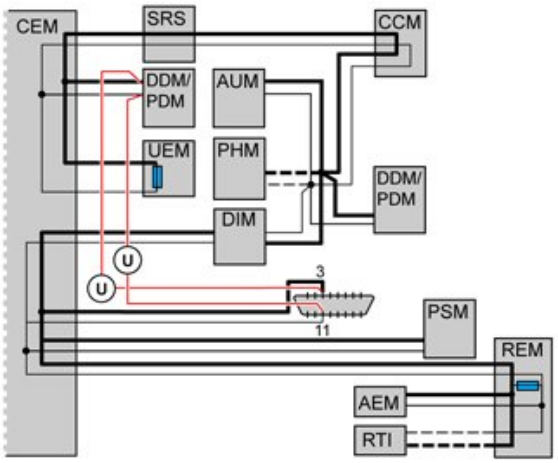
Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy wiring as necessary.

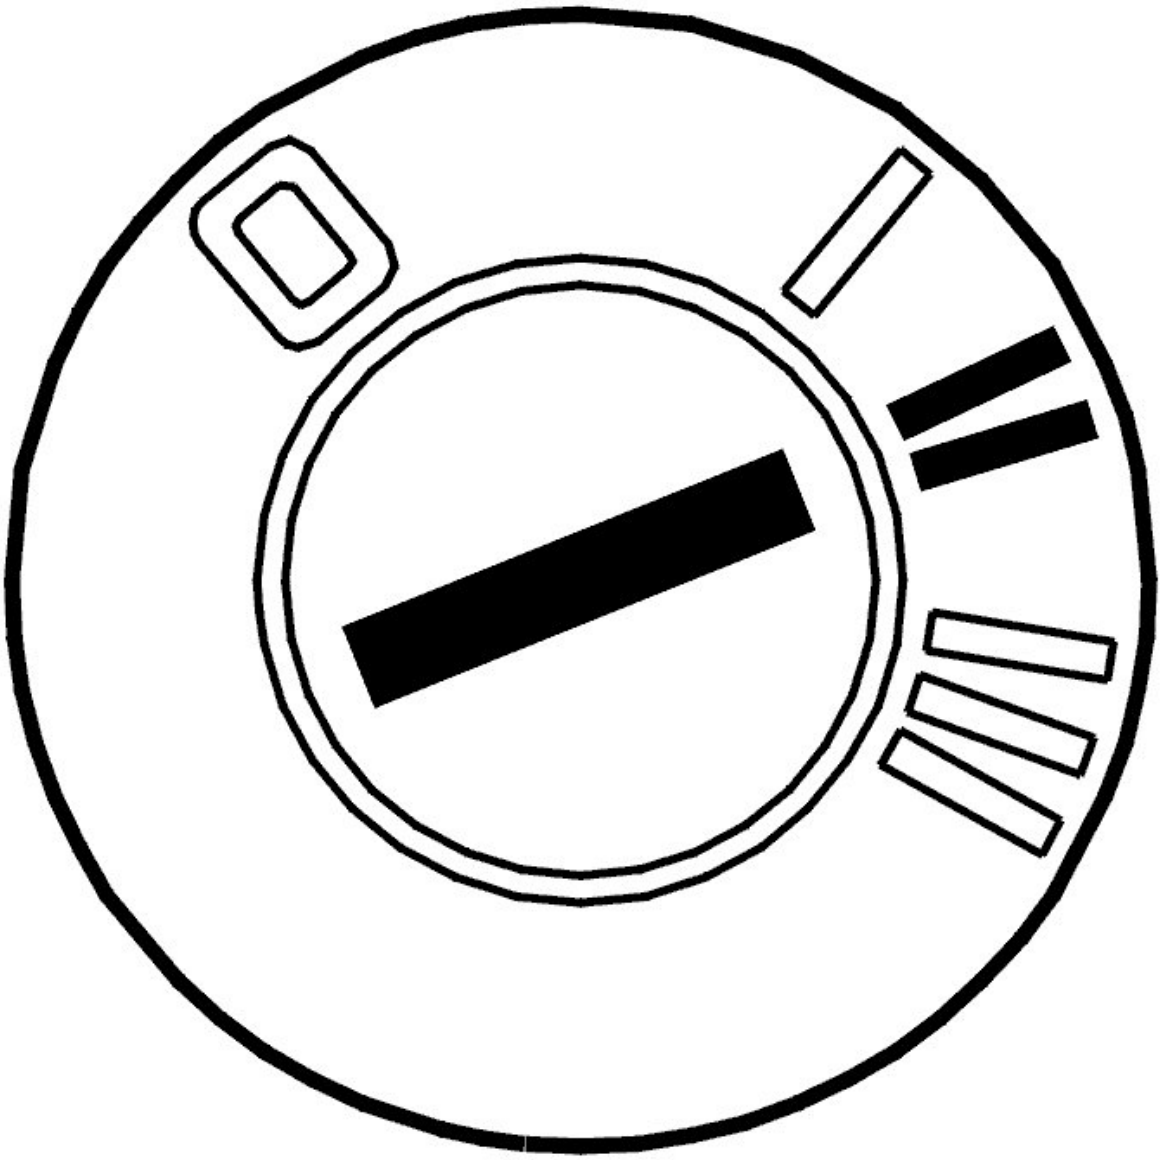
Other information
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

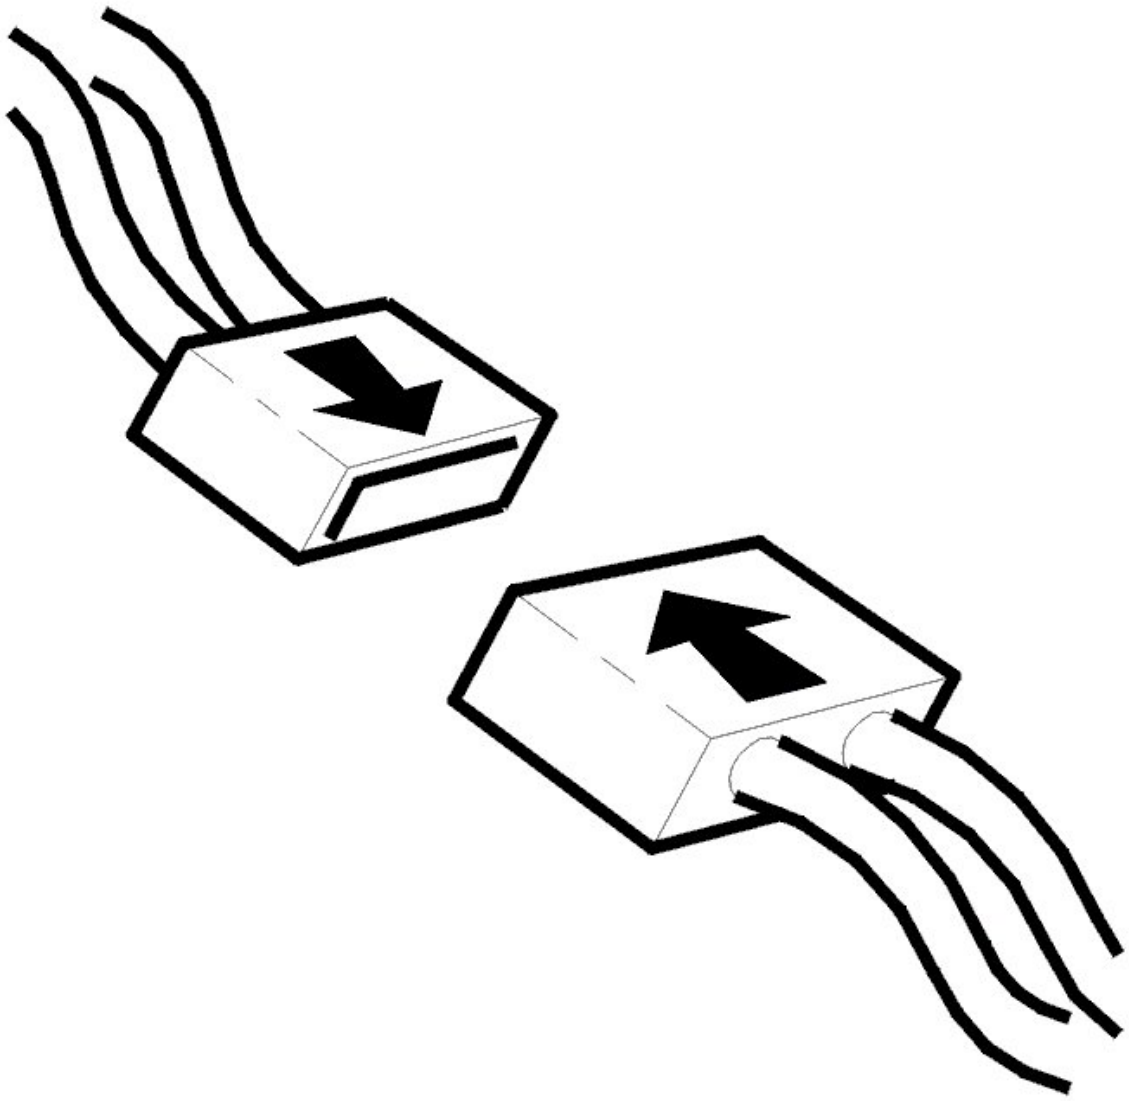


Continue - Verification

Checking the function of the audio module (AUM)

Hint: After carrying out the repair, check that the fault has been remedied.





- Ignition off
- Reconnect the connectors. Reinstall the components
- Ignition on.

Check the power supply for the control module by switching on the radio or playing a CD.
There must be sound from the radio or CD.

Note! Radio reception may be poor indoors. On certain cars, the radio reception may deteriorate if the trunk lid is open.

Is there sound from the radio?

Yes - **Fault Found**

No - Fault-tracing information

Fault-tracing information

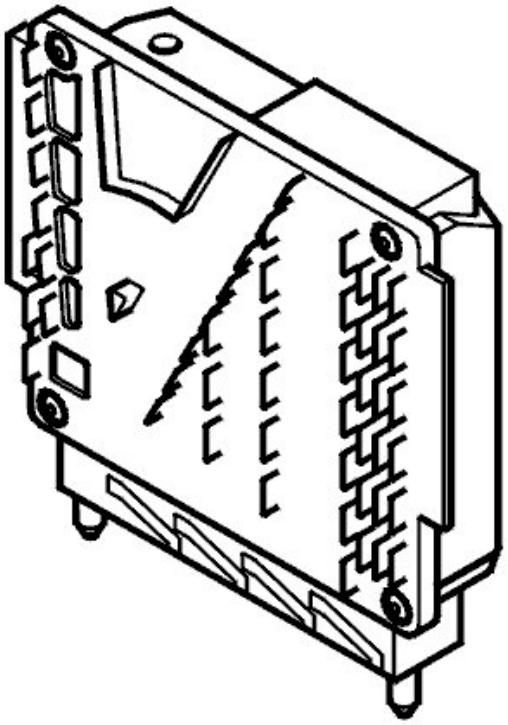
Information
FAULT-TRACING FAILED - **FAULT-TRACING FAILED**

Attempt New Test - Checking the function of the audio module (AUM)

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CEM-1A61

Condition



The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers that communication with the transmission control module (TCM) is not operating.
The diagnostic trouble code (DTC) can be diagnosed when the ignition has been on for more than 10 seconds.

Note! If CEM-1A6X diagnostic trouble codes (DTCs) are stored, the central electronic module (CEM) must not be replaced as the diagnostic trouble code (DTC) indicates a communication fault in the Control area network!

Substitute value
- None.

Possible source
- No power supply to the transmission control module (TCM)
- Open-circuit in the ground lead to the transmission control module (TCM)
- Contact resistance in the terminals
- Open-circuit in the wiring for the CAN high speed network to the transmission control module (TCM)
- The transmission control module (TCM) is not intended for this vehicle, for example a used control module with different software/hardware.

