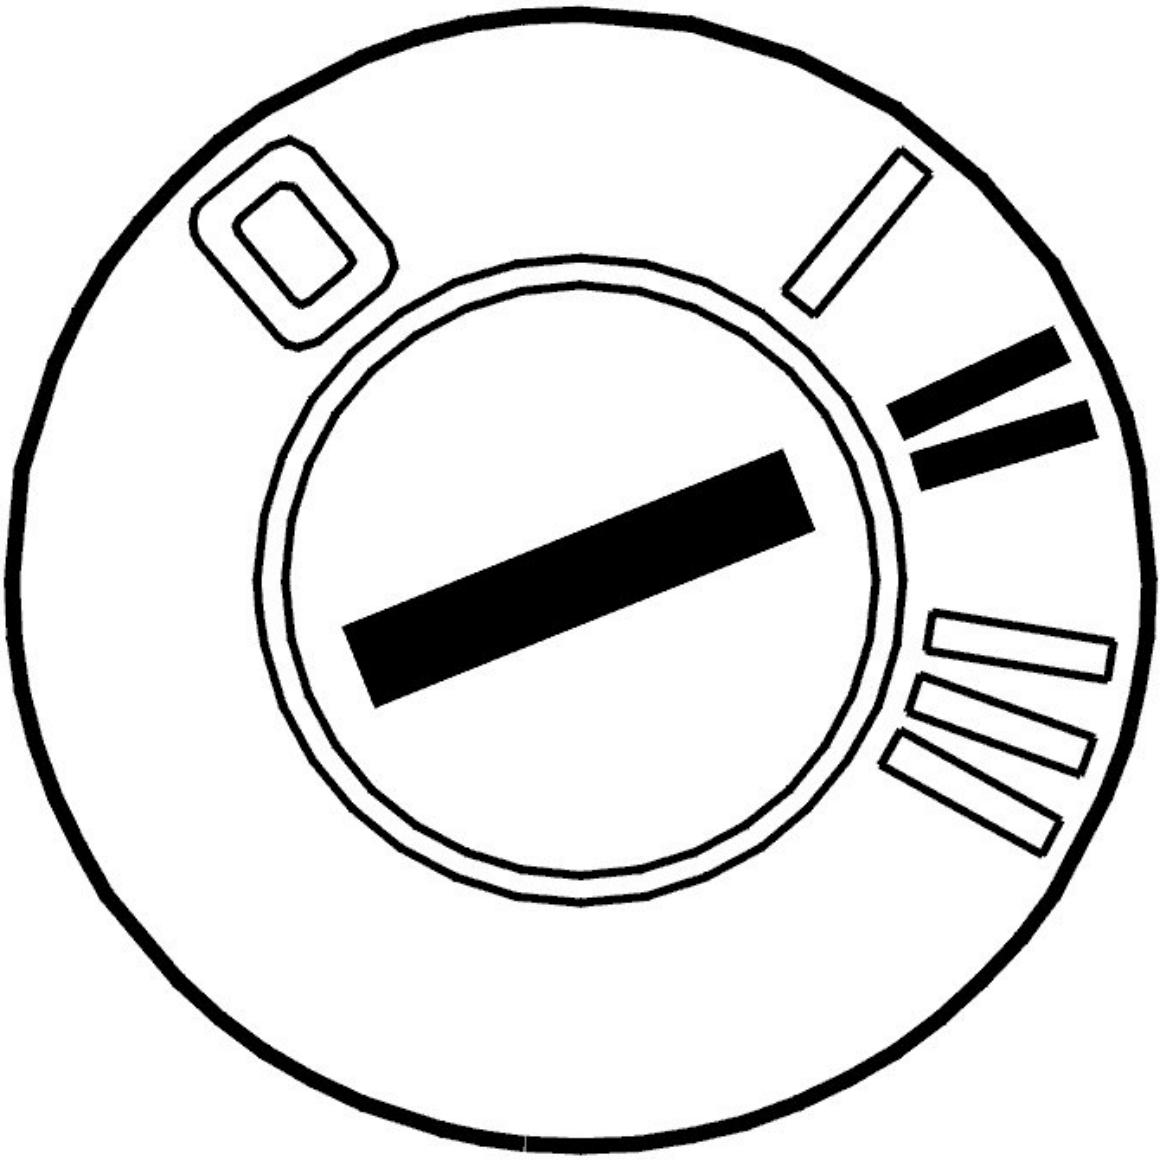
Activate reading off diagnostic trouble codes (DTCs).
If any of the above diagnostic trouble codes (DTCs) are stored they must be remedied and erased first.

Are any of the above diagnostic trouble codes (DTCs) stored?

Yes - No Fault Found

No - Quick test of the fuel tank system

Quick test of the fuel tank system



- Switch off the ignition to ensure that the status of the quick test for the fuel tank system is "Not completed". The test cannot be started if the status is "Completed".
- Ignition on
- Activate the quick test of the fuel tank system
- Read off the battery voltage, the status of the quick test of the fuel tank system and the status of the test phase. Check the parameters according to the conditions for starting the quick test of the fuel tank system.

Note! The following conditions must be met in order for the quick test of the fuel tank system to be run correctly.

Conditions for the quick test of the fuel tank system to start:

- There must be no diagnostic trouble codes (DTCs) stored for the evaporative emission system (EVAP) and valve or leak diagnostic unit
- Engine off, ignition on
- The battery voltage must be 11-14 V
- The status of the test phase must be "Not running".
- The status of the quick test for the fuel tank system must be "Not completed".

Note! The battery voltage must be correct throughout the entire test. The test can take up to 10 minutes depending on the amount of fuel in the tank. Connect a battery charger if necessary.

- Activate the quick test for the fuel tank system by clicking the start button. Click the stop button to cancel the test.

Check that the quick test has started by reading off the status of the test phase. The test has started when the status of the test phase is "Reference". Wait until the test is complete. When the test is completed, the status of the test phase must be "Not running" and the status of the quick test for the fuel tank system must be "Completed".
If no faults are detected after the quick test of the fuel tank system, the test result for the leak diagnostic unit and the fuel tank system will be "No fault found".
If a fault is detected after the quick test of the fuel tank system is complete, the test result for the fuel tank system or leak diagnostic unit will be "Fault found" with the corresponding relevant diagnostic trouble code (DTC), depending on the fault.

Hint: A diagnostic trouble code (DTC) for the fault will be stored in the engine control module (ECM) if the test result is "Fault found".

Other information

- For information about leak diagnostics, see VIDA Design and Function
- Description of parameters, quick test of the fuel tank system, B5244T5, B5254T2 See: Diagnostic Trouble Code Tests and Associated Procedures/Related Tests, Information and Procedures/Description of Parameters, Quick Test of the Fuel Tank System
- Test phases, quick test fuel tank system, B5244T5, B5254T2 See: Scan Tool Testing and Procedures/Quick Testing the System/Test Phases, Quick Test Fuel Tank System

Select an alternative to continue when the test is complete:

Select an alternative to continue when the test is completed:

1. All test results are OK, "No fault found".
2. The test result for the fuel tank system, major leak (ECM-439C) or minor leak (ECM-434C) is "Fault found".
3. The quick test does not start or the test result for the leak diagnostic unit (ECM-436X) is "Fault found".

1 - **No Fault Found**

2 - Fault-tracing information:

3 - Fault-tracing information:

Fault-tracing information:

- The engine control module (ECM) has detected a fault during the fuel tank system quick test. The diagnostic trouble code (DTC) is stored in the engine control module (ECM).

Read off diagnostic trouble codes (DTCs) from the vehicle communication socket. Fault trace the diagnostic trouble code (DTC) stored in the engine control module (ECM)

- Remedy as necessary.

Select a suitable alternative to continue:

1. Repeat the quick test for the fuel tank system
2. Exit.

1 - engine control module (ECM)

2 - **No Fault Found**

Fault-tracing information:

- The engine control module (ECM) cannot run the leak diagnostic by activating the quick test of the fuel tank system. This may be because the conditions for starting the quick test of the fuel tank system have not been met or because there is a fault preventing the quick test from starting
- The quick test for the fuel tank system cannot be run if the battery voltage varies too much. The voltage may vary if the battery is being charged with a battery charger. Charge the battery before beginning the quick test to avoid voltage variations.

Hint: Cancel fault-tracing for this fault. Then read off diagnostic trouble codes (DTCs) from the vehicle communication socket. Fault trace any other diagnostic trouble codes (DTCs) stored in the engine control module (ECM).

- Remedy as necessary.

Select a suitable alternative to continue:

1. Repeat the quick test for the fuel tank system
2. Exit.

1 - engine control module (ECM)

2 - **No Fault Found**

Test Phases, Quick Test Fuel Tank System

Test phases, quick test fuel tank system

Reference

The reference phase for leaks and the function test of the leak diagnostic unit are running. If no faults are detected during this phase the leak test in the fuel tank system starts. If any faults are detected during the phase, the test is interrupted and the test result for the leak diagnostic unit (ECM-436X) will be "Fault found".

Fuel tank system

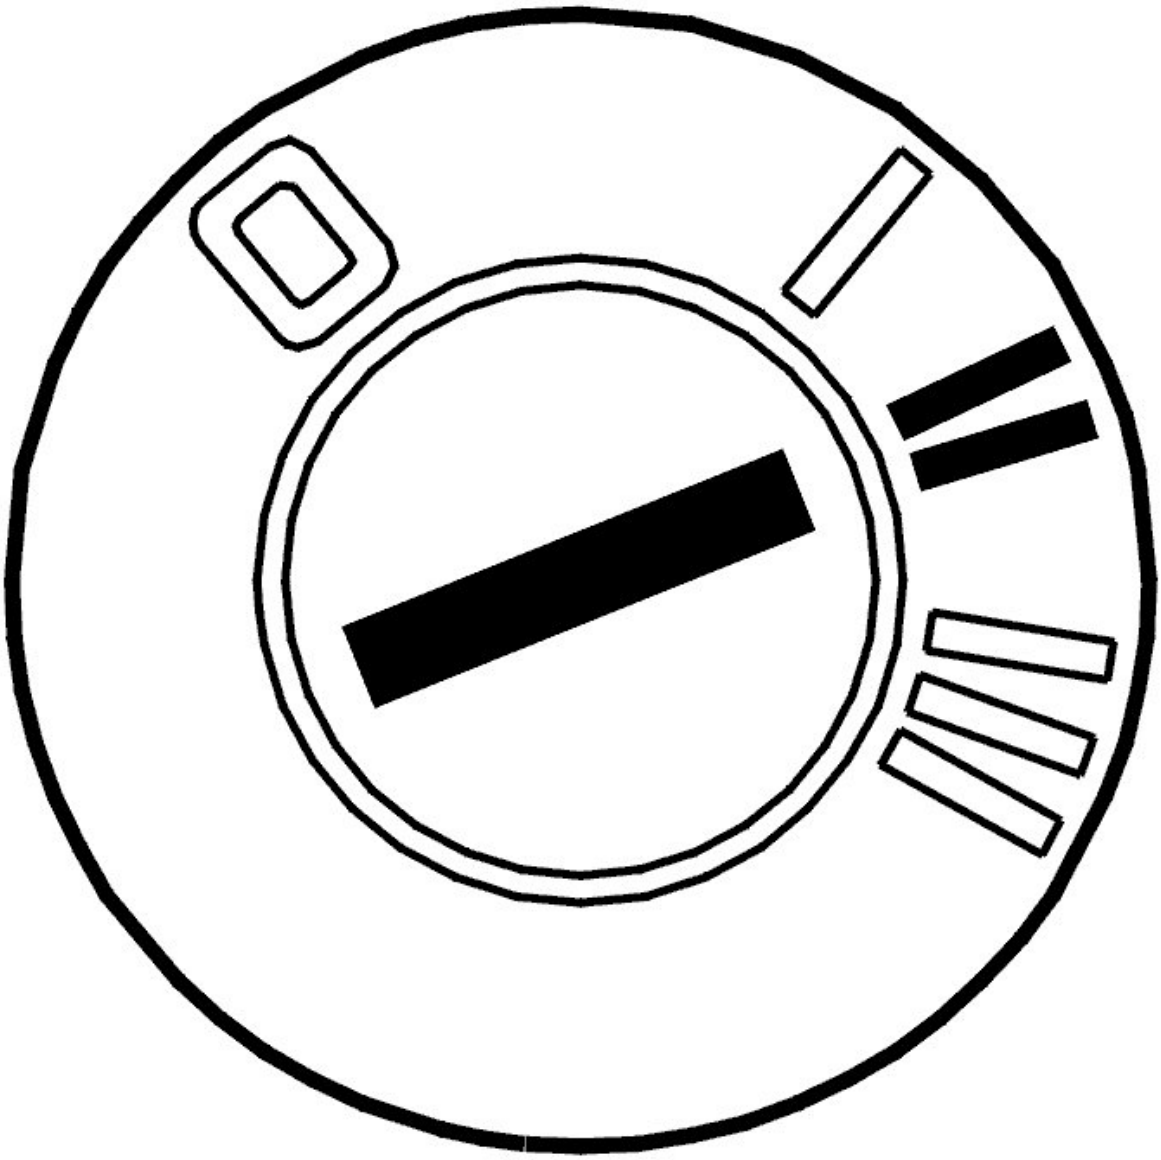
Testing for leakage in the fuel tank system is running. During the first half of the test, major leaks (leaks larger than 1.0 mm) can be detected. Diagnostic trouble code (DTC) is stored in the engine control module (ECM) if leakage is detected.
After a certain amount of time (time is dependent on the fuel level in the tank) the engine control module (ECM) assesses the seal of the fuel tank system. Assessment is made using the results of the calculations of time, measured reference power consumption of the pump, measured power consumption of the pump during the time of assessment and from the shape of the power supply curve and characteristics during pressurization. If the leak in the fuel tank system is larger than 0.5 mm but smaller than 1.0 mm a diagnostic trouble code (DTC) is stored for minor leakage in the engine control module (ECM).

Not running

The leak diagnostic is not running, the quick test of the fuel tank system has not started or has finished.

Reading Off Control Module ID

Reading off the control module ID



- Ignition on or start engine.

Read off control module ID by clicking on the VCT 2000 symbol.

Identifying control module

The information that is read off identifies the control module hardware and software versions and the diagnostic status.

Continue - DONE

Numeric Result 0 - Communication fault

Communication fault

Communication has been interrupted for one of the following reasons:
- The ignition is switched off
- VCT2000 disconnected from the data link connector (DLC)
- VCT2000 disconnected from the VIDA cart
- Communication problems in VIDA application or in car.
- No voltage in the data link connector (DLC).

Check therefore:
- That the control module power supply and ground terminal are fault-free.
- That the fuse for the data link connector (DLC) is intact.
- that the ignition is on
- that the battery voltage (system voltage) is normal (approximately 12 V).

If necessary a battery charger can be connected during the test.
For information about charge currents and the battery, see: Battery, charging See: Starting and Charging/Battery/Service Precautions/Technician Safety Information/Battery, Charging
- that VCT2000 is correctly connected to the VIDA cart and the data link connector (DLC)
- that VCT2000 and the wiring is fault-free.

Other information
- For information about fuse and terminal numbers, see the relevant Wiring Diagram.

Try to establish communication again or exit reading off diagnostic trouble codes (DTCs). Depending on the communication fault, select one of the following options.
1. Try again
2. Fault-trace more comprehensively for the communication problem that has occurred
3. Exit fault-tracing / Read off from the next system.

Which alternative is requested?

1 - Reading off the control module ID

2 - Checking communication problems

3 - **FAILED**

Checking communication problems

Checking communication errors

Selecting car model

Select car model to obtain relevant troubleshooting information.

Select one of the following model alternatives
1. S40 (04-) / V50.
2. V70 (00-), V70 XC (01-) / XC70, S60, S80 and XC90.
3. V70 (-00), V70 XC and S70 / C70.

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

4. S40 (-04)/ V40.

1 - car model S40 (04-) / V50

2 - car model V70 (00-), V70 XC (01-) / XC70, S60, S80 and XC90

3 - car model V70 (-00), V70 XC and S70 / C70

4 - Checking communication errors car model S40 (-04) / V40

Checking communication errors, car model S40 (04-) / V50

Hint: Test the communication with another corresponding vehicle to decide if the malfunction is in the vehicle or in VIDA/VCT/cable harness. If the communication works on another vehicle, the malfunction is in the vehicle.

Hint: For current information about each circuit and signals, see wiring diagram and signal description for each system.

Diagnostic outlet
- Check the voltage feed to diagnostic outlet #16. The voltage shall match battery voltage.
- Check the cable for power ground and signal ground to diagnostic outlet #4 and #5.

Hint: When VCT2000 is connected to the diagnostic outlet (is supplied with voltage), the indicator diode shall be activated with a green light. Then the indicator diode flashes quickly when communication takes place with a control module. In case of certain internal malfunctions on VCT2000 the indicator diode is activated with a red light!

Communication cables
- For communication problems with control units on**the high-speed network**, check communication cables between diagnostic outlet #6/ #14 and central electronic module (CEM) #B11/ #B12 for open circuit, short-circuit to ground and short-circuit to voltage according to references above.
- For communication problems with control units on**the low-speed network**, check communication cables between diagnostic outlet #3/#11 and central electronic module (CEM) #B16/#B15 for open circuit, short-circuit to ground and short-circuit to voltage according to references above.
- Also check the communication cables for the low and high-speed net between the central electronic module (CEM) and the other connected control modules according to troubleshooting above.

Control modules
- Check that the control module's voltage feed and ground connection are trouble-free.

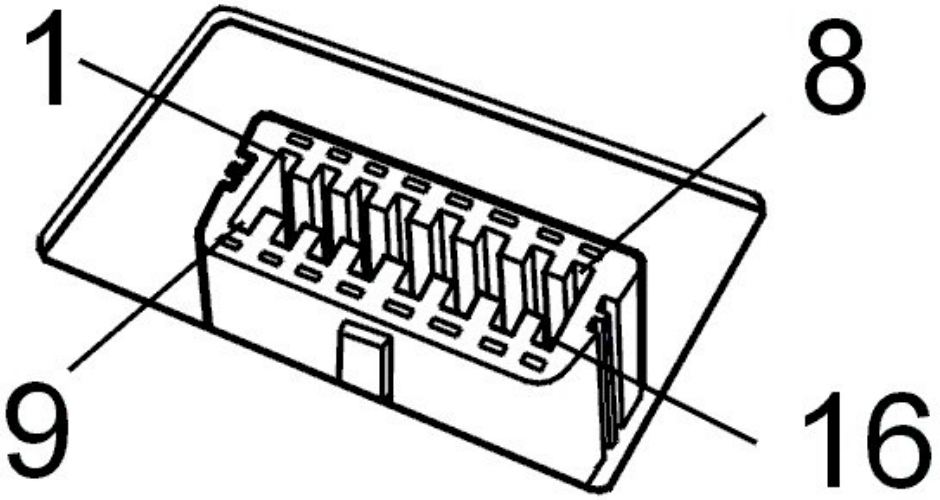
Caution! If none of the above checks help, try reading out diagnostic trouble codes in the central electronic module (CEM). Done via VIDA vehicle communication. A prerequisite for being able to communicate with the control modules in the vehicle is that the central electronic module (CEM) is active and can be communicated with. If communication is not possible with the central electronic module (CEM), check the voltage feed and ground for the central electronic module (CEM).

VCT2000 and cable harness
- Connect VCT2000 to the vehicle so that it is supplied with voltage. Test VCT2000 by selecting the system's self-test and VCT Test in the VIDA main menu. If any malfunction is found according to the test, first replace the cable harness then the VCT2000, if the test still indicates a malfunction.
- If no malfunctions were found after troubleshooting according to above, try with a new cable harness and/or new VCT2000.

VIDA
- If no malfunctions were found after troubleshooting according to above, try performing a complete system reset of VIDA.

Other information
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2



Continue - Fault Found

Checking communication errors, car model V70 (00-), V70 XC (01-) / XC70, S60, S80 and XC90

Hint: Test the communication with another corresponding vehicle to decide if the malfunction is in the vehicle or in VIDA/VCT/cable harness. If the communication works on another vehicle, the malfunction is in the vehicle.

Hint: For current information about each circuit and signals, see wiring diagram and signal description for each system.

Different speed on the CAN-communication can lead to problems

Volvo's vehicles have different speed of communication on the high-speed part of the CAN-network (HS-CAN), depending on model year.
- Model year -2004 communicates with 250 kbit/s.
- Model year 2005- communicates with 500 kbit/s.

Due to this, it is very important to specify correct vehicle profile before any communication is started with the vehicle's HS-CAN. This is normally done by pressing on " Retrieve VIN" or by manually specifying vehicle parameters under "Vehicle profile".
If the wrong model year has been selected, it may lead to blocking of the CAN-net, diagnostic trouble codes being stored in several control modules or missing response from control modules at continued communication. The following control modules may be affected by this problem:
- Brake control module (BCM)/(ABS)
- Engine control module (ECM)
- Electronic Throttle Module (ETM)
- Suspension Module (SUM)
- Central electronic module (CEM)
- Transmission control module (TCM)
- Steering wheel angle sensor module (SAS)
- Steering Wheel Module (SWM)
- Electrical Power Steering Module (EPS)

If this happens, take the following action:
- Turn off the ignition and remove the ignition key. Insert the key again in position II.
- If the above does not work, remove the battery cable and connect it again after a minute to reset the control modules.
- Select the correct vehicle profile in VIDA and erase the diagnostic trouble codes. Check that the symptoms have disappeared.

Diagnostic outlet
- Check the voltage feed to diagnostic outlet #16. The voltage shall match battery voltage.
- Check the cable for power ground and signal ground to diagnostic outlet #4 and #5.

Hint: When VCT2000 is connected to the diagnostic outlet (is supplied with voltage), the indicator diode shall be activated with a green light. Then the indicator diode flashes quickly when communication takes place with a control module. In case of certain internal malfunctions on VCT2000 the indicator diode is activated with a red light!

Communication cables
- Check the communication cable (k-line) between diagnostic outlet #7 and central electronic module (CEM) #D6 and other connected control modules for open circuit, short-circuit to ground and short-circuit to voltage.

Caution! In case of malfunction on this communication cable, communication cannot be established on either the low or high-speed network. First when communication takes place on this cable, the low and high-speed cables between the diagnostic outlet and central electronic module (CEM) are connected to the rest of the network in the vehicle. This is controlled via a relay in the central electronic module (CEM). This relay is only found on vehicles of model year -2004.

- For communication problems with control units on**the high-speed network**, check communication cables between diagnostic outlet #6/ #14 and central electronic module (CEM) #B7/ #B8 for open circuit, short-circuit to ground and short-circuit to voltage according to references above.
- For communication problems with control units on**the low-speed network**, check communication cables between diagnostic outlet #3/#11 and central electronic module (CEM) #B19/#B20 for open circuit, short-circuit to ground and short-circuit to voltage according to references above.
- Also check the communication cables for the low and high-speed net between the central electronic module (CEM) and the other connected control modules according to troubleshooting above.

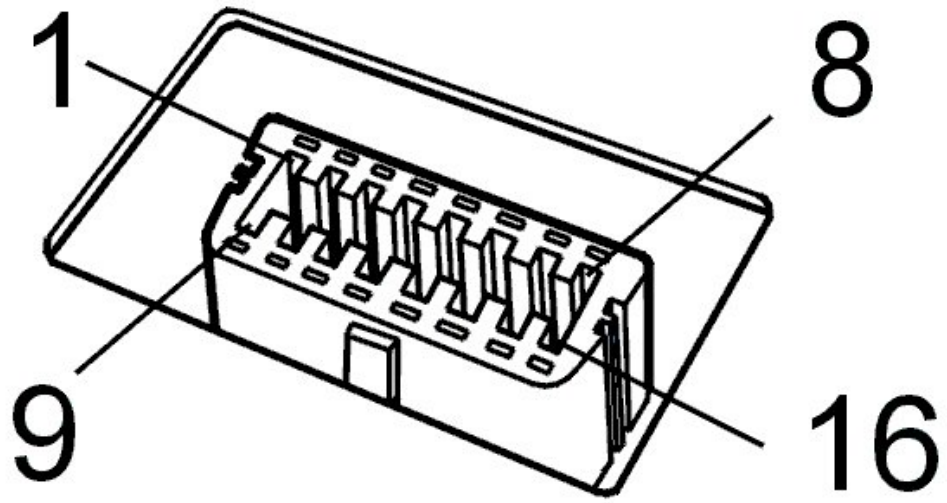
Control modules
- Check that the control module's voltage feed and ground connection are trouble-free.

Caution! If none of the above checks help, try reading out diagnostic trouble codes in the central electronic module (CEM). Done via VIDA vehicle communication. A prerequisite for being able to communicate with the control modules in the car is that the central electronic module (CEM) is active and can be communicated with. If communication is not possible with the central electronic module (CEM), check the voltage feed and ground for the central electronic module (CEM).

VCT2000 and cable harness
- Connect VCT2000 to the vehicle so that it is supplied with voltage. Test VCT2000 by selecting the system's self-test and VCT Test in the VIDA main menu. If any malfunction is found according to the test, first replace the cable harness then the VCT2000, if the test still indicates a malfunction.
- If no malfunctions were found after troubleshooting according to above, try with a new cable harness and/or new VCT2000.

VIDA
- If no malfunctions were found after troubleshooting according to above, try performing a complete system reset of VIDA.

Other information
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals



Continue - Fault Found

Checking communication errors, car model V70 (-00), V70 XC and S70/C70

Hint: Test the communication with another corresponding vehicle to decide if the malfunction is in the vehicle or in VIDA/VCT/cable harness. If the communication works on another vehicle, the malfunction is in the vehicle.

Hint: For current information about each circuit and signals, see wiring diagram and signal description for each system.

Diagnostic outlet
- Check the voltage feed to diagnostic outlet #16. The voltage shall match battery voltage.
- Check the cable for power ground and signal ground to diagnostic outlet #4 and #5.

Hint: When VCT2000 is connected to the diagnostic outlet (is supplied with voltage), the indicator diode shall be activated with a green light. Then the indicator diode flashes quickly when communication takes place with a control module. In case of certain internal malfunctions on VCT2000 the indicator diode is activated with a red light!

Communication cables

- Check the communication cable (k-line) between diagnostic outlet #7 and the driver information module (DIM) #B4 and other connected control modules for open circuit, short-circuit to ground and short-circuit to voltage.

Caution! In case of malfunction on this communication cable, communication cannot be established on the high-speed network. First when communication takes place on this cable, the high-speed cables between the diagnostic outlet and driver information module (DIM) are connected to the high-speed network in the vehicle. This is controlled via a relay in the driver information module (DIM).

- Check communication cables between diagnostic outlet #6/#14 and the driver information module (DIM) #A19/#A20 for open circuit, short-circuit to ground and short-circuit to voltage according to references above.
- Also check the communication cables for the**high-speed network**between the driver information module (DIM) and the other connected control modules according to troubleshooting above.

Communication cable for cruise control as own system (not integrated)

- Check the communication cable between diagnostic outlet #13 and cruise control for open circuit, short-circuit to ground and short-circuit to voltage according to references above.

Communication cable for engine management system Fenix 5.2

- Check the communication cable between diagnostic outlet #3 and engine control module (ECM) for open circuit, short-circuit to ground and short-circuit to voltage according to references above.

Control modules

- Check that the control module's voltage feed and ground connection are trouble-free.

Caution! Model year 99- and control modules on the CAN-network. If none of the above checks help, try reading out diagnostic trouble codes in the driver information module (DIM). Done via VIDA vehicle communication. A prerequisite for being able to communicate with the control modules in the vehicle is that the driver information module (DIM) is active and can be communicated with. If communication is not possible with the driver information module (DIM), check the voltage feed and ground for the control module.

VCT2000 and cable harness

- Connect VCT2000 to the vehicle so that it is supplied with voltage. Test VCT2000 by selecting the system's self-test and VCT Test in the VIDA main menu. If any malfunction is found according to the test, first replace the cable harness then the VCT2000, if the test still indicates a malfunction.

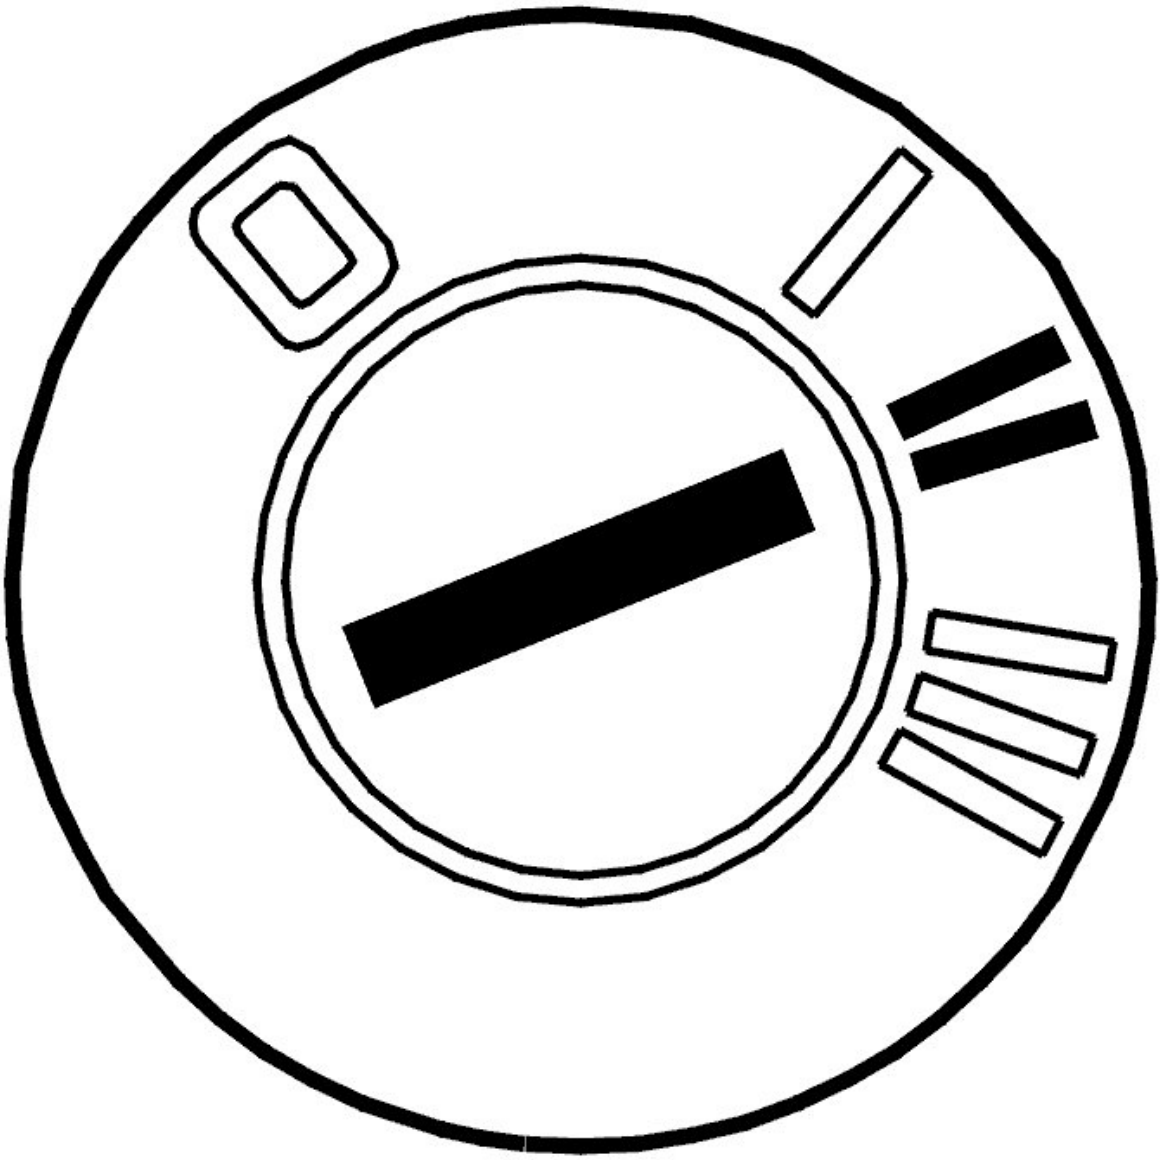
Reading Off Detailed Diagnostic Data

Reading off detailed diagnostic data

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

General information about reading off



- Ignition on.

This function is used to read off the diagnostic data from the control module in the**background**. If the VIDA log function is activated**while**the read out is taking place, all data that is read off will be logged. The VIDA log function allows logs to be saved or read off. This makes it easier to analyze data or to include the log files in a report for example.

- VIDA log function activated (log status on).

Note! If this has not already been done, exit this procedure. Select vehicle profile and set the logging status to On.

If the VIDA log function is already activated and has previously logged other activities which are not required, exit this procedure and log off VIDA. The existing log can then be removed. Delete the log and close it. Then log on to VIDA again.

Do you want to start reading off? The data read off starts automatically when YES is selected.

Yes - Reading off the engine control module (ECM) diagnostic data

No - DONE

Reading off the engine control module (ECM) diagnostic data

Numeric Result 0 - Communication fault

Finishing the read off

The read off is now complete.
Exit this procedure. Log off VIDA. The completed log can now be printed or saved.
Save the log to a disc or save it locally. To save it locally, name the file**vehcom.log**under**C:\volvo\logs**.