Hint: If several diagnostic trouble codes (DTCs) are stored in the central electronic module (CEM) for communication faults with other control modules in the high speed network, this indicates a common fault in the Control area network, see the wiring diagram.

Fault symptom[s]
- No shifting.
- Malfunction indicator lamp (MIL) lit
- Message in the display.

Signal Missing

Signal missing

Checking the power supply and ground for the transmission control module (TCM)

Check that the fuse for the control module is intact.
Check the power supply and ground for the transmission control module (TCM) as follows.
Remedy as necessary.

Other information:
- Checking the power supply and ground terminals, AW50/51 AWD, AW55-50/51SN See: Transmission Control Systems/Testing and Inspection/Component Tests and General Diagnostics/Checking the Power Supply and Ground Terminals for the Control Module

General information

Note! Figures shown are only examples.

Hint: For general information about CAN-troubleshooting, see:

- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

General about CAN-related diagnostic trouble codes.
CEM-DF01 - DF17can only be stored in Central electronic module (CEM). These diagnostic trouble codes are stored when an electric fault is detected in CAN-lines. Start with these diagnostic trouble codes first.
CEM-1AXX only stored in Central electronic module (CEM). One diagnostic trouble code for every control module on the CAN-net. These diagnostic trouble codes indicate that Central electronic module (CEM) does not receive any reply from other control modules.
XXX-E000 (HS-CAN)/E001 (LS-CAN) can be stored in all CAN-connected control modules. These diagnostic trouble codes indicate that the control module has detected interference on the CAN-net.
XXX-E003 can be stored in all CAN-connected control modules except in Central electronic module (CEM). The control modules on the CAN-net listen for a message (identity number) that is sent out at regular intervals from Central electronic module (CEM). This diagnostic trouble code indicates that the control module has not received any identity number, or that the expected number is not correct. Interference on the CAN-net can also store this diagnostic trouble code.

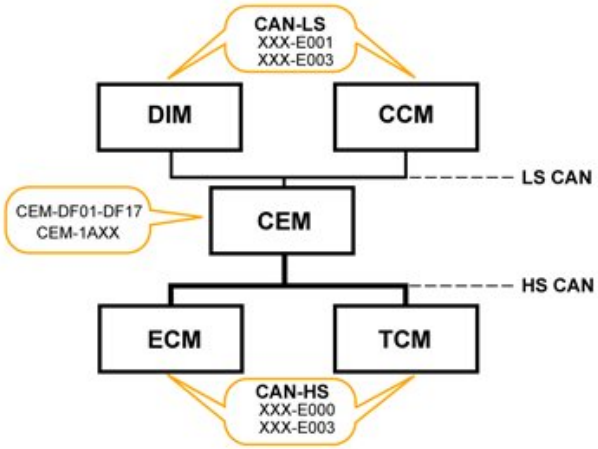
Note! In case of CAN-related faults, it is likely that a combination of above diagnostic trouble codes occur.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

If diagnostic trouble codes (DTCs) for communication faults can be read off from a control module, the fault is probably intermittent.
Intermittent fault in the voltage supply and ground to a control module on the CAN network results in the Central electronic module (CEM) storing a diagnostic trouble code (DTC) for an open-circuit in communication with the control module where the voltage supply does not work. There will probably not be a diagnostic trouble code (DTC) in the control module where the open-circuit in the voltage supply occurred as the control module cannot store a diagnostic trouble code (DTC) when it is not supplied with power.

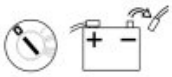
Note! Central electronic module (CEM) should not be replaced in case of CAN-fault, unless troubleshooting reveals that Central electronic module (CEM) has an internal fault.

Caution! During this fault-tracing use the wiring diagram to provide support when taking readings.



Continue - Checking resistance in CAN-net

Checking resistance in CAN-net



- Ignition off
- Disconnect the battery negative lead
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #3 and #11. The resistance should be approx. 55 - 65 ohms.
- If resistance is approx. 120 ohms, this indicates open circuit in the circuit so that only one terminating resistor (120 ohms) has been measured.
- If resistance is above 1 kohms this indicates open circuit/high contact resistance somewhere in the circuit.
- If resistance is below 55 ohms this indicates short-circuiting/contact resistance between the CAN-lines somewhere in the circuit.

Hint: For LS-CAN (Low Speed), terminating resistors are located in Upper electronic module (UEM) and Rear electronic module (REM).

Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

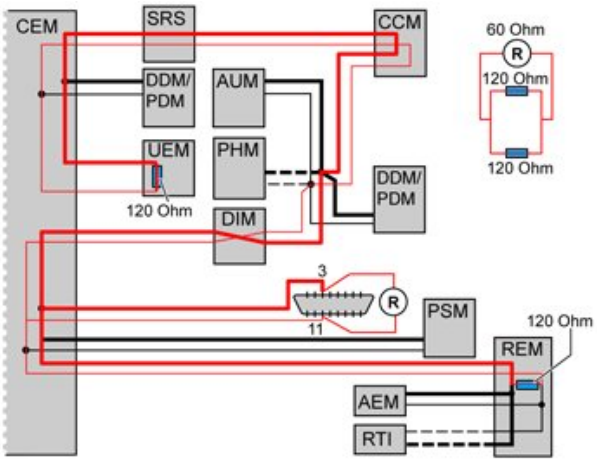
Note! Resistance measurement measures only main lines in the CAN-net (in circuit where both terminating resistors are found), not branches to certain control modules. See wiring diagram for vehicle model in question. Open circuit on branching without a terminating resistor cannot be detected with this measurement. However, short-circuiting on a branch can be detected. To measure resistance in the CAN-net to control modules located in a branching of their own, the measurement shall be done against the CAN-net at that control module. The values shall be as above.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy as necessary.

Other information
- Battery, disconnecting See: Starting and Charging/Battery/Service and Repair/Procedures/Battery, Disconnecting
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

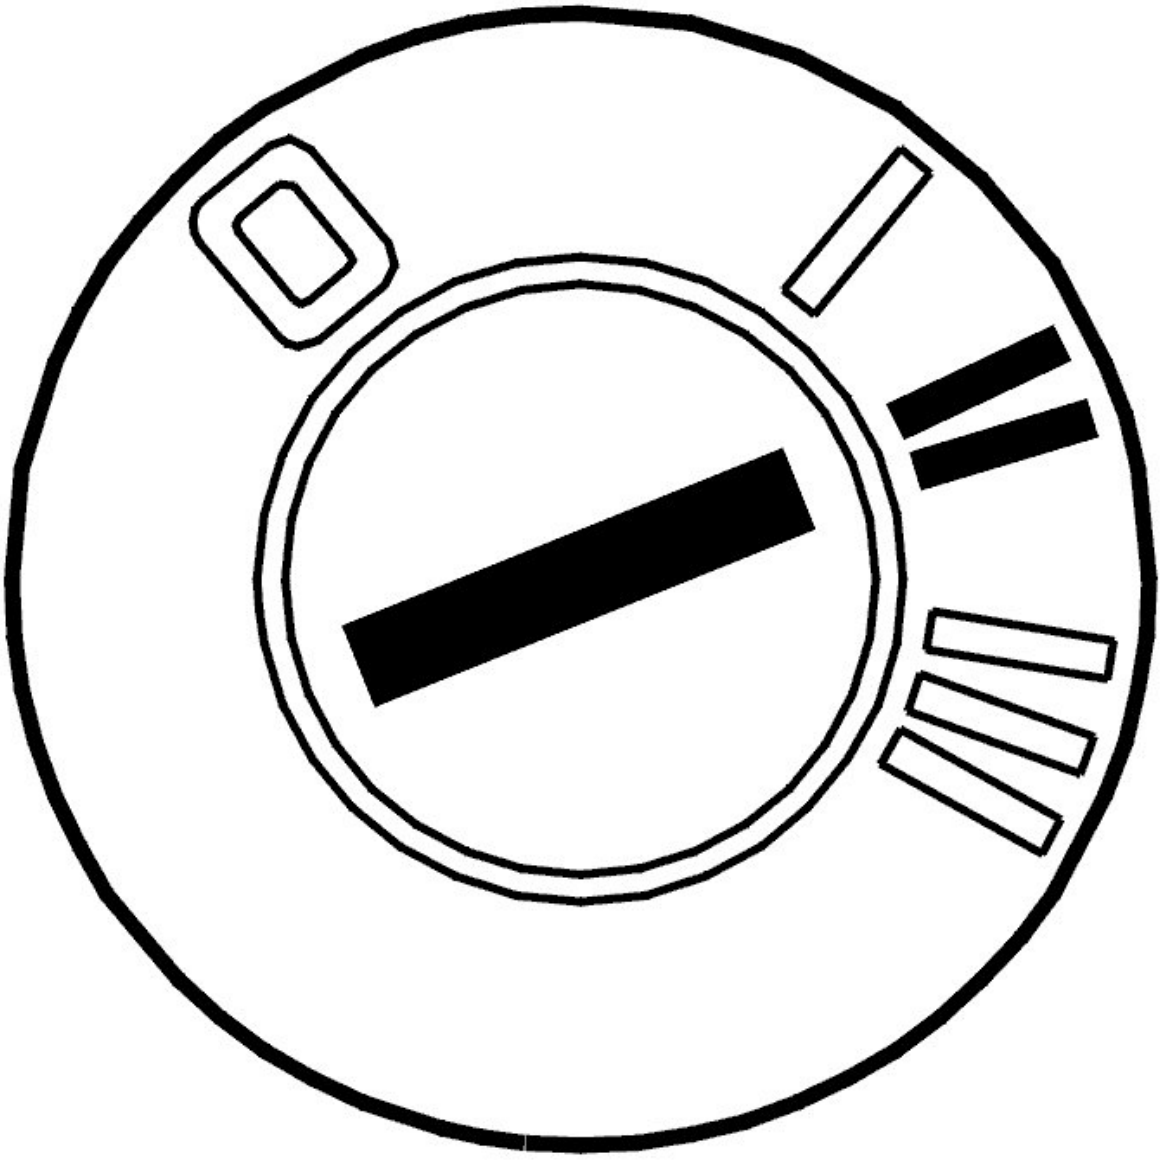


Was a fault detected?

Yes - Verification

No - Checking short-circuiting to ground/voltage in CAN-net

Checking the amount of traffic on the LS-CAN



- Connect the battery
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
Faults in the CAN network may be due to a control module sending faulty messages that disrupt normal communication. When messages are sent incorrectly, this results in a considerable increase in the amount of traffic on the CAN network. The load can be checked by reading the average value of the voltage on the CAN cables in relation to ground.
For further information, see the wiring diagram.
Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #3 and #4 (ground). The voltage should be approx: 2,8 - 3,2 V.
- #11 and #4 (ground). The voltage should be approx: 1,8 - 2,2 V.
- #3 and #11. The voltage shall be between approx. 0.55-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Hint: DiCE Error Frame Finder can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools: **951 3010** (memory card) as well as associated TJ 20402.

- Ignition on.
- Connect DiCE Error Frame Finder to the diagnostics socket.
- Note the blue LED-indicator. The indicator flashes to show detection of fault messages.

Note! Certain interference may occur without any real fault!

Cable fault

- Shake the cables lightly and pull lightly on the connections during the check to locate any fault. Note the blue LED-indicator.

"Chatting" control modules

- "Chatting" control modules may be difficult to find and troubleshooting may take time. Let the vehicle stand with DiCE connected for an extended time period. Afterwards, activate functions to provoke a malfunction. It may take up to several hours before the fault messages are sent. When the indicator starts to flash, remove the fuse for one control module at a time until the indicator stops flashing. When the indicator stops flashing, restore the fuse for the relevant control module and check that the indicator starts to flash again. Then it is likely that the problem is identified.

Remedy wiring as necessary.

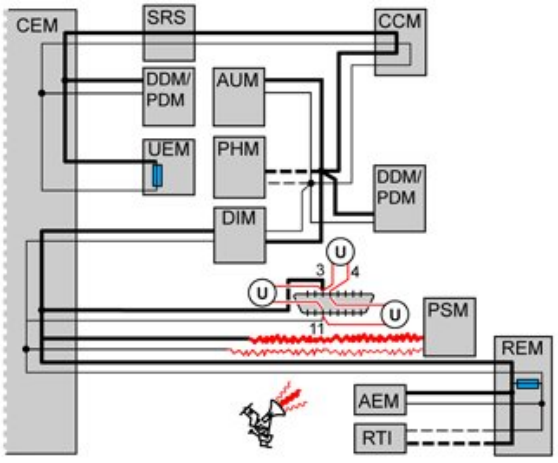
- Battery, disconnecting See: Starting and Charging/Battery/Service and Repair/Procedures/Battery, Disconnecting
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals



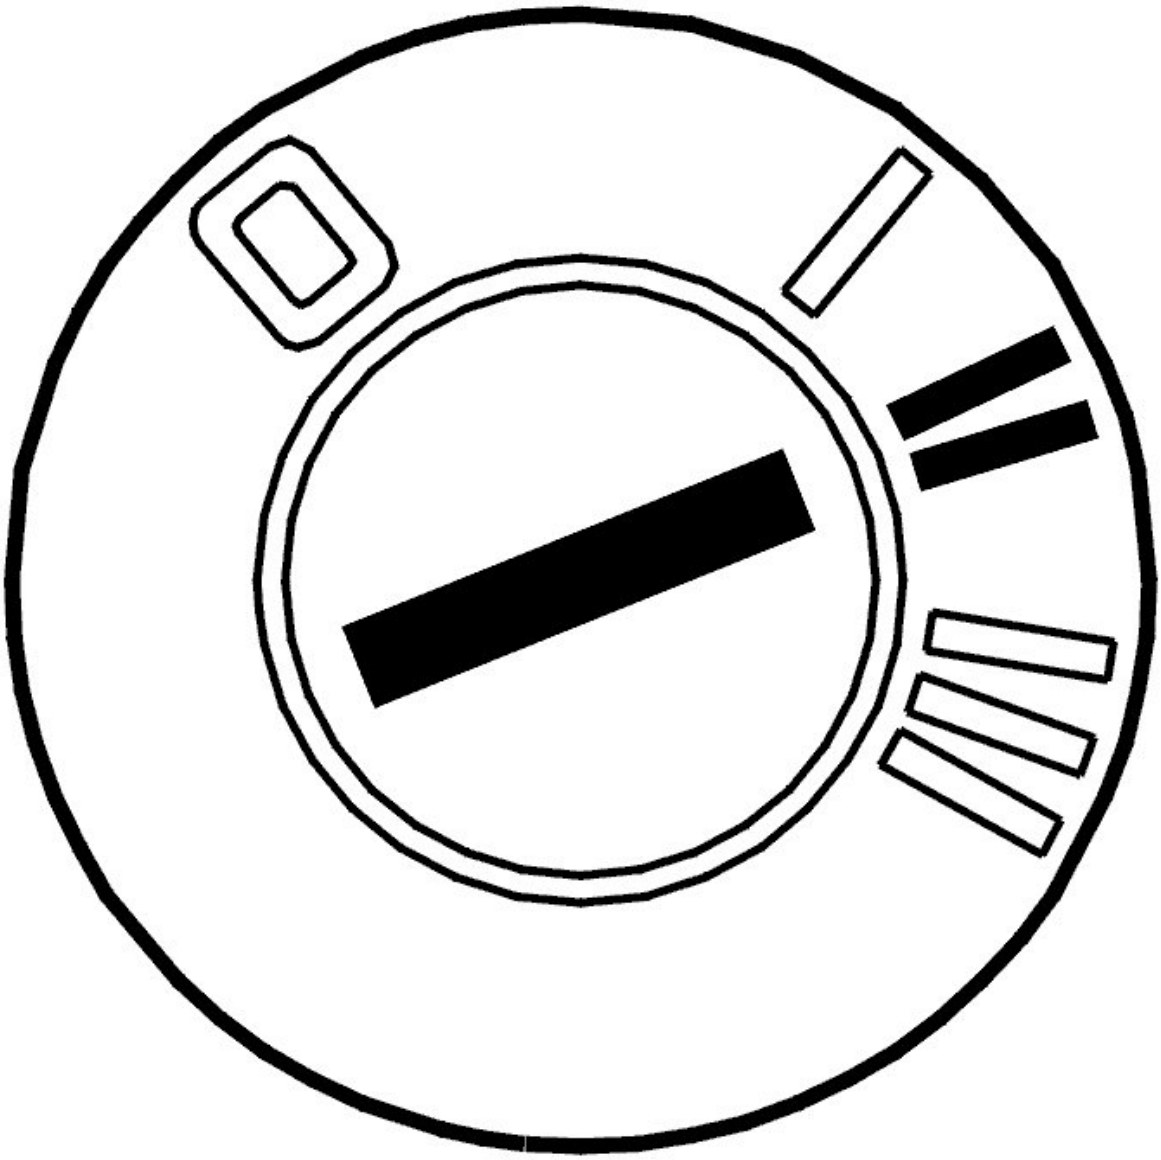
Was a fault detected?

Yes - Identifying a control module in the CAN network

No - Checking voltage-drop in cable for CAN-H and CAN-L, respectively

---

Identifying a control module in the CAN network



Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:

- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Hint: DiCE Error Frame Finder can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools: **951 3010** (memory card) as well as associated TJ 20402. If the load on the CAN network is too high, this may be due to a control module transmitting faulty messages on the CAN network. This is called a disruptive control module. The fault may also be due to an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The fault may occur without any of the control modules storing a diagnostic trouble code (DTC). The voltage can be measured between the CAN cables in order to check the load on the CAN network.

Note! It is not necessarily the control module that has set the diagnostic trouble code that communicates incorrectly. Faulty messages can come from any control module in the same section of the CAN network. However, faulty communication in one network cannot affect the communication on the other network. In other words, faulty communication on the LS-CAN cannot disrupt communication on the HS-CAN and vice versa.

- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Check communication/load on CAN-net by measuring voltage between CAN-L and CAN-H. Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #3 and #11. The average value of the voltage must be approximately 0.6-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage

is considerably higher than the above stated values.
In order to identify which control module has faulty communication, cut the power supply to one control module at a time. Check the voltage in the CAN cables again. The easiest way to cut the power supply is to remove the fuse(s) for the relevant control module. Repeat until the voltage between the CAN wiring drops to the normal level.

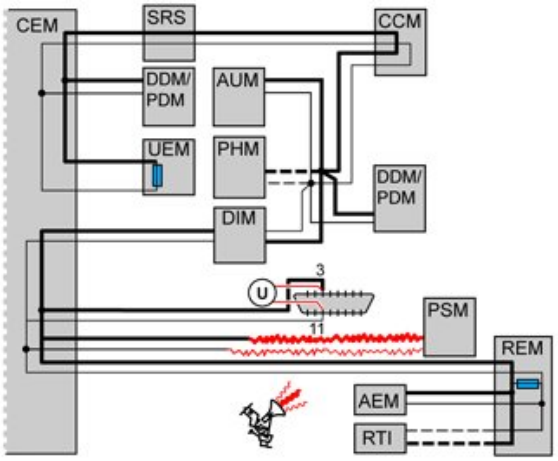
Note! When connecting and disconnecting certain control modules, diagnostic trouble codes (DTCs) may be stored in other control modules.

Hint: When the suspected defective control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the malfunction appears and disappears. Switch off the ignition between each check.

Note! Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.

A control module that is communicating incorrectly must be replaced. See Repairing and installing/Removing, replacing and installing.

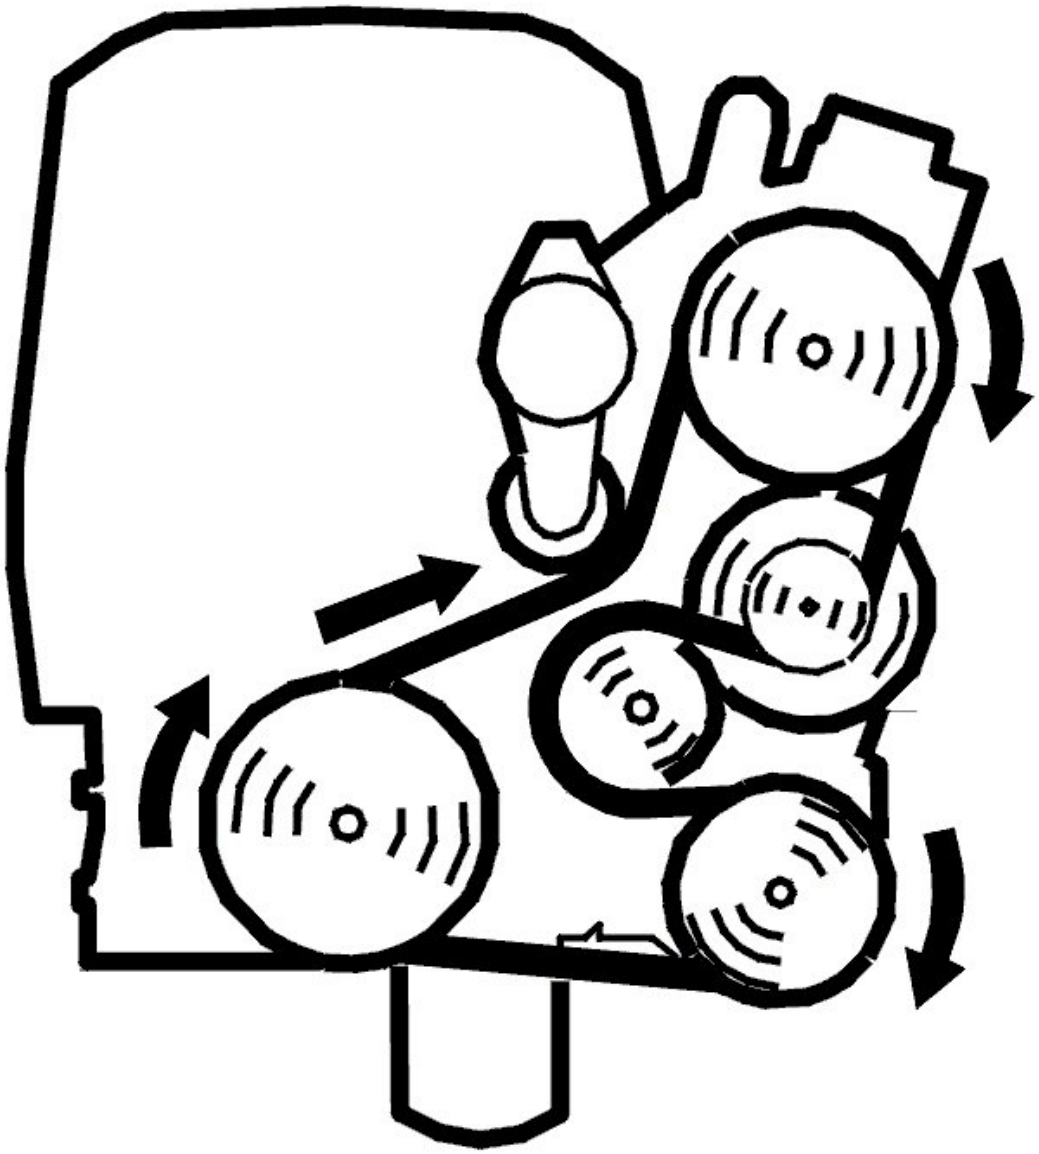
Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