Continue - **DONE**

Communication fault

Communication has been interrupted for one of the following reasons:
- The ignition is switched off
- VCT2000 disconnected from the data link connector (DLC)
- VCT2000 disconnected from the VIDA cart
- Communication problems in VIDA application or in car.
- No voltage in the data link connector (DLC).

Check therefore:
- That the control module power supply and ground terminal are fault-free.
- That the fuse for the data link connector (DLC) is intact.
- that the ignition is on
- that the battery voltage (system voltage) is normal (approximately 12 V).

If necessary a battery charger can be connected during the test.
For information about charge currents and the battery, see: Battery, charging See: Starting and Charging/Battery/Service Precautions/Technician Safety Information/Battery, Charging
- that VCT2000 is correctly connected to the VIDA cart and the data link connector (DLC)
- that VCT2000 and the wiring is fault-free.

Other information
- For information about fuse and terminal numbers, see the relevant Wiring Diagram.

Try to establish communication again or exit reading off diagnostic trouble codes (DTCs). Depending on the communication fault, select one of the following options.
1. Try again
2. Fault-trace more comprehensively for the communication problem that has occurred
3. Exit fault-tracing / Read off from the next system.

3 - car model V70 (-00), V70 XC and S70 / C70

4 - Checking communication errors car model S40 (-04) / V40

Checking communication errors, car model S40 (04-) / V50

Hint: Test the communication with another corresponding vehicle to decide if the malfunction is in the vehicle or in VIDA/VCT/cable harness. If the communication works on another vehicle, the malfunction is in the vehicle.

Hint: For current information about each circuit and signals, see wiring diagram and signal description for each system.

Diagnostic outlet
- Check the voltage feed to diagnostic outlet #16. The voltage shall match battery voltage.
- Check the cable for power ground and signal ground to diagnostic outlet #4 and #5.

Hint: When VCT2000 is connected to the diagnostic outlet (is supplied with voltage), the indicator diode shall be activated with a green light. Then the indicator diode flashes quickly when communication takes place with a control module. In case of certain internal malfunctions on VCT2000 the indicator diode is activated with a red light!

Communication cables
- For communication problems with control units on**the high-speed network**, check communication cables between diagnostic outlet #6/ #14 and central electronic module (CEM) #B11/ #B12 for open circuit, short-circuit to ground and short-circuit to voltage according to references above.
- For communication problems with control units on**the low-speed network**, check communication cables between diagnostic outlet #3/#11 and central electronic module (CEM) #B16/#B15 for open circuit, short-circuit to ground and short-circuit to voltage according to references above.
- Also check the communication cables for the low and high-speed net between the central electronic module (CEM) and the other connected control modules according to troubleshooting above.

Control modules
- Check that the control module's voltage feed and ground connection are trouble-free.

Caution! If none of the above checks help, try reading out diagnostic trouble codes in the central electronic module (CEM). Done via VIDA vehicle communication. A prerequisite for being able to communicate with the control modules in the vehicle is that the central electronic module (CEM) is active and can be communicated with. If communication is not possible with the central electronic module (CEM), check the voltage feed and ground for the central electronic module (CEM).

VCT2000 and cable harness
- Connect VCT2000 to the vehicle so that it is supplied with voltage. Test VCT2000 by selecting the system's self-test and VCT Test in the VIDA main menu. If any malfunction is found according to the test, first replace the cable harness then the VCT2000, if the test still indicates a malfunction.
- If no malfunctions were found after troubleshooting according to above, try with a new cable harness and/or new VCT2000.

VIDA
- If no malfunctions were found after troubleshooting according to above, try performing a complete system reset of VIDA.

Other information

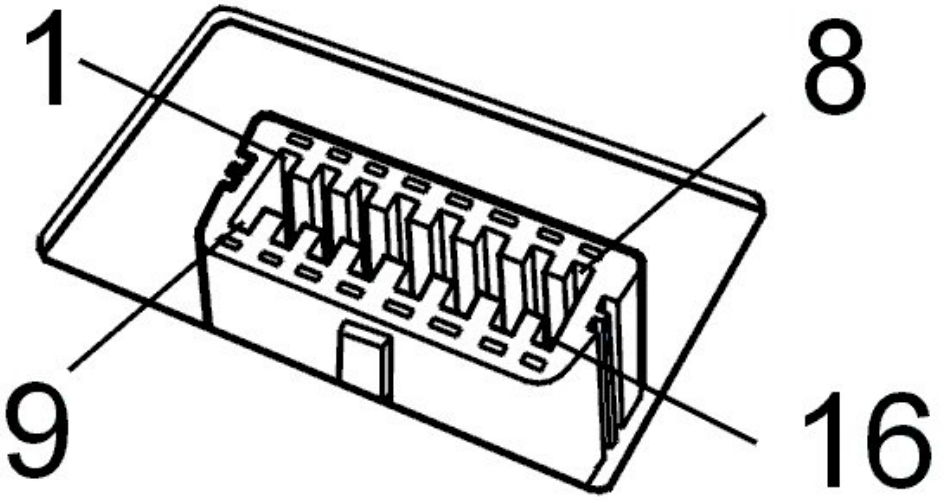
Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2



Continue - Fault Found

Checking communication errors, car model V70 (00-), V70 XC (01-) / XC70, S60, S80 and XC90

Hint: Test the communication with another corresponding vehicle to decide if the malfunction is in the vehicle or in VIDA/VCT/cable harness. If the communication works on another vehicle, the malfunction is in the vehicle.

Hint: For current information about each circuit and signals, see wiring diagram and signal description for each system.

Different speed on the CAN-communication can lead to problems

Volvo's vehicles have different speed of communication on the high-speed part of the CAN-network (HS-CAN), depending on model year.
- Model year -2004 communicates with 250 kbit/s.
- Model year 2005- communicates with 500 kbit/s.

Due to this, it is very important to specify correct vehicle profile before any communication is started with the vehicle's HS-CAN. This is normally done by pressing on " Retrieve VIN" or by manually specifying vehicle parameters under "Vehicle profile".
If the wrong model year has been selected, it may lead to blocking of the CAN-net, diagnostic trouble codes being stored in several control modules or missing response from control modules at continued communication. The following control modules may be affected by this problem:
- Brake control module (BCM)/(ABS)
- Engine control module (ECM)
- Electronic Throttle Module (ETM)
- Suspension Module (SUM)
- Central electronic module (CEM)
- Transmission control module (TCM)
- Steering wheel angle sensor module (SAS)
- Steering Wheel Module (SWM)
- Electrical Power Steering Module (EPS)

If this happens, take the following action:
- Turn off the ignition and remove the ignition key. Insert the key again in position II.
- If the above does not work, remove the battery cable and connect it again after a minute to reset the control modules.
- Select the correct vehicle profile in VIDA and erase the diagnostic trouble codes. Check that the symptoms have disappeared.

Diagnostic outlet
- Check the voltage feed to diagnostic outlet #16. The voltage shall match battery voltage.
- Check the cable for power ground and signal ground to diagnostic outlet #4 and #5.

Hint: When VCT2000 is connected to the diagnostic outlet (is supplied with voltage), the indicator diode shall be activated with a green light. Then the indicator diode flashes quickly when communication takes place with a control module. In case of certain internal malfunctions on VCT2000 the indicator diode is activated with a red light!

Communication cables
- Check the communication cable (k-line) between diagnostic outlet #7 and central electronic module (CEM) #D6 and other connected control modules for open circuit, short-circuit to ground and short-circuit to voltage.

Caution! In case of malfunction on this communication cable, communication cannot be established on either the low or high-speed network. First when communication takes place on this cable, the low and high-speed cables between the diagnostic outlet and central electronic module (CEM) are connected to the rest of the network in the vehicle. This is controlled via a relay in the central electronic module (CEM). This relay is only found on vehicles of model year -2004.

- For communication problems with control units on**the high-speed network**, check communication cables between diagnostic outlet #6/ #14 and central electronic module (CEM) #B7/ #B8 for open circuit, short-circuit to ground and short-circuit to voltage according to references above.
- For communication problems with control units on**the low-speed network**, check communication cables between diagnostic outlet #3/#11 and central electronic module (CEM) #B19/#B20 for open circuit, short-circuit to ground and short-circuit to voltage according to references above.
- Also check the communication cables for the low and high-speed net between the central electronic module (CEM) and the other connected control modules according to troubleshooting above.

Control modules
- Check that the control module's voltage feed and ground connection are trouble-free.

Caution! If none of the above checks help, try reading out diagnostic trouble codes in the central electronic module (CEM). Done via VIDA vehicle communication. A prerequisite for being able to communicate with the control modules in the car is that the central electronic module (CEM) is active and can be communicated with. If communication is not possible with the central electronic module (CEM), check the voltage feed and ground for the central electronic module (CEM).

VCT2000 and cable harness
- Connect VCT2000 to the vehicle so that it is supplied with voltage. Test VCT2000 by selecting the system's self-test and VCT Test in the VIDA main menu. If any malfunction is found according to the test, first replace the cable harness then the VCT2000, if the test still indicates a malfunction.
- If no malfunctions were found after troubleshooting according to above, try with a new cable harness and/or new VCT2000.

VIDA
- If no malfunctions were found after troubleshooting according to above, try performing a complete system reset of VIDA.

Other information

Continue - Fault Found

Checking communication errors, car model V70 (-00), V70 XC and S70/C70

Hint: Test the communication with another corresponding vehicle to decide if the malfunction is in the vehicle or in VIDA/VCT/cable harness. If the communication works on another vehicle, the malfunction is in the vehicle.

Hint: For current information about each circuit and signals, see wiring diagram and signal description for each system.

Diagnostic outlet
- Check the voltage feed to diagnostic outlet #16. The voltage shall match battery voltage.
- Check the cable for power ground and signal ground to diagnostic outlet #4 and #5.

Hint: When VCT2000 is connected to the diagnostic outlet (is supplied with voltage), the indicator diode shall be activated with a green light. Then the indicator diode flashes quickly when communication takes place with a control module. In case of certain internal malfunctions on VCT2000 the indicator diode is activated with a red light!

Communication cables

- Check the communication cable (k-line) between diagnostic outlet #7 and the driver information module (DIM) #B4 and other connected control modules for open circuit, short-circuit to ground and short-circuit to voltage.

Caution! In case of malfunction on this communication cable, communication cannot be established on the high-speed network. First when communication takes place on this cable, the high-speed cables between the diagnostic outlet and driver information module (DIM) are connected to the high-speed network in the vehicle. This is controlled via a relay in the driver information module (DIM).

- Check communication cables between diagnostic outlet #6/#14 and the driver information module (DIM) #A19/#A20 for open circuit, short-circuit to ground and short-circuit to voltage according to references above.
- Also check the communication cables for the**high-speed network**between the driver information module (DIM) and the other connected control modules according to troubleshooting above.

Communication cable for cruise control as own system (not integrated)

- Check the communication cable between diagnostic outlet #13 and cruise control for open circuit, short-circuit to ground and short-circuit to voltage according to references above.

Communication cable for engine management system Fenix 5.2

- Check the communication cable between diagnostic outlet #3 and engine control module (ECM) for open circuit, short-circuit to ground and short-circuit to voltage according to references above.

Control modules

- Check that the control module's voltage feed and ground connection are trouble-free.

Caution! Model year 99- and control modules on the CAN-network. If none of the above checks help, try reading out diagnostic trouble codes in the driver information module (DIM). Done via VIDA vehicle communication. A prerequisite for being able to communicate with the control modules in the vehicle is that the driver information module (DIM) is active and can be communicated with. If communication is not possible with the driver information module (DIM), check the voltage feed and ground for the control module.

VCT2000 and cable harness

- Connect VCT2000 to the vehicle so that it is supplied with voltage. Test VCT2000 by selecting the system's self-test and VCT Test in the VIDA main menu. If any malfunction is found according to the test, first replace the cable harness then the VCT2000, if the test still indicates a malfunction.
- If no malfunctions were found after troubleshooting according to above, try with a new cable harness and/or new VCT2000.

VIDA

- If no malfunctions were found after troubleshooting according to above, try performing a complete system reset of VIDA.

Description of Activations

Description of activation

Hint: Not all the components/functions described need to be implemented in the control module. This varies between different systems and markets.

Parameters, value

Throttle position (TP) sensor, potentiometer 1 (V)

The parameter can be read off to check the function when activating the "Throttle unit".
Measurement range: 0 - 80 V.
The engine control module (ECM) derives the value from potentiometer 1 for the throttle position (TP) sensor.
The value must increase with increased throttle angle.
Approximately 0.5 V = throttle closed.
Approximately 4.0 V = wide open throttle (WOT).

Throttle position (TP) sensor, potentiometer 2 (V)

The parameter can be read off to check the function when activating the "Throttle unit".
Measurement range: 0-80 V.
The engine control module (ECM) derives the value from potentiometer 2 for the throttle position (TP) sensor.
The value must decrease with an increased throttle angle.
Approximately 4.0 V = throttle closed.
Approximately 0.5 V = wide open throttle (WOT).

Component / function

Injector x

The injector opens and closes at high frequency. A clicking or buzzing noise is heard from the valve.
The engine must be switched off at activation.

Throttle unit

The throttle in the throttle unit opens depending on which activation has been selected (50, 75 or 100 %).
Read off "Throttle position (TP) sensor, potentiometer 1" or "Throttle position (TP) sensor, potentiometer 2" to check the function.
The engine must be switched off at activation.

Air conditioning (A/C) relay

The air conditioning (A/C) relay is activated and powers the air conditioning (A/C) compressor magnetic clutch.
A clear click is heard from the air conditioning (A/C) relay and from the magnetic clutch for the air conditioning (A/C) compressor.

Engine cooling fan (FC)

The speed of the engine cooling fan (FC) changes depending on which activation is selected.
The fan can be heard.

Leak diagnostic unit, valve

Certain markets only.
A clicking noise is heard from the valve in the leak diagnostic unit at activation.

Evaporative emission system (EVAP) valve

The evaporative emission system (EVAP) valve opens and closes at a certain frequency.
There is a weak click from the EVAP valve.

Turbocharger (TC) control valve

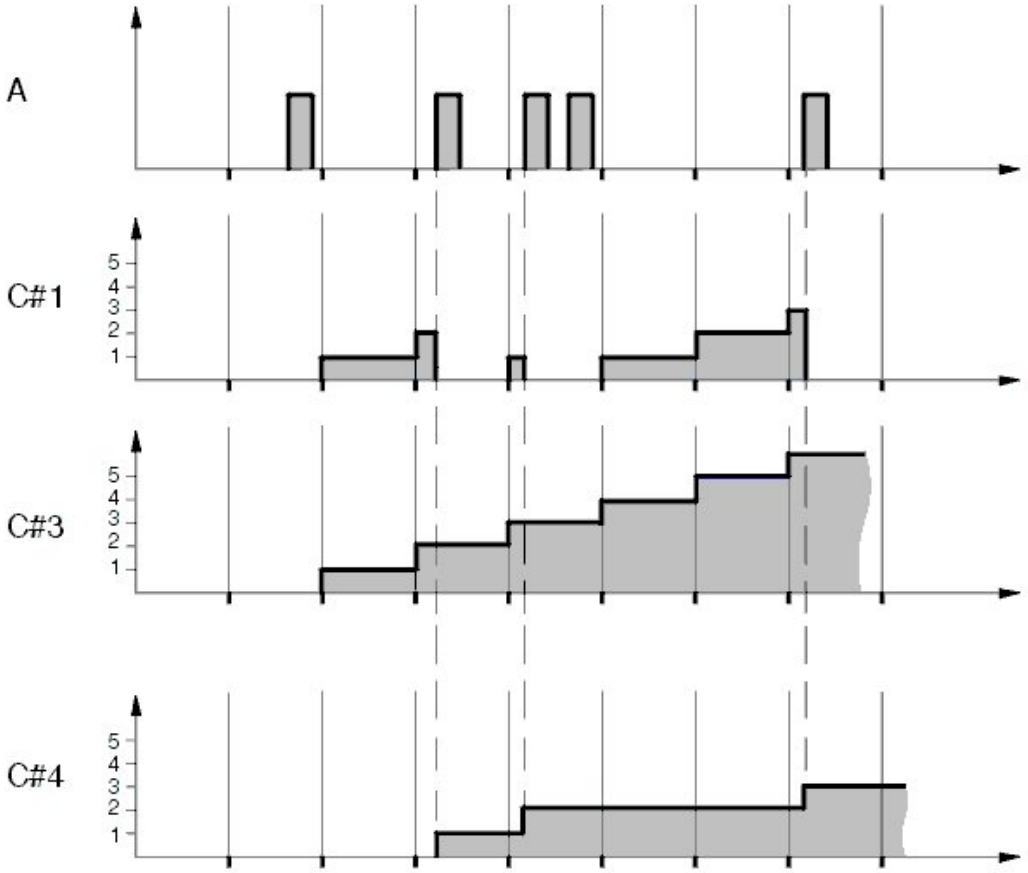
The turbocharger (TC) control valve opens and closes at a certain frequency.
There is a weak click from the turbocharger (TC) control valve.

Description of Counter

Description of counter

Counter
There are eight different counters that are stored individually for each diagnostic trouble code (DTC). For an intermittent malfunction, the values of the different counters can be studied to determine how intermittent the malfunction is. All counters do not need to be implemented in one control module, this varies from system to system. The possible counters are described below.

Counter	Function
C#1	Counts the number of operating cycles since the malfunction was**last**validated. This information can be used to determine whether the malfunction is active during the current operating cycle or not. The malfunction is present now if the value is zero.
C#2	Counts the number of operating cycles since the malfunction was**last**validated, where test for the diagnostic trouble code was performed without the malfunction being detected and validated. When a test is performed, no malfunction is detected, the counter will count up by 1 for each operating cycle.
C#3	Counts the number of operating cycles since the malfunction was validated**the first time**. For each completed operating cycle the counter will count up by 1.
C#4	Counts the number of operating cycles in which the malfunction was validated since it was first validated. Counts the number of times the malfunction has occurred since the first time.
C#5	Counts the number of warm-up cycles since the MIL-light has gone off.
C#6	The counter counts the number of internal detections of the malfunction that have been performed for the diagnostic trouble code. When this counter reaches + 127, the control module considers that the malfunction is active right now. When counter is at value -127 the malfunction is not active. The value is reset to zero at each new operating cycle. If the value increases toward +127 the control module has detected a malfunction and, for each internal test, the value counts up. When the malfunction is not active, the control module counts down to minimum -127. Value can only be changed when the control module has started the test for the diagnostic trouble code. The increments with which the control module counts up or down the value may vary between control modules.
C#7	Shows maximum value for current operating cycle.
C#8	Shows maximum value for current and/or earlier operating cycle.



Description of Frozen Values

Description of frozen values

Explanation

Hint: Not all described parameters are implemented in the control module. This varies between systems and markets.

Bank 1: indicates cylinders 1-3 on 6-cylinder engines and all cylinders on 5-cylinder engines. The rear heated oxygen sensor of a vehicle with closed loop control following the Y concept (two front and one rear heated oxygen sensor) is designated "Bank 1".
Bank 2: indicates cylinders 4-6 on 6-cylinder engines.

Engine speed (rpm)

The engine control module (ECM) calculates engine speed from the impulse sensor signal.

Boost pressure (hPa)

The value is calculated from the boost pressure sensor and indicates the pressure in the induction system after the turbocharger but before the throttle.
The engine control module (ECM) calculates boost pressure from the boost pressure sensor. The pressure is relative to atmospheric pressure.

°

Engine temperature (C)

The engine control module (ECM) calculates temperature from the engine temperature sensor signal.

°

Engine temperature, start (C)

The engine control module (ECM) calculates temperature from the engine temperature sensor signal. The value indicates the temperature of the engine upon engine start in the operating cycle in which the diagnostic trouble code (DTC) was generated.

Calculated load (%)

The value, calculated by the engine control module, indicates engine efficiency. The engine control module (ECM) calculates the value from air mass, engine speed, boost pressure, throttle angle, etc. A value over 100% indicates turbocharging (overpressure).

Fuel pressure (Pa)

The engine control module (ECM) calculates the pressure from the fuel pressure sensor signal.
The parameter indicates absolute pressure.

Speed (km/h)

The value indicates vehicle speed.
The engine control module (ECM) receives information on vehicle speed from the brake control module (BCM) via CAN communication.

°

Ignition angle (BTDC)

The value indicates the ignition angle for cylinder 1.

Atmospheric pressure (Pa)

The value indicates atmospheric pressure at the engine control module (ECM).
The engine control module (ECM) calculates the value from the integrated atmospheric pressure sensor.
The normal value at 0 meters above sea level is 1013 hPa.

°

Outside temperature (C)

The engine control module (ECM) calculates the temperature from the outside temperature sensor signal.

°

Intake air temperature (C)

The engine control module (ECM) calculates the temperature from the intake air temperature sensor.

EVAP valve (%)

The value indicates the control module output signal for EVAP valve regulation, i.e. how much the EVAP valve should open to purge the canister.
0 % = no regulation (EVAP valve closed).
100 % = full regulation (EVAP valve fully open).

Throttle angle (%)

The engine control module (ECM) calculates the value from the throttle position sensor. The value is calculated linearly from the throttle position sensor's output signal (0-5V) and indicates how much the throttle is open.
Approx. 6-14 % = idling (0% throttle angle, desired value).
Approx. 85-100 % = throttle fully open (100% throttle angle, desired value).

Accelerator pedal position sensor, PWM (%)

PWM signal from the accelerator pedal position sensor to the engine control module (ECM). The control module calculates the value from the accelerator pedal position sensor's digital output.
The value indicates the position of the accelerator pedal.

Approx. 8 % = accelerator pedal fully released.
Approx. 88 % = accelerator pedal fully depressed.

Accelerator pedal position sensor, analog (%)

Analog signal from the accelerator pedal position sensor to the engine control module (ECM). The control module calculates the value from the accelerator pedal position sensor's analog output.
The value indicates the position of the accelerator pedal.
Approx. 8 % = accelerator pedal fully released.
Approx. 88 % = accelerator pedal fully depressed.

Throttle angle, desired value (%)

The value indicates the engine control module (ECM) calculated value for throttle opening (throttle angle).
The parameter value cannot be directly compared to the actual value for the throttle angle.
0% = idling.
100% = throttle fully open.

Fuel trim, rapid adjustment, bank X (%)

Rapid adjustment is the continual adaptation of the fuel/air mixture during operation.
Bank 2 only applies to 6-cylinder engines.

Hint: Fuel trim returns to 0% once diagnostic trouble codes (DTCs) have been cleared.

Fuel trim, slow adjustment, bank X (%)

Slow adjustment is the fuel trim value that adjusts the fuel/air mixture for a longer period of time and factors in component aging, tolerances, etc.
Bank 2 only applies to 6-cylinder engines.

Hint: Fuel trim returns to 0% once diagnostic trouble codes (DTCs) have been cleared.

Power supply, engine control module (ECM) (V)

The value indicates the power supplied to the engine control module (ECM).

Time after engine start (s)

The value indicates how much time has elapsed between engine start and diagnostic trouble code (DTC) generation.

Description of Parameters

Description of parameters

Hint: Not all the parameters described need to be implemented in the control module. This varies between different systems and markets.
Bank 1: indicates cylinders 1-3 on 6 cylinder engines and **all cylinders on 5 cylinder engines.** The rear heated oxygen sensor (HO2S) on cars with fuel trim using the Y-concept (two front heated oxygen sensors (HO2S) and one rear heated oxygen sensors (HO2S)) is called "Bank 1".
Bank 2: indicates cylinders 4-6 on 6-cylinder engines.

Parameters, value

Engine speed (rpm)

Measurement range: 0-10400 rpm.
The engine control module (ECM) derives the engine speed (RPM) from the engine speed (RPM) sensor signal.
The idle speed varies depending on the engine coolant temperature (ECT).

Idling speed, difference desired value (rpm)

Measurement range: between -1280-1270 rpm.
The value indicates the idle speed deviation from the engine control module (ECM) desired value (target value).

Battery voltage (V)

Measurement range: 0-17.95 V.
The normal value is 13.5-14.5 V when the generator (GEN) is charging.
The value indicates the voltage from the system relay to the engine control module (ECM).

°

Engine coolant temperature (ECT) (C)

Measurement range: -48 to +143 °C.
The engine control module (ECM) derives the temperature from the engine coolant temperature (ECT) sensor signal.

°
Intake air temperature (IAT) (C)

Measurement range: -48 to +143 °C.
The engine control module (ECM) calculates the temperature from the temperature sensor for the intake air.
The temperature sensor is integrated in the boost pressure sensor.

°
Outside temperature (C)

Measurement range: -40 to +110 °C.
The engine control module (ECM) derives the temperature from the outside temperature sensor signal.

Atmospheric pressure (Pa)

Measurement range: 0-5120 hPa.
The value indicates atmospheric pressure at the engine control module (ECM).
The sensor is integrated in the engine control module (ECM).
Normal value at sea level is 1,013 hPa.

°
Ignition advance (BTDC)

Measurement range: -96 to +95.3° before top dead center (BTDC).
The value is calculated from the engine speed (RPM) sensor signal.
The value when idling varies depending on the engine coolant temperature (ECT).

Boost pressure (hPa)

Measurement range: 0-2550 hPA.
The value is calculated from the boost pressure. It indicates the pressure in the intake system downstream of the turbocharger (TC).
The engine control module (ECM) calculates the boost pressure from the boost pressure sensor. The pressure is relative to atmospheric pressure.

Turbocharger (TC) control valve (%)

Measurement range: 0-100%.
The value indicates the deployment signal from the control module for deploying the turbocharger (TC) control valve, the amount the turbocharger (TC) control valve opens to adjust the turbo pressure.
0% = no control (turbocharger (TC) control valve closed).
100% = full control (the turbocharger (TC) control valve opens completely).

Mass air flow (kg/h)

Measurement range: 0-1020 kg/h.
The value indicates the mass air flow that passes through the mass air flow (MAF) sensor.
The engine control module (ECM) calculates the value based on the signal from the mass air flow (MAF) sensor.
Normal value with the engine at operating temperature and idling, neutral and air conditioning (A/C) switched off: approximately 12-20 kg/h.

Note! Other values apply if the generator (GEN) is under load, if for example, high beam is on, the heated rear windshield is on etc.

Mass air flow, correction value

Measurement range: 0-4.
The value is a stored average of the correction factor of the mass air flow that the engine draws in.
Mass air flow, correction factor= The control module's calculated desired value for the mass air flow divided by (/) the actual measured mass air flow.
Normal range: 1 (±0.2).

Accelerator pedal (AP) position sensor, analog (V)

Measurement range: 0-320 V.
Analog signal from the accelerator pedal (AP) position sensor to the engine control module (ECM). The control module derives the value from the analog output for the accelerator pedal (AP) position sensor.
The value indicates the accelerator pedal (AP) position.
Approximately 0.5 V = the accelerator pedal (AP) completely released.

Approximately 4.0 V = the accelerator pedal (AP) completely depressed.

Throttle angle (%)

Measurement range: 0-100%.
The engine control module (ECM) calculates the value from potentiometer 1 for the throttle position (TP) sensor. The value indicates the throttle opening.
If a fault is detected in the throttle position (TP) sensor, potentiometer 1 by the engine control module (ECM), the value from the throttle position (TP) sensor potentiometer 2 will be used to represent the throttle angle.
0% = throttle shut.
100% = throttle fully open.

Hint: The value must follow the parameter "Throttle angle, desired value" when the accelerator pedal (AP) is affected.

Accelerator pedal (AP) position sensor, pulse width modulation (PWM) (%)

Measurement range: 0-100%.
The PWM signal from the accelerator pedal (AP) position sensor to the engine control module (ECM). The control module derives the value from the digital output for the accelerator pedal (AP) position sensor.
The value indicates the accelerator pedal (AP) position.
Approximately 5% = the accelerator pedal (AP) is completely released.
Approximately 80% = the accelerator pedal (AP) is fully depressed.

Throttle angle, desired value (%)

Measurement range: 0-100%.
The engine control module (ECM) calculates a target value for the throttle opening (throttle angle).
The value indicates what the throttle angle should be.
0% = throttle shut.
100% = throttle fully open.

Throttle position (TP) sensor, potentiometer 1 (V)

Measurement range: 0-80 V.
The engine control module (ECM) derives the value from potentiometer 1 for the throttle position (TP) sensor.
The value must increase with increased throttle angle.
Approximately 0.5 V = throttle closed.
Approximately 4.0 V = wide open throttle (WOT).

Throttle position (TP) sensor, potentiometer 2 (V)

Measurement range: 0-80 V.
The engine control module (ECM) derives the value from potentiometer 2 for the throttle position (TP) sensor.
The value must decrease with an increased throttle angle.
Approximately 4.0 V = throttle closed.
Approximately 0.5 V = wide open throttle (WOT).

Leakage flow over the throttle (kg/h)

Measurement range: 0-655 kg/h.
The value indicates how much air passes through the throttle at closed throttle position (CTP). The engine control module (ECM) calculates the value from the mass air flow (MAF) sensor and the throttle position (TP) sensor signals.

Air conditioning (A/C) pressure (kPa)

Measurement range: -176 to +3277 kPa.
The engine control module (ECM) calculates the value from the signal from the air conditioning (A/C) pressure sensor.
The value indicates the pressure at the high-pressure side of the air conditioning (A/C) system.
The engine control module (ECM) calculates the pressure based on the signal from the air conditioning (A/C) pressure sensor. The pressure is given as a value relative to the atmospheric pressure.

Evaporative emission system (EVAP) valve (%)

Measurement range: 0-100%.
The value indicates the deployment signal from the control module for deploying the evaporative emission system (EVAP) valve (the amount the valve opens to empty the canister).
0% = no control (Evaporative emission system (EVAP) valve closed).
100% = full control (Evaporative emission system (EVAP) valve opens completely).

EVAP, flow (kg/h)

Measurement range: 0-25 kg/h.
The engine control module (ECM) calculates the flow through the evaporative emission system (EVAP) valve. This value increases with increased flow.

Injection period bank x (ms)

Measurement range: 0.0-150 ms.
The signal transmitted by the engine control module (ECM) for injection period.
Normal value when the engine is idling at operating temperature: 1.0-3.0 ms

Short-term fuel trim, bank x

Measurement range: 0-2.
The value displays how much the injection period needs to be corrected (from the preprogrammed injection period in the control module) to reach lambda=1. If the engine runs lean or rich (lambda deviates from 1), the short-term fuel trim injection period is increased or decreased so that lambda=1. The average value of this parameter from different engine speed and load ranges is used for the different fuel trim adaptations (idling, lower partial load and upper partial load) so that the short-term fuel trim is always around 1.
Short-term fuel trim = the actual injection period required to reach lambda=1, divided by (/) the injection period in preprogrammed in the control module to reach lambda=1.
The normal value oscillates around 1, when the lambda adaptations for each engine speed (RPM) / load range are ready.
Value over 1: the control module increases the injection period (to prevent a lean fuel / air mix).
Value under 1: the control module decreases the injection period (to prevent a rich fuel air mix).
The parameter must be checked under stable conditions, such as stable engine speed (RPM) and load.

Hint: When lambda deviates from 1, the short-term fuel trim initially compensates at every engine speed (RPM) / load range (idle speed and load). When erasing the diagnostic trouble codes (DTCs), the adaptation values will be reset. This means the short-term fuel trim will be high or low when driving in the low engine speed/load ranges before the adaptations are ready. For more information about fuel-trim adaptation, see VIDA Design and Function, Fuel trim.

Long-term fuel trim bank x, idle speed (%)

Measurement range: between -72 and +72%.
Additive adaptation of the short-term fuel trim (correcting the injection period), adaptation that occurs at idle speed. The value indicates how much the short-term fuel trim has been corrected at idle speed so that the short-term fuel trim value can again oscillate around 1.
In the event of an air leakage for example, the value will increase at idle speed (= longer injection time). This is to compensate the fuel / air mix for air capacity. Regardless of the load /engine speed, the same injection time is added. This means that the parameter value does not significantly affect the fuel / air mix at higher loads / engine speeds.
Normal value when the engine is idling: 0 ±5%.
Value over 0%: the control module increases the injection period (to prevent a lean fuel / air mix).
Value less than 0%: the control module decreases the injection period (to prevent a rich fuel air mix).

Hint: When diagnostic trouble codes (DTCs) are erased, the adaptation returns to 0%. For more information about fuel-trim adaptation, see VIDA Design and Function, Fuel trim.

Long-term fuel trim bank x, lower part load

Measurement range: 0-2.
Multiplicative adaptation of the short-term fuel trim (correcting the injection period), adaptation that occurs at lower part load (normal road driving). The value stored in the control module indicates how much the short-term fuel trim in the upper part load range has been corrected so that the short-term fuel trim value can again oscillate around 1 at the lower part load. In the event of low fuel pressure for example, the value will increase (= longer injection time). This is to compensate the fuel/air mix for the lack of fuel. Normal value 1±0.1. The lower part load range of the engine must be reached for the value to be updated (normal road driving). Approximately 30 minutes of driving in the lower part load may be required before the adaptation is complete (complete = short-term fuel trim oscillates around 1 at lower part load). Value over 1: the control module increases the injection period (to prevent a lean fuel / air mix). Value under 1: the control module decreases the injection period (to prevent a rich fuel air mix).