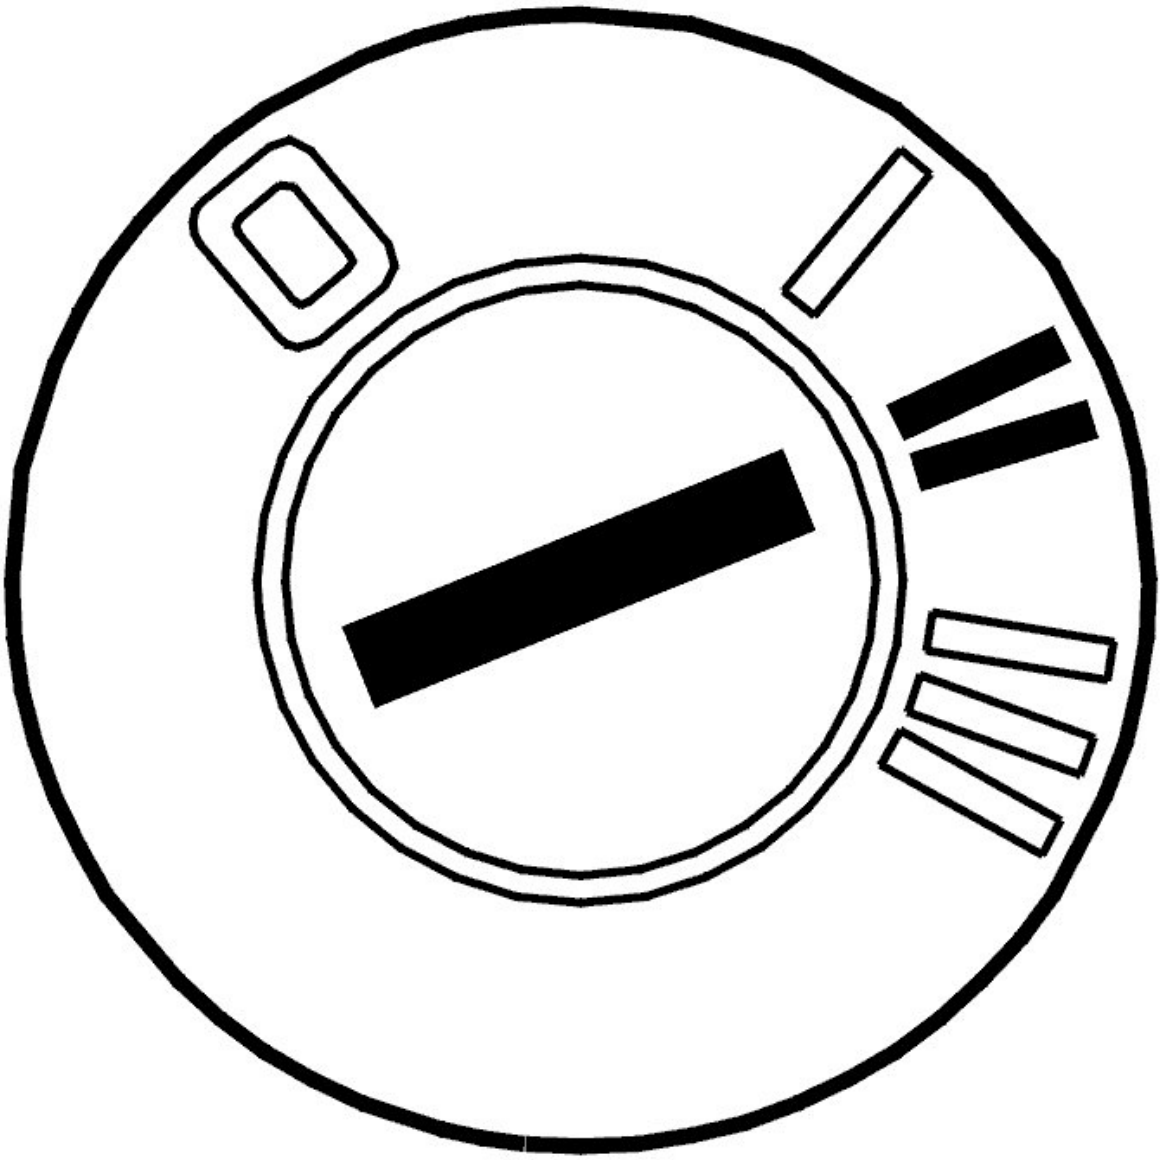


Continue - Verification

Verification

Hint: After rectifying a fault, a verification should be carried out.





- Reinstall the connectors, components etc.
- Ignition on.

Note! For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

- Erase diagnostic trouble codes (DTCs) in all control modules.
- Ignition off.
- Ignition on.
- Start the vehicle. Allow the vehicle to run for 10 minutes. Start the engine. Allow the engine to run at idle speed for 10 minutes
- Read out the diagnostic trouble codes in the vehicle via the DIAGNOSTICS tab.

Does the diagnostic trouble code (DTC) for faulty communication return?

Yes - Fault-tracing information

No - Fault Found

Fault-tracing information

Fault-tracing information

The fault should have been detected and remedied. As this is not the case fault-tracing has failed.
Exit fault-tracing for this diagnostic trouble code (DTC) or make another attempt.

Do you want to exit fault-tracing?

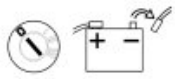
Yes - **FAULT-TRACING FAILED**

No - **Attempt New Test**

FAULT-TRACING FAILED - **FAULT-TRACING FAILED**

Attempt New Test - Signal missing

Checking short-circuiting to ground/voltage in CAN-net



- Ignition off.
- Disconnect the battery negative lead.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Checking for a short-circuit to ground

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #3 and #4 (ground). Measurement is shown in the figure. The resistance should be above 1 kohms.
- #11 and #4 (ground). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and ground.

Checking for a short-circuit to voltage

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #3 and #16 (voltage). Measurement is shown in the figure. The resistance should be above 1 kohms.
- #11 and #16 (voltage). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and voltage cable.
Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

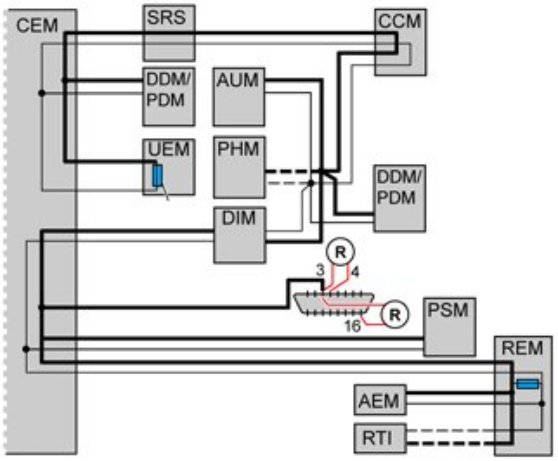
Hint: Part the CAN-net at suitable points to decide where a short-circuit may be found.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy as necessary.

Other information
- Battery, disconnecting See: Starting and Charging/Battery/Service and Repair/Procedures/Battery, Disconnecting
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

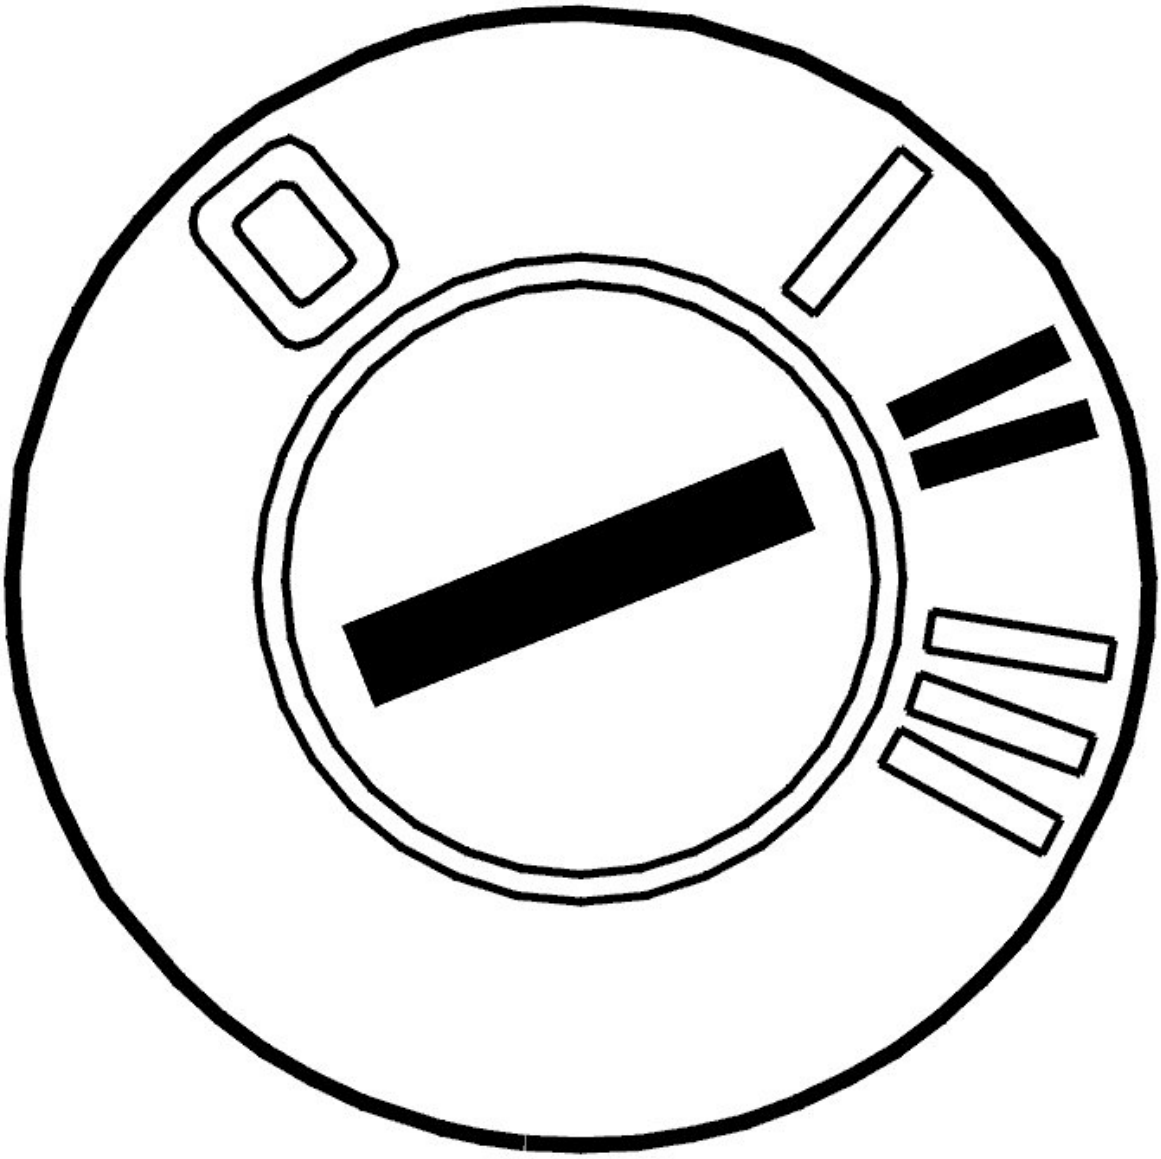


Was a fault detected?