Hint: When diagnostic trouble codes (DTCs) are erased, the adaptation returns to 1. For more information about fuel-trim adaptation, see VIDA Design and Function, Fuel trim.

Long-term fuel trim bank x, upper part load

Measurement range: 0-2.
Multiplicative adaptation of the short-term fuel trim (correcting the injection period), adaptation that occurs at lower part load (normal road driving). The value stored in the control module indicates how much the short-term fuel trim in the upper part load range has been corrected so that the short-term fuel trim value can again oscillate around 1 at the lower part load. In the event of low fuel pressure for example, the value will increase (= longer injection time). This is to compensate the fuel/air mix for the lack of fuel. Normal value 1±0.1. The lower part load range of the engine must be reached for the value to be updated (normal road driving). Approximately 30 minutes of driving in the lower part load may be required before the adaptation is complete (complete = short-term fuel trim oscillates around 1 at lower part load). Value over 1: the control module increases the injection period (to prevent a lean fuel / air mix). Value under 1: the control module decreases the injection period (to prevent a rich

fuel air mix).

Hint: When diagnostic trouble codes (DTCs) are erased, the adaptation returns to 1. For more information about fuel-trim adaptation, see VIDA Design and Function, Fuel trim.

lambda
Front heated oxygen sensor (HO2S), bank x ()

Measurement range: 0-16.
Normal value is lambda=1.
If the mixture is rich, lambda is less than 1.
If the mixture is lean, lambda is greater than 1.

Rear heated oxygen sensor (HO2S), bank x (V)

Measurement range: -0.2 to +1.13.
The signal from the rear heated oxygen sensor (HO2S) to the engine control module (ECM).
Normal value when the engine is running at even load is approximately 0.6 V.
The voltage may vary between -0.2 and 0.9 V. The voltage may, during engine braking for example, drop to -0.2 V.

Fuel pressure (Pa)

Measurement range: 50-4680 kPa.
The parameter indicates absolute pressure.
The engine control module (ECM) derives the pressure from the fuel pressure sensor signal. When idling, with the engine at operating temperature and in neutral, the value should be approximately 400 kPa.

Hint: The value must follow "Fuel pressure, desired value".

Fuel pressure, desired value (Pa)

Measurement range: 0-6553.5 kPa.
The parameter indicates absolute pressure.
The engine control module (ECM) calculates the target value for "Fuel pressure". The value indicates what the fuel pressure should be.

°
Fuel temperature (C)

Measurement range: -40 to +215 °C.
The engine control module (ECM) derives the temperature from the fuel temperature sensor signal. The fuel temperature sensor is integrated in the fuel pressure sensor.

Fuel pump (FP), workload (%)

Measurement range: 0-100%.
The value shows the PWM signal between the engine control module (ECM) and the fuel pump (FP) control module. A higher pulse ratio gives a higher fuel pressure. At 400 kPa the pulse ratio must be approximately 35% (±5%). The values are not relevant if the battery voltage is too low.

Oil level (%)

Measurement range 0-100%.
The value indicates the oil level signal pulse ratio from the PWM signal generated by the oil level sensor. The signal passes between the engine control module (ECM) and the oil level sensor. The value must be between 17-83% depending on the oil level.

Brake pedal position (via the brake control module (BCM))

Measurement range 0-100%.
The engine control module (ECM) receives the value from the brake control module (BCM) via the Control area network (CAN). The value indicates the brake pedal position.
When the brake pedal is not affected the value is approximately 0%. The value increases as the brake pedal is pressed.

Speed (km/h)

Measurement range: 0-319 km/h
The vehicle speed is shown from the brake control module (BCM) via the controller area network (CAN).

Engine cooling fan (FC) (%)

Measurement range: 0-100%
Pulse width modulation (PWM) signals transmitted by the engine control module (ECM) to the engine cooling fan (FC) control module to control

the speed of the engine cooling fan (FC).

Reset valve camshaft, intake / exhaust (CA)

Measurement range: 0-100%
The pulse ratio transmitted by the engine control module (ECM) to control the camshaft reset valve.
The value indicates control of the camshaft reset valve to control the camshaft position (angle).
The normal value when the camshaft is deployed and in the fixed position is approximately 50%. The value increases/decreases depending on control of the camshaft.

°

Camshaft shift angle, (intake/ exhaust) ()

Measurement range: between -256 CA and +256 CA.
The engine control module (ECM) calculates the value by comparing the position of the camshaft with the position of the crankshaft. The value indicates the angle of the camshaft. This is the offset of the camshaft 0 position in relation to the crankshaft TDC (0). (The camshaft 0-position = the set alignment of the camshaft position with the crankshaft.)

Desired value for the camshaft shift angle, intake/exhaust

Measurement range: between -256 CA and +256 CA.
The value indicates the target value of the engine control module (ECM) for "Camshaft shift angle " (actual shift angle). The "Desired value for the camshaft shift angle" can be altered by changing the engine speed (RPM)/load.

Camshaft shift angle leeway, intake/exhaust

Measurement range: between -256 CA and +256 CA.
The value indicates the difference between the "Camshaft shift angle" (actual shift angle) and the desired value for the camshaft shift angle (target value for the engine control module (ECM)). Changing the "Camshaft shift angle" is achieved by changing the engine speed (RPM)/load. The normal value varies depending on how far the camshaft is operated and the temperature/grade of the engine oil, although the value must never deviate by more than between ± 10 degrees for longer than approximately 4 seconds.

Camshaft adaptation, intake/exhaust (CA)

Measurement range: between -511 to +511 degrees.
The value indicates the camshaft deviation from the basic setting.
The value is 0 degrees when the camshaft position (angle) corresponds with the crankshaft position (angle). Normal value is 0 degrees ±8 degrees.
The value is updated following adaptation of the camshaft position (angle position). The adaptation is performed when the camshaft control is not active (fully returned camshaft).

Misfire counter

The engine control module (ECM) calculates the overall total for the number of misfires affecting emissions or causing catalytic converter damage for all cylinders during a certain number of crankshaft revolutions.
The normal value is 0 (no misfiring).

Misfire counter, cyl x

The value indicates the number of misfires for each cylinder during the present operating cycle.
The value is affected by misfires which affect emissions and cause catalytic converter damage.
The normal value is 0 (no misfiring).
The value is reset when the ignition is switched off.

Parameter, status

Coolant level sensor

The engine control module (ECM) calculates the status from the engine coolant level switch.
The status indicates the engine coolant level in the expansion tank.

Throttle unit adaptation

If necessary the engine control module (ECM) runs an adaptation of the throttle unit by guiding the throttle to the limit positions (open/closed) so that it " learns" the parameters of that actual throttle unit.
The status indicates if the adaptation has been run or not.
OK = Adaptation of the throttle unit has run.
NOT OK = Adaptation of the throttle unit has not run.

Note! The basic conditions must be met before an adaptation of the throttle unit can be carried out.

Automatic transmission

Only vehicles that have an automatic transmission.
The engine control module (ECM) calculates the status of the signal from the transmission control module (TCM) via CAN.
ON = the gear selector is in position "D" or another gear is selected.
OFF = the gear selector is in position "P" or "N"

Cruise control resume

The cruise control must be on when reading this parameter.
OFF= resume button unaffected.
ON = resume button activated.

Cruise control set+

The cruise control must be on when reading this parameter.
OFF= SET+ unaffected.
ON = SET+ affected.

Cruise control set-

The cruise control must be on when reading this parameter.
OFF= SET- unaffected.
ON = SET- affected.

Stop lamp switch

The engine control module (ECM) calculates the value from the stop lamp switch.
ON = stop lamp switch on.
OFF = stop lamp switch unaffected.

Air conditioning (A/C) compressor, active

The signal transmitted by the engine control module (ECM) for activating the air conditioning (A/C) compressor relay.
OFF = The engine control module (ECM) does not activate the air conditioning (A/C) compressor relay.
ON = The engine control module (ECM) activates the air conditioning (A/C) compressor relay.

Oil pressure sensor

The engine control module (ECM) calculates the value from the oil pressure switch signal.
ON = the oil pressure switch circuit is closed, signal to the driver information module (DIM) via CAN for lit oil pressure warning lamp.
OFF = the oil pressure switch circuit is open, signal to the driver information module (DIM) via CAN for oil pressure warning lamp not lit.

Long-term fuel trim, bank x

C/L= Closed Loop, fuel trim is active
O/L = Open Loop, fuel trim is not active

Fuel pump (FP) relay

OFF = The engine control module (ECM) does not request fuel pump (FP) relay activation.
ON = The engine control module (ECM) requests fuel pump (FP) relay activation via CAN to the central electronic module (CEM).

Boost pressure (actual value)

Measurement range: 0-2000 hPa, absolute pressure (boost pressure- absolute zero pressure(0 hPa)).
The Engine control module (ECM) receives information about the current boost pressure via the boost pressure sensor.
The actual value must correspond to the desired value ± 50hPa.

Boost pressure (desired value)

Measurement range: 0-2000 hPa, absolute pressure (boost pressure- absolute zero pressure(0 hPa)).
The engine control module (ECM) receives information about the current throttle angle via the throttle position sensor, speed (rpm), engine load, knocks etc. These parameters are used to calculate the boost pressure that is permitted in various operating conditions.

Description of Parameters, DENSO

Description of parameters, Denso

Hint: Not all the parameters described need to be implemented in the control module. This varies between different systems and markets.

Parameters, value

Speed (km/h)

Measurement range 0 -255 km/h
The value displays the vehicle speed.

Hint: Miles per hour in certain markets.

Engine speed (rpm)

Measurement range 0-10400 rpm.
The control module derives the engine speed (RPM) from the engine speed (RPM) sensor signal.
The idle speed varies depending on the engine coolant temperature (ECT) (850 ± 50 rpm).

Battery voltage (V)

Measurement range 0-20 V.
The normal value is 13-14.5 V when the generator (GEN) is charging.
The value indicates the voltage at the engine control module (ECM).

°
Engine coolant temperature (ECT) (C)

Measurement range -40 - +120 °C.
The control module derives the temperature from the engine coolant temperature (ECT) sensor signal.

Engine coolant temperature sensor (V)

Measurement range 0-5 V.
Operating range 0.28 - 4.83 V. The voltage drops as the temperature rises.

Atmospheric pressure (Pa)

Measurement range 0-2267 hPa.
The value indicates atmospheric pressure at the engine control module (ECM).
Normal value at sea level is 1,013 hPa.

°
Outside temperature (C)

Measurement range -40 - +120 °C.
The engine control module (ECM) derives the temperature from the outside temperature sensor signal.

Outside temperature sensor, signal (V)

Measurement range 0-5 V.
Operating range 0.09 -4.62 V. The voltage drops as the temperature rises.

Accelerator pedal (AP), analog (%)

Measurement range 0 -100 %.
Analog signal from the accelerator pedal (AP) position sensor to the engine control module (ECM).
The value indicates the accelerator pedal (AP) position.
Approximately 8 %= the accelerator pedal (AP) completely released.
Approximately 88 %= the accelerator pedal (AP) completely depressed.
The analog signal is usually used by the engine control module (ECM).

Hint: The value must follow the parameter "Accelerator pedal (AP), PWM".

Accelerator pedal (AP), PWM (%)

Measurement range 0 -100 %.
PWM signal from the accelerator pedal (AP) position sensor to the engine control module (ECM).
The value indicates the accelerator pedal (AP) position.
Approximately 8 %= the accelerator pedal (AP) completely released.
Approximately 88 %= the accelerator pedal (AP) completely depressed.

The PWM signal is used if there is a fault with the analog signal.

Hint: The value must follow the parameter "Accelerator pedal (AP), analog".

Accelerator pedal (AP) input signal, analog (V)

Measurement range 0-5 V.
The value is close to 0.4 V when the accelerator pedal (AP) is unaffected.
The voltage falls as the pedal is pressed.

Brake pedal position (%)

Measurement range 0 -100 %.
The value indicates the brake pedal position.
The normal value when the brake pedal is unaffected is approximately 0 %. The value increases as the pedal is depressed.

Hint: The brake pedal position sensor signal is transmitted to the engine control module (ECM) from the brake control module (BCM) via CAN.

Clutch pedal position (%)

Measurement range 0 -100 %.
The engine control module (ECM) calculates the value from the clutch pedal sensor signal.
The value indicates the clutch pedal position.
The value increases as the pedal is depressed.

Clutch pedal position sensor (V)

Measurement range 0-5 V.
Operating range approximately 3 - 4.5 V. The voltage drops as the pedal is pressed.

Throttle angle, desired value (%)

Measurement range 0 -100 %.
The value indicates the deployment signal from the engine control module (ECM) to the throttle unit.
0 % = throttle shut.
100 % = throttle fully open. This corresponds to an opening angle of approximately 84 degrees.

Throttle angle, actual value (%)

Measurement range 0 -100 %.
The control module derives the value from the throttle position (TP) sensor, potentiometer 1. The value indicates the throttle opening.
If a fault is detected in the throttle position (TP) sensor, potentiometer 1, by the engine control module (ECM), the value from the throttle position (TP) sensor, potentiometer 2, will be used to represent the throttle angle. This presumes that the function of throttle position (TP) sensor, potentiometer 2 is OK.
0 % = throttle shut.
100 % = throttle fully open. This corresponds to an opening angle of approximately 84 degrees.
Must follow the parameter "Throttle angle, desired value".

Throttle position, circuit 1 (%)

Measurement range -3 - +130 %.
Normal value 0 - 100 %.
There is an electrical fault if the displayed value is outside the measurement range.
The value must increase with increased throttle angle.
Approximately 0 % = throttle closed.
Approximately 100 % = wide open throttle (WOT). This corresponds to an opening angle of approximately 84 degrees.

Throttle position, circuit 2 (%)

Measurement range -4 - +140 %.
Normal value 0 - 100 %.
There is an electrical fault if the displayed value is outside the measurement range.
The value must increase with increased throttle angle.
Approximately 0 % = throttle closed.
Approximately 100 % = wide open throttle (WOT). This corresponds to an opening angle of approximately 84 degrees.

Air conditioning (A/C) linear pressure sensor (V)

Measurement range 0-5 V.
The value indicates the air conditioning (A/C) pressure sensor signal. The sensor must detect any change in pressure in the high pressure section of

the air conditioning (A/C) system.

Air conditioning (A/C) pressure (Pa)

Measurement range 0- +3100 kPa.
The engine control module (ECM) calculates the value from the signal from the air conditioning (A/C) pressure sensor.
The value indicates the pressure at the high-pressure side of the air conditioning (A/C) system.
The engine control module (ECM) calculates the pressure based on the signal from the air conditioning (A/C) pressure sensor. The pressure is given as a value relative to the atmospheric pressure.

°

Fuel temperature, raw (C)

Certain markets only.
Measurement range -40 - +120 °C.

Fuel pressure (Pa)

Certain markets only.
Measurement range 0-1067 kPa.
Normal value 380 ± 5 kPa when idling. The pressure drops when the ignition is switched off.

Fuel pump (FP), workload (%)

Certain markets only.
Measurement range 0 -100 %.
Operating range 10 - 85 %. >75 % is considered high load.
The value indicates the signal transmitted from the engine control module (ECM) to the fuel pump (FP) control module.

Leak diagnostic unit, pump (A)

Certain markets only.
Measurement range 0-65.5 mA.
The control module calculates the value from the pump in the leak diagnostic unit.
The value varies depending on the pressure in the fuel tank system. Higher pressure results in increased power consumption.
Normal value when the leak diagnostic is not running is 65 mA. A fictional value and not the actual power consumption.

Purge valve, flow (liters per minute)

Measurement range 0-100 liters per minute.
The value indicates the estimated flow of the system through the purge valve. Used as an input parameter during compensation for other parts of the system.
Normal value at idle is 0 liters per minute when there is no purging and 5 - 40 liters per minute during purging.

EVAP valve, operating time on (s)

Measurement range 0 - 100 000Âµs.
The value indicates the time that the PWM signal to the EVAP signal is high, i.e. the time that the valve is open and purging. 1 000 Âµs corresponds to 1 % opening.
The normal value at idle is 0 Âµs when there is no purging and 0 - 35 000 Âµs during purging.

Intake pressure sensor, signal (V)

Measurement range 0-5 V.
The normal value (atmospheric pressure at sea level) is approximately 3.6 V with the ignition on (open throttle) and approximately 1.9 V at idle.
The voltage increases with pressure in the intake manifold.

Pressure, intake manifold (Pa)

Measurement range -400 - +2267 hPa.
The pressure is given as a value relative to the atmospheric pressure.

°

Intake air temperature (IAT) (C)

Measurement range -40 - +120 °C.
The engine control module (ECM) calculates the temperature from the temperature sensor for intake air (integrated in the mass air flow (MAF) sensor).

Intake air temperature (IAT) sensor (V)

Measurement range 0-5 V.
Operating range 0.21 -4.87 V. The voltage drops as the temperature rises.
The engine control module (ECM) retrieves the value from the temperature sensor for intake air (integrated in the mass air flow (MAF) sensor).

Mass air flow (Ga, g/s)

Measurement range 0-200 g/s.
The value indicates the mass air flow that passes through the mass air flow (MAF) sensor.
The engine control module (ECM) calculates the value based on the signal from the mass air flow (MAF) sensor.
Normal value with the engine at operating temperature and idling and under no load, neutral and air conditioning (A/C) switched off: approximately 4 g/s.

Note! Other values apply if the generator (GEN) is under load, if for example, high beam is on, the heated rear windshield is on etc.

Air mass (V)

Measurement range 0-5 V.
Operating range approximately 0.5 - 4.5 V. The voltage increases with load.

Camshaft reset valve, desired value intake (CA)

Measurement range 0 - 160 CA.
The value indicates the expected control of the shift angle for the intake camshaft.
CA = Crank Angle.

Camshaft reset valve, actual value intake (CA)

Measurement range 0 - 160 CA.
The value indicates the controlled shift angle for the intake camshaft.
Must follow the parameter "Camshaft reset valve, desired value intake".
CA = Crank Angle.

Camshaft reset valve, desired value exhaust (CA)

Measurement range 0 - 160 CA.
The value indicates the expected control of the shift angle for the exhaust camshaft.
CA = Crank Angle.
The parameter value is not relevant for engines without exhaust camshaft control.

Camshaft reset valve, actual value exhaust (CA)

Measurement range 0 - 160 CA.
The value indicates the controlled shift angle for the exhaust camshaft.
Must follow the parameter "Camshaft reset valve, desired value exhaust".
CA = Crank Angle.
The parameter value is not relevant for engines without exhaust camshaft control.

Misfire counter 1-5

Counts the number of misfires in each cylinder.
Normal value is 0.

Knock sensor (CA)

Knock retardation requested due to knock in the cylinders.
Measurement range 0 -72 CA.
Normal value 0 CA.
This value indicates the mean value of the timing retardation for all cylinders.
CA = Crank Angle.

°
Ignition advance ()

Measurement range -20 - +62 °btdc.
Normal value at idle, engine at operating temperature, A/C off, is approximately +12 ° btdc.

Injection period (s)

Measurement range 0 - 262140 Âµs.

the signal transmitted by the engine control module (ECM) for injection period.
Normal value when the engine is idling at operating temperature: 2000 - 4000 Âµs.

Front heated oxygen sensor (HO2S), power consumption heater pad (A)

Probe heating in the front heated oxygen sensor (HO2S).
Measurement range -63 - +3163 mA.
Actual electrical consumption required to maintain the correct probe temperature.

Front heated oxygen sensor (HO2S)

Measurement range 0 -2.
Normal value is lambda=1.
At rich mixture is lambda < 1.
At lean mixture is lambda>1.

Signal, rear heated oxygen sensor (V)

Measurement range 0-5 V.
The signal from the rear heated oxygen sensor (HO2S) to the engine control module (ECM).
Normal value when the engine is running at even load is approximately 0.6 V.

Long term fuel trim

The parameter displays the adaptation factor of the lambda probe.
Measurement range 0-2 lambda-adap.
Compensates the injection period at the relevant load so that the lambda value can be correctly reached.
Normal value 1.
There are six adaptation windows. Which window is active depends on the load.
Works together with "Lambda compensation".
When there is adjustment, this is visible in "Adaptation area 1-6".

Lambda compensation

The parameter displays the compensation factor of the lambda probe.
Measurement range 0 -2.
lambda value compensation increases or reduces the injection period depending on the deviation.
Normal value 1.
Works together with "Long term fuel trim".

Actual adaptation range

This parameter displays which of the six adaptation ranges the engine is in.

B5244S/S2/S6, Model year2003-

Area	Load	Driving conditions
1	0.2 g/rev	Downhill deceleration without fuel shut-off.
2	0.3 g/rev	Idle to 40 km/h.
3	0.5 g/rev	Steady at approximately 70-90 km/h on a flat road.
4	1.1 g/rev	Higher speeds, acceleration.
5	1.5 g/rev	Full load.
6	2.0 g/rev	Will not be adapted.

Note! Note that the air conditioning (A/C) compressor increases the load by approximately 0.05 g per rpm. The use of the A/C compressor often results in a change of adaptation area.

Hint: The adaptations are weighted between the values of each adaptation point in an adaptation area.

Adaptation area 1-6

This parameter displays the actual adaptation value for each adaptation area.
Measurement range 0 -2.
Normal operating range 0.8-1.2.

Parameter, status

Air conditioning (A/C) compressor, active

The deployment signal from the engine control module (ECM) to the air conditioning (A/C) compressor relay.
OFF = The engine control module (ECM) does not activate the air conditioning (A/C) compressor relay.
ON = The engine control module (ECM) activates the air conditioning (A/C) compressor relay.

Engine cooling fan (FC)

ON = The engine control module (ECM) activates the engine cooling fan (FC).
OFF = The engine control module (ECM) does not activate the engine cooling fan (FC).

Stop lamp switch

The engine control module (ECM) calculates the value from the stop lamp switch signal.
ON = stop lamp switch on.
OFF = stop lamp switch unaffected.

Fuel pump (FP) relay

OFF = The engine control module (ECM) does not activate the fuel pump (FP) relay.
ON = The engine control module (ECM) activates the fuel pump (FP) relay via the central electronic module (CEM), 12 V.

EVAP canister shut-off valve

Certain markets only.
Displays whether the EVAP canister shut-off valve is open or closed.
The valve is normally open but closes when the leak diagnostic is run.

Camshaft position (CMP) sensor, intake

Displays the pulses from the camshaft position (CMP) sensor (intake).
Switches between high and low as the camshaft rotates.

Adaptation status

Activated = The adaptation has been activated.
Not activated = Adaptation is inactive.
When all conditions are met for fuel system adaptation, the adaptation is considered to be active.

Ignition key in position II

OFF = ignition off.
ON = ignition on.

Ignition key in position III

OFF = starting mode off.
ON= start mode on.

Cruise control ON/OFF button

OFF = ON/OFF button unaffected.
ON = ON/OFF button affected.

Cruise control resume button

The cruise control must be on when reading this parameter.
OFF = resume button unaffected.
ON = resume button activated.

Cruise control SET- button

The cruise control must be on when reading this parameter.
OFF= SET- button unaffected.
ON = SET- button affected.

Cruise control SET+ button

The cruise control must be on when reading this parameter.
OFF= SET+ button unaffected.
ON = SET+ button affected.

Description of Status Identifier

Description of status identifier

Status identifier
There are different status identifiers that can be read out for each diagnostic trouble code (DTC). The control module tests each connection more or less continuously. By reading out the diagnostic trouble code (DTC) and the associated status identifier (which detects the malfunction and stores the DTC), information about the test is obtained. Not all status identifiers need to be implemented in one control module, this varies from system to system. All status identifiers are reset and start counting again each time the control module is powered up and when erasing diagnostic trouble codes (DTCs). The possible status identifiers are described below.

Status identifier	Explanation
SI#01	The malfunction is validated now. Shows if the control module detects the malfunction right now. It is only when the test is in progress that the control module can detect malfunction and generate diagnostic trouble code.
SI#02	The malfunction is validated in the current operating cycle. Shows if the control module has detected the malfunction any time during this operating cycle.
SI#03	Intermittent not yet confirmed diagnostic trouble code.
SI#04	Confirmed diagnostic trouble code.
SI#05	Test status in current and/or earlier operating cycle. Shows if control module has performed test for this diagnostic trouble code in current and/or earlier operating cycle.
SI#06	The malfunction is validated in an earlier operating cycle. Shows if the control module has detected the malfunction any time during an earlier operating cycle.
SI#07	Test status in current operating cycle. Shows if control module has performed test for this diagnostic trouble code in current operating cycle.
SI#08	Request activate warning light/text message. Information about the diagnostic trouble code activates a warning light or text message.

Description of Parameters, Quick Test of the Fuel Tank System

Description Of Parameters, Quick Test Of The Fuel Tank System

Leak diagnostic unit pump
Graphic display in the fuel tank system quick test.

Measurement range **0-400 mA**.

The engine control module (ECM) calculates the value from the pump in the leak diagnostic unit.

The value varies depending on the pressure in the fuel tank system. Higher pressure results in increased power consumption.

Battery voltage
Measurement range **0-17.95 V**.

The value indicates the voltage from the system relay to the engine control module (ECM).

The voltage must not be below **11 V** when the quick test of the fuel tank system is run.

Fuel tank system quick test
In order for the quick test to start, the status of this parameter must be "Not completed".

- Completed = The engine control module (ECM) has completed the quick test / diagnostic of the fuel tank system during the present operating cycle
- Not completed = The engine control module (ECM) has not completed the quick test / diagnostic of the fuel tank system during the present operating cycle.

Test phase
In order for the quick test to start, the status of this parameter must be "Not running".

The parameter indicates the phase of the test.

- Reference= Reference phase for leaks and function test of the leak diagnostic unit is running
- Fuel tank system = Diagnostics for major leak and minor leak running
- Not running = No quick test or diagnostic is running.

For more information about these parameters:
Test phases, quick test fuel tank system

ECM-439C
The parameter indicates the result of the diagnostic for leakage in the fuel tank system.

This diagnostic is run during the "Fuel tank system" test phase
- No fault found= No leak corresponding to the definition of major leak detected by the engine control module (ECM)
- Fault found= Leakage >**1.0 mm** detected by the engine control module (ECM). Diagnostic Trouble Code (DTC) ECM-439C will be stored in the engine control module (ECM).

ECM-434C
The parameter indicates the result of the diagnostic for leakage in the fuel tank system.

This diagnostic is run during the "Fuel tank system" test phase.
- No fault found= No leak corresponding to the definition of minor leak detected by the engine control module (ECM)
- Fault found= **1.0 mm**>leakage ¡>=0.5 is detected by the engine control module (ECM).

Diagnostic Trouble Code (DTC) ECM-434C will be stored in the engine control module (ECM).

ECM-4360
The parameter displays the result of the diagnostic for the function in the leak diagnostic unit corresponding to the diagnostic trouble code (DTC) ECM-4360.

The diagnostic is run during "Reference" test phase.
- No fault found = No fault is detected by the engine control module (ECM)
- Fault found= Fault in the leak diagnostic unit detected by the engine control module (ECM).

Diagnostic Trouble Code (DTC) ECM-4360 will be stored in the engine control module (ECM).

ECM-436B
The parameter displays the result of the diagnostic for the function in the leak diagnostic unit corresponding to the diagnostic trouble code (DTC) ECM-436B.

The diagnostic is run during "Reference" test phase.
- No fault found = No fault is detected by the engine control module (ECM)
- Fault found= Fault in the leak diagnostic unit detected by the engine control module (ECM).

Diagnostic Trouble Code (DTC) ECM-436B will be stored in the engine control module (ECM).

ECM-436C
The parameter displays the result of the diagnostic for the function in the leak diagnostic unit corresponding to the diagnostic trouble code (DTC) ECM-436C.

The diagnostic is run during "Reference" test phase.
- No fault found = No fault is detected by the engine control module (ECM)
- Fault found= Fault in the leak diagnostic unit detected by the engine control module (ECM).

Diagnostic Trouble Code (DTC) ECM-436C will be stored in the engine control module (ECM).

ECM-436D
The parameter displays the result of the diagnostic for the function in the leak diagnostic unit corresponding to the diagnostic trouble code (DTC) ECM-436D.

The diagnostic is run during "Reference" test phase.
- No fault found = No fault is detected by the engine control module (ECM)
- Fault found= Fault in the leak diagnostic unit detected by the engine control module (ECM).

Diagnostic Trouble Code (DTC) ECM-436D will be stored in the engine control module (ECM).

Test Phases

Test phases

- **REFERENCE PHASE 1** Reference phase for leaks of 0.5 mm and function test of the leak diagnostic unit is running. If any faults are detected during this phase the major leak test starts. If any faults are detected during the phase the test and the test result for the leak diagnostic unit will be " FAULT FOUND" with the fault type

- **MAJOR LEAK** Leak diagnosis for major leaks is in progress. If leakage is detected during this phase the minor leak test starts. If leakage is detected during this phase (the power consumption of the pump is equal to or lower than a desired value) the test stops and the test result for the fuel tank system will be " FAULT FOUND, MAJOR LEAK".

- **MINOR LEAK** Leak diagnosis for minor leaks is in progress. If no leakage is detected during this phase the test stops and the test result for the fuel tank system will be "NO FAULT FOUND". If leakage is detected during this phase (the power consumption of the pump is equal to or lower than the power consumption during the reference phase), the control module will run reference phase 2

- **REFERENCE PHASE 2** The control module runs a second reference phase (the function of the leak diagnostic unit is checked) if leakage is detected during the leakage diagnostic phase (minor leak). When this phase is completed and if no fault is detected by the leak diagnostic unit, the test result for the fuel tank system will be "FAULT FOUND, MINOR LEAK".

- **NOT RUNNING** The leak diagnostic is not running, the quick test of the fuel tank system has not started or has finished.

System Overview

System Overview

The following modules communicate with the Engine Control Module (ECM) via the network:
- Electronic Throttle System (ETS) including Electronic Throttle Module (ETM) and Accelerator Pedal Module (APM),
- Continuously Variable Valve Timing (CVVT)
- Transmission Control Module (TCM)
- Anti-lock Braking System (ABS)
- Central Electronic Module (CEM)
- Data Link Connector (DLC) for connection to VADIS/ VIDA (Volvo Aftersales Diagnostic and Information System / Vehicle Information and Diagnostics for Aftersales)
- Driver Information Module (DIM), combined instrument panel
- Climate Control Module (CCM)
- Steering Wheel Module (SWM)

Central Electronic Module (CEM) is the central computer in the network, which handles the exchange between the network's high speed and low speed sections. The high-speed section covers the following modules: Engine Control Module (ECM), Electronic Throttle Module (ETM), Transmission Control Module (TCM), Anti-lock Braking System (ABS) and the Central Electronic Module (CEM).

ME 7.01 contain a large number of sensors that send information by analog signals directly to the ECM.

Diagnose Functions - Overview

DIAGNOSE FUNCTIONS - OVERVIEW

General

The Engine Control Module (ECM) in itself diagnoses internal signals and functions, together with signals and functions from connected components.

Conditions for diagnosis

To start a diagnosis of a component or function, specific conditions must be fulfilled. The conditions for a diagnosis are different depending on which component or function being diagnosed. To be able to complete the diagnosis its driving cycle has to be performed. A driving cycle varies depending on which component or function being diagnosed.

Certain diagnoses only demand ignition on and ignition off in order to have a driving cycle performed. Other diagnoses demands several different conditions to be fulfilled, for example concerning:
- Vehicle speed
- Engine temperature
- Time passed after start
- Different load ratio and ratio of revolutions during the same driving
- A certain event (for instance the EVAP-valve is regulating).

When Engine Control Module (ECM) has performed all implemented diagnoses it is called the ECM has run a "trip". To run a "trip" it demanded long time driving during different working conditions. Also, it can be demanded the engine be off during a specific time and then be driven again.

Emission related diagnosis functions

The Engine Control Module (ECM) controls that the emission related systems are worked properly. These systems are controlled by performing a diagnose function. In the diagnose function the included components and the very system function are controlled.

Fault code memory

When the Engine Control Module (ECM) detects a fault the fault code with qualifier and status is stored in the fault code memory of the ECM. At certain fault codes the failed signal is replaced with a substitute value so the system is able to continue working.

If a fault is healed the fault code will be still in the fault code memory a time period, but the status on the fault code will change.

Lighting of Check engine lamp

At emission related fault codes when the fault code is set, even a counter is stored which counts down to determine when check engine lamp shall be lighted. The conditions of check engine lamp lighting vary depending on which fault cod is set.