Yes - Verification

No - Checking the amount of traffic on the LS-CAN

Checking voltage-drop in cable for CAN-H and CAN-L, respectively



- Connect the battery.
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

In principle, the voltage measured in each cable in the CAN-net shall be the same at each control module in the network. This means that the voltage-drop in the cable for CAN-H and CAN-L, respectively, between the control modules should be very low. If there is a voltage-difference in the CAN-lines between the diagnostics socket/Central electronic module (CEM) and a control module due to, e.g., contact resistance in a connector or branching, communication may be lost/interfered with. Check if there is voltage-drop in the cable for CAN-H and CAN-L between the diagnostics socket/Central electronic module (CEM) and the control module where there is problem with communication.
Carry out the following:
Measure voltage between the following connections on the OBDII-box/diagnostics socket.
- #3 and corresponding connection on relevant control module for CAN-H. The voltage shall be lower than 50 mV.
- #11 and corresponding connection on relevant control module for CAN-L. The voltage shall be lower than 50 mV.

If voltage is too high, this indicates too high contact resistance in cable, connector, or branching. Check the circuit between the diagnostics socket and control module in question for contact resistance and oxidation.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy wiring as necessary.

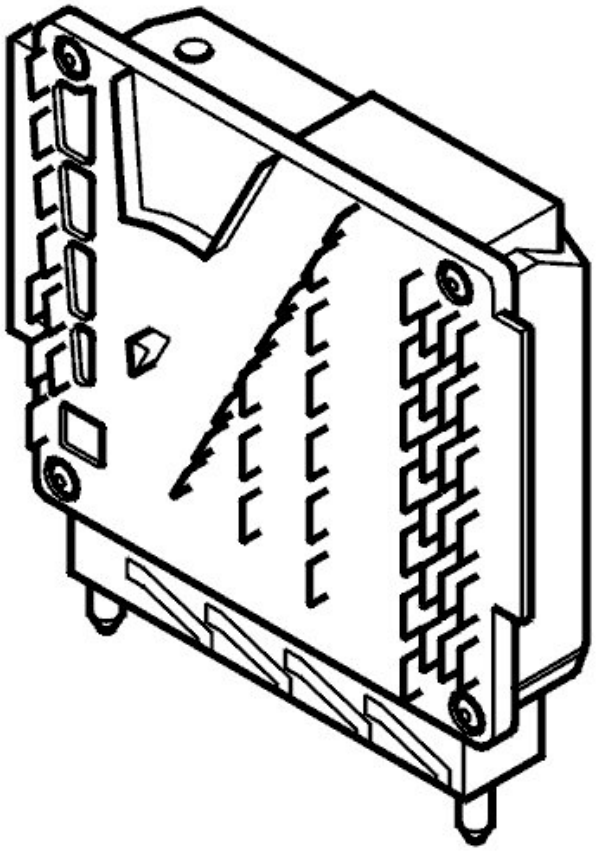
CEM-1A62

Diagnostic trouble code (DTC) information CEM-1A62

Condition



The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers that communication with the engine control module (ECM) is not operating.
The diagnostic trouble code (DTC) can be diagnosed when the ignition has been on for more than 10 seconds.

Note! If CEM-1A6X diagnostic trouble codes (DTCs) are stored, the central electronic module (CEM) must not be replaced as the diagnostic trouble code (DTC) indicates a communication fault in the Control area network!

Substitute value
- None.

Possible source
- No power supply to the engine control module (ECM)
- Open-circuit in the ground lead for the engine control module (ECM)
- Contact resistance in the terminals
- Open-circuit in the wiring for the CAN high speed network to the engine control module (ECM)
- The engine control module (ECM) is not intended for this vehicle, for example a used control module with different software/hardware.

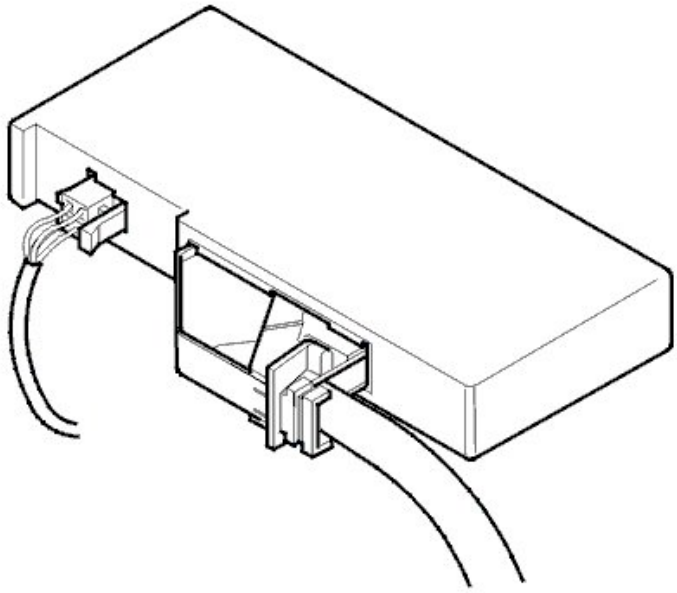
Hint: If several diagnostic trouble codes (DTCs) are stored in the central electronic module (CEM) for communication faults with other control modules in the high speed network, this indicates a common fault in the Control area network, see the wiring diagram.

Fault symptom[s]
- The engine does not start.
- Engine cuts out when running
- Engine feels sluggish.
- Malfunction indicator lamp (MIL) lit.
- Message in the display.

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CEM-1A63

Condition



The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers that communication with the accessory electronic module (AEM) is not operating.
The diagnostic trouble code (DTC) can be diagnosed when the ignition has been on for more than 10 seconds.

Note! If CEM-1A6X diagnostic trouble codes (DTCs) are stored, the central electronic module (CEM) must not be replaced as the diagnostic trouble code (DTC) indicates a communication fault in the Control area network!

Substitute value
- None.

Possible source
- No power supply to the accessory electronic module (AEM)
- Open-circuit in the ground lead for the accessory electronic module (AEM)
- Contact resistance in the terminals
- Open-circuit in the wiring for the CAN low speed network to the accessory electronic module (AEM)
- The accessory electronic module (AEM) is not intended for this vehicle, for example a used control module with different software/hardware.

Hint: If several diagnostic trouble codes (DTCs) are stored in the central electronic module (CEM) for communication faults with other control modules in the low speed network, this indicates a common fault in the Control area network, see the wiring diagram.

Fault symptom[s]
- Accessories connected to the control module do not function.

Signal Missing

Signal missing

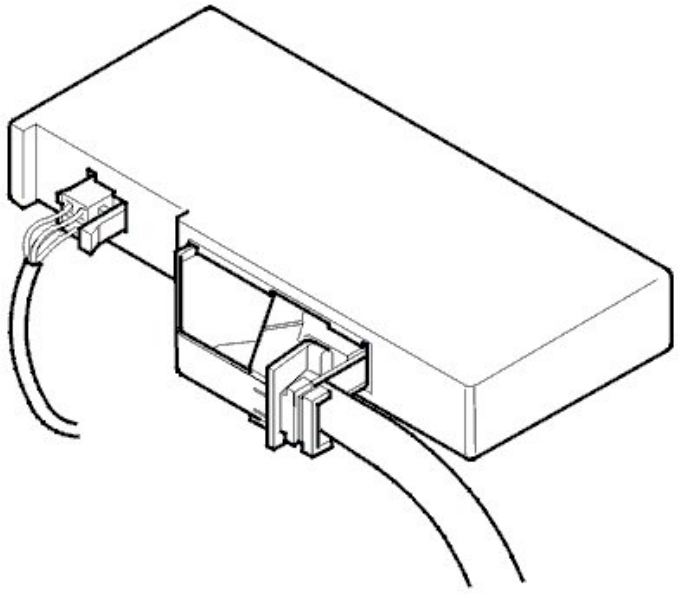
Checking communication with the accessory electronic module (AEM)

Hint: The CAN communication with the control module is probably OK if the control module ID can be read off. In that case the fault is probably intermittent and will then be more difficult to trace.

- Try to communicate with the accessory electronic module (AEM) by reading off the control module ID
- Click on the symbol for VCT2000 to begin reading off



Continue - Signal missing

Signal missing

General information

Note! Figures shown are only examples.

Hint: For general information about CAN-troubleshooting, see:

- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

General about CAN-related diagnostic trouble codes.
CEM-DF01 - DF17can only be stored in Central electronic module (CEM). These diagnostic trouble codes are stored when an electric fault is detected in CAN-lines. Start with these diagnostic trouble codes first.
CEM-1AXX only stored in Central electronic module (CEM). One diagnostic trouble code for every control module on the CAN-net. These diagnostic trouble codes indicate that Central electronic module (CEM) does not receive any reply from other control modules.
XXX-E000 (HS-CAN)/E001 (LS-CAN) can be stored in all CAN-connected control modules. These diagnostic trouble codes indicate that the control module has detected interference on the CAN-net.
XXX-E003 can be stored in all CAN-connected control modules except in Central electronic module (CEM). The control modules on the CAN-net listen for a message (identity number) that is sent out at regular intervals from Central electronic module (CEM). This diagnostic trouble code indicates that the control module has not received any identity number, or that the expected number is not correct. Interference on the CAN-net can also store this diagnostic trouble code.

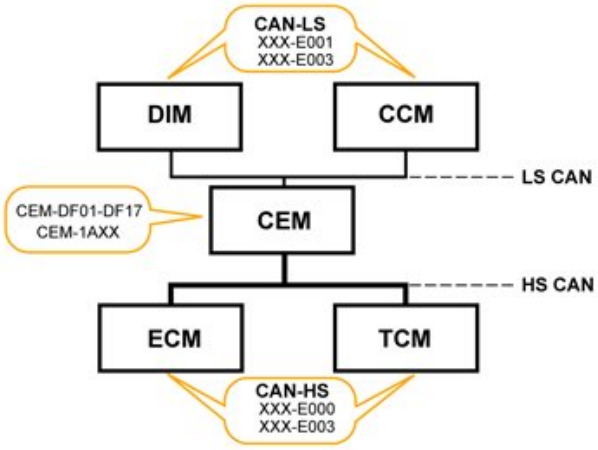
Note! In case of CAN-related faults, it is likely that a combination of above diagnostic trouble codes occur.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

If diagnostic trouble codes (DTCs) for communication faults can be read off from a control module, the fault is probably intermittent.
Intermittent fault in the voltage supply and ground to a control module on the CAN network results in the Central electronic module (CEM) storing a diagnostic trouble code (DTC) for an open-circuit in communication with the control module where the voltage supply does not work. There will probably not be a diagnostic trouble code (DTC) in the control module where the open-circuit in the voltage supply occurred as the control module cannot store a diagnostic trouble code (DTC) when it is not supplied with power.

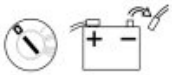
Note! Central electronic module (CEM) should not be replaced in case of CAN-fault, unless troubleshooting reveals that Central electronic module (CEM) has an internal fault.

Caution! During this fault-tracing use the wiring diagram to provide support when taking readings.



Continue - Checking resistance in CAN-net

Checking resistance in CAN-net



- Ignition off
- Disconnect the battery negative lead
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #3 and #11. The resistance should be approx. 55 - 65 ohms.
- If resistance is approx. 120 ohms, this indicates open circuit in the circuit so that only one terminating resistor (120 ohms) has been measured.
- If resistance is above 1 kohms this indicates open circuit/high contact resistance somewhere in the circuit.
- If resistance is below 55 ohms this indicates short-circuiting/contact resistance between the CAN-lines somewhere in the circuit.

Hint: For LS-CAN (Low Speed), terminating resistors are located in Upper electronic module (UEM) and Rear electronic module (REM).

Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

Note! Resistance measurement measures only main lines in the CAN-net (in circuit where both terminating resistors are found), not branches to certain control modules. See wiring diagram for vehicle model in question. Open circuit on branching without a terminating resistor cannot be detected with this measurement. However, short-circuiting on a branch can be detected. To measure resistance in the CAN-net to control modules located in a branching of their own, the measurement shall be done against the CAN-net at that control module. The values shall be as above.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy as necessary.