Component	Signal type/explanation
Ignition switch + 50 supply	Provides early information to the Engine Control Module (ECM) to prepare for start.
Brake light switch	Informs ECM that the car is braking. The signal is a safety feature in addition to the brake pedal sensor. The ECM carries out a range test between the signals from both sources.
Electronic Climate Control (ECC) Manual Climate Control (MCC)	Provides information if the A/C is switched on or not. The ECM controls connection/ disconnection of the compressor dependent on load, engine speed (RPM), engine coolant temperature etc.
Oil pressure switch	Provides information about engine oil pressure. The information is sent to Driver Information Module (DIM) which via the display informs the driver to stop the engine and/or check the oil level.
A/C pressure sensor (linear)	Provides information using a linear signal about any pressure changes on the high-pressure side. Depending on the pressure the ECM can activate the engine Cooling Fan (FC) at high/low speed and shut off the A/C compressor.
Front Oxygen Sensor (HO2S) Bank 1, (linear signal)	Provides information about the oxygen level in the exhaust gases downstream of combustion and upstream of the catalytic converter.
Rear Oxygen Sensor (HO2S) Bank 1	Provides information about the oxygen level downstream of the catalytic converter (TWC).
Front Oxygen Sensor (HO2S) Bank 2, (linear signal)	Provides information about the oxygen level in the exhaust gases upstream of the catalytic converter (TWC). (Only 6 cylinder engines)
Rear Oxygen Sensor (HO2S) Bank 2	Provides information about the oxygen level downstream of the catalytic converter (TWC). (Only 6 cylinders engine)
Engine coolant temperature sensor	Provides information about engine coolant temperature (ECT).
Mass Air Flow (MAF) sensor (heated film principle)	Provides information about the intake air mass. The Mass Air Flow (MAF) sensor for turbo charged engines has no resistor for the intake air temperature, but is complemented instead by a separate sensor downstream of the Charge Air Cooler (CAC).
Camshaft Position (CMP) sensor	Provides information about cylinder intake and compression phase.
Knock Sensor (KS) 1 Knock Sensor (KS) 2	Provides information if the engine knocks.
Engine speed (RPM)/position sensor	Informs about the crankshaft position and engine speed (RPM). Has flywheel adaptation for mechanical faults/damage.
Accelerator Pedal (AP) position sensor	Provides information about accelerator pedal position. The signal is sent via two separate cables at the same time, one analog signal and one digital signal.
Engine coolant level switch	Provides information about engine coolant level. The information is sent to Driver Information Module (DIM) which informs the driver via the display to stop the engine and/or check the engine coolant level.
Intake Air Temperature Sensor	Informs about the intake air actual temperature after Charge Air Cooler (CAC). Used for Boost Pressure Control (BPC). The sensor is used together with intake air pressure sensor. Turbos only.
Intake air pressure sensor	Provides information about the intake air actual pressure after Charge Air Cooler (CAC). The most important sensor for Boost Pressure Control (BPC). The sensor is used together with intake air pressure sensor. Turbochargers only.
Diagnosis Module Tank Leakage (DMTL) module	Provides information about changes of the currents in the fuel tank system. Used for leak diagnostic.
Ambient air temperature sensor (located in left door mirror)	Provides information about ambient air temperature. Affects control of the engine Cooling Fan (FC).
Clutch pedal position sensor	Provides information that the clutch pedal is depressed.
CAN communication	Exchange of information between the ECM and the following: BCM, TCM, CCM, CDM and DLC.

Input Signals

Component	Signal type/explanation
Air Conditioning (A/C) relay	Connecting and disconnecting A/C compressor.
Fuel Pump relay	Signal for Fuel Pump (FP) on/off switch. In a collision where the SRS is deployed it also sends a signal via the Central Electronic Module (CEM) to the Engine Control Module (ECM) to turn off supply to the Fuel Pump (FP).
System relay	Controlled by the ECM and provides sensors and functions with voltage supply.
Transmission Control Module (TCM)	Engine load, throttle opening, torque limiting, MIL request, constant idle speed compensation.
Electronic Climate Control (ECC) Manual Climate Control (MCC)	Signals engine coolant temperature to climate control system which can then determine how the blower fan should be controlled after cold start.
Electronic Throttle Actuator	Controls the air flow to the engine.
Electronic Fan Control Module	Electronic fan speed.
Central Electronic Module (CEM)	Controls communication between other modules.
Front Oxygen Sensor (HO2S) Bank 1, signal	Power supply for heating PTC element.
Rear Oxygen Sensor (HO2S) Bank 1, signal	Power supply for heating PTC element.
Front Oxygen Sensor (HO2S) Bank 2, signal	Power supply for heating PTC element. (Only 6 cylinder engines)
Rear Oxygen Sensor (HO2S) Bank 2, signal	Power supply for heating PTC element. (Only 6 cylinder engines)
Fuel Injectors	Controlled individually (sequentially).
Diagnosis Module Tank Leakage (DMTL) module	Provides information about changes of the currents in the fuel tank system. Used for leak diagnostic.
Canister Purge (CP) valve	Continuously controlled, it controls the flow from EVAP canister to engine intake side.
Continuously Variable Valve Timing control valve	Continuously controlled, it regulates camshaft setting. On turbocharged engines it regulates the exhaust camshaft and on normally aspirated it regulates the intake camshaft.
Turbocharger (TC) control valve	Controls turbocharger (TC) boost pressure, see turbocharger (TC) control system description section S0805.
Ignition coil/Ignition Discharge Module (IDM) for cylinders 1 – 5 (1 – 6 for 6 cylinder engines)	Separate ignition coil with integrated Ignition Discharge Modules (IDM) for each cylinder. Gives shorter charging interval and more power.
Malfunction Indicator Lamp (MIL) USA/CDN = Check Engine Other = Engine symbol	The lamp lights up for faults affecting the emissions. The lamp flashes for misfires, which cause risk of damage to the catalytic converter. Can also light up when requested by the Transmission Control Module (TCM).

Output Signals

Via CAN-Communication

Via CAN-Communication

Brake Control Module (BCM):
Provides information so that the ECM can determine whether any misfiring is due to road condition or to a fault in the engine management system. Also provides a vehicle speed signal.

Climate Control Module (CCM):
Informs the ECM about A/C selection and requests A/C activation.

Central Electronic Module (CEM):
Is the "main computer" in the network and coordinates required information between other modules. It also controls diagnostic function by connecting the Data Link Connector (DLC) to the network for programming and reading off diagnostic trouble codes (DTCs) and parameters. The CEM also includes the Immobilizer.

Steering Wheel Module (SWM):
Provides information to the ECM that the cruise control is selected and that the driver requests changing the cruise control speed.

Transmission Control Module (TCM):
The Transmission Control Module (TCM) is only implemented in automatic transmission cars. The following signals are being sent on the network from the ECM and picked up by the TCM:

- Engine load
- Throttle opening
- Response to torque limiting
- Accelerator pedal position
- Cruise control status

The following signals are sent out on the network from the TCM and taken up by the ECM:

- Request for torque limiting step I and II
- Request to light Malfunction Indicator Lamp (MIL)
- Signal for constant idle speed compensation (P/N position)
- Engaged gear

Data Link Connector (DLC) (OBD II):
The serial communication via the Data Link Connector (DLC) is used when reading off the Volvo on-board diagnostic (OBD) system.

Serial communication:
The ECM communicates serially with the Data Link Connector (DLC).

Misfire Diagnostic

Misfire Diagnostic

With the crankshaft sensor the segment time deviation between two following ignitions is measured. The crankshaft is divided into 5 or 6 segments depending on engine cylinder type. Each segment corresponds to a specific ignition/cylinder. To avoid incorrect segment time deviations, due to manufacturing tolerances, a crankshaft adaptation must be accomplished. The crankshaft adaptation is performed during fuel-on and fuel-off..

Misfire detection is shut-off for loads below the Zero Load-line at engine speeds up to **3000 rpm**, and also shut-off for loads under the 4"Hg-line from **3000 rpm** up to redline. It is also shut-off during rough road operation, which is determined by signal from the ABS control unit.

Misfire detection is enabled when the engine speed has reached **150 rpm** below warm idle speed plus two crankshaft revolutions or after nine ignitions, depending on which occurs first.For detection of emission related misfires, the number of misfires which have occurred within the first interval of 1000 engine revolutions or the 4th exceedance (for the rest of DCY) over the emission threshold value after the first 1000 engine revolutions are relevant. If the number is so high that the exhaust emission standard is exceeded by a factor of 1.5, then the emission related misfire rate has been reached and exceeded a fault code will be stored. If misfires occur and the threshold is exceeded in the following DCY, MIL illuminates.

For detection of catalyst damaging misfires, the numbers of misfires that have occurred during an interval of 200 engine revolutions are relevant. If the number of misfires are so high that the catalyst is endangered (by various number of misfires depending on actual engine operating range), then the cat. Damaging mis-fire rate has been reached and exceeded. The the fuel will be cut off to the misfiring cylinder and a fault code will be stored. MIL will blink with one Hertz as long as the engine has catalyst-damaging misfires. The fuel is cut off until engine is restarted.

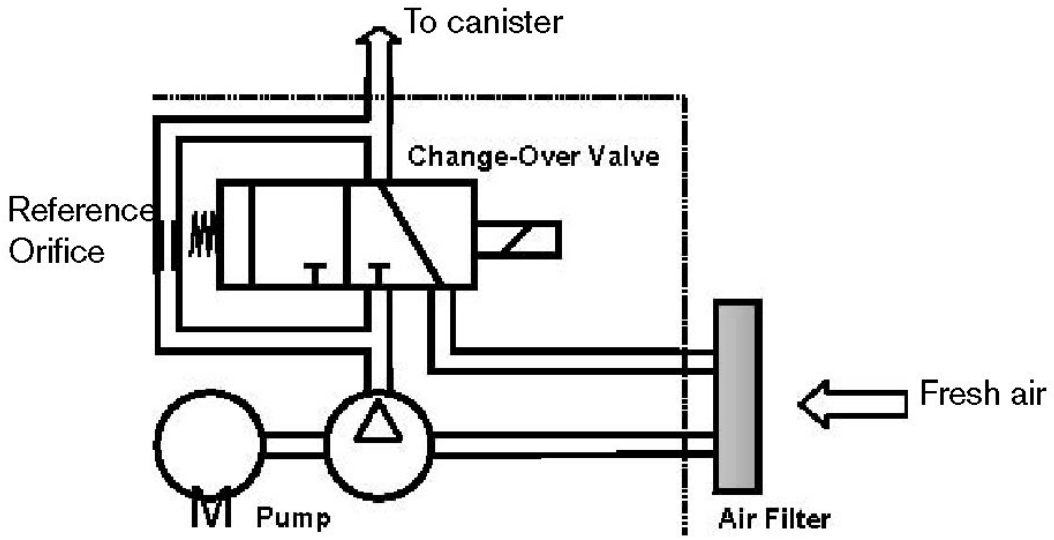
Leakage Diagnostic

Leakage Diagnostic

Vapor that evaporates from the fuel in the fuel tank is routed to and stored in the EVAP canister from where it is introduced into the combustion process via the Canister Purge (CP) valve.

A leak diagnostic has been introduced in certain markets to ensure that there are no leaks in the fuel tank system. The diagnostic is designed to detect leakage corresponding to a **0.20 inch** or larger hole. The fuel tank system consists of fuel tank, fuel filler pipe, EVAP canister, CP valve and all pipes between these components. To be able to diagnose the fuel tank system, it is also equipped with a diagnostic module (DMTL = Diagnostic Module Tank Leakage) including the electrical driven air pump.



Leakage diagnostic (LD) is performed in after run mode, when key off.

The diagnostic is divided into different phases as follow:
- Reference leak measurement, performed every LD
- Rough leak test, performed every DCY
- Small leak test performed every second DCY when enabling conditions are met.

The diagnostic is performed by measuring the motor current and then compares it to a specified reference current. If a fault is detected in any of the phases the diagnostic is interrupted and the diagnostic trouble code (DTC) for the component identified is stored. Diagnosis is carried out in the following stages:
- While fuel level sensors are working correctly and the fuel level is higher than 85% all leakage tests and healing attempts are aborted.
- While the fuel level sensors are not working correctly, the test is aborted if the initial rate of change is higher than a calibrated level due to a combination of high fuel level and high evaporation. In case of healing when the fuel level sensor are not working correctly the attempt is aborted if the initial rate of change is higher than a calibrated level due to a combination of high fuel level and high evaporation. This level is calibrated to approximate 70%.

1. Reference leak measurement phase
   For the reference current measurement, the motor pump is switched on. In this mode fresh air is pumped through a **0.02-inch** reference orifice, situated internally in the module, and the pump motor current is measured. At some unusual operating conditions the pump current may not stabilize. In this case the leak check is aborted and a new leak check will be performed in the next after run. To prevent a permanent disablement of the leak check due to a DM-TL module problem, the number of subsequent irregular current measurements is counted and a module error is set as soon as the counter exceeds a calibrated value.

2. Rough leak test phase
   In this monitoring mode the changeover valve is switched over (the purge control valve remains closed). The motor current drops to a zero load level. Fresh air is now pumped through the canister into the tank. This creates a small overpressure at a tight evaporative system, which leads to a current increase.

   The rough leak check **(>= 0.04-inch)** is performed by monitoring the pump motor current gradient. Relative pump motor current is created by

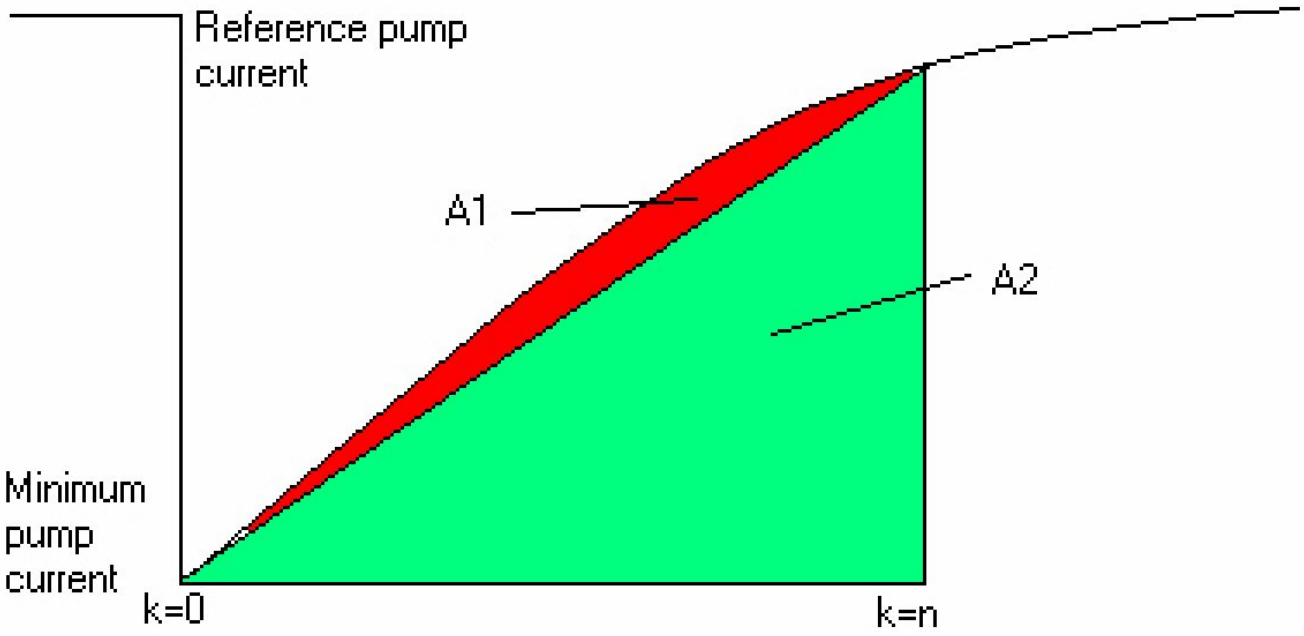
using minimum pump motor current and reference pump motor current. Area ratio is created by dividing integrated relative current with ideal area, which is the linear integrated area from minimum pump current to current sample of the current. If the relative current has increased above an upper limit but not exceeded a calibrated area, within a calibrated time, the rough leak check has passed without a fault. If the calibrated area ratio is reached before the relative pump current limit, within the calibrated time, a rough leak fault code is set. The integrated relative pump current area A-int is defined by;

A-int = A1 + A2

and the ideal area A-ideal,

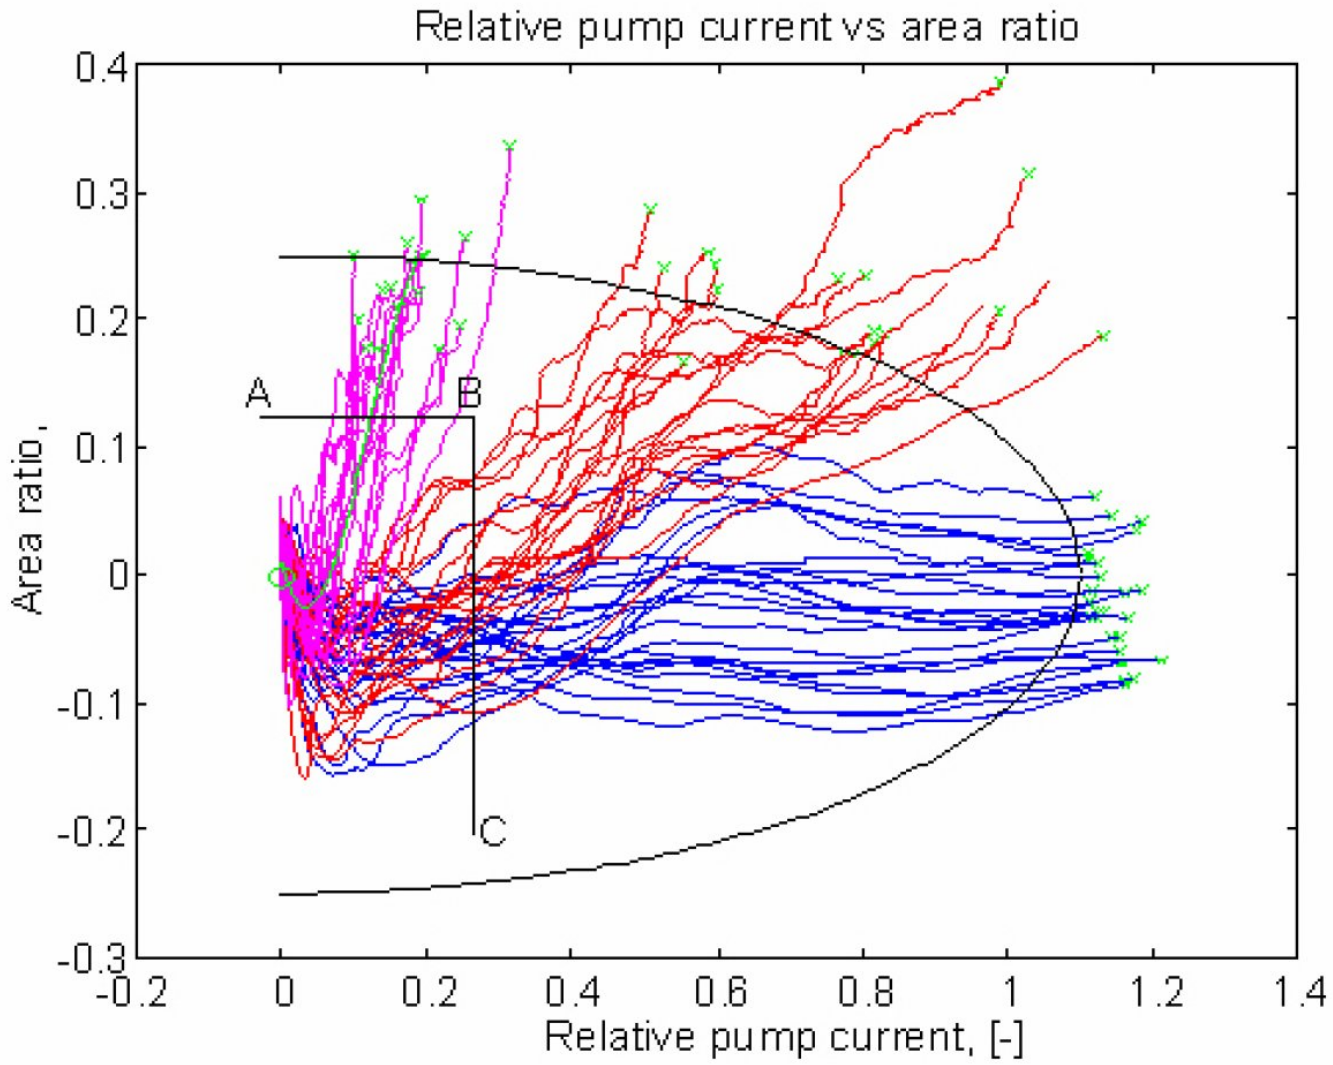
A-ideal = A2.

See figure below.

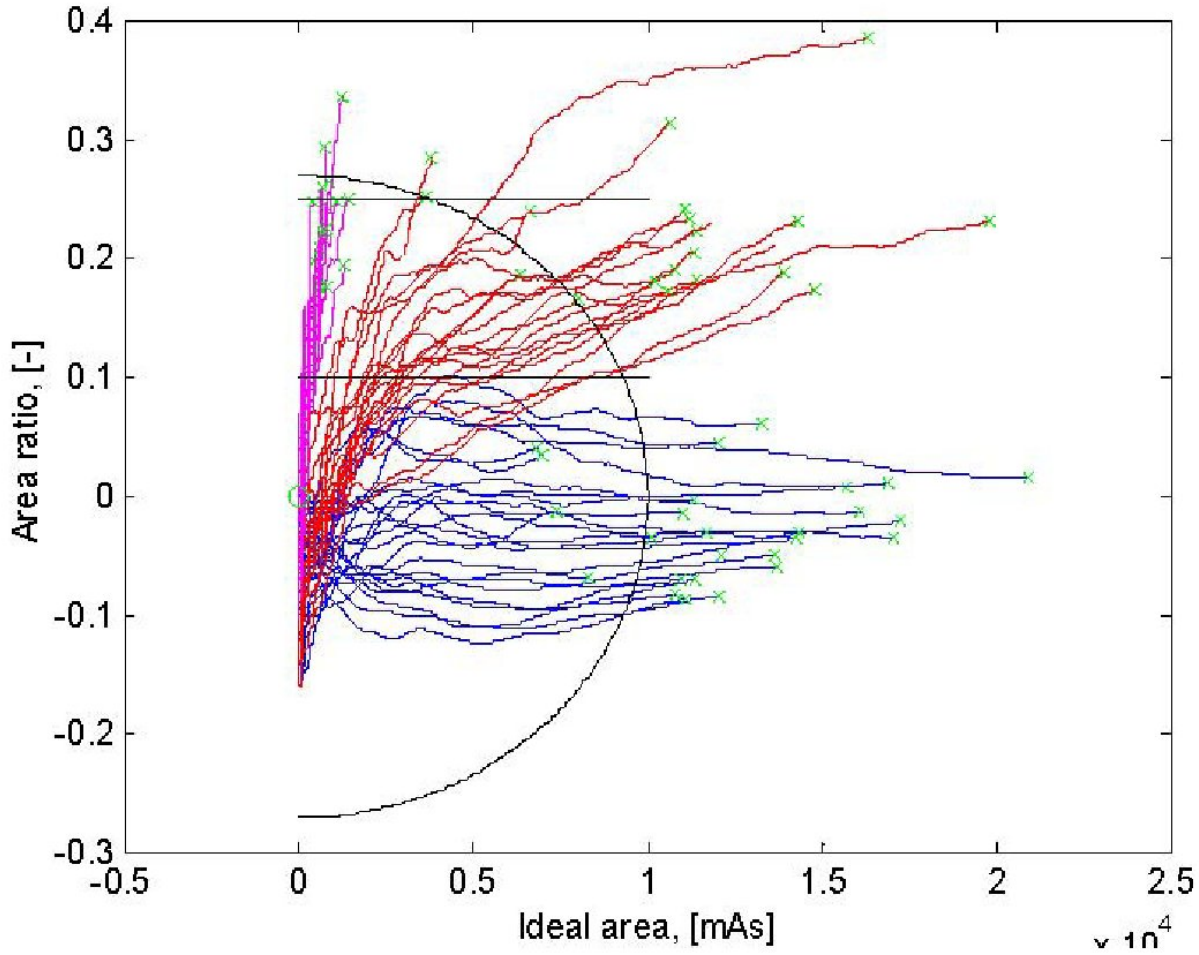


3. Small leak test phase
   If the conditions for a small leak check **(>=0.02-inch)** are set the pump motor remains on in monitoring mode until an elliptic combination of the relation pump current and area ratio are fulfilled, or a maximum time limit has been reached.The judgment is based on a test value which is a combination of the actual area ratio and gradient of area ratio with respect to relative pump current.

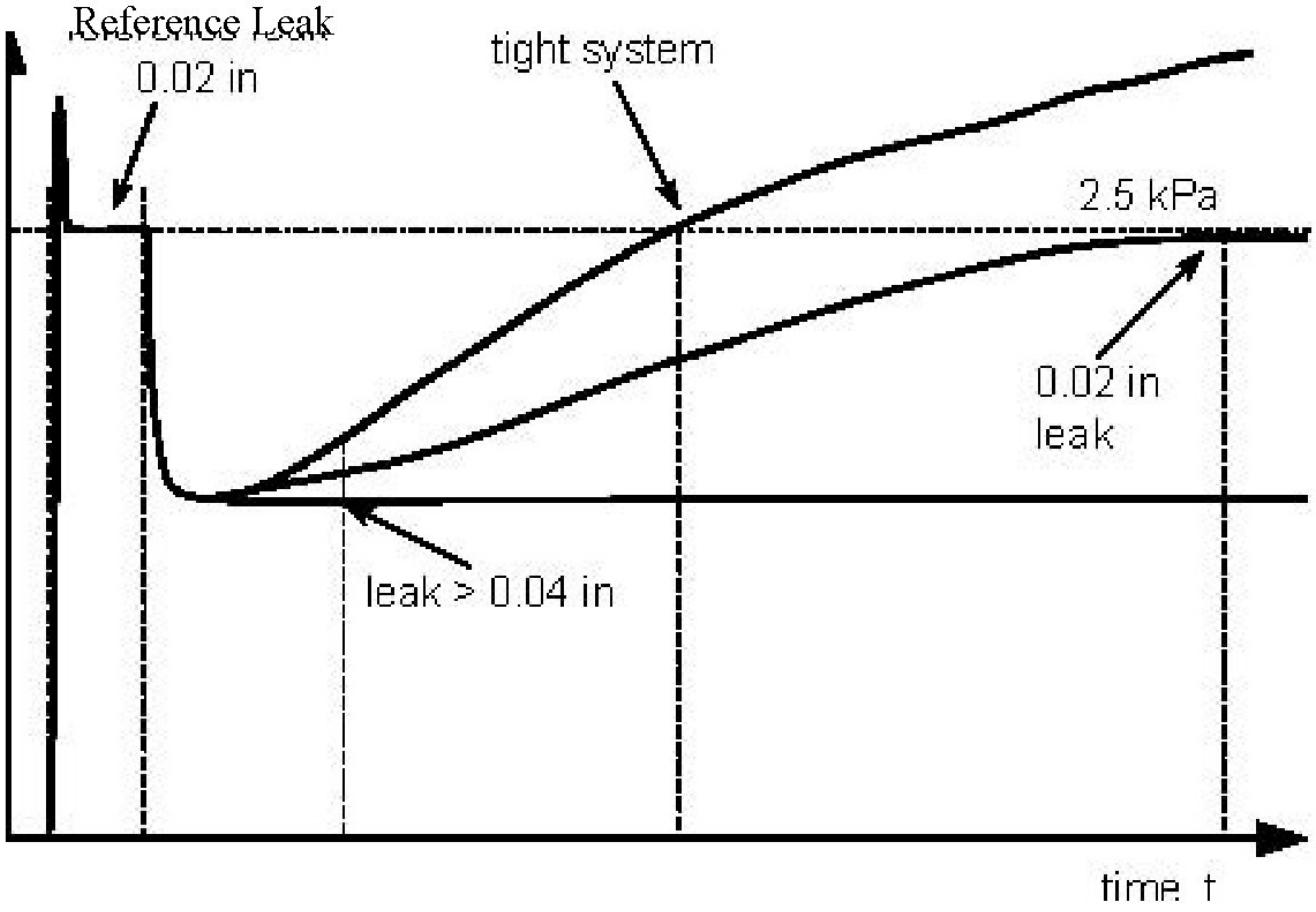
Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2



Results from simulation using old measurements and creating the area ratio and relative pump current and plot them versus each other.Blue curves correlates to no leakage, red curves to **0.5 mm** leakage and the magenta to **1.0 mm** leakage.



Results from simulation using old measurements and plotting the area ratio vs. the ideal area. Blue curves correlates to no leakage, red curves to **0.5 mm** leakage and the magenta to **1.0 mm** leakage.



If the motor current decreases or increases too much during one of the tests, the test is aborted and a new leak test will be performed in the next after-run.

Monitoring Conditions

Monitoring Conditions

To carry out the leak diagnostic it is necessary that:
- Engine-on time is at least **10 minutes** and last engine-off time is more than **5 hours**.
- ECM (=Engine Control Module) is in after run mode
- Engine speed is **0 rpm**
- Vehicle speed is **0 km/h**
- Altitude is less than (or equal to) **2500 meters**
- Engine coolant temperature is above (or equal to) **-5 Degrees C**
- Ambient temperature is between **-5 Degrees C and +35 Degrees C**
- Fuel level between 0% to 85%
- Concentration of fuel vapor in the EVAP canister is not excessive
- Battery voltage between **11.0 V and 14.5 V**
- Purge valve is closed

With the following errors the leakage detection monitoring can not be performed. These errors will therefore disable the leakage detection monitoring and the MIL (and the corresponding fault code) will be set. The disable conditions are:
- Error on power stages DM-TL pump (E_dmpme)
- Error on power stage purge valve (E_teve)
- Error on purge valve (E_tes)
- Error on change-over valve (E_dmmve)
- Error on vehicle speed signal (E_vfz)
- Error on coolant temperature sensor (E_tm)
- Error on altitude sensor (E_dsu).

Heated Oxygen Sensor Diagnostic

Heated Oxygen Sensor Diagnostic

Heated oxygen sensors are used in the system. These sensors are checked as usual for short-circuits and open-circuits. When these faults occur, corresponding errors are stored for each sensor.

Function of oxygen sensors

The basic functionality of these sensors is the concept of a pump current of the oxygen in fuel-air mixtures, from where the sensor system can compute the actual fuel-air mixture. Heating of the sensors is also undertaken in order to decrease the internal resistance and to further improve the performance of the sensors.

The internal resistance of the front sensors is constantly monitored for the heating diagnosis. A comparison is therefore made with a reference in

order to consider aging and sample deviations. Also, power stage diagnosis is made for the front sensors where a comparison of the control signal (input) and the output signal is made. Through this procedure all various possible types of short-circuits will be detected.

Diagnosis of oxygen sensors

Diagnosis of incorrect lambda measurements due to shunting effects is performed through a lambda offset of the downstream-control if a difference of air-fuel mixture exceeds a threshold (3%). By monitoring the voltage output of the specific processor CJ125 a check is made that it operates correct, avoiding hardware errors. Insufficient heating of the LSU, i.e., the front sensor, and disconnection of the pump current are detected through a comparison of the fuel-air mixture with the rear sensors. The criterion is that if the front sensor indicates a fuel-air mixture with a ratio of 1, while the rear sensor indicates a lean or rich mixture, one of these failures has occurred. Through different comparisons of the front and rear sensors, also short-circuits and high resistance to battery and ground, are detected for the front sensors. Low resistance connection between heater and the sensor, i.e. the heater coupling, is detected by monitoring lambda changes due to the heater pulse rate. A decrease of the actual performance, known as the dynamics, of the sensor due to aging or fouling can be detected through a comparison of the estimated (model based) signal and the actual measured signal.

Similar testing as these above are also undertaken for the rear sensors, where the major differences in the diagnosis can be found through oscillation checks, checking of the sensor voltage and the dynamics during fuel cut-off, for the rear sensors.

During active oxygen sensor aging diagnosis the sensor signal (shape and frequency) can be considered as characteristic for the quality of the installed upstream sensor. Thus, for this purpose several parameters are calculated continuously. These calculated values are then provided via a tester interface (Scan Tool), together with the correction value of the downstream controller, the dynamic property value of the upstream continuous sensor and different constants by this tester interface. It is by this functionality the legislative authorities (for instance CARB) determine the standard of the oxygen sensor system.

Canister Purge Valve Diagnostic

Canister Purge Valve Diagnostic

The task of the canister purge valve diagnosis is to detect a defective purge control valve. The purge control valve is checked with regard to

controllability of the flow rate such as permanently open as well as permanently closed. In this cases purge control valve is detected. Minor leaks or slightly blocked valves are not detected if the valve is still controllable to a large extent. A check for absolute tightness must be performed separately or it can be derived from a possibly given canister leak test.

The diagnosis is used in addition to the electrical diagnosis. Provided the electrical diagnosis has already detected a fault, the canister purge valve diagnosis remains inactive. If the electrical diagnosis should not yet have detected a fault it will be detected by the canister purge valve diagnosis.

There are two possibilities for an OK check:

1. From active check at idle. A deviation of the Lambda controller from its value prior to opening, the purge control valve indicates that the purge control valve can be controlled and thus is OK.
2. If a stoichiometric mixture is coming there is no deviation of the Lambda controller.

a. Only the reaction of the idle control, which closes the throttle valve, can be evaluated.
b. Indication for an OK check is the decrease of the air mass flowing through the throttle valve
c. If the valve cannot close any further the ignition angle efficiency is worsened. This is also detected.

There is one possibility for defective purge control valve check:

1. If neither a reaction of the Lambda controller or of the idle controller can be observed during the active check by controlling the purge control valve open. Then the purge control valve can no longer be controlled (jammed at closed or open position), so the purge control valve is defective. The canister purge valve diagnosis is depending on lambda controller, throttle angle and ignition efficiency.

Monitoring conditions

To carry out the purge valve diagnosis it is that:

- Ambient temperature is above **-7.5 Degrees C**
- Engine temperature is above **+65 Degrees C**
- Altitude is less than (or equal to) **4000 meters**
- Vehicle speed is **0 km/h**
- Condition for Lambda closed loop control fulfilled
- Critical misfire or limp home on velocity pick-up signal not detected

With the following errors the purge control monitoring can not be performed. These errors will therefore disable the purge control diagnosis and the MIL (and the corresponding fault code) will be set. The disable conditions are:

- Condition for fault type "implausible signal" detected in the DM-TL module.
- Error on DM-TL change-over valve power stage, short circuit to ground.

Canister purge valve diagnostic

	Evaporative Emission System	*Monitor Strategy description*	Corresponding Monitor ID
DTCs	P0496 Max error P0497 Min error	Incorrect purge flow	3D

Typical canister purge valve diagnostic enable conditions

Enable condition	*Minimum*	*Maximum*
Engine temperature at start	65.25°C	
Altitude		4000 meters
Ambient air temperature	-7.5°C	

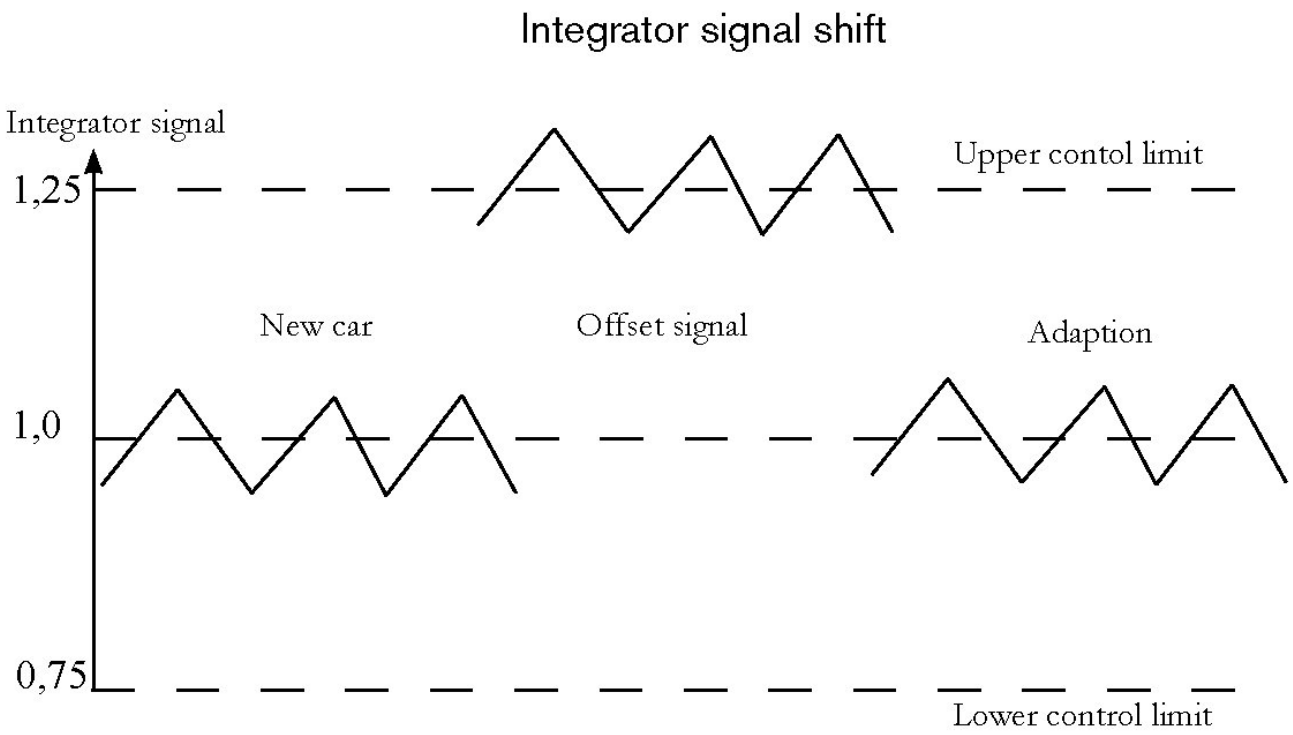
Typical canister purge valve diagnostic malfunction thresholds

Malfunction criteria	*Threshold value*
Delta resistant torque from resistant torque adaptation	<-2.99 %

Fuel System Monitoring

Fuel System Monitoring

The fuel injection system has a function which compensates for changes in the lambda (lambda) control which occur slowly over its service life. It is called lambda adaptation and its purpose is to keep the integrator signal within its limits of control (see figure below).



The integrator signal controls the fuel injection time, in a new car the integrator signal oscillates about 1 (equivalent lambda = 1).

The amount of lambda integrator offset is calculated when the set lambda is equal to 1 and the canister close valve is closed.

The fuel adaptation will compensate the fuel amount so that the lambda integrator will remain in the middle (lambda=1.0).

The lambda control adaptation is divided into two adaptation areas: The additive adaptation at idle conditions (ora) and the multiplicative adaptation area at loaded engine (frau).

The correction of the fuel amount = calculated fuel amount * frai + ora. The speed of the fuel adaptation is depending on the lambda integrator offset (big offset is equal to high adaptation speed). The amount of the lambda integrator offset is also used in calculation of the physical urgency. The purge functionality is also calculating a physical urgency (dependant of charcoal canister load). This means that the fuel adaptation will get more time for adaptation if there is an offset and/ or low charcoal canister load.

Fuel Pressure System Diagnosis

Fuel Pressure System Diagnosis

New fuel pressure system diagnosis function is implemented. It is due to new hardware design for this model year, with a variable fuel pump, a fuel pressure sensor and a fuel temperature sensor. The function target is to be able to point out the fuel pressure system as incorrect due to performance specification and fulfill legal requirements. The function will detect the fuel pressure to be stuck high (higher pressure than target), stuck low, noisy pressure signal or plausibility.

The function, fuel temperature sensor diagnosis will detect min and max error.

The function, fuel pressure sensor diagnosis will detect min and max error.

And the function fuel power stage diagnosis will detect min, max and signal error.

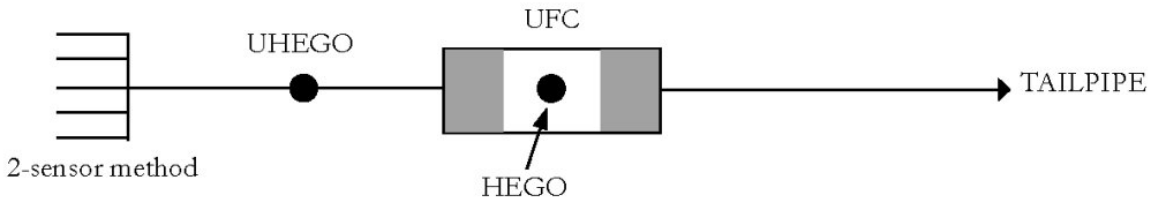
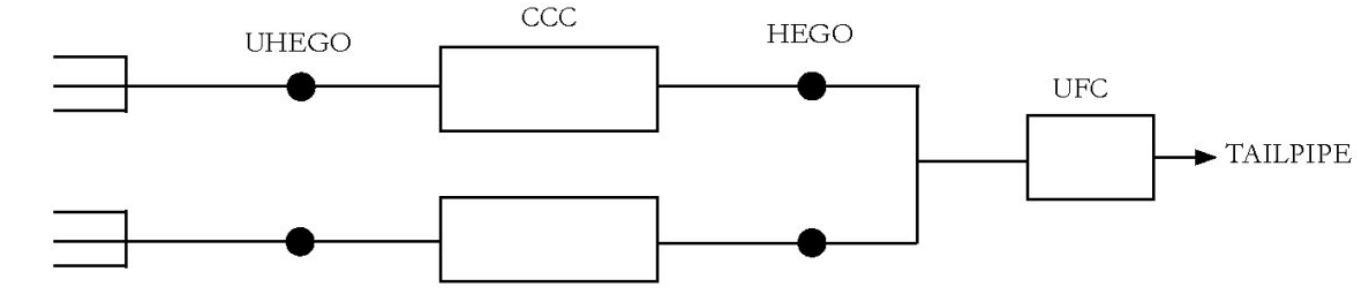
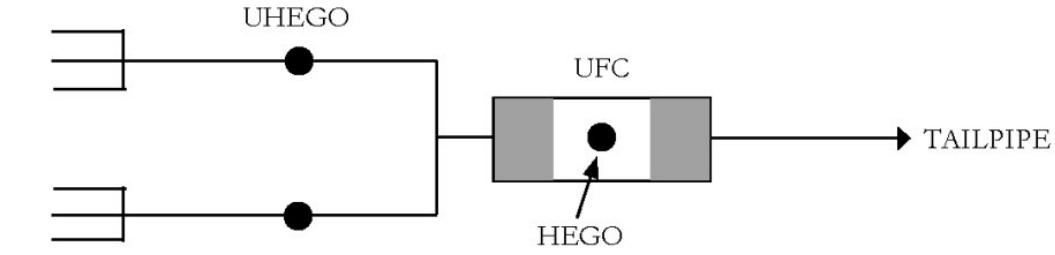
Catalyst Monitoring

Catalyst Monitoring

General Description







HEGO = Universal Heated Exhaust Gas Oxygen Sensor = ”Binary sensor”
UHEGO = Universal Heated Exhaust Gas Oxygen Sensor = ”Linear sensor”
CCC = Close Coupled Catalyst
UFC = Under Floor Catalyst

Sensor methods

- The two-sensor method makes use of one upstream and one downstream oxygen sensor, one sensor (UHEGO) before the catalytic converter and one sensor (HEGO) inserted into the catalytic converter, monitoring the front part of the catalyst.
- The two-sensor method stereo makes use of one upstream and one downstream oxygen sensor for each cylinder bank, each bank has one sensor (UHEGO) before the catalytic converter and one sensor (HEGO) after.
- The three-sensor method makes use of two upstream and one downstream sensor, two sensors (UHEGO) before the catalytic converter and one sensor (HEGO) inserted into the catalytic converter, monitoring the front part of the catalyst.

Catalyst monitoring is based on monitoring the oxygen storage capability. The (nonlinear) correlation between conversion efficiency and storage capability has been shown in various investigations.

The engine mixture control results in regular Lambda oscillations of the exhaust gas. When using a linear sensor Lambda control, Lambda oscillations are artificially created during catalyst monitoring.

These oscillations are dampened by the storage activity of the catalyst. The amplitude of the remaining Lambda oscillations downstream the catalyst indicates the storage capability. This information is evaluated during one single engine load and speed range. According to the described operating principle the following main parts can be distinguished:

- Computation of the amplitude of the downstream Lambda sensor
- Modeling of a borderline catalyst and of the signal amplitudes of the downstream Lambda sensor
- In the 3-sensor case, an additional modeling of a single air fuel mixture corresponding to the two front sensors, before the catalytic converter.
- Signal evaluation
- Fault processing
- Check of monitoring conditions

Continuous Variable Valve Timing (CVVT)

Continuous Variable Valve Timing (CVVT)

The Engine Control Module (ECM) infinitely variable controls the CVVT valve which in turn controls the CVVT unit with engine oil pressure.

The CVVT unit is mounted either on the exhaust camshaft or the intake camshaft or both, depending on which engine it is. The CVVT unit is used on all 5 and 6 cylinder engines.

The variable camshaft is hydraulically controlled by the engine oil. (The camshaft rotation takes place by the engine oil, using the CVVT valve it is transferred to either the CVVT unit front or rear chambers.) The chambers are divided by a piston.

When oil presses the piston back or forward it results in a rotating motion in the piston because it is installed in the CVVT unit cover with splines. The tooth wheel for the timing belt is located on the CVVT unit outer cover.

The control is fast and exact, it only takes approximately **500 ms** to transfer between the outer positions.

The variable camshaft main task is to minimize exhaust emissions, mainly at cold start, but also gives an improved idling quality.

Before the engine starts an internal check occurs as follows:

1. When the ignition is switched on an electrical check is carried out on the signal cable, the power supply cable and the solenoid. The check is carried out for a short-circuit to supply voltage/ground and open-circuit.
2. The camshaft checks if it is in the correct position compared to the flywheel, when the camshaft is in its 0-position (mechanical resting position). This can be done by comparing the signals from The Camshaft Position (CMP) sensor and the engine speed (RPM)/ position sensor. This is being done while the engine is running and is saved until the next start.

   If the deviations are too large between these the CVVT valve does not activate and the diagnostic trouble code (DTC) is stored.

3. In case of larger controlled deviations at the variable camshaft the time taken to regulate to the control value is measured. This time is used partially to determine how long it takes to alter the camshaft angle and partially to switch off the variable camshaft if the time exceeds a certain maximum time. The camshaft uses the engine oil and oil pressure to turn. The rotation time depends on engine speed (RPM), oil pressure, viscosity etc. which in turn depends on oil temperature and quality etc.
4. To check that the Camshaft Position (CMP) sensor is correct it is compared to the signal from the engine speed (RPM)/position sensor when the engine turns. If the check gives faulty values a DTC is stored and CVVT control ceases.

Engine Speed (RPM) Sensor

Engine Speed (RPM) Sensor

The periphery of the flywheel/flex plate is provided with a series of holes. As it passes, each transition between hole and metal induces a voltage in the pickup coil of RPM sensor. The resulting signal is an A/C signal whose frequency is a function of the number of holes passing per second and whose voltage can vary between **0.1 V and 100 V AC**, depending on the engine speed and the air gap. Voltage and frequency increases with engine speed. The engine control module (ECM) determines the engine speed and of the crankshaft by detecting the voltage pulses.

At approximately **90 degrees** before TDC for cylinder 1 there is a section without any gap. When this longer metal section (= missing holes) passes the RPM sensor, voltage pulses stop and the ECM can calculate angular crankshaft position.

Camshaft Position (CMP) Sensor

Camshaft Position (CMP) Sensor

The sensor consists of an MRE (Magnetic Resistance Element). It is a permanent magnet with 2 special semiconductor resistors, which are connected in series with each other, as described in the picture above. The output signal is an analog sine curve which passes through an analog/digital converter in the Camshaft Position (CMP) sensor before being sent on to the Engine Control Module(ECM).

When a tooth on the pulse wheel nears the sensor the magnetic field is bent and affects the resistor located nearest to the ground, resistance affects the voltage and the output signal to the ECM is low. When the same tooth continues past the sensor the magnetic field follows and so affects the other resistor that is located nearest to the voltage supply, this resistor affects the voltage so that the output signal to the ECM is high.

The magnetic field swings backwards and forwards between the teeth on the pulse wheel and the ECM senses the signals between the teeth, partly before and partly after the sensor.

The pulse wheel has 4 teeth. The ECM calculates the time interval from one tooth to the next and can decide exactly which cylinder must be supplied with fuel and ignition spark respectively.

Faults in the CMP sensor:

- The engine can still be started and driven in event of faults in the CMP sensor.
- The engine may need to be cranked for a long time before the ECM sends a spark to the correct cylinder and the engine starts.

Mass Air Flow Meter (MAF)

Mass Air Flow Meter (MAF)

The mass air flow (MAF) sensor supplies the engine control module (ECM) with a signal describing the intake air mass.

This information is for instance used to:
- Regulate fuel/air conditions
- Regulate emission
- Calculate torque.

The MAF sensor consists of a plastic housing containing a connector, electronic circuitry and an aluminum heat sink. The MAF sensor measuring device is a heated film mounted in a pipe which is cooled by the intake air to the engine.

The heated film consists of four resistors. The MAF sensor is supplied with battery voltage and has separate power and signal ground points. The sensor signal varies from **0 V to 5 V**, depending on the air mass. Voltage increases with air flow.

The ECM will adopt substitute (limp home) values if the MAF sensor signal is missing or faulty.

The MAF sensor is located between the air cleaner cover and the intake air hose.

Unfiltered MAF sensor value (max error)	> 940.0 kg/h

Engine Coolant Temperature Sensor

Engine Coolant Temperature Sensor

The engine coolant temperature (ECT) sensor transmits a signal to the engine control module (ECM) describing the temperature of the engine coolant. This gives the ECT sensor a measurement of engine temperature and influences the control of:

- Injection period
- Idling speed
- Engine coolant fan (FC)
- Ignition timing
- On-board diagnostic (OBD) functions.

The sensor incorporates a temperature-sensitive resistance with a negative temperature coefficient (NTC). The sensor is supplied with a stabilized voltage of **5 V** from ECM.

The voltage across the sensor is a function of engine temperature and, therefore, of sensor resistance. Voltage can be between **0 V and 5 V**.

The ECM uses substitute values if the signal from the ECT sensor is missing or faulty, however, substitute values can cause starting problems in very cold weather.

The sensor is mounted in the thermostat housing.

Request On-board Monitoring Test Results For Specific Monitored Systems

The purpose of this service is to allow access to the results for on-board diagnostic monitoring tests of specific components / systems that are continuously monitored (e.g. mis-fire monitoring) and non-continuously monitored (e.g. catalyst system).

The request message for test values includes an On-Board Diagnostic Monitor ID (see below) that indicates the information requested.

The latest test values (results) are to be retained, even over multiple ignition OFF cycles, until replaced by more recent test values (results). Test values (results) are requested by On-Board Diagnostic Monitor ID. Test values (results) are always reported with the Minimum and Maximum Test Limits. The Unit and Scaling ID included in the response message defines the scaling and unit to be used by the external test equipment to display the test values (results), Minimum Test Limit, and Maximum Test Limit information.

If an On-Board Diagnostic Monitor has not been completed at least once since Clear/reset emission-related diagnostic information or battery disconnect, then the parameters Test Value (Results), Minimum Test Limit, and Maximum Test Limit shall be set to zero ($00) values.

The diagnostic communication for external Scan Tools follows ISO 15765-4.

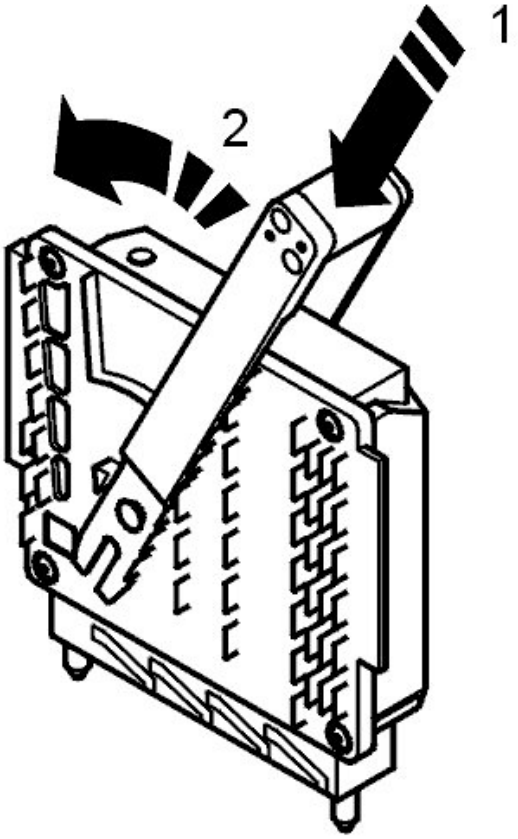
Connecting the Breakout Box

Connecting the breakout box

Special tools:

951 1504 Adapter 120 pin See: Tools and Equipment/951 1504 Adapter 120 Pin
951 1428 Breakout box See: Tools and Equipment/951 1428 Breakout Box
951 1499 Cable See: Tools and Equipment/951 1499 Cable
999 5722 Wrench See: Tools and Equipment/999 5722 Wrench

Removing the control module

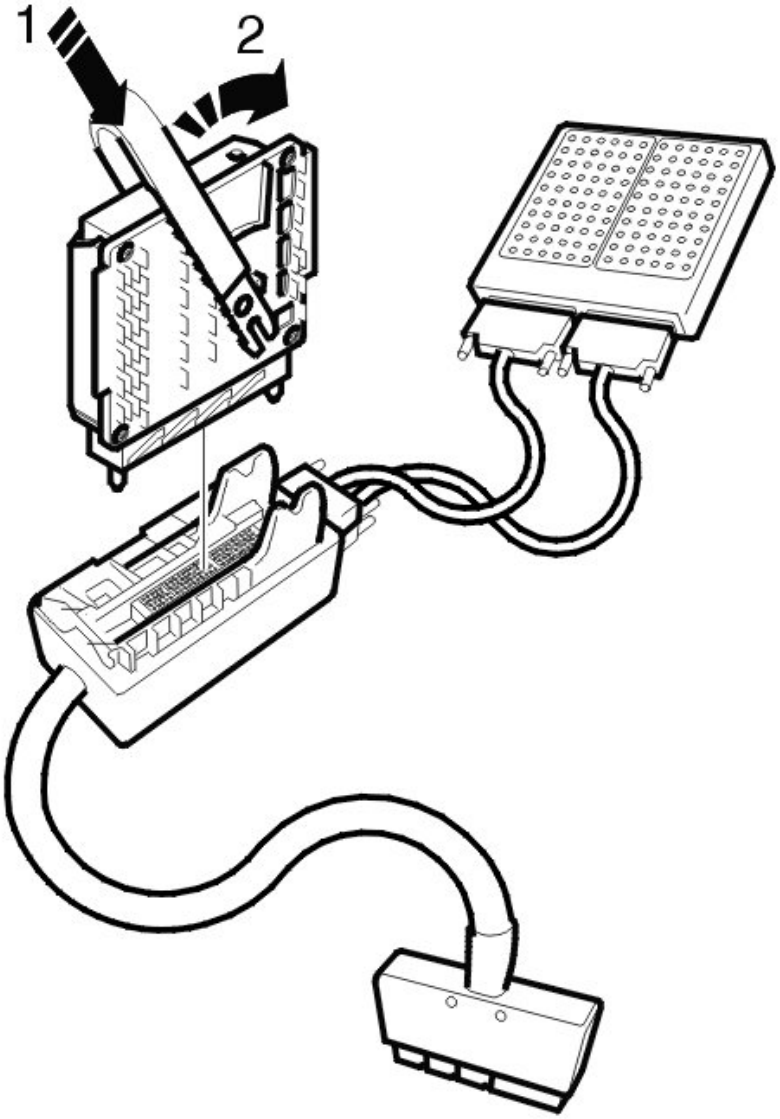


- Wait 2 minutes after the ignition has been switched off. The main relay must be voltage free**before**the control module is removed from the car. If the engine cooling fan (FC) runs on after the ignition has been switched off, wait until it stops and then wait for a further 2 minutes
- Remove the cover over the control module box. Put the cover to one side.

Note! Do not touch the control module terminal pins with your fingers. Static electricity may damage components in the control module.

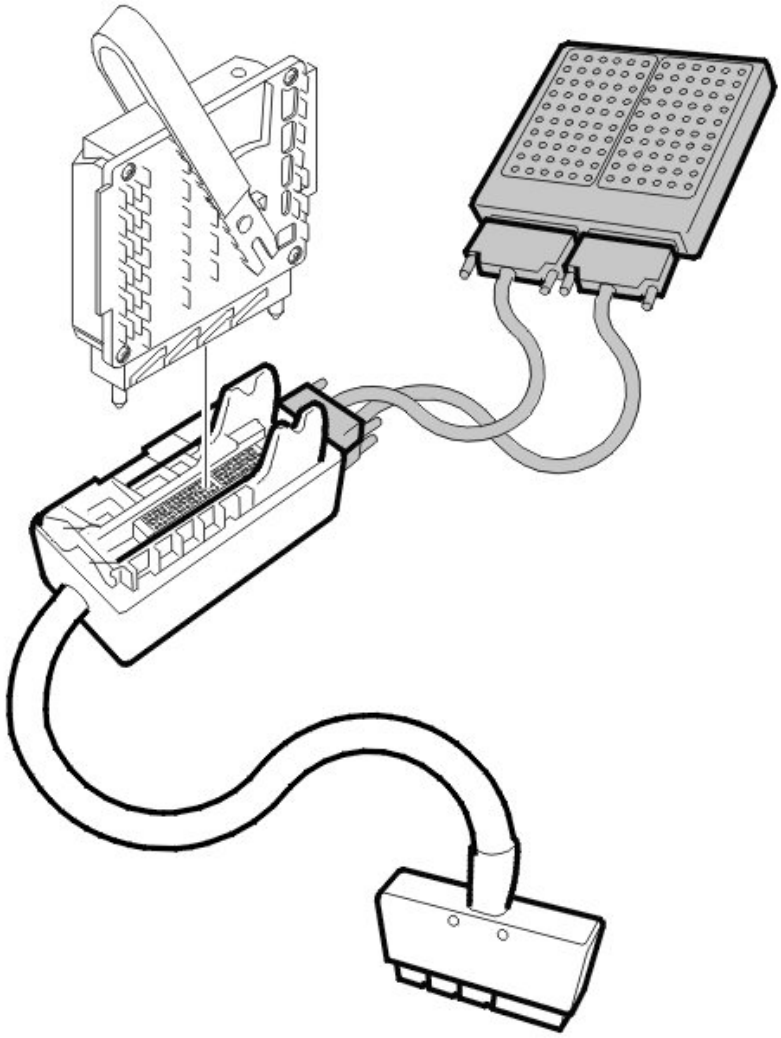
- Insert tool999 5722 Wrench See: Tools and Equipment/999 5722 Wrench around the control module
- Move the upper section of the tool backwards as far as it will go. Pull up the tool
- Carefully pull up the control module.

Connecting the adapter



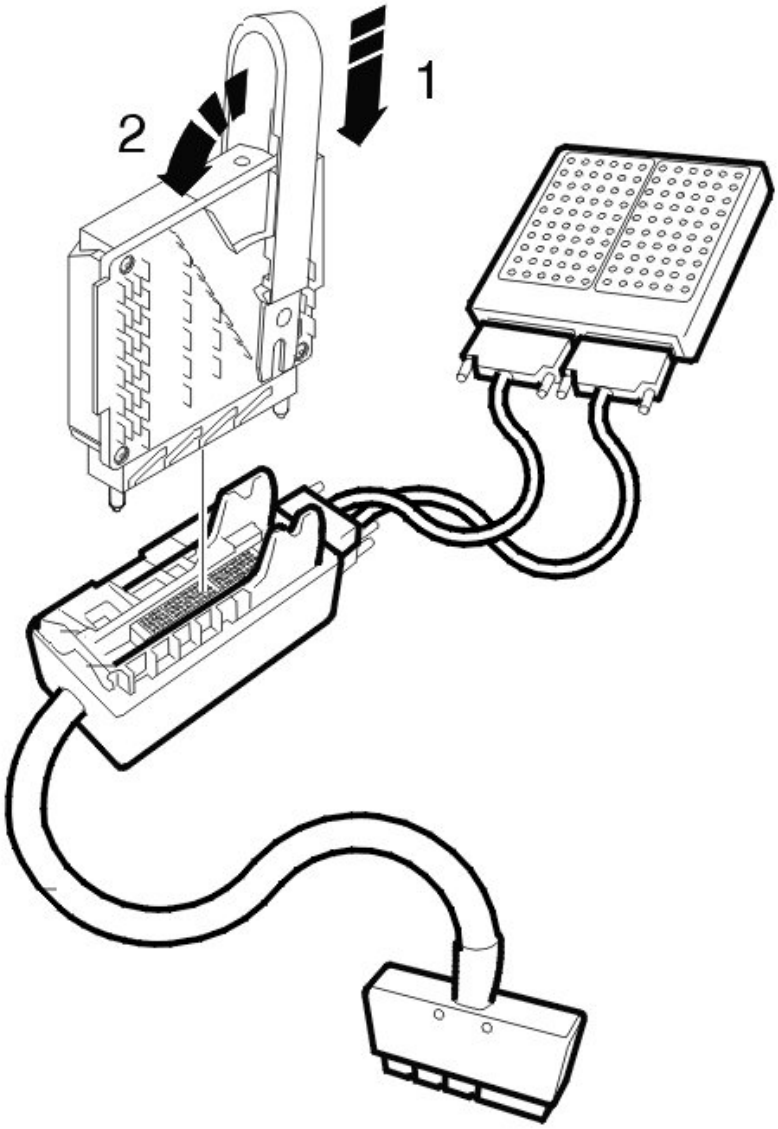
- Check that no pins or sockets are damaged on the connector
- Gently press adapter951 1504 Adapter 120 pin See: Tools and Equipment/951 1504 Adapter 120 Pin down into the grooves inside the control module box. Press to the limit position!
- Insert tool999 5722 Wrench See: Tools and Equipment/999 5722 Wrench around the adapter
- Move the upper section of the tool forwards as far as it will go. Pull the tool up.

Connecting the breakout box



- Check the control module and control module connectors to ensure that the male and female terminals are undamaged and secure (cannot be pressed in). Check that the cables to the female terminals are secured to the terminal pins
- Connect adapter951 1504 Adapter 120 pin See: Tools and Equipment/951 1504 Adapter 120 Pin to the control module connector (wiring side). Connect breakout box951 1428 Breakout box See: Tools and Equipment/951 1428 Breakout Box to the adapter via wiring951 1499 Cable See: Tools and Equipment/951 1499 Cable
- The breakout box is designed to facilitate reading off the control module input and output signals when the control module is connected; and the cable and component resistance when the control module is disconnected. The use of a breakout box reduces the risk of accidental short-circuits and damage to the connector pins.

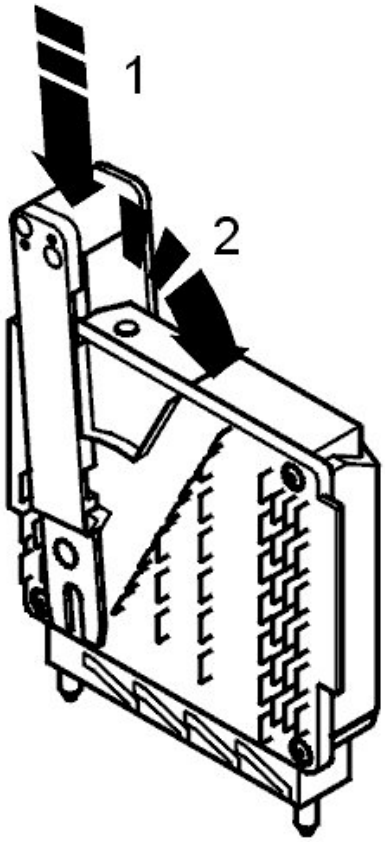
Removing the adapter



- Wait 2 minutes after the ignition has been switched off. The main relay must be voltage free**before**removing the control module from the car. If the engine cooling fan (FC) runs on after the ignition has been switched off, wait until it stops and then wait for a further 2 minutes
  Note! Do not touch the control module terminal pins with your fingers. Static electricity may damage components in the control module.

- Insert tool999 5722 Wrench See: Tools and Equipment/999 5722 Wrench around the adapter
- Move the upper section of the tool backwards as far as it will go. Pull up the tool
- Carefully pull up the adapter.

Installing the control module

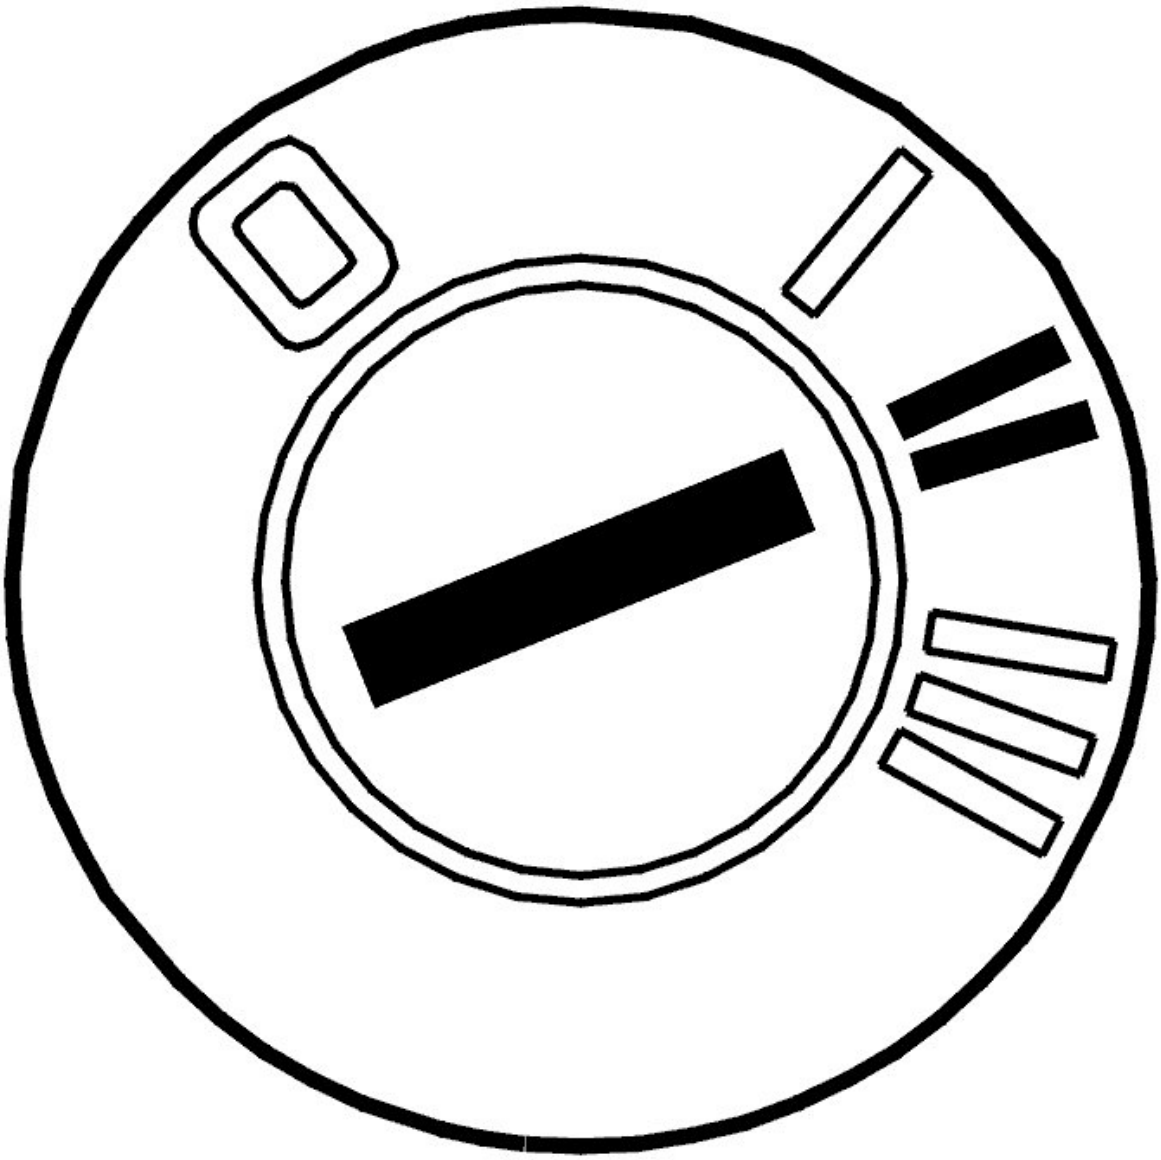


- Check that no pins or sockets are damaged on the connector
- Gently press the control module down into the grooves inside the control module box. Press to the limit position!
- Insert tool999 5722 Wrench See: Tools and Equipment/999 5722 Wrench around the control module
- Move the upper section of the tool forwards as far as it will go. Pull the tool up
- Press the cover into place over the control modules
- Check that the air ducts are correctly positioned.