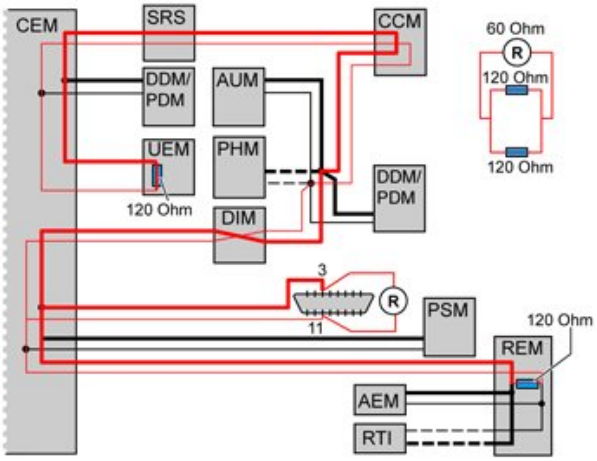
Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

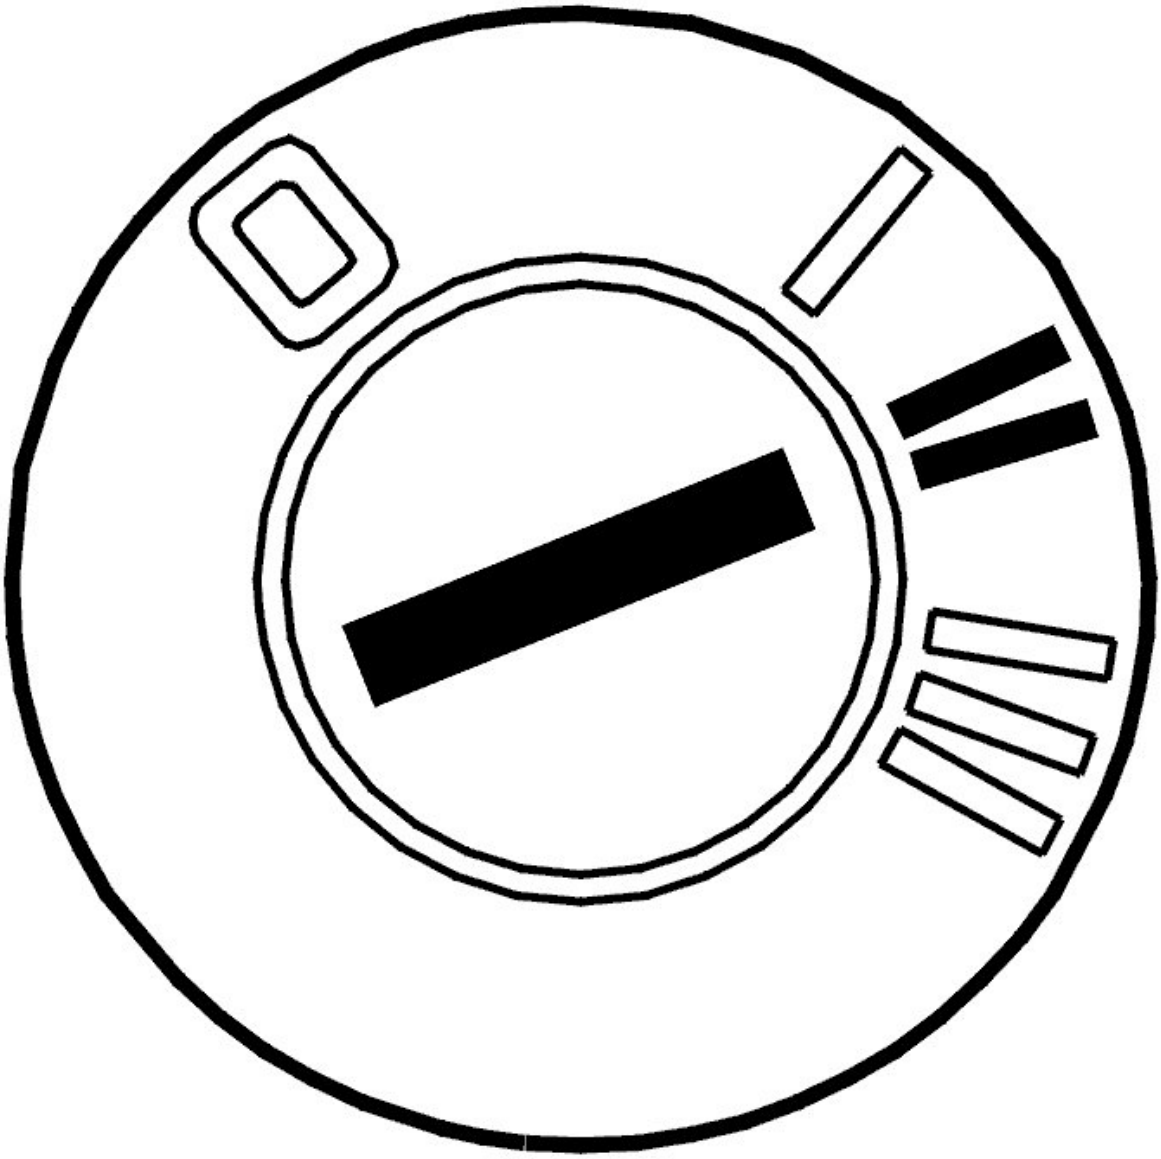


Was a fault detected?

Yes - Verification

No - Checking short-circuiting to ground/voltage in CAN-net

Checking the amount of traffic on the LS-CAN



- Connect the battery
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
Faults in the CAN network may be due to a control module sending faulty messages that disrupt normal communication. When messages are sent incorrectly, this results in a considerable increase in the amount of traffic on the CAN network. The load can be checked by reading the average value of the voltage on the CAN cables in relation to ground.
For further information, see the wiring diagram.
Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #3 and #4 (ground). The voltage should be approx: 2,8 - 3,2 V.
- #11 and #4 (ground). The voltage should be approx: 1,8 - 2,2 V.
- #3 and #11. The voltage shall be between approx. 0.55-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Hint: DiCE Error Frame Finder can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools: **951 3010** (memory card) as well as associated TJ 20402.

- Ignition on.
- Connect DiCE Error Frame Finder to the diagnostics socket.
- Note the blue LED-indicator. The indicator flashes to show detection of fault messages.

Note! Certain interference may occur without any real fault!

Cable fault

- Shake the cables lightly and pull lightly on the connections during the check to locate any fault. Note the blue LED-indicator.

"Chatting" control modules

- "Chatting" control modules may be difficult to find and troubleshooting may take time. Let the vehicle stand with DiCE connected for an extended time period. Afterwards, activate functions to provoke a malfunction. It may take up to several hours before the fault messages are sent. When the indicator starts to flash, remove the fuse for one control module at a time until the indicator stops flashing. When the indicator stops flashing, restore the fuse for the relevant control module and check that the indicator starts to flash again. Then it is likely that the problem is identified.

Remedy wiring as necessary.

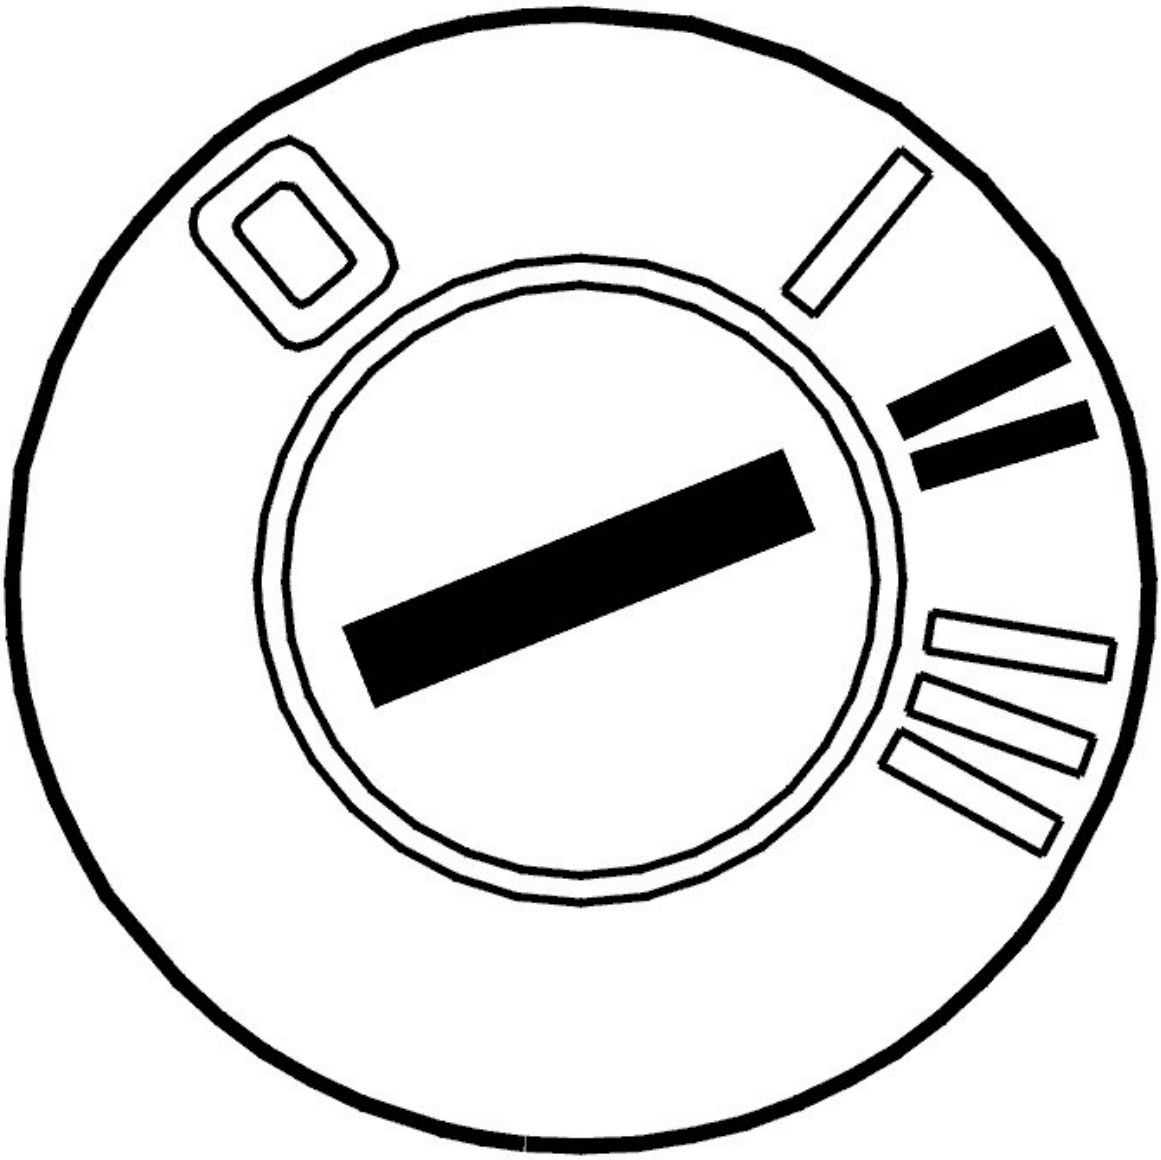
Was a fault detected?

Yes - Identifying a control module in the CAN network

No - Checking voltage-drop in cable for CAN-H and CAN-L, respectively

---

Identifying a control module in the CAN network



Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:

- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Hint: DiCE Error Frame Finder can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools: **951 3010** (memory card) as well as associated TJ 20402. If the load on the CAN network is too high, this may be due to a control module transmitting faulty messages on the CAN network. This is called a disruptive control module. The fault may also be due to an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The fault may occur without any of the control modules storing a diagnostic trouble code (DTC). The voltage can be measured between the CAN cables in order to check the load on the CAN network.