Reading Off Parameters, Digital Display

Reading off parameters, digital display

Parameter, digital display



- Ignition on.

Activate reading off of the parameters: Click on the VCT2000 symbol.
Description of parameters, B5244T5, B5254T2 See: Scan Tool Testing and Procedures/Vehicle Communication Information, Engine Control Module (ECM)/Description of Parameters

Continue - **DONE**

Numeric Result 0 - Communication fault

Communication fault

Communication has been interrupted for one of the following reasons:
- The ignition is switched off
- VCT2000 disconnected from the data link connector (DLC)
- VCT2000 disconnected from the VIDA cart
- Communication problems in VIDA application or in car.
- No voltage in the data link connector (DLC).

Check therefore:
- That the control module power supply and ground terminal are fault-free.
- That the fuse for the data link connector (DLC) is intact.

- that the ignition is on
- that the battery voltage (system voltage) is normal (approximately 12 V).

If necessary a battery charger can be connected during the test.
For information about charge currents and the battery, see: Battery, charging See: Starting and Charging/Battery/Service Precautions/Technician Safety Information/Battery, Charging

- that VCT2000 is correctly connected to the VIDA cart and the data link connector (DLC)
- that VCT2000 and the wiring is fault-free.

Other information

- For information about fuse and terminal numbers, see the relevant Wiring Diagram.

Try to establish communication again or exit reading off diagnostic trouble codes (DTCs). Depending on the communication fault, select one of the following options.

1. Try again
2. Fault-trace more comprehensively for the communication problem that has occurred
3. Exit fault-tracing / Read off from the next system.

Which alternative is requested?

1 - digital display

2 - Checking communication faults

3 - **FAILED**

Checking communication faults

Checking communication errors

Selecting car model

Select car model to obtain relevant troubleshooting information.

Select one of the following model alternatives

1. S40 (04-) / V50.
2. V70 (00-), V70 XC (01-) / XC70, S60, S80 and XC90.
3. V70 (-00), V70 XC and S70 / C70.
4. S40 (-04)/ V40.

1 - car model S40 (04-) / V50

2 - car model V70 (00-), V70 XC (01-) / XC70, S60, S80 and XC90

3 - car model V70 (-00), V70 XC and S70 / C70

4 - Checking communication errors car model S40 (-04) / V40

Checking communication errors, car model S40 (04-) / V50

Hint: Test the communication with another corresponding vehicle to decide if the malfunction is in the vehicle or in VIDA/VCT/cable harness. If the communication works on another vehicle, the malfunction is in the vehicle.

Hint: For current information about each circuit and signals, see wiring diagram and signal description for each system.

Diagnostic outlet

- Check the voltage feed to diagnostic outlet #16. The voltage shall match battery voltage.
- Check the cable for power ground and signal ground to diagnostic outlet #4 and #5.

Hint: When VCT2000 is connected to the diagnostic outlet (is supplied with voltage), the indicator diode shall be activated with a green light. Then the indicator diode flashes quickly when communication takes place with a control module. In case of certain internal malfunctions on VCT2000

the indicator diode is activated with a red light!

Communication cables

- For communication problems with control units on**the high-speed network**, check communication cables between diagnostic outlet #6/ #14 and central electronic module (CEM) #B11/ #B12 for open circuit, short-circuit to ground and short-circuit to voltage according to references above.
- For communication problems with control units on**the low-speed network**, check communication cables between diagnostic outlet #3/#11 and central electronic module (CEM) #B16/#B15 for open circuit, short-circuit to ground and short-circuit to voltage according to references above.
- Also check the communication cables for the low and high-speed net between the central electronic module (CEM) and the other connected control modules according to troubleshooting above.

Control modules

- Check that the control module's voltage feed and ground connection are trouble-free.

Caution! If none of the above checks help, try reading out diagnostic trouble codes in the central electronic module (CEM). Done via VIDA vehicle communication. A prerequisite for being able to communicate with the control modules in the vehicle is that the central electronic module (CEM) is active and can be communicated with. If communication is not possible with the central electronic module (CEM), check the voltage feed and ground for the central electronic module (CEM).

VCT2000 and cable harness

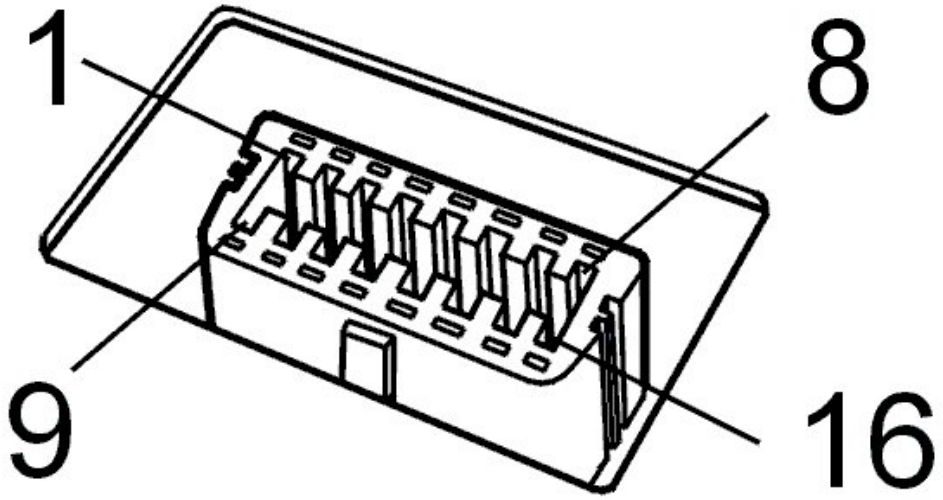
- Connect VCT2000 to the vehicle so that it is supplied with voltage. Test VCT2000 by selecting the system's self-test and VCT Test in the VIDA main menu. If any malfunction is found according to the test, first replace the cable harness then the VCT2000, if the test still indicates a malfunction.
- If no malfunctions were found after troubleshooting according to above, try with a new cable harness and/or new VCT2000.

VIDA

- If no malfunctions were found after troubleshooting according to above, try performing a complete system reset of VIDA.

Other information

- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals



Continue - Fault Found

Checking communication errors, car model V70 (00-), V70 XC (01-) / XC70, S60, S80 and XC90

Hint: Test the communication with another corresponding vehicle to decide if the malfunction is in the vehicle or in VIDA/VCT/cable harness. If the communication works on another vehicle, the malfunction is in the vehicle.

Hint: For current information about each circuit and signals, see wiring diagram and signal description for each system.

Different speed on the CAN-communication can lead to problems

Volvo's vehicles have different speed of communication on the high-speed part of the CAN-network (HS-CAN), depending on model year.

- Model year -2004 communicates with 250 kbit/s.
- Model year 2005- communicates with 500 kbit/s.

Due to this, it is very important to specify correct vehicle profile before any communication is started with the vehicle's HS-CAN. This is normally done by pressing on " Retrieve VIN" or by manually specifying vehicle parameters under "Vehicle profile".

If the wrong model year has been selected, it may lead to blocking of the CAN-net, diagnostic trouble codes being stored in several control modules or missing response from control modules at continued communication. The following control modules may be affected by this problem:

- Brake control module (BCM)/(ABS)
- Engine control module (ECM)
- Electronic Throttle Module (ETM)
- Suspension Module (SUM)
- Central electronic module (CEM)
- Transmission control module (TCM)
- Steering wheel angle sensor module (SAS)
- Steering Wheel Module (SWM)
- Electrical Power Steering Module (EPS)

If this happens, take the following action:

- Turn off the ignition and remove the ignition key. Insert the key again in position II.
- If the above does not work, remove the battery cable and connect it again after a minute to reset the control modules.
- Select the correct vehicle profile in VIDA and erase the diagnostic trouble codes. Check that the symptoms have disappeared.

Diagnostic outlet

- Check the voltage feed to diagnostic outlet #16. The voltage shall match battery voltage.
- Check the cable for power ground and signal ground to diagnostic outlet #4 and #5.

Hint: When VCT2000 is connected to the diagnostic outlet (is supplied with voltage), the indicator diode shall be activated with a green light. Then the indicator diode flashes quickly when communication takes place with a control module. In case of certain internal malfunctions on VCT2000 the indicator diode is activated with a red light!

Communication cables

- Check the communication cable (k-line) between diagnostic outlet #7 and central electronic module (CEM) #D6 and other connected control modules for open circuit, short-circuit to ground and short-circuit to voltage.

Caution! In case of malfunction on this communication cable, communication cannot be established on either the low or high-speed network. First when communication takes place on this cable, the low and high-speed cables between the diagnostic outlet and central electronic module (CEM) are connected to the rest of the network in the vehicle. This is controlled via a relay in the central electronic module (CEM). This relay is only found on vehicles of model year -2004.

- For communication problems with control units on**the high-speed network**, check communication cables between diagnostic outlet #6/ #14 and central electronic module (CEM) #B7/ #B8 for open circuit, short-circuit to ground and short-circuit to voltage according to references above.
- For communication problems with control units on**the low-speed network**, check communication cables between diagnostic outlet #3/#11 and central electronic module (CEM) #B19/#B20 for open circuit, short-circuit to ground and short-circuit to voltage according to references above.
- Also check the communication cables for the low and high-speed net between the central electronic module (CEM) and the other connected control modules according to troubleshooting above.

Control modules

- Check that the control module's voltage feed and ground connection are trouble-free.

Caution! If none of the above checks help, try reading out diagnostic trouble codes in the central electronic module (CEM). Done via VIDA vehicle communication. A prerequisite for being able to communicate with the control modules in the car is that the central electronic module (CEM) is active and can be communicated with. If communication is not possible with the central electronic module (CEM), check the voltage feed and ground for the central electronic module (CEM).

VCT2000 and cable harness

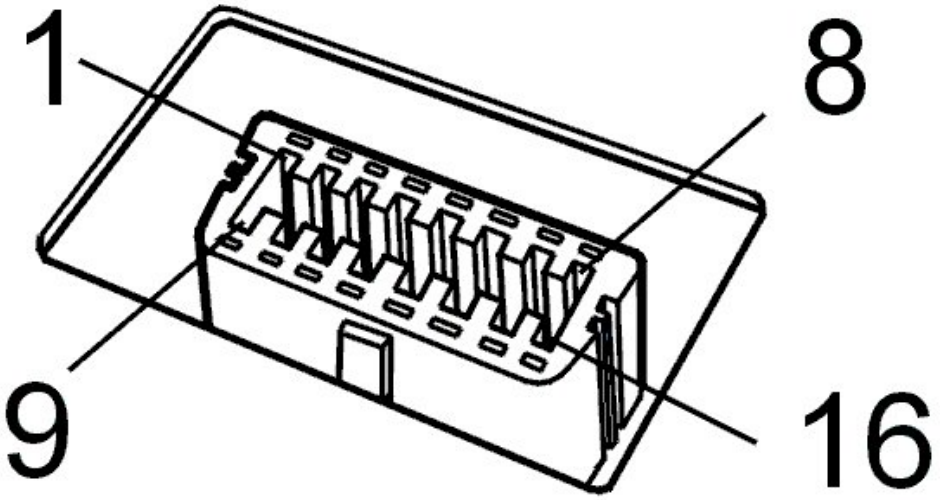
- Connect VCT2000 to the vehicle so that it is supplied with voltage. Test VCT2000 by selecting the system's self-test and VCT Test in the VIDA main menu. If any malfunction is found according to the test, first replace the cable harness then the VCT2000, if the test still indicates a malfunction.
- If no malfunctions were found after troubleshooting according to above, try with a new cable harness and/or new VCT2000.

VIDA

- If no malfunctions were found after troubleshooting according to above, try performing a complete system reset of VIDA.

Other information

- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals



Continue - Fault Found

Checking communication errors, car model V70 (-00), V70 XC and S70/C70

Hint: Test the communication with another corresponding vehicle to decide if the malfunction is in the vehicle or in VIDA/VCT/cable harness. If the communication works on another vehicle, the malfunction is in the vehicle.

Hint: For current information about each circuit and signals, see wiring diagram and signal description for each system.

Diagnostic outlet
- Check the voltage feed to diagnostic outlet #16. The voltage shall match battery voltage.
- Check the cable for power ground and signal ground to diagnostic outlet #4 and #5.

Hint: When VCT2000 is connected to the diagnostic outlet (is supplied with voltage), the indicator diode shall be activated with a green light. Then the indicator diode flashes quickly when communication takes place with a control module. In case of certain internal malfunctions on VCT2000 the indicator diode is activated with a red light!

Communication cables
- Check the communication cable (k-line) between diagnostic outlet #7 and the driver information module (DIM) #B4 and other connected control modules for open circuit, short-circuit to ground and short-circuit to voltage.

Caution! In case of malfunction on this communication cable, communication cannot be established on the high-speed network. First when communication takes place on this cable, the high-speed cables between the diagnostic outlet and driver information module (DIM) are connected to the high-speed network in the vehicle. This is controlled via a relay in the driver information module (DIM).

- Check communication cables between diagnostic outlet #6/#14 and the driver information module (DIM) #A19/#A20 for open circuit, short-circuit to ground and short-circuit to voltage according to references above.
- Also check the communication cables for the**high-speed network**between the driver information module (DIM) and the other connected control modules according to troubleshooting above.

Communication cable for cruise control as own system (not integrated)
- Check the communication cable between diagnostic outlet #13 and cruise control for open circuit, short-circuit to ground and short-circuit to voltage according to references above.

Communication cable for engine management system Fenix 5.2
- Check the communication cable between diagnostic outlet #3 and engine control module (ECM) for open circuit, short-circuit to ground and short-circuit to voltage according to references above.

Control modules
- Check that the control module's voltage feed and ground connection are trouble-free.

Caution! Model year 99- and control modules on the CAN-network. If none of the above checks help, try reading out diagnostic trouble codes in the driver information module (DIM). Done via VIDA vehicle communication. A prerequisite for being able to communicate with the control modules in the vehicle is that the driver information module (DIM) is active and can be communicated with. If communication is not possible with the driver information module (DIM), check the voltage feed and ground for the control module.

VCT2000 and cable harness
- Connect VCT2000 to the vehicle so that it is supplied with voltage. Test VCT2000 by selecting the system's self-test and VCT Test in the VIDA main menu. If any malfunction is found according to the test, first replace the cable harness then the VCT2000, if the test still indicates

a malfunction.

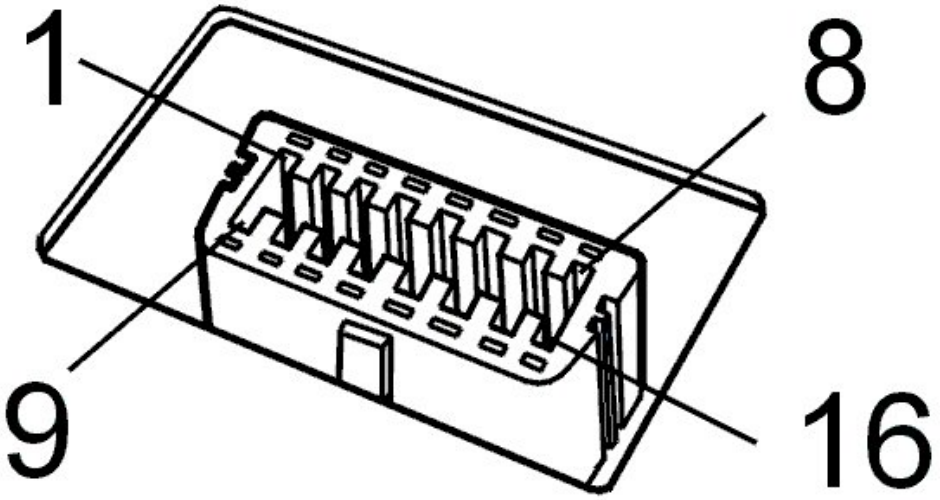
- If no malfunctions were found after troubleshooting according to above, try with a new cable harness and/or new VCT2000.

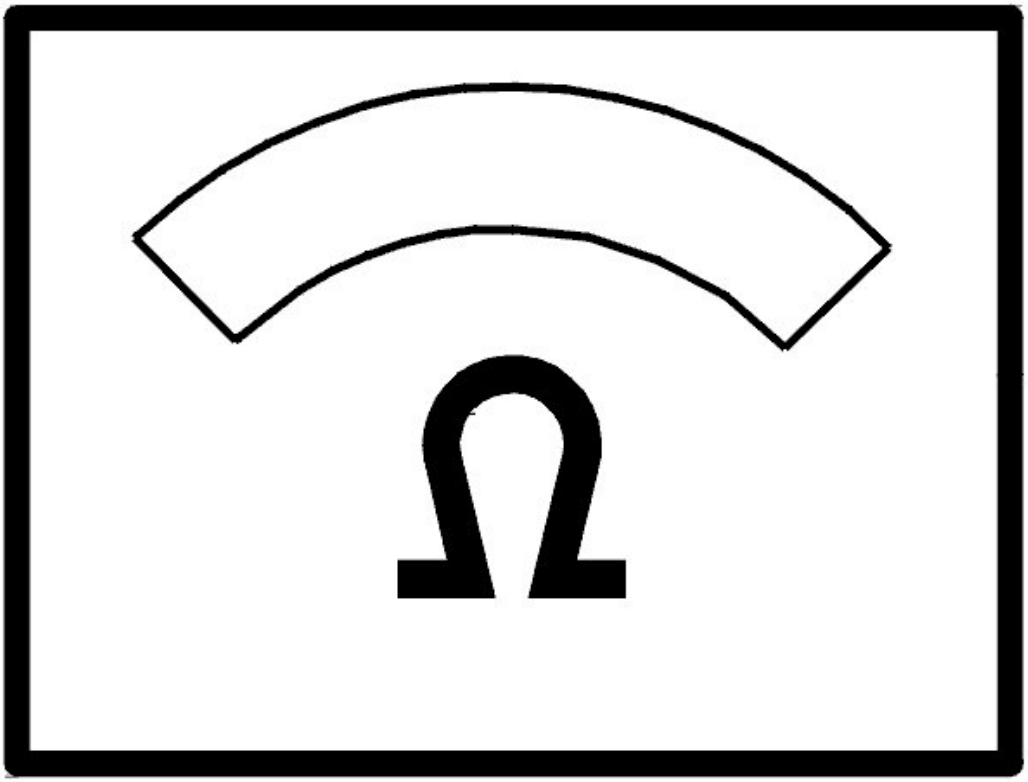
VIDA

- If no malfunctions were found after troubleshooting according to above, try performing a complete system reset of VIDA.

Other information

- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals





Continue - Fault Found

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

Checking communication errors car model S40 (-04) / V40

Hint: Test the communication with another corresponding vehicle to decide if the malfunction is in the vehicle or in VIDA/VCT/cable harness. If the communication works on another vehicle, the malfunction is in the vehicle.

Hint: For current information about each circuit and signals, see wiring diagram and signal description for each system.

Diagnostic outlet

- Check the voltage feed to diagnostic outlet #16. The voltage shall match battery voltage.
- Check the cable for power ground and signal ground to diagnostic outlet #4 and #5.

Hint: When VCT2000 is connected to the diagnostic outlet (is supplied with voltage), the indicator diode shall be activated with a green light. Then the indicator diode flashes quickly when communication takes place with a control module. In case of certain internal malfunctions on VCT2000 the indicator diode is activated with a red light!

Communication cables k-line

- Check the communication cables between diagnostic outlet #7 and connected control modules for open circuit, short-circuit to ground and short-circuit to voltage.

Communication cable for cruise control as own system (not integrated)

- Check the communication cable between diagnostic outlet #13 and cruise control for open circuit, short-circuit to ground and short-circuit to voltage according to references above.

Communication cable for engine management system Fenix 5.1 and diesel (not Lucas)

- Check the communication cables between diagnostic outlet #11/#15 and engine control module (ECM) for open circuit, short-circuit to ground and short-circuit to voltage according to references above.

Control modules

- Check that the control module's voltage feed and ground connection are trouble-free.

VCT2000 and cable harness

- Connect VCT2000 to the vehicle so that it is supplied with voltage. Test VCT2000 by selecting the system's self-test and VCT Test in the VIDA main menu. If any malfunction is found according to the test, first replace the cable harness then the VCT2000, if the test still indicates a malfunction.
- If no malfunctions were found after troubleshooting according to above, try with a new cable harness and/or new VCT2000.

VIDA

- If no malfunctions were found after troubleshooting according to above, try performing a complete system reset of VIDA.

Numeric Result 0 - Communication fault

Communication fault

Communication has been interrupted for one of the following reasons:
- The ignition is switched off
- VCT2000 disconnected from the data link connector (DLC)
- VCT2000 disconnected from the VIDA cart
- Communication problems in VIDA application or in car.
- No voltage in the data link connector (DLC).

Check therefore:

- That the control module power supply and ground terminal are fault-free.
- That the fuse for the data link connector (DLC) is intact.
- that the ignition is on
- that the battery voltage (system voltage) is normal (approximately 12 V).

If necessary a battery charger can be connected during the test.
For information about charge currents and the battery, see: Battery, charging See: Starting and Charging/Battery/Service Precautions/Technician Safety Information/Battery, Charging

- that VCT2000 is correctly connected to the VIDA cart and the data link connector (DLC)
- that VCT2000 and the wiring is fault-free.

Other information

- For information about fuse and terminal numbers, see the relevant Wiring Diagram.

Try to establish communication again or exit reading off diagnostic trouble codes (DTCs). Depending on the communication fault, select one of the following options.

1. Try again
2. Fault-trace more comprehensively for the communication problem that has occurred
3. Exit fault-tracing / Read off from the next system.

Selecting car model

Select car model to obtain relevant troubleshooting information.

Select one of the following model alternatives

1. S40 (04-) / V50.
2. V70 (00-), V70 XC (01-) / XC70, S60, S80 and XC90.
3. V70 (-00), V70 XC and S70 / C70.
4. S40 (-04)/ V40.

1 - car model S40 (04-) / V50

2 - car model V70 (00-), V70 XC (01-) / XC70, S60, S80 and XC90

3 - car model V70 (-00), V70 XC and S70 / C70

4 - Checking communication errors car model S40 (-04) / V40

Checking communication errors, car model S40 (04-) / V50

Hint: Test the communication with another corresponding vehicle to decide if the malfunction is in the vehicle or in VIDA/VCT/cable harness. If the communication works on another vehicle, the malfunction is in the vehicle.

Hint: For current information about each circuit and signals, see wiring diagram and signal description for each system.

Diagnostic outlet

- Check the voltage feed to diagnostic outlet #16. The voltage shall match battery voltage.

- Check the cable for power ground and signal ground to diagnostic outlet #4 and #5.

Hint: When VCT2000 is connected to the diagnostic outlet (is supplied with voltage), the indicator diode shall be activated with a green light. Then the indicator diode flashes quickly when communication takes place with a control module. In case of certain internal malfunctions on VCT2000 the indicator diode is activated with a red light!

Communication cables

- For communication problems with control units on**the high-speed network**, check communication cables between diagnostic outlet #6/ #14 and central electronic module (CEM) #B11/ #B12 for open circuit, short-circuit to ground and short-circuit to voltage according to references above.
- For communication problems with control units on**the low-speed network**, check communication cables between diagnostic outlet #3/#11 and central electronic module (CEM) #B16/#B15 for open circuit, short-circuit to ground and short-circuit to voltage according to references above.
- Also check the communication cables for the low and high-speed net between the central electronic module (CEM) and the other connected control modules according to troubleshooting above.

Control modules

- Check that the control module's voltage feed and ground connection are trouble-free.

Caution! If none of the above checks help, try reading out diagnostic trouble codes in the central electronic module (CEM). Done via VIDA vehicle communication. A prerequisite for being able to communicate with the control modules in the vehicle is that the central electronic module (CEM) is active and can be communicated with. If communication is not possible with the central electronic module (CEM), check the voltage feed and ground for the central electronic module (CEM).

VCT2000 and cable harness

- Connect VCT2000 to the vehicle so that it is supplied with voltage. Test VCT2000 by selecting the system's self-test and VCT Test in the VIDA main menu. If any malfunction is found according to the test, first replace the cable harness then the VCT2000, if the test still indicates a malfunction.
- If no malfunctions were found after troubleshooting according to above, try with a new cable harness and/or new VCT2000.

VIDA

- If no malfunctions were found after troubleshooting according to above, try performing a complete system reset of VIDA.

Other information

- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

Checking communication errors, car model V70 (00-), V70 XC (01-) / XC70, S60, S80 and XC90

Hint: Test the communication with another corresponding vehicle to decide if the malfunction is in the vehicle or in VIDA/VCT/cable harness. If the communication works on another vehicle, the malfunction is in the vehicle.

Hint: For current information about each circuit and signals, see wiring diagram and signal description for each system.

Different speed on the CAN-communication can lead to problems

Volvo's vehicles have different speed of communication on the high-speed part of the CAN-network (HS-CAN), depending on model year.

- Model year -2004 communicates with 250 kbit/s.
- Model year 2005- communicates with 500 kbit/s.

Due to this, it is very important to specify correct vehicle profile before any communication is started with the vehicle's HS-CAN. This is normally done by pressing on " Retrieve VIN" or by manually specifying vehicle parameters under "Vehicle profile".
If the wrong model year has been selected, it may lead to blocking of the CAN-net, diagnostic trouble codes being stored in several control modules or missing response from control modules at continued communication. The following control modules may be affected by this problem:

- Brake control module (BCM)/(ABS)
- Engine control module (ECM)
- Electronic Throttle Module (ETM)
- Suspension Module (SUM)
- Central electronic module (CEM)
- Transmission control module (TCM)
- Steering wheel angle sensor module (SAS)
- Steering Wheel Module (SWM)
- Electrical Power Steering Module (EPS)

If this happens, take the following action:

- Turn off the ignition and remove the ignition key. Insert the key again in position II.
- If the above does not work, remove the battery cable and connect it again after a minute to reset the control modules.
- Select the correct vehicle profile in VIDA and erase the diagnostic trouble codes. Check that the symptoms have disappeared.

Diagnostic outlet

- Check the voltage feed to diagnostic outlet #16. The voltage shall match battery voltage.
- Check the cable for power ground and signal ground to diagnostic outlet #4 and #5.

Hint: When VCT2000 is connected to the diagnostic outlet (is supplied with voltage), the indicator diode shall be activated with a green light. Then the indicator diode flashes quickly when communication takes place with a control module. In case of certain internal malfunctions on VCT2000 the indicator diode is activated with a red light!

Communication cables

- Check the communication cable (k-line) between diagnostic outlet #7 and central electronic module (CEM) #D6 and other connected control modules for open circuit, short-circuit to ground and short-circuit to voltage.

Caution! In case of malfunction on this communication cable, communication cannot be established on either the low or high-speed network. First when communication takes place on this cable, the low and high-speed cables between the diagnostic outlet and central electronic module (CEM) are connected to the rest of the network in the vehicle. This is controlled via a relay in the central electronic module (CEM). This relay is only found on vehicles of model year -2004.

- For communication problems with control units on**the high-speed network**, check communication cables between diagnostic outlet #6/ #14 and central electronic module (CEM) #B7/ #B8 for open circuit, short-circuit to ground and short-circuit to voltage according to references above.
- For communication problems with control units on**the low-speed network**, check communication cables between diagnostic outlet #3/#11 and central electronic module (CEM) #B19/#B20 for open circuit, short-circuit to ground and short-circuit to voltage according to references above.
- Also check the communication cables for the low and high-speed net between the central electronic module (CEM) and the other connected control modules according to troubleshooting above.

Control modules

- Check that the control module's voltage feed and ground connection are trouble-free.

Caution! If none of the above checks help, try reading out diagnostic trouble codes in the central electronic module (CEM). Done via VIDA vehicle communication. A prerequisite for being able to communicate with the control modules in the car is that the central electronic module (CEM) is active and can be communicated with. If communication is not possible with the central electronic module (CEM), check the voltage feed and ground for the central electronic module (CEM).

VCT2000 and cable harness

- Connect VCT2000 to the vehicle so that it is supplied with voltage. Test VCT2000 by selecting the system's self-test and VCT Test in the VIDA main menu. If any malfunction is found according to the test, first replace the cable harness then the VCT2000, if the test still indicates a malfunction.
- If no malfunctions were found after troubleshooting according to above, try with a new cable harness and/or new VCT2000.

VIDA

- If no malfunctions were found after troubleshooting according to above, try performing a complete system reset of VIDA.

Other information

- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

Signal Description / Specification

Signal specification

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

General

All values given below are between the terminals stated in column 2 (Control module terminal) and breakout box terminal #B3 unless otherwise indicated in column 6 (Miscellaneous). Control module terminals #A1-#A70 correspond to terminals #A1-#B10 on the breakout box, terminals #B1-#B50 correspond to #B11 - #B60 on the breakout box.

Note! It is important to connect the breakout box and check the ground terminals before taking readings.

Hint: If the numbering of the connector is different from the numbering on the breakout box, the connector number is given first, terminal #A61, followed by the breakout box number in brackets, (#B1). Example: #A61 (#B1).