Note! It is not necessarily the control module that has set the diagnostic trouble code that communicates incorrectly. Faulty messages can come from any control module in the same section of the CAN network. However, faulty communication in one network cannot affect the communication on the other network. In other words, faulty communication on the LS-CAN cannot disrupt communication on the HS-CAN and vice versa.

- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Check communication/load on CAN-net by measuring voltage between CAN-L and CAN-H. Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #3 and #11. The average value of the voltage must be approximately 0.6-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage

is considerably higher than the above stated values.
In order to identify which control module has faulty communication, cut the power supply to one control module at a time. Check the voltage in the CAN cables again. The easiest way to cut the power supply is to remove the fuse(s) for the relevant control module. Repeat until the voltage between the CAN wiring drops to the normal level.

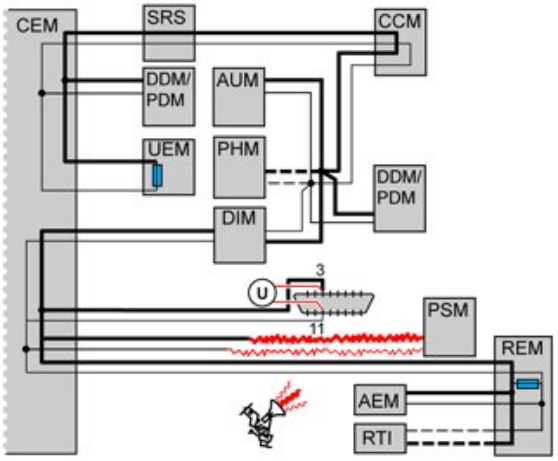
Note! When connecting and disconnecting certain control modules, diagnostic trouble codes (DTCs) may be stored in other control modules.

Hint: When the suspected defective control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the malfunction appears and disappears. Switch off the ignition between each check.

Note! Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.

A control module that is communicating incorrectly must be replaced. See Repairing and installing/Removing, replacing and installing.

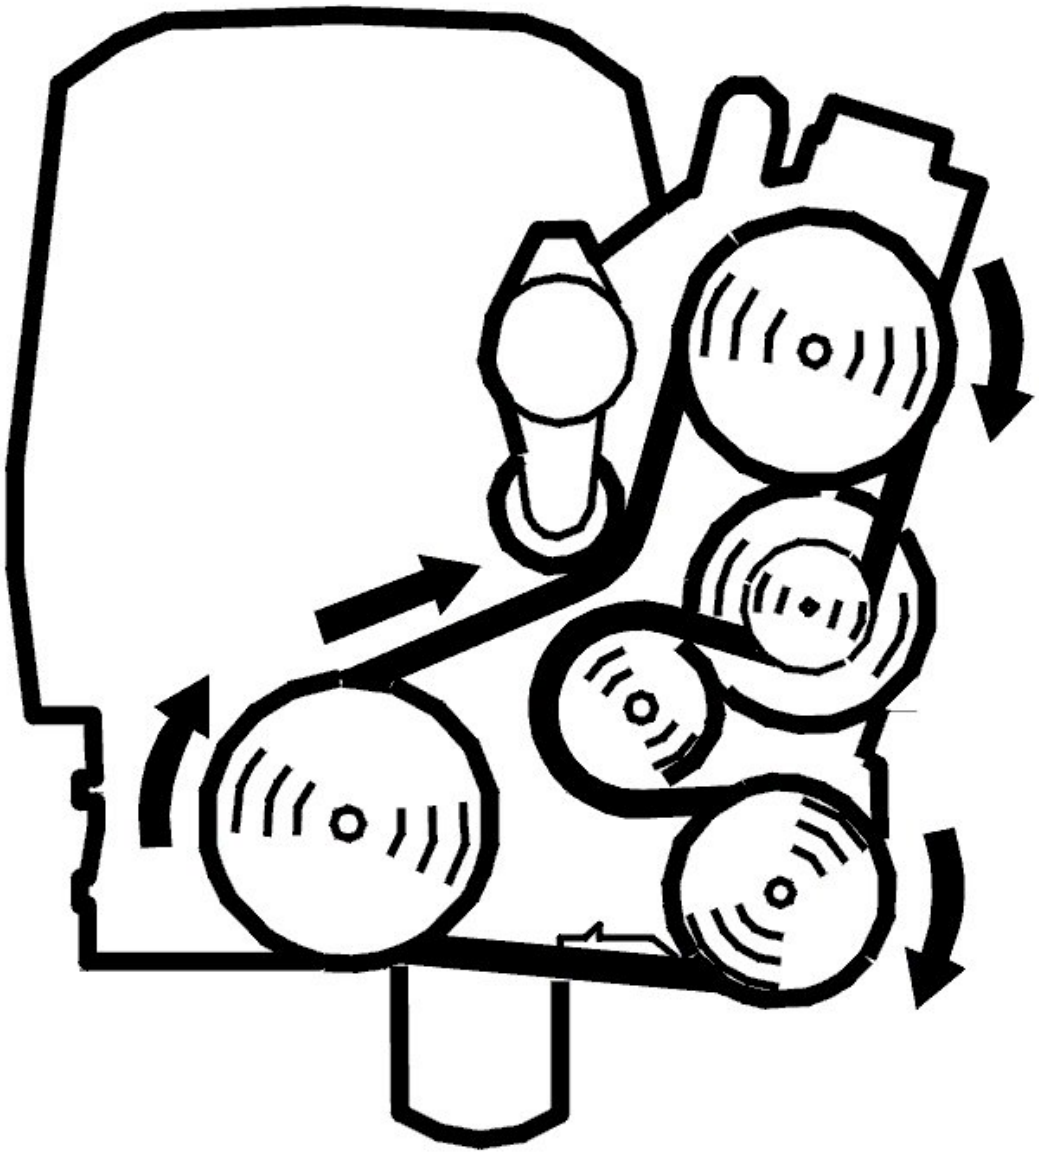
Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

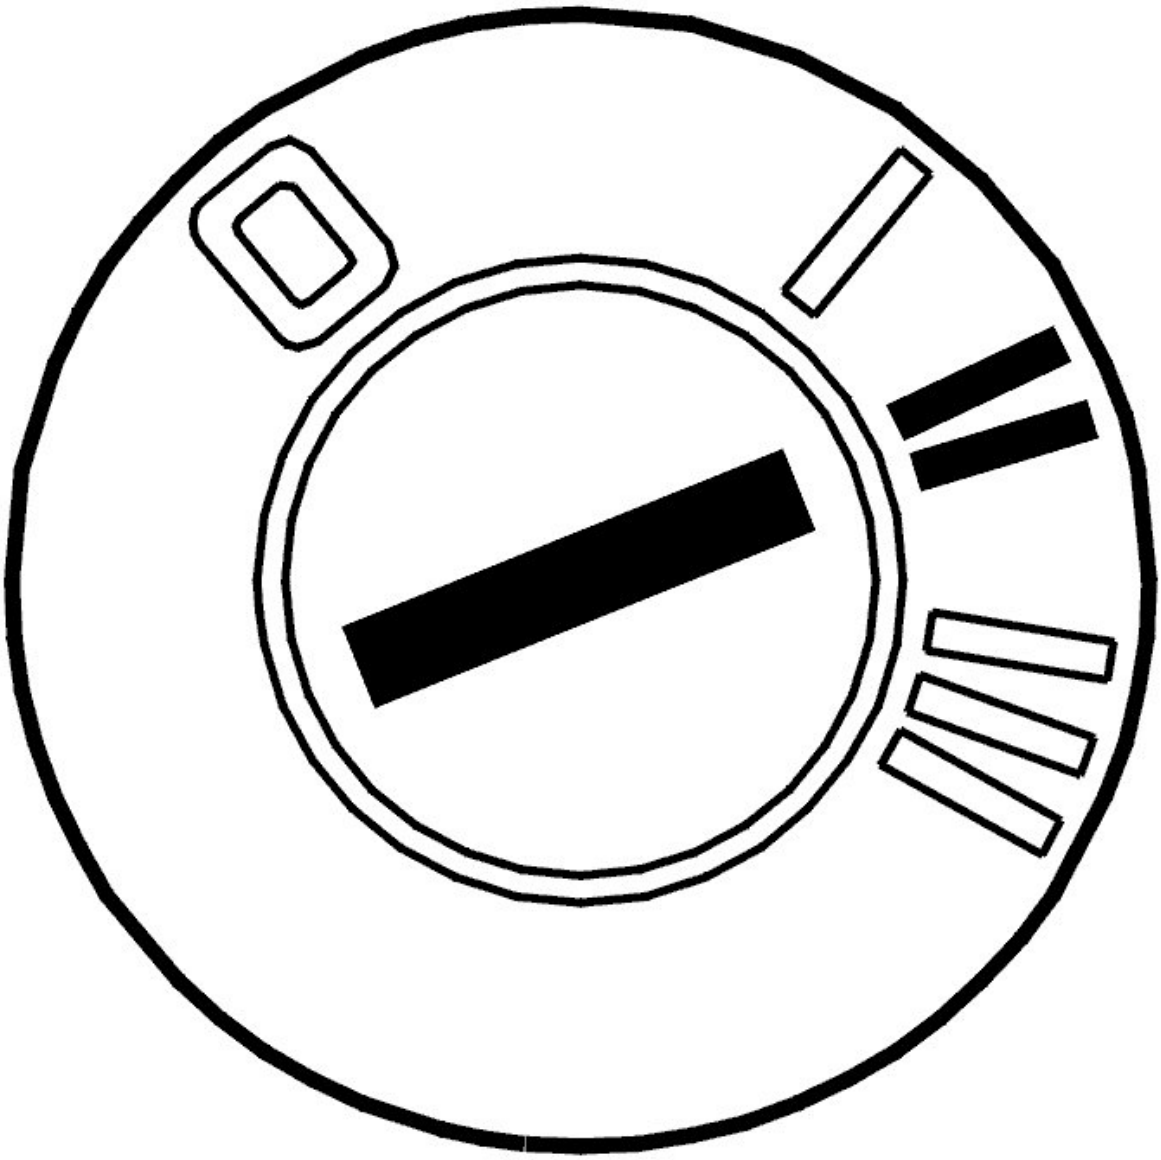


Continue - Verification

Verification

Hint: After rectifying a fault, a verification should be carried out.





- Reinstall the connectors, components etc.
- Ignition on.

Note! For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

- Erase diagnostic trouble codes (DTCs) in all control modules.
- Ignition off.
- Ignition on.
- Start the vehicle. Allow the vehicle to run for 10 minutes. Start the engine. Allow the engine to run at idle speed for 10 minutes
- Read out the diagnostic trouble codes in the vehicle via the DIAGNOSTICS tab.

Does the diagnostic trouble code (DTC) for faulty communication return?

Yes - Fault-tracing information

No - Fault Found

Fault-tracing information

Information

Fault-tracing information

The fault should have been detected and remedied. As this is not the case fault-tracing has failed.
Exit fault-tracing for this diagnostic trouble code (DTC) or make another attempt.

Do you want to exit fault-tracing?

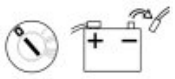
FAULT-TRACING FAILED - FAULT-TRACING FAILED

Attempt New Test - Signal missing

Checking short-circuiting to ground/voltage in CAN-net



- Ignition off.
- Disconnect the battery negative lead.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Checking for a short-circuit to ground

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #3 and #4 (ground). Measurement is shown in the figure. The resistance should be above 1 kohms.
- #11 and #4 (ground). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and ground.