U=	DC voltage in volts (V)	U_{AC} =	AC voltage in volts (V)
U_{bat} =	Battery voltage (V)	f =	Frequency in Hertz (Hz)
U_{low} =	Voltage approximately 0 V	% duty =	Duty cycle (pulse ratio) as a percentage (%)
t =	Time in milliseconds (ms)	I =	Current in amperes (A)

Connector A

Breakout box terminal	Control module terminal	Signal type	Ignition on	Engine idling	Other
#A1	#A1	Throttle unit signal, potentiometer 1 (circuit 1)	U≈ 0.4 - 4 V	-	The voltage varies depending on the position of the throttle. U increases with throttle opening.
#A2	#A2	Fuel pressure sensor signal	-	350 - 400 kPa (absolute pressure) U=1.8-2 V	The voltage increases with increased fuel pressure.
#A3	#A3	Fuel temperature sensor signal	-	U≈ 0.5 V- 4.5 V	The voltage falls with increased fuel temperature. The fuel temperature sensor is integrated in the fuel pressure sensor.
#A4	#A4	Engine coolant temperature (ECT) sensor signal	-	(+30°C) U=1.22 V (+80°C) U = 0.29 V (+100°C) U = 0.17 V	
#A5	#A5	Intake air temperature (IAT) sensor signal	-	(+20°C) U = 3.50 V (+30°C) U = 3.00 V (+40°C) U = 2.50 V	The intake air temperature (IAT) sensor is integrated in the boost pressure sensor.
#A6	#A6	Control signal, rear heated oxygen sensor (HO2S) preheating	$U=U_{bat}$	Preheating off: $U = U_{bat}$ Preheating on $U=U_{low}$	
#A7	#A7	Engine cooling fan (FC) control signal	Pulse width modulation (PWM) signal U_{high} at least 70% of U_{bat} U_{low} = 1.2 V f = 100 Hz Pulse ratio = 10-95%		
#A8	#A8	-	-	-	
#A9	#A9	Control signal, canister purge (CP) valve	$U=U_{bat}$	-	PWM signal during activation of the canister purge (CP) valve
#A10	#A10	-	-	-	
#A11	#A11	-	-	-	
#A12	#A12	-	-	-	
#A13	#A13	Control signal, intake camshaft reset valve	-	Pulse width modulation (PWM) signal $U_{top}=U_{bat}$ f=250 Hz (±12.5 Hz) Pulse ratio 20-95%	The pulse ratio governs control of the camshaft
#A14	#A14	Injector no. 5 control signal	$U=U_{bat}$	t= 2-3 ms	t increases with engine speed (RPM) and load
#A15	#A15	Injector no. 3 control signal	$U=U_{bat}$	t= 2-3 ms	t increases with engine speed (RPM) and load
#A16	#A16	Injector no. 1 control signal	$U=U_{bat}$	t= 2-3 ms	t increases with engine speed (RPM) and load
#A17	#A17	Power supply	$U=U_{bat}$	-	Supplied via the system relay
#A18	#A18	Control signal, front heated oxygen sensor (HO2S) preheating	$U=U_{bat}$	Preheating off: $U = U_{bat}$ Preheating on $U=U_{low}$	

#A19	#A19	Signal ground, throttle unit, potentiometers 1 and 2	$U=U_{low}$	-	
#A20	#A20	Throttle unit signal, potentiometer 2 (circuit 2)	U≈ 4-0.4 V	-	The voltage varies depending on the position of the throttle. U decreases with increasing throttle opening.
#A21	#A21	Exhaust camshaft reset valve control signal	-	Pulse width modulation (PWM) signal $U_{top}=U_{bat}$ f=250 Hz (±12.5 Hz) Pulse ratio 20-95%	The pulse ratio governs control of the camshaft
#A22	#A22	Mass air flow (MAF) sensor signal	U = 1 V	U = 1.7 V	U increases with increasing air mass
#A23	#A23	Boost pressure sensor signal	U = 1.96 V	-	U increases with increasing boost pressure.
#A24	#A24	Front heated oxygen sensor (HO2S), pump current	-	-	Pulsed current supply, not measured
#A25	#A25	-	-	-	
#A26	#A26	Oil pressure switch signal	$U=U_{low}$	$U=U_{bat}$	
#A27	#A27	Signal camshaft position (CMP) sensor 2, exhaust camshaft	U =5 V	U = Pulsed signal U_{top}=5 V U_{offset}=2.5V	The frequency varies according to engine speed (RPM)
#A28	#A28	Front heated oxygen sensor (HO2S), calibration current	-	-	Not measured
#A29	#A29	Power supply, 5 V camshaft position (CMP) sensor	U =5 V	-	
#A30	#A30	Control signal ignition coil C, cylinder 4	$U=U_{low}$	U=2.5 V t_{high}=2 ms	The frequency varies according to engine speed (RPM)
#A31	#A31	Control signal ignition coil B, cylinder 2	$U=U_{low}$	U=2.5 V t_{high}=2.5 ms	The frequency varies according to engine speed (RPM)
#A32	#A32	-	-	-	
#A33	#A33	Injector no. 4 control signal	$U=U_{bat}$	t_{low}=2-3 ms	t increases with engine speed (RPM) and load
#A34	#A34	Injector no. 2 control signal	$U=U_{bat}$	t_{low}=2-3 ms	t increases with engine speed (RPM) and load
#A35	#A35	Control signal (+) damper motor for the throttle unit	-	Pulse width modulation (PWM) signal $U_{top}=U_{bat}$ Pulse ratio 0-100% The polarity of the control signal changes when the damper motor is deployed against the direction of rotation.	The damper motor is controlled using a pulse width modulation (PWM) signal from the integrated power stage in the engine control module (ECM) measured to terminal #A36 (#A36)

#A36	#A36	Control signal (-) damper motor for the throttle unit	-	Pulse width modulation (PWM) signal $U_{top}=U_{bat}$ Pulse ratio 0-100% The polarity of the control signal changes when the damper motor is deployed against the direction of rotation.	The damper motor is controlled using a pulse width modulation (PWM) signal from the integrated power stage in the engine control module (ECM) measured to terminal #A35 (#A35)
#A37	#A37	-	-	-	
#A38	#A38	Turbocharger (TC) control valve control signal	$U=U_{bat}$	-	During turbocharger (TC) control: Pulse width modulation (PWM) signal f = 32 Hz
#A39	#A39	Sensor, power supply 5 V	U =5 V		See the relevant wiring diagram for information about connected sensors
#A40	#A40	Oil level sensor	-	Pulse width modulation (PWM) signal U_{top}=5 V Pulse ratio 17-83% T=120 ms Pulse train with three pulses, then pause for 1.2 seconds. Pulse no. 1= oil temperature. Pulse no. 2= oil level. Pulse no. 3= oil grade. The pulse ratio for each pulse changes depending on the present: - oil temperature - oil level - oil grade.	The PWM signal is generated by the oil level sensor.

Readiness Monitor (Certain Markets Only)

Readiness Monitor (certain markets only)

This is a function in Engine control module (ECM) that controls the control module's emission-related sub-system. With the function you can read out if the control module has run all diagnostics for the following sub-systems:

- Misfiring
- Fuel system
- Catalytic converter
- Evaporative emission (EVAP) system
- Heated oxygen sensors (HO2S)
- Other related components

Thus, Readiness refers only to if the diagnostics (tests) have been run or not, not if a malfunction was found or not. If a malfunction is found during the test, a diagnostic trouble code is stored and the malfunction light (MIL-light) is lit.
If the tests are run in the driving cycle without detecting a malfunction, then "Readiness" is immediately generated to OK.
However, if a malfunction is found in the driving cycle, then Readiness is generated to Not OK, and another driving cycle is required where the test is run to generate Readiness to OK.

The following alternatives are possible:

- Readiness is run (OK), no malfunction detected, which means that the vehicle can be approved in a check.
- Readiness is run (OK), with malfunction detected, which means that the vehicle cannot be approved in a check.
- Readiness is not run (Not OK), which means that the vehicle cannot be approved in a check.

Readiness was originally a requirement from the American authority, United States Environmental Protection Agency (EPA), and is used there for Inspection and maintenance test (IM-test) (corresponds to annual inspection). Depending on legal requirements, the function may also be found on other markets.

Generic Drive Cycle

Readiness Code Resetting Procedure (Generic Drive Cycle)

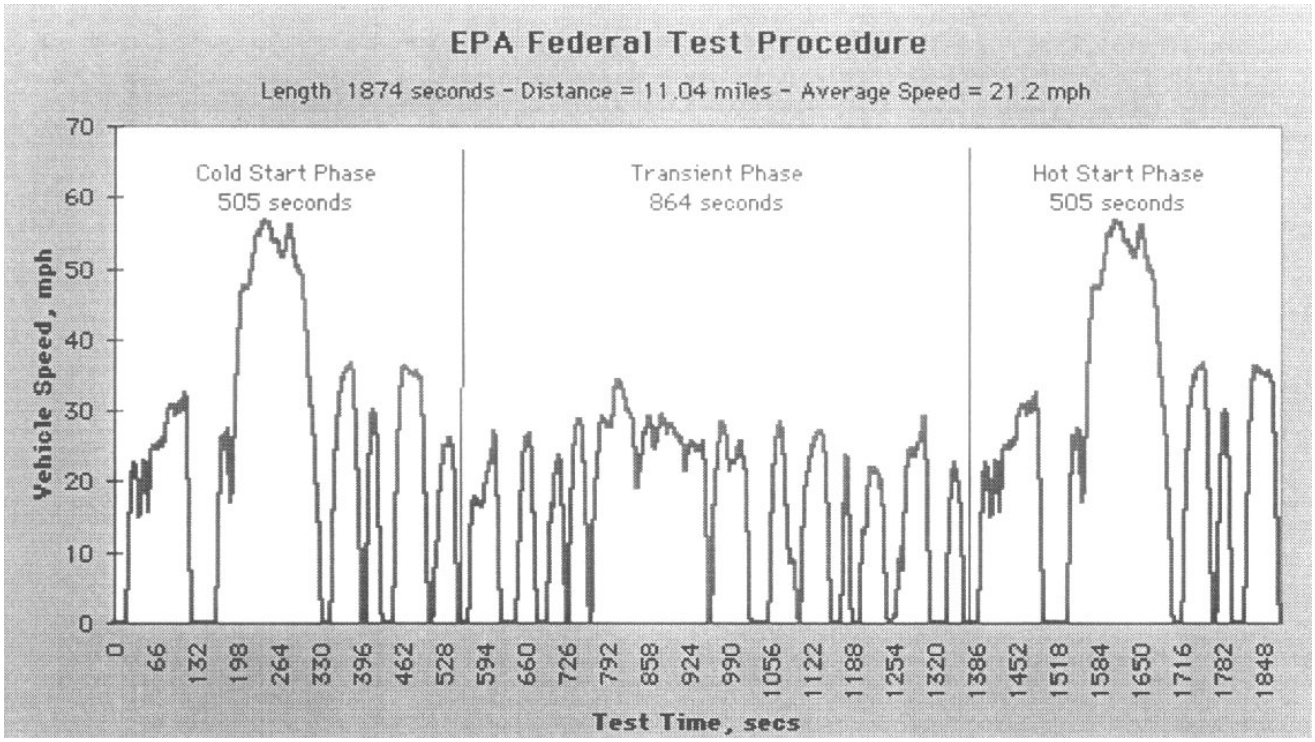
Readiness Monitors and Drive Cycles

"Readiness Monitors" are indicators that demonstrate whether or not emission system components are being monitored (checked) by the OBD-II system. If a monitor is set to "Ready" the monitor is checking its assigned component and, if no DTC's are present, the vehicle should pass an emissions test.

NOTE: If the appropriate number of Readiness Monitors (codes) are not flagged as "Ready", in most cases, the vehicle can not pass an emissions test. See State and Federal Laws.

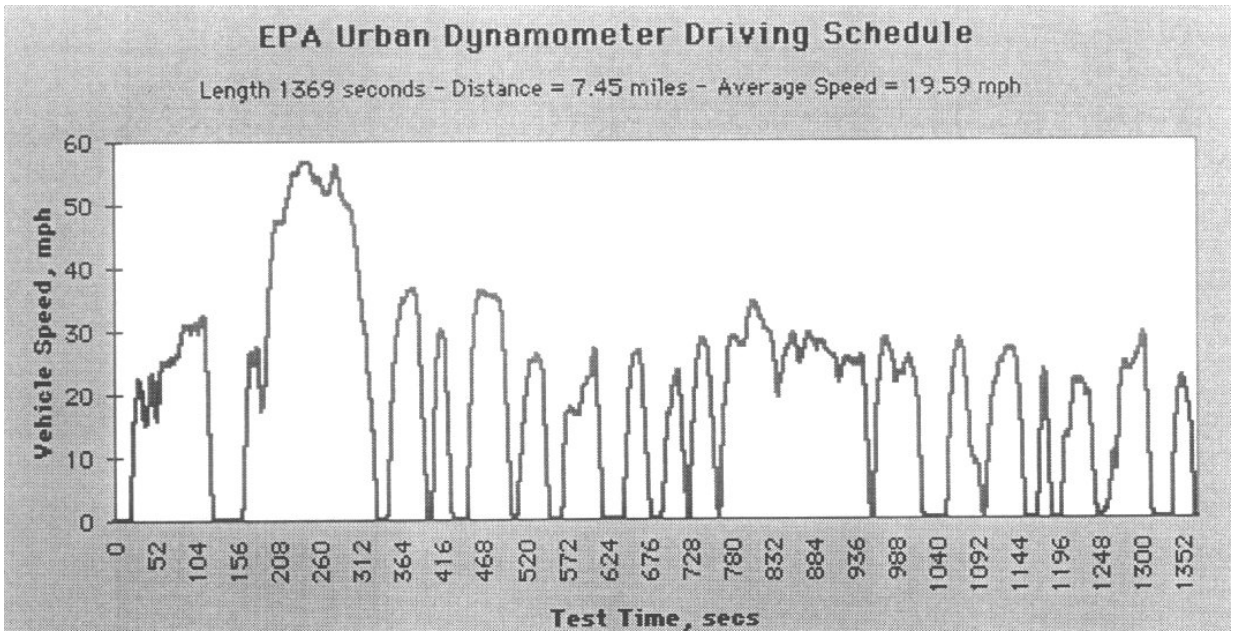
The status of all readiness monitors is reset to **"Not Ready"**:
Each time DTC's are cleared.
The battery is disconnected.
The ECM is disconnected.

The status of all readiness monitors is reset to **"Ready"**:
After DTC's are cleared and the appropriate drive cycle(s) is successfully completed.



EPA Federal Test Procedure

Manufacturers are required to validate monitors during the first 23 minutes (1372 seconds) of the Federal Test Procedure Drive Cycle.



EPA Urban Dynamometer Driving Schedule

Completing the Drive Cycle successfully one (1) time should reset most drive cycle monitors to a "Ready" status. However, there are "two trip" monitors, which require that the drive cycle be successfully completed two (2) times, to achieve a "Ready" status. Furthermore, systems which use averaging, may require the drive cycle to be completed more than 2 times.

Verify the status of the readiness monitors with the appropriate function of your scan tool.

NOTE: Certain vehicles have known OBD-II Readiness issues. Please be sure to review TSB's for special circumstances and or exceptions to readiness monitor resetting procedures.

Before Beginning the Drive Cycle

Check the status of the Readiness Monitors, check for DTC's, correct faults, clear DTC's before beginning the Drive Cycle.

Begin Drive Cycle

The vehicle should be driven approximately 7.5 miles within a period of approx. 23 minutes (1372 seconds) from a cold start. However, due to manufacture variations, it is necessary to perform only as much of the Drive Cycle as is necessary to reset the required monitors to a "Ready" status. Operate the throttle smoothly to obtain best results. **Do not shut the engine off** during the drive cycle.

CAUTION: Obey all traffic laws and drive in a safe manner!

NOTE: Extreme driving conditioning such as very high/low temperatures, rough roads and high altitudes may prevent some monitors from attaining a "Ready" status.

Step 1 **(Engine Cold)** Start engine, idle 20 seconds. Accelerate gradually and drive at 20-25 mph for 1 minute, varying speed.

Step 2 Accelerate gradually to 32 mph within 35 seconds. Decelerate to 0 mph in 10 seconds. Idle for 40 seconds.

Step 3 Accelerate at part throttle to 25 mph in 10 seconds. Cruise at 17-25 mph for 15 seconds. Accelerate gradually to 57 mph in 45 seconds. Cruise at 50-56 mph for 1 minute. Decelerate gradually to 0 mph in 40 seconds. Idle for 15 seconds.

Step 4 Accelerate at part throttle to 36 mph and maintain for 10 seconds. Decelerate to 0 mph in 15 seconds. Idle for 5 seconds.

Step 5 Accelerate to 30 mph and back to 0 mph within 30 seconds. Idle for 20 seconds.

Step 6 Accelerate to 36 mph in 20 seconds. Drive at 35 mph for 20 seconds. Decelerate to 0 mph in 15 seconds. Idle 5 seconds.

Step 7 Accelerate gradually to 26 mph and decelerate to 0 within 40 seconds. Idle 15 seconds.

Step 8 Accelerate to 27 mph in 40 seconds. Decelerate to 0 mph in 10 seconds. Idle 25 seconds.

Step 9 Accelerate to 26 mph in 15 seconds, maintain speed for 10 seconds, decelerate to 0 mph in 10 seconds. Idle 15 seconds.

Step 10 Accelerate to 23 mph in 20 seconds, decelerate to 0.5 mph in 10 seconds (no complete stop). Accelerate to 28 mph and back to 0 mph (momentary stop 1 second) within 35 seconds.

Step 11 Accelerate gradually to 34 mph in 45 seconds. Vary speed between 34 and 19 mph for 2 minutes. Decelerate from 25 to 0 mph in 25 seconds. Idle for 5 seconds.

Step 12 Accelerate to 29 mph in 15 seconds, decelerate gradually to 0 mph in 45 seconds. Idle for 30 seconds.

Step 13 Accelerate gradually to 28 mph and back to 0 mph (momentary stop 1 second) within 50 seconds. Accelerate gradually to 27 mph and back to 0 mph within 55 seconds. Idle for 15 seconds.

Step 14 Accelerate to 24 mph and back to 0 mph within 18 seconds. Idle for 10 seconds. Accelerate gradually to 22 mph and back to 0 mph within 50 seconds. Idle for 8 seconds.

Step 15 Accelerate gradually to 30 mph within 50 seconds. Decelerate to 0 mph in 10 seconds. Idle for 25 seconds.

Step 16 Accelerate to 23 mph and back to 0 mph within 30 seconds. Idle for 10 seconds.

Step 17 Repeat steps 1 - 16 once again. Recheck the status of the "Readiness Monitors".

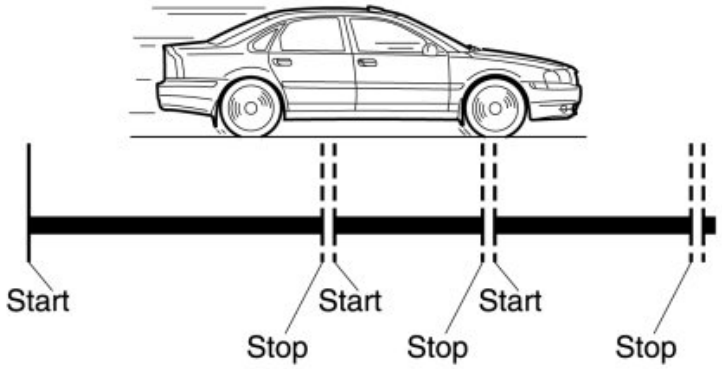
NOTE: Remember, clearing DTC's or interrupting power to the ECM after the readiness monitors have been reset to **"Ready"** will require that the Drive Cycle be repeated.

Completing the Drive Cycle successfully one (1) time should reset most drive cycle monitors to a "Ready" status. However, there are "two trip" monitors, which require that the drive cycle be successfully completed two (2) times, to achieve a "Ready" status. Furthermore, systems which use averaging, may require the drive cycle to be completed more than 2 times. It is necessary to perform only as much of the Drive Cycle as is necessary to reset the required monitors to a "Ready" status.

End Drive Cycle

Driving Cycle/Operation Cycle

Driving cycle/operation cycle



All control modules' diagnostics require that some form of driving cycle or operation cycle is run for diagnostics to be considered as complete. The terms driving cycle or operation cycle appear, these mean the same, they are only different designations.
Example

The illustration above shows an example of a driving cycle or operation cycle. The vehicle is started and driven **(Start)**, is stopped sometime and the ignition is turned off **(Stop)**. When the ignition is turned on again **(Start)** a new driving cycle starts.
A new driving cycle or operation cycle usually starts every time the ignition is turned on, which means that you should turn on the ignition, turn off the ignition, and then turn on the ignition again.
However, the condition varies from control module to control module, there are also, e.g., speed and temperature conditions, before a driving cycle or operation cycle is considered to be complete.
When a malfunction is detected and then is confirmed as a real malfunction and is stored, various counters are also stored, indicating how frequent the malfunction is. These counters use driving cycles or operation cycles as basis for updating the counters' values.
For information on counters, see further on in the document.

Readiness Code

Readiness Code

Read the readiness code

Read off diagnostic trouble codes (DTCs) and the readiness status.
If readiness is "OK" and no diagnostic trouble codes are stored, two cycles have run, i.e. the system's diagnostic functions have run two times without detecting a fault.

Hint: Readiness is reset (to "NOT OK") when the diagnostic trouble codes are cleared or if power is cut off to the engine control module (ECM).

US government information (US only)

The United States Environmental Protection Agency (EPA) has issued a guidance letter, "Performing Onboard Diagnostic System checks as Part of a Vehicle Inspection and Maintenance Program" (EPA420-R-01-015 June 2001), that incorporates various implementation issues associated with OBD-I/M testing. One being that the EPA has revised the readiness criteria to allow states to not reject MY 1996-2000 vehicles with two or fewer unset readiness codes, or MY 2001 and newer vehicles with no more than one unset readiness code. As mentioned herein this is suggested practice. Each individual state may abide by this guidance or enforce state regulations suited to their individual environmental needs. Please consult your State Department of Motor Vehicle for your current I/M testing regulations and procedures.

Select the appropriate remedy depending on this status:

1. If diagnostic trouble codes (DTCs) are stored
2. If readiness is "NOT OK".
3. If readiness is "OK" and no diagnostic trouble codes (DTCs) are stored.

1 - Diagnostic Trouble Code (DTC) stored

2 - Read the diagnostic status for readiness

3 - **DONE**

Read the diagnostic status for readiness

Read off the status of the diagnostic functions.

Select the appropriate remedy depending on this status:

1. Readiness for probe diagnostics, diagnostics for heated oxygen sensor (HO2S) preheating three-way catalytic converter (TWC) diagnostics "NOT READY".
2. Readiness for leak diagnostics "NOT READY".

Hint: The diagnostic for evaporative emission control is included in readiness for leak diagnostics.

1 - Carry out TRIP

2 - Quick test of the fuel tank system

Carry out TRIP

Perform a TRIP following Verifying repairs See: Monitors, Trips, Drive Cycles and Readiness Codes/Verifying Repairs so that the engine control module (ECM) executes a diagnosis for diagnostic functions.

Continue - Read the readiness code

Quick test of the fuel tank system

Run a quick test of the fuel tank system via the vehicle communication socket.
The engine must be run to operating temperature and then left idling for a few minutes before the diagnostic function for EVAP control can be run.

Select Continue

Continue - DONE

Diagnostic Trouble Code (DTC) stored

Fault-trace and remedy stored diagnostic trouble codes (DTCs).

Continue - ANOTHER TEST

Verifying Repairs

Verifying repairs

General

After carrying out repairs it may be necessary to check that the fault really has been remedied. One way of doing this is to check that the engine control module (ECM) has carried out a self diagnostic for the function / component that has been repaired, and that the diagnostic trouble code (DTC) has not recurred.
Verifying repairs is only intended as an aid if uncertain whether the fault persists or not. If an obvious fault is detected during fault-tracing it is not necessary to verify the repair.

Completing a TRIP

Check all diagnostic functions as follows.
To complete a TRIP as fast as possible follow a special driving schedule.

- If the engine control module (ECM) has been without power the engine must be started a few times before the test is carried out

- If the vehicle has been without power and misfire-related diagnostic trouble codes (DTCs) are being verified, a flywheel adaptation must be carried out before verification. See Misfire diagnostics under Design and Function.
- The test must take place on a road with little traffic where it is possible to drive slowly and stop at the side of the road
- The air conditioning (A/C) can be on when the engine is running at part load but must be switched off before the engine is run at idle speed
- For all diagnostics to be carried out, the engine coolant temperature (ECT) should not be above 25° C when the engine is started before the test
- Ensure that there are no diagnostic trouble codes (DTCs) stored in the system before carrying out verification
- Start the engine. Drive according to driving schedule.

Driving schedule:

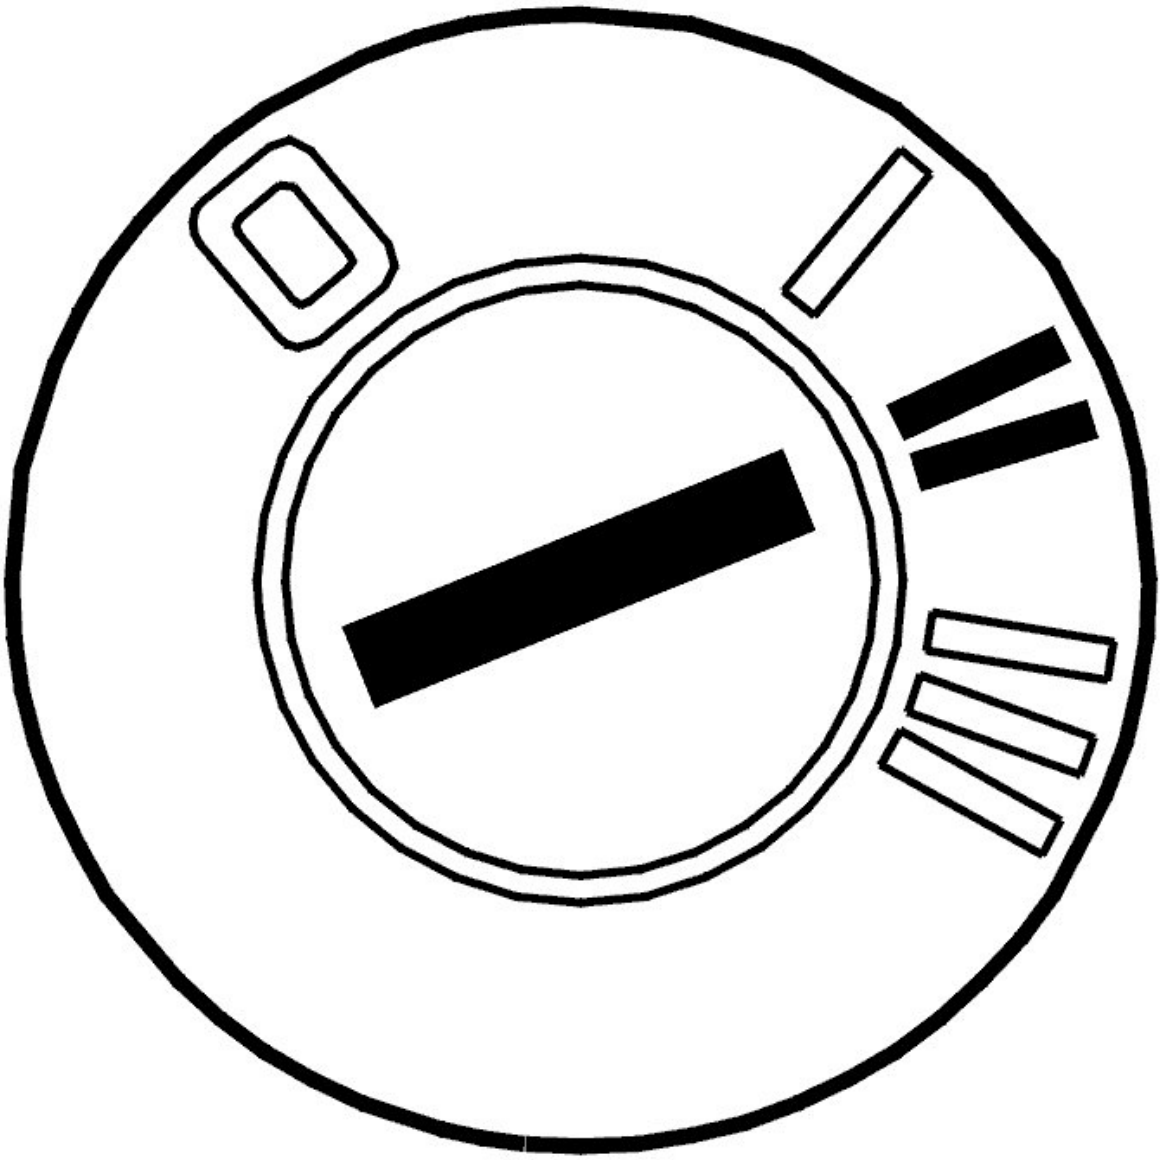
- Start the engine
- shift gear selector to drive
- accelerate gently to 1500-2000 rpm
- drive for 5 minutes at 1500-2000 rpm
- run the engine at idle speed for 70 seconds
- drive engaged, air conditioning (A/C) off
- drive for 6 minutes at 1500-2000 rpm
- run the engine at idle speed for 40 seconds
- drive engaged
- air conditioning (A/C) off
- drive for 5 minutes at 1500-2000 rpm
- run the engine at idle speed for 50 seconds
- drive for 5 minutes at 1500-2000 rpm
- Engine brake from 4000 rpm to approximately 1300 rpm a few times.

Note! Do not use the accelerator pedal (AP) during engine braking.

Adaptation of the Throttle Unit

Adaptation of the throttle unit

Checking diagnostic trouble codes (DTCs)



- Ignition on
- Read off diagnostic trouble codes (DTCs).

Check to see if any diagnostic trouble codes (DTCs) are stored. Any other diagnostic trouble codes (DTCs) may mean that adaptation of the engine control module (ECM) is not possible.

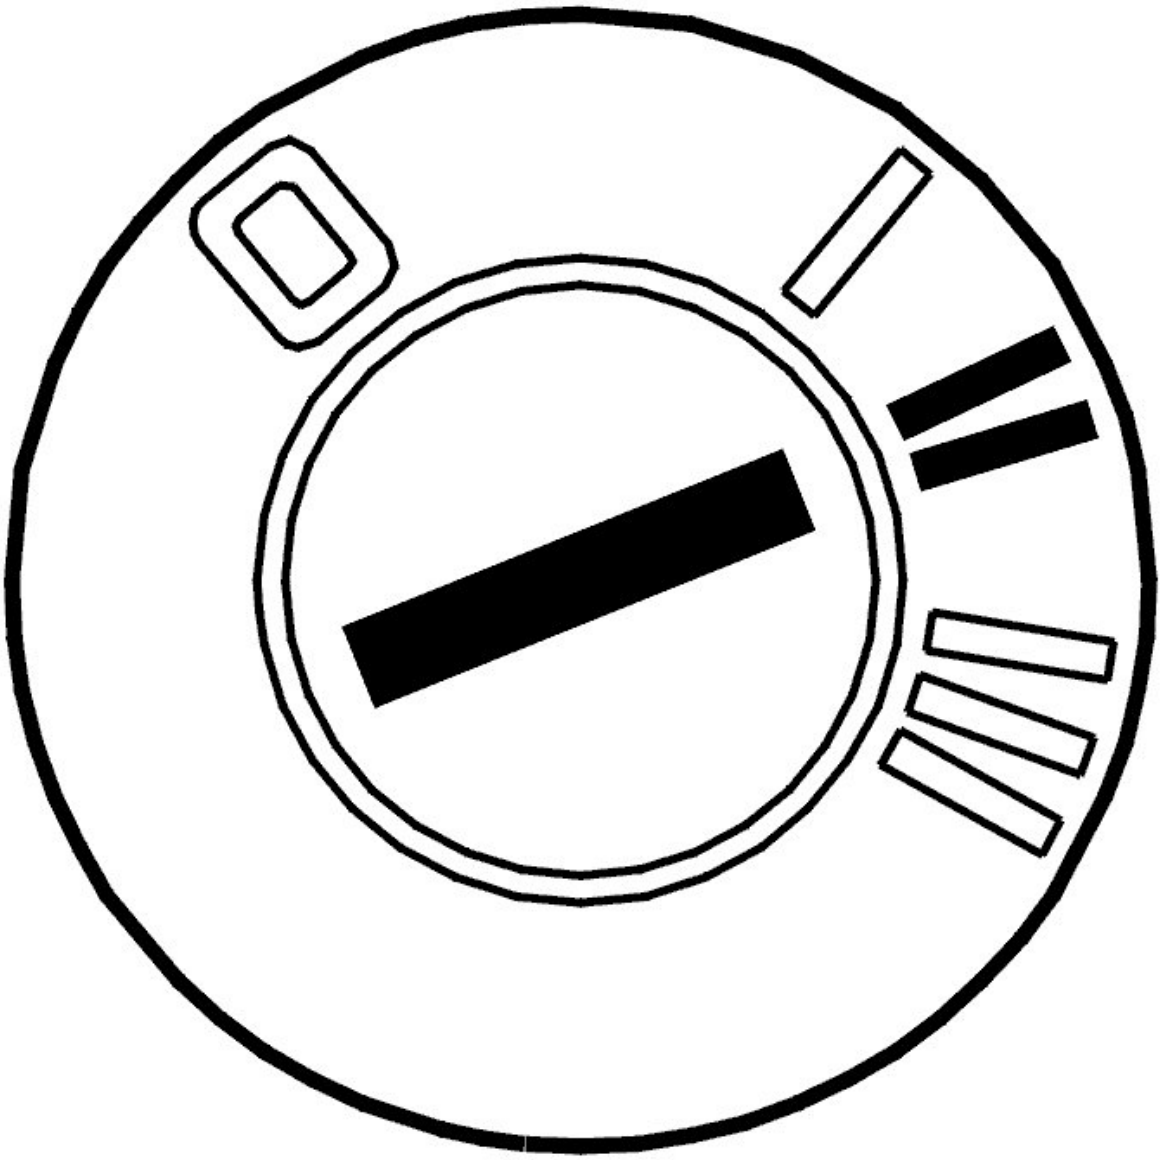
Are other diagnostic trouble codes (DTC) stored?

Yes - Fault-tracing information

No - Adaptation of the throttle unit

Adaptation of the throttle unit

Note! The ignition must be switched on for at least 30 seconds after the basic conditions are met in order for the adaptation to start. It takes approximately 10 seconds to run the adaptation.



- Ignition off
- Ignition on
- Read off the parameters.

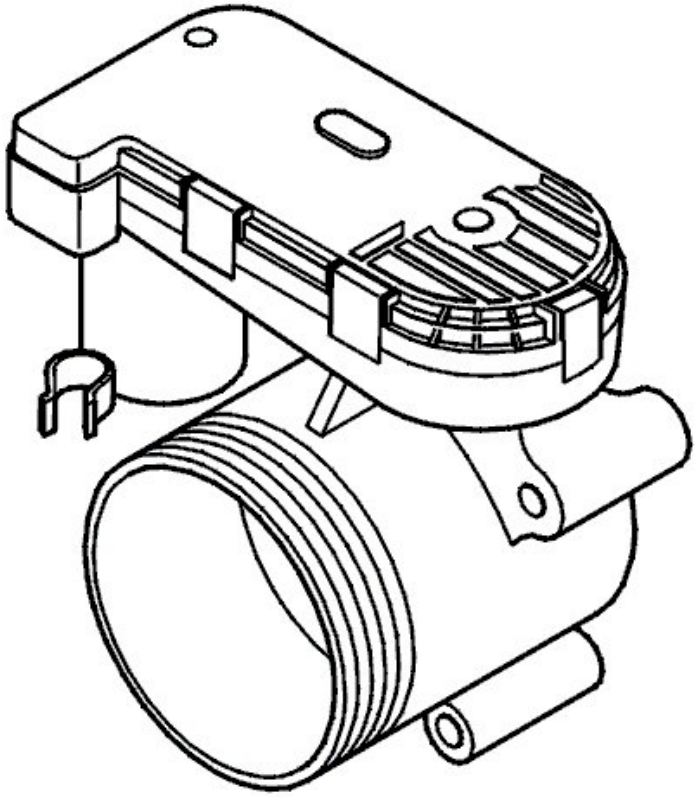
Check that the following basic conditions for adaptation of the throttle unit are met.

1. Ignition on / engine off
2. Battery voltage above 10 V
3. Accelerator pedal (AP) unaffected
4. The car must be stationary (no vehicle speed signal)
5. Engine coolant temperature (ECT) between 5-100 °C
6. Intake air temperature (IAT) above 5 °C.

Remedy as necessary.

Check that the adaptation is correctly run after the "Adaptation of the throttle unit running" parameter changes status from "YES" to "NO". When all basic conditions are met, the adaptation must be completed after approximately 40 seconds. When the adaptation is completed correctly, the following information will be displayed:

- Adaptation of the throttle unit: OK
- Adaptation of the throttle unit running: NO.



Continue - DONE

Fault-tracing information

Remedy stored diagnostic trouble code(s) (DTCs).
Remedy as necessary.

Continue - DONE

Downloading Software and Replacing the Control Module

Downloading software and replacing the control module

New software can be downloaded into the engine control module (ECM). When ordering software, the hardware and the software in the car is compared to the information in the Volvo central database. If the comparison is OK the software is downloaded to the control module. If the comparison between the car and Volvo central database is not OK, the database is updated with the car configuration. When this is complete the software is downloaded. For further information regarding downloading, see Design and Function, Downloading Software.
The engine control module (ECM) is positioned in the cool box in the engine compartment.
The engine control module (ECM) contains a unique code for each car for the immobilizer. The central electronic module (CEM) checks this code at engine start up. The engine will not start if the central electronic module (CEM) detects an incorrect code for the immobilizer. This means that the engine control module (ECM) cannot be switched from car to car.
The engine control module (ECM) must first be "unlocked" using a unique PIN for each car before it can be programmed with a code for the immobilizer. When the engine control module (ECM) has approved the PIN, the code for the immobilizer can be programmed.
The PIN and the code for the immobilizer are obtained from the Volvo central database and sent out with the software package when software for downloading has been ordered.
All new engine control modules (ECM) have the same PIN which is preprogrammed by the control module supplier. After the engine control module (ECM) has been programmed successfully the original PIN for the car will be programmed in the engine control module (ECM) memory and replace the preprogrammed PIN code.

Identifying Upgraded Software ECM/ETM

Identifying upgraded software ECM/ETM

Upgraded software for the engine control module (ECM) and electronic throttle module (ETM), available during 2006 or later, can be identified. The updated software has the **diagnostic number/software number** as set out in the table below. The diagnostic number/software number can be

read using VIDA/DIAGNOSTICS/NETWORK.
USA/Canada market
All markets except USA/Canada

Caution! For the USA/Canada market, with turbocharged and 6-cylinder normally aspirated engines the software of the engine control module (ECM) can be identified using the software number or diagnostic number, depending on the version of the software involved.

The differences between the **first version**, which is identified by the software number, and the **second version**, which is identified by the diagnostic number, include the following:

- Improved driveability after engine control module (ECM) reset. The start values for some system adaptations are adjusted to facilitate handling of aged/worn systems/components after diagnostic trouble code deletion or when the control module has been without power.
- Increased hardiness to certain combinations of aging/wear in the system. The work areas for some adaptations are adjusted to better match the aging of certain components.
- Supplements as to which faults are to generate a message to the driver.
- Improved serviceability (diagnostic trouble code generation) for some intermittent faults that generate driveability problems.

The diagnostic number (also known as diagnostic version in VIDA) and the software number can be read out via VIDA/DIAGNOSTICS/NETWORK. The electronic throttle module (ETM) is identified solely by the diagnostic number.
If the diagnostic number/software number is within the following series, it is the **latest** software downloaded:

- **5-cyl non-turbo engines B5244SG/B5244SG2 (Bifuel)**, (all markets excluding USA/Canada): Engine control module (ECM) diagnostic number 31219965 - 31219968 or 30788502 and Electronic throttle module (ETM) diagnostic number 30785387.
- **Other 5-cyl non-turbo engines**, (all markets): Engine control module (ECM) diagnostic number 30785129 - 30785132 or 30785667 and electronic throttle module (ETM) 30785387.
- **Turbocharged and 6-cylinder normally aspirated engines** (USA/Canada market):

First version, engine control module (ECM) **software number** 30785203 - 30785240 and electronic throttle module (ETM) diagnostic number 30785388.
Second version, engine control module (ECM) **diagnostic number** 30785372 - 30785378 and electronic throttle module (ETM) diagnostic number 30785388.

- **Turbo engines and 6-cylinder non-turbo engines**, (all markets except the USA/Canada market): Engine control module (ECM) software number 30785372 - 30785378 and electronic throttle module (ETM) diagnostic number 30785388.

USA/Canada market

Turbo engines and 6 cyl non turbo engines ECM (Bosch)/ETM (Magneti Marelli)
Note! The version letters at the end of the diagnostic number are not accounted for and should be ignored during identification.

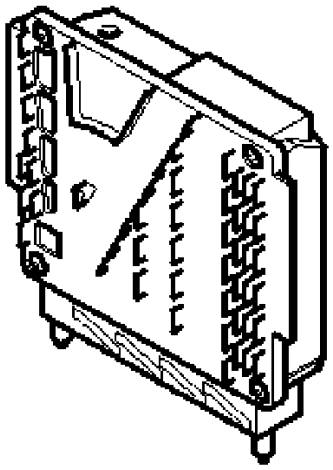
General

General



A control module can be reprogrammed in two ways using VIDA. Either different software can be downloaded or a customer parameter can be changed (via vehicle communication).

NOTE: Customer parameters are only programmed locally in one control module. Certain parameters have already been reprogrammed at the factory which makes this remedy very important.

The customer parameters are functions in certain control modules which can be modified or adjusted to the customer's wishes, for example the temperature of the heated seats or the duration of the interior lighting. It is important to read off the customer parameters before ordering software. These parameters are only stored in the control module and not in the Volvo central database.

Customer parameters are reset to the default value when new software is downloaded and must be reprogrammed after the download.

VIDA vehicle communication is used to read off and programming the customer parameters.

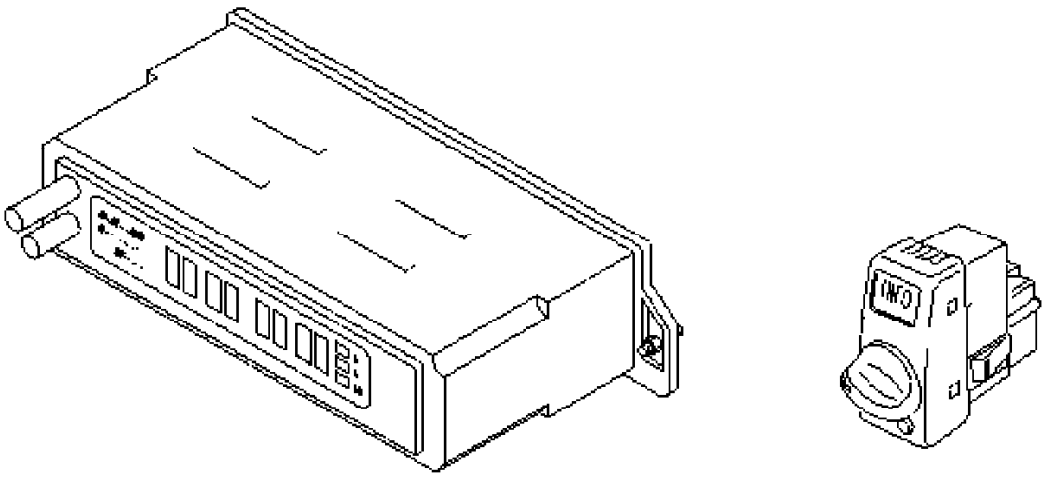
Usually a fault in the car is due to hardware faults such as: loose connections, oxidation, open-circuits, short-circuits or other faults which can lead to defective function.

Software is not perishable and does not deteriorate with time. However the software may behave in an unexpected manner because of the difficulty of testing all the possible combinations in such a complex system. It may also be necessary to upgrade the software to meet legal requirements or movement to another market.

It is recommended that the VIDA symptom input is used for fault-tracing. Suitable tests are also suggested for faults which do not generate a diagnostic trouble code (DTC).

History

History



In earlier cars each control module handled a particular specific function. Cars with a trip computer required an extra control module to run the trip computer functions. If a problem arose in a control module it was replaced, regardless of whether the fault was a hardware or a software fault.

As the number of variants and amount of functionality increased, it became both impractical and uneconomic to have one control module per

function as before. A new type of electrical system was required. The new electrical system uses distributed functionality, CAN communication and re-programmable control modules.

Distributed functionality means that a function need not be connected to a particular control module. A single function can be divided between several different control modules.

The lock and alarm system function is distributed between the central electronic module (CEM), upper electronic module (UEM), driver information module(DIM), driver door module (DDM), passenger door module (PDM) and rear electronic module (REM).

The controller area network (CAN) is a high speed digital network, which permits the control units in the car to transmit a large amount of information in a very short time.

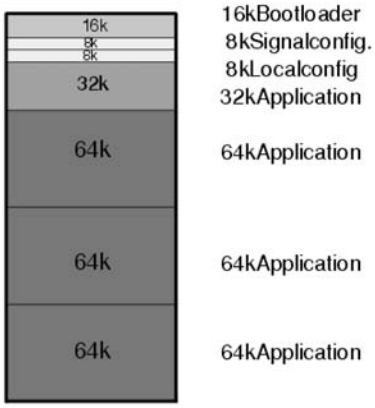
Re-programmable control units permit programming of increased functionality, without needing to replace the control module. This decreases the repair costs for the customer.

Software downloading has a number of advantages:
- To obtain a new function, for example to add a trip computer to a car without a trip computer, a new control stalk is installed and a new car configuration file is downloaded into the central electronic module (CEM). The other control modules in the car use the car configuration file to function in a particular way. The software in the driver information module (DIM), for example, reads off whether the trip computer information is to be displayed or not depending on the car's level of equipment
- Fewer control module variants. A good example is the engine control module (ECM). There are 60 different engine variants, which previously required 60 different replacement parts to be stored in the replacement parts stocks. When downloading software, three different hardware packages manage all the variants
- Market adaptation. The application file for the driver information module (DIM) can be the same for all markets. But other market files can be downloaded, to separate different market requirements
- Language. The language in the combined instrument panel can be changed by downloading different language files to the driver information module (DIM)
- This allows faster introduction of improved functionality
- Time saving when working with a particular type of fault. Previously it was necessary to replace a control module. Now a software upgrade can now be downloaded instead.

NOTE: All data is overwritten during a software download. This includes diagnostic trouble codes (DTCs) and frozen values which were stored.

Software

Software



General
Each control module requires a number of software files in order to function. Most of these are downloaded via VIDA, but in certain cases they are already in the system.

The files are stored in the Volvo central database and can be ordered via the replacement parts catalogue.

The exceptions are individual configurations which are not in the replacement part catalogue. These must be ordered using an action code via the software manager in VIDA. The part numbers are given in the Technical Journal.

Extended information about files in the control modules
The following is a technical explanation of which files are in the control modules. The information is not necessary for a mechanic to be able to repair the car. The information is presented here for those who wish to have a greater understanding of how the system functions.

The following types of software files are included:
- Primary boot loader
- Secondary boot loader
- Application file

- Signal configuration file
- Market file (driver information module (DIM) only)
- Language file (driver information module (DIM) only)
- Car configuration file (central electronic module (CEM) only)
- Security configuration file (central electronic module (CEM) only)
- Local configuration file (central electronic module (CEM) and rear electronic module (REM) only).

Most of the control modules on the controller area network (CAN) can download software via VIDA. All control modules need an application file and a signal configuration file to function. Not all control modules receive these two files when downloading software using VIDA.

In addition most of the control modules require a secondary boot load file to download the software to the control module.

Primary boot loader
The aim of the primary boot loader is to allow the download of software to a control module.

Secondary boot loader
The secondary boot loading file is a collection of instructions which work together with the primary boot loader to download the software package into the control module. It then has no other function.

Application file
The application file is the software which contains the control module functions. If software is updated because of quality improvements for example, a new application file is required.

Signal configuration file
All the control modules on the controller area network (CAN) must have the correct signal configuration file downloaded to communicate with each other. The file specifies which signals should be transmitted, where and which signals should be read, and where they can be found. This file ensures that all the control modules speak the same language. This means that an application file need not be modified if the controller area network (CAN) environment in the car is modified.

An example is two S80 model cars. One car is structure week 0135, the other has a structure week after 0135. The application file for these cars is the same, however the signal configuration files are different.

Car configuration file and security configuration file
The car configuration file and the security configuration file are always downloaded to the car when downloading via VIDA. The first file to be downloaded is the car configuration file. This is download into the central electronic module (CEM). This is loaded to indicate to VIDA that downloading has started. This file loads twice. The file is downloaded first and last in the download sequence. The first file sets an error flag and the second file resets the error flag. If the download is interrupted before the whole package has been downloaded, a user message is posted indicating that the vehicle is only half loaded.

The car configuration file is also downloaded to the central electronic module (CEM) to store general information about the car. The file is also used so that the car can continue in different modes. The file is generated in the factory just before the car is completed and is delivered by the Volvo central database when the software is ordered. The file is unique. No two cars have the same car configuration file. This file contains the car's VIN number, structure week and variant information. This information is distributed to the other control modules via the controller area network (CAN).

An example of how the car configuration file functions can be illustrated through the seat belt warning function. There are two different market requirements for how the seat belt warning should function. The central electronic module (CEM) reads out instructions from the car configuration file about how the seatbelt warning should function. The software sets itself for this function. In this way the number of variants of the software has decreased by half. In total there are over 100 parameters stored in the car configuration file. Each parameter can assume at least two values.

The car configuration file can be read off using VIDA. The file can contain a lot of information about the car which is useful for the mechanic such as the VIN, structure week and the configuration of the car. Structure week and week of manufacture are not necessarily the same week. Week of manufacture is the week that the car was built in the factory. The contents of the car are guided by the structure week. A structure week can stretch over several weeks of manufacture. An example of this is the new upper electronic module (UEM), which was introduced for structure week 0031.

Market, language and local configuration files
The market, language and local configuration files are different types of data files which contain parameters which guide the software.

The language file contains information about how the different text messages should be displayed in the text display in the combined instrument panel. There is a language file for each language. This file downloads to the driver information module (DIM).

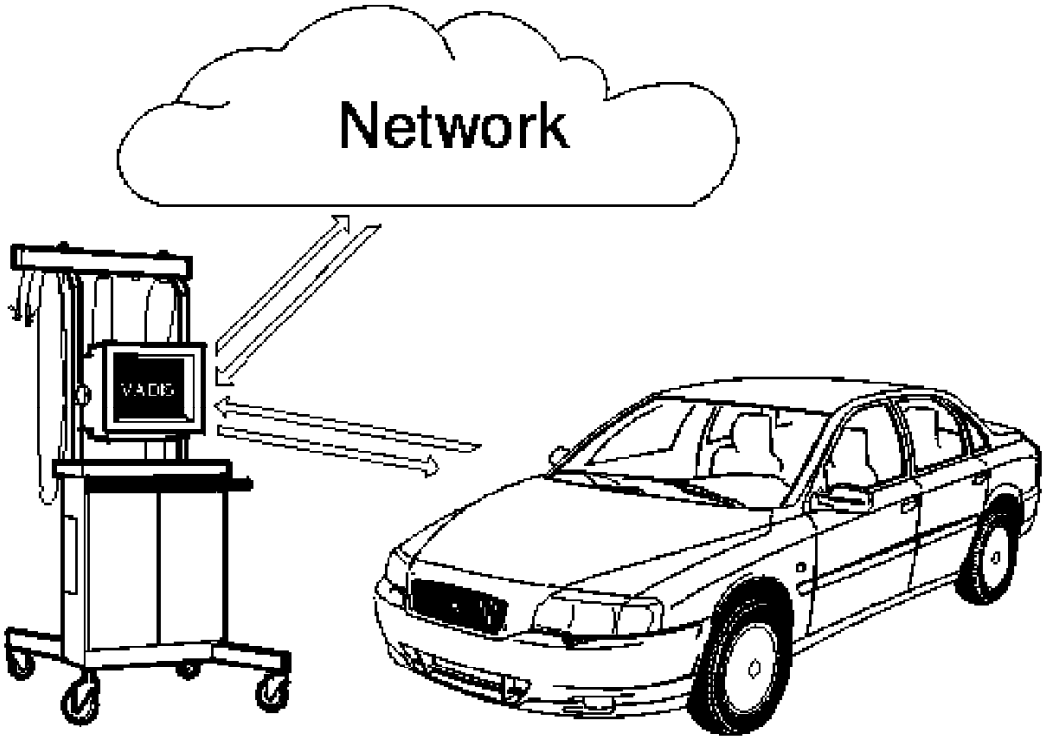
The market file contains information about when the service reminder indicator (SRI) should light and all the other market specific settings, such as units in the trip computer and temperature gauges. A number of market parameters, such as trip computers and service reminder indicator (SRI), can also be modified to the customer's requirements. This is carried out via VIDA vehicle communication.

Other market settings, such as fog lamps, cannot be reset because of legal requirements.

NOTE: Customer parameters are only programmed locally in one control module. Certain parameters have already been reprogrammed at the factory.

Ordering Software

Ordering Software



The ordering procedures for software can differ in different markets. Only ordering software via VIDA is described here.

Generally software downloading can be divided into two stages: First the software must be ordered and transmitted from the Volvo central database to the VIDA station. Then the software must be downloaded from VIDA to the car.

Each replacement part at Volvo has a part number. This also applies to software. Software is listed in the replacement parts catalogue in exactly the same way as any other component.

Each file in a control module also has a part number. This part number can be read from the car by reading off the control module ID via VIDA vehicle communication.

NOTE: It does not necessarily mean that these part numbers are not used in the replacement parts catalogue. These are the unique numbers for each file in the software package. The part number is used to determine if a software update, for a specific control module, has been carried out or not.

It is important to note that the files included in the software package are not chosen by the mechanic. The content of the software package is determined by the software designer when the software is designed.

Software is ordered as follows:

The mechanic specifies which article must be ordered, and for what car (model and chassis number). This can either be carried out from the replacement parts catalogue (via the part number) or using the VIDA software manager (via the software product).

A dialog box in VIDA asks if a control module has been replaced. If the mechanic responds that a control module has been replaced, the mechanic is instructed to connect VIDA to the vehicle so that the hardware number and serial numbers can be read off, before the software is ordered.

If the mechanic replies that the control module has not been changed, the system will assume that the car and the Volvo database correspond. A verification which ensures that this is the case will be carried out just before downloading.

If this verification indicates that the car and the database do not correspond, a fault adaptation will be run.

NOTE: The same software can be downloaded again without a new order being made. This is carried out by retrieving the same software package which failed, but this time VIDA ignores the error flag.

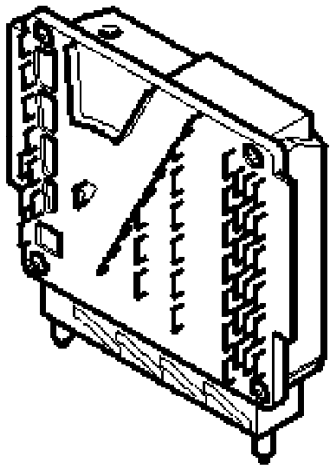
In all cases a check that the desired software applies to the relevant vehicle is made in the Volvo central database. An error message is displayed for the mechanic if any of these checks are not approved. The mechanic must determine what the fault is and reorder the software when the fault has been remedied.

HINT: Assistance in seeing what type of fault it is in the relevant software package can be obtained by clicking "Components".

Downloading can start when the software has been supplied to the VIDA station and is accessible.

Software Downloading

Software downloading



Software is ordered via VIDA replacement parts catalogue (upgrades are ordered via VIDA software manager). This section describes the procedure for software downloading between the VIDA station and the car.

The control modules are pre-programmed by the supplier using the primary boot loader. The aim of the software is that VIDA and the factory systems should be able to load software to the car. This software contains a number of commands, the primary boot loader commands, which handle the actual download and function while there are no applications in the control module.

The primary boot loader is located in a section of the control module which cannot be erased, in a Read Only Memory (ROM). This is necessary because if the primary boot loader file is erased no contact with the control module can be established. Downloading will also be impossible.

After VIDA has opened the control modules in the car for communication VIDA transmits a reset command to the vehicle. The reset command is sent so that all control modules are restarted. VIDA then transmits a command to continue the control modules in programming mode. This is always carried out by the primary boot loader, even if the control module is loaded with software. Each time that a control module is supplied with voltage the primary boot loader starts in the first **20 ms (0.02 seconds)**.

If the control module receives a programming command during these 20 ms the control module continues in programming mode.

Otherwise the application software of the control module takes over the function in the control module.

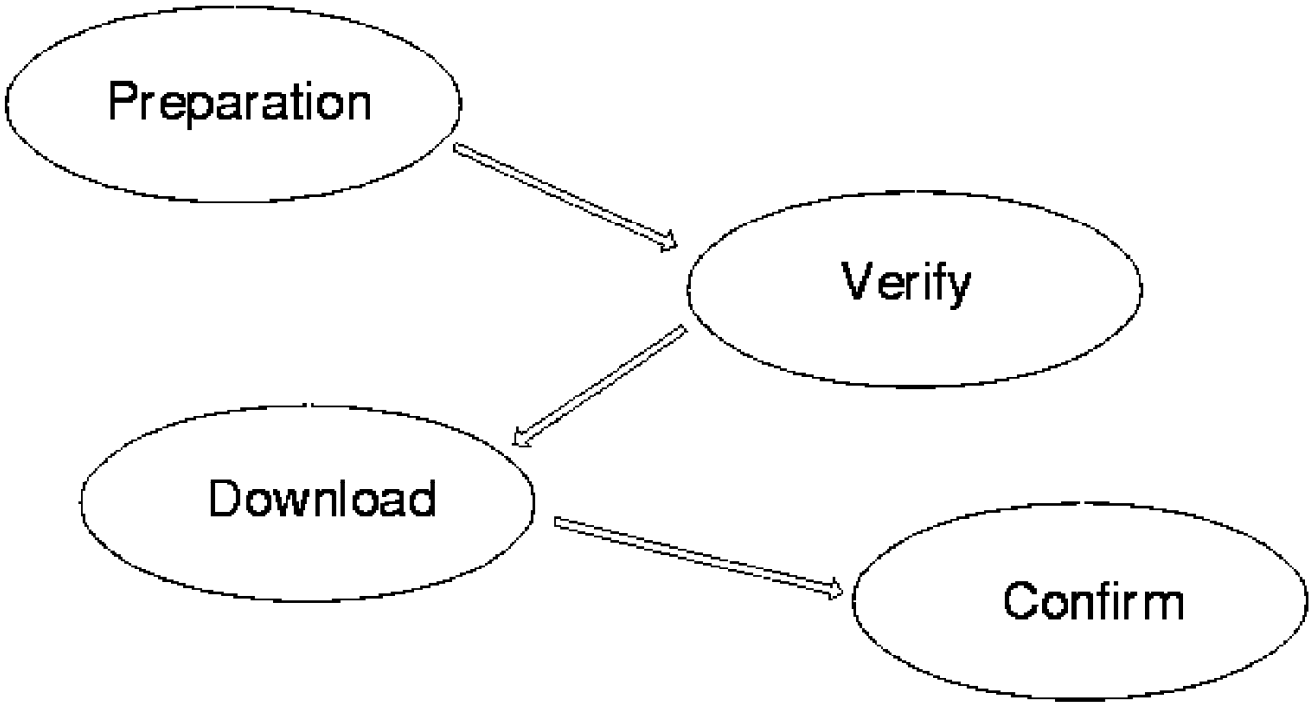
This means that it is always possible to continue with a control module in programming mode, even if the application software is corrupted. This could happen in the event of an unsuccessful download for example.

The programming command is transmitted for approximately **2 seconds** so that all the control modules will have time to carry out the command and continue in programming mode. In programming mode the control modules stop sending controller area network (CAN) messages and await new software.

After the primary boot load file, the secondary boot load file is run (if present). Any old software is erased so that it will not affect the new software being downloaded. The software is then downloaded into the control module. A reset command is sent to the vehicle so that it returns from programming mode to normal mode. All control modules then continue in normal operation.

Software Download Method

Software download method



When downloading software to the car there are several stages in VIDA. The stages in VIDA are as follows:

- Preparations
- Verification
- Downloading
- If necessary a method, for example entering PIN codes for new remote controls
- Confirmation.

The preparations include the user being asked to connect a battery charger. At which point a number of checks are made, such as of the voltage level and the ignition key positions to see if they are correct.

A verification is then carried out. During verification VIDA compares the software, hardware and serial numbers in the car with those delivered in the software package. If the reply via the dialog box is that the hardware has been replaced, the control module which has been replaced will not be included in the verification. This is because the new identity of the control module does not correspond to the old identity stored in the Volvo central database.

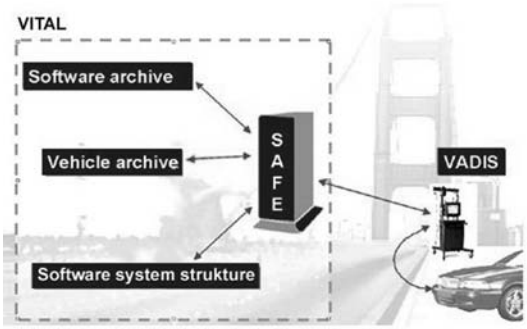
If the verification was OK, the car continues in programming mode and the software is downloaded. If the verification was not OK, a misalignment has occurred and the Volvo central database must be updated.

The confirmation means that a confirmation file, with the new configuration of the car, is created and sent to the Volvo central database. Upon confirmation, the configuration of the car is updated in the Volvo central database. This is so that a misalignment will not occur at the next download.

The Volvo Central Database

The Volvo central database
The Volvo central database has records of all the data of all the Volvo cars in the world from the 1999 model year inclusive (not including the S40 (-04) and V40).

All the VIDA stations where software downloading is possible are connected to the Volvo central database via a local area network (LAN) or a modem. There are two servers. One in North America and one in Europe. If communication cannot be established or if communication is interrupted with one server, a connection will automatically be made to the other server where all the information is available.



The Volvo central database is a collective name for a number of different databases. The databases are:
- The software archive
- Vehicle archive
- System structure for software.

SAFE is the interface between VIDA and the databases and handles the file transfer between the databases and VIDA.

The software archive
The software archive contains all the software produced by Volvo.

Vehicle archive
The vehicle archive contains all the vehicle unique information.

The system holds information about all the controller area network (CAN) control modules such as:
- Hardware numbers
- Software numbers, that is which files are in each individual control module
- Control module serial numbers
- Vehicle configuration, the equipment level of a vehicle, where the vehicle was built, the structure week and the VIN
- Software ID side impact sensors (SRS (supplemental restraint system))
- PIN codes.

The PIN codes are downloaded to VIDA when a control module has been replaced, and a reload has been ordered for the control module via the replacement parts catalogue.

The PIN codes are then used by VIDA (unseen by the user) to make the software work in the control module.

When a car is built in the factory the vehicle information is sent to the vehicle archive where the vehicle configuration is stored. When downloading using VIDA, the vehicle archive is updated with the modifications. This occurs when the confirmation file is sent to the Volvo central database.

System structure for software
System structure for software is the set of rules which determine which software should be downloaded to a vehicle. The system structure for software can alert the user to any error messages and warnings via VIDA. The system structure has complete control over whether a certain control module is suitable for the relevant vehicle.

Advantages of system structure for software over previous systems.

Some advantages of system structure for software are:
- When a software package arrives in VIDA it states which control modules will be loaded.

NOTE: The customer parameters must be read off prior to downloading.

- The exchange of control modules between vehicles can be managed. The control module will function if it is suitable for the that particular car. If not the User receives an error message
- An error message is displayed if a faulty control module is installed
- In certain cases when the software is to be downloaded to a control module, which in turn requires a certain status for hardware/software in another control module, the system also takes this into account
- Previously one was unaware if there was better software for a specific car. Now the database is aware of this. Therefore the most recent software status is available when replacing, reloading or upgrading a control module
- A control module no longer requires several different upgrades. It is however possible to run an individual configuration.
- If the car already has the most recent status it will not load, a message will be displayed instead.

Software Products

Software products
The following types of software products are available:
- Reloading
- Complete reloading
- Upgrading

- Complete upgrading
- Adding and removing functionality or accessories (with or without the addition of hardware)
- Individual configuration
- PIN codes.

Reloading
Software product type reloading is used when a control module has been replaced. To retain the software which corresponds to a replaced control module, the data of the vehicle is read when ordering. If the software is already in the car it is reloaded.

Complete reloading
Software product type complete reloading is used when more than one control module has been replaced at the same time.

Upgrading
The software product type upgrading is used to replace the software in a control module when there is a complaint and a solution is available to correct a characteristic. No data is read from the car when ordering because no hardware needs to be replaced. If the latest software is already in the car no software package is assembled. A message that the car already has the latest software status is displayed to the user.

Complete upgrading
The software product complete upgrading is used to replace the software in several control modules.

Add or remove functionality or accessories
The software product type add or remove functionality is used to expand or decrease the functionality in the car. This is mainly carried out by modifying the car configuration file in the central electronic module (CEM) (applies to accessories which do not require hardware to be replaced). Modifying this file results in new functionality for the car. There are certain functions which also require software, such as when adding a control module to the car.

The vehicle data is read off when adding a function but not when removing functionality.

The "remove" function does not actually erase any software. It is a parameter in the car configuration file which is modified so that the control modules in the controller area network (CAN) interpret the function as no longer being present. There is only one occasion on which software is erased and that is immediately before new software is loaded to a control module. This is so that the earlier software does not interfere with the new software.

Individual configuration
The software product individual configuration is used to replace the software in a control module so that it no longer corresponds to the system structure for the software. The software product individual configuration is not in the VIDA replacement parts catalogue.

If an individual configuration has been downloaded to the car previously, the mechanic receives a warning before it is overwritten.

A list of software products for individual configuration is available in the Technical Journals.

PIN codes
The software product PIN code is used to order a specific protected function. These functions are for example:
- for the immobilizer function
- when replacing the engine control module (ECM)
- for remote controls
- when replacing the upper electronic module (UEM).

System Type Number for the Control Module

System type number for the control module

The table indicates which system type number the control modules have.
VCT2000 and some of the control modules are supplied with power via the same fuse.
In these cases VCT2000 must be supplied with power separately via a network adapter. There is a power socket on VCT2000 (12V).
Check that the lamp comes on in VCT2000 when the fuse is removed.

System type number	Control module	Number of fuses for the power supply	Separate adapter
0	All control modules are in programming mode		
2560	Electronic throttle module	1	No
2841	Engine control module (ECM), diesel NED (2002-)	1	No
2842	Engine control module (ECM), gasoline, diesel MSA15.8 (1999-2001)	1	No
3601	Phone module (PHM)	1	No
3648	Accessory electronic module (AEM)	1	No
3650	Rear electronic module (REM)	1	No
3651	Central electronic module (CEM)	2	No
3670	Road traffic information module (RTI)	1	No
3680	Infotainment Control Module (ICM)	1	No
3811	Driver information module (DIM)	1	No
3901	Audio module (AUM)	1	No
3902	Antenna module (ATM)	1	No
3930	MD player module (MP1)	1	No
3931	CD player module (MP2)	1	No
3932	Multimedia module (MMM)	1	No
3933	Audio module (AUD)	1	No
3934	Subwoofer module (SUB)	1	No
4376	Transmission control module (TCM)	1	No
4601	Differential electronic module (DEM)	1	No
5931	Anti-lock brake system module(ABS)/Brake control module (BCM)	1	No
6401	Steering wheel angle sensor module (SAS)	1	No
6402	Steering wheel module (SWM)	1	Yes
7601	Suspension module (SUM)	1	No
8301	Passenger door module (PDM)	1	No
8302	Driver door module (DDM)	1	No
8527	Power seat module (PSM)	1	No
8711	Climate control module (CCM)	1	Yes
8847	Supplemental restraint system module (SRS)	1	No
8901	Upper electronic module (UEM)	1	No