Checking for a short-circuit to voltage

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #3 and #16 (voltage). Measurement is shown in the figure. The resistance should be above 1 kohms.
- #11 and #16 (voltage). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and voltage cable.
Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

Hint: Part the CAN-net at suitable points to decide where a short-circuit may be found.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy as necessary.

Other information
- Battery, disconnecting See: Starting and Charging/Battery/Service and Repair/Procedures/Battery, Disconnecting

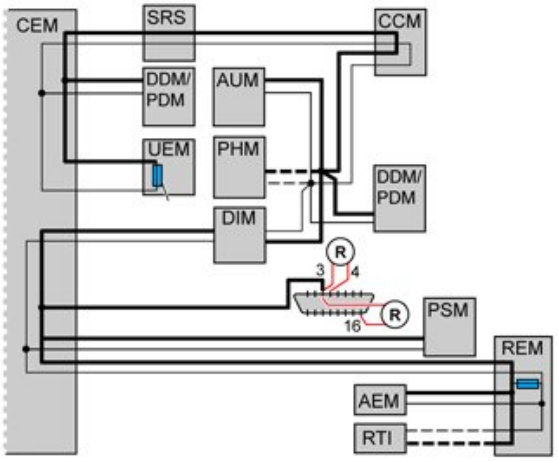
Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

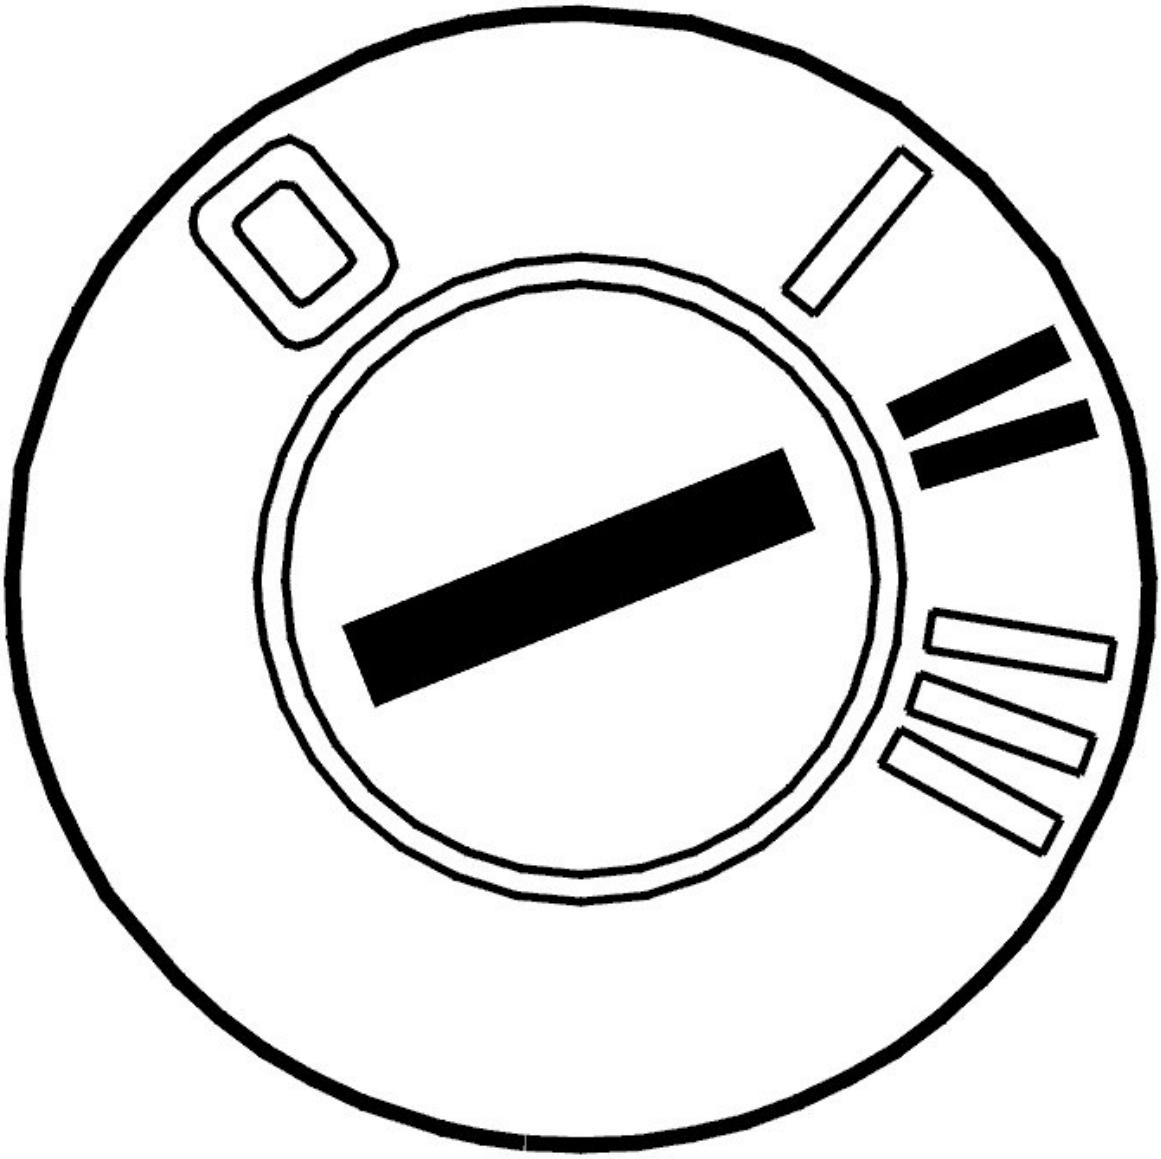


Was a fault detected?

Yes - Verification

No - Checking the amount of traffic on the LS-CAN

Checking voltage-drop in cable for CAN-H and CAN-L, respectively



- Connect the battery.
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

In principle, the voltage measured in each cable in the CAN-net shall be the same at each control module in the network. This means that the voltage-drop in the cable for CAN-H and CAN-L, respectively, between the control modules should be very low. If there is a voltage-difference in the CAN-lines between the diagnostics socket/Central electronic module (CEM) and a control module due to, e.g., contact resistance in a connector or branching, communication may be lost/interfered with. Check if there is voltage-drop in the cable for CAN-H and CAN-L between the diagnostics socket/Central electronic module (CEM) and the control module where there is problem with communication.
Carry out the following:
Measure voltage between the following connections on the OBDII-box/diagnostics socket.
- #3 and corresponding connection on relevant control module for CAN-H. The voltage shall be lower than 50 mV.
- #11 and corresponding connection on relevant control module for CAN-L. The voltage shall be lower than 50 mV.

If voltage is too high, this indicates too high contact resistance in cable, connector, or branching. Check the circuit between the diagnostics socket and control module in question for contact resistance and oxidation.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy wiring as necessary.

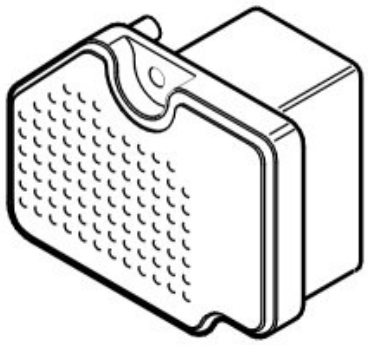
FAULT-TRACING FAILED - FAULT-TRACING FAILED

Attempt New Test - Checking the power supply and ground for the accessory electronic module (AEM)

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CEM-1A64

Condition



The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers that communication with the differential electronic module (DEM) is not operating.
The diagnostic trouble code (DTC) can be diagnosed when the ignition has been on for more than 10 seconds.

Note! If CEM-1A6X diagnostic trouble codes (DTCs) are stored, the central electronic module (CEM) must not be replaced as the diagnostic trouble code (DTC) indicates a communication fault in the Control area network!

Substitute value
- None.

Possible source
- No power supply to the differential electronic module (DEM)
- Open-circuit in the ground lead for the differential electronic module (DEM)
- Contact resistance in the terminals
- Open-circuit in the wiring for the CAN high speed network to the differential electronic module (DEM)
- The differential electronic module (DEM) is not intended for this vehicle, for example a used control module with different software/hardware.

Hint: If several diagnostic trouble codes (DTCs) are stored in the central electronic module (CEM) for communication faults with other control modules in the high speed network, this indicates a common fault in the Control area network, see the wiring diagram.

Fault symptom[s]
- Four wheel drive is not functioning.
- Message in the display
- General warning lamp lit

Signal Missing

Signal missing

Checking the power supply and ground for the differential electronic module (DEM)

Check that the fuse for the control module is intact.
Checking the power supply and ground terminal for the differential electronic module (DEM).

Signal missing

General information

Note! Figures shown are only examples.

Hint: For general information about CAN-troubleshooting, see:

- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

General about CAN-related diagnostic trouble codes.
CEM-DF01 - DF17can only be stored in Central electronic module (CEM). These diagnostic trouble codes are stored when an electric fault is detected in CAN-lines. Start with these diagnostic trouble codes first.
CEM-1AXX only stored in Central electronic module (CEM). One diagnostic trouble code for every control module on the CAN-net. These diagnostic trouble codes indicate that Central electronic module (CEM) does not receive any reply from other control modules.
XXX-E000 (HS-CAN)/E001 (LS-CAN) can be stored in all CAN-connected control modules. These diagnostic trouble codes indicate that the control module has detected interference on the CAN-net.
XXX-E003 can be stored in all CAN-connected control modules except in Central electronic module (CEM). The control modules on the CAN-net

listen for a message (identity number) that is sent out at regular intervals from Central electronic module (CEM). This diagnostic trouble code indicates that the control module has not received any identity number, or that the expected number is not correct. Interference on the CAN-net can also store this diagnostic trouble code.

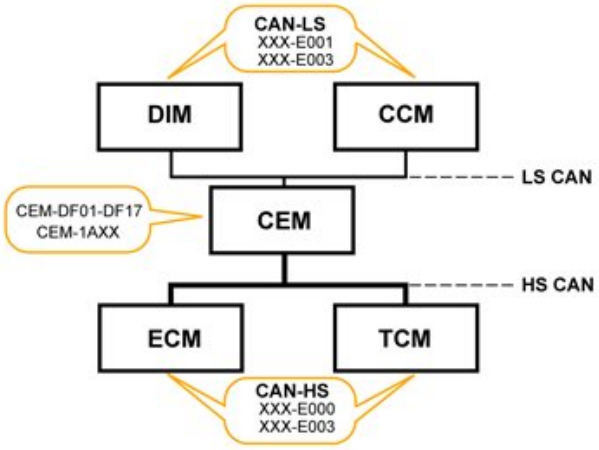
Note! In case of CAN-related faults, it is likely that a combination of above diagnostic trouble codes occur.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

If diagnostic trouble codes (DTCs) for communication faults can be read off from a control module, the fault is probably intermittent. Intermittent fault in the voltage supply and ground to a control module on the CAN network results in the Central electronic module (CEM) storing a diagnostic trouble code (DTC) for an open-circuit in communication with the control module where the voltage supply does not work. There will probably not be a diagnostic trouble code (DTC) in the control module where the open-circuit in the voltage supply occurred as the control module cannot store a diagnostic trouble code (DTC) when it is not supplied with power.

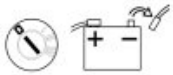
Note! Central electronic module (CEM) should not be replaced in case of CAN-fault, unless troubleshooting reveals that Central electronic module (CEM) has an internal fault.

Caution! During this fault-tracing use the wiring diagram to provide support when taking readings.



Continue - Checking resistance in CAN-net

Checking resistance in CAN-net



- Ignition off
- Disconnect the battery negative lead
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #3 and #11. The resistance should be approx. 55 - 65 ohms.
- If resistance is approx. 120 ohms, this indicates open circuit in the circuit so that only one terminating resistor (120 ohms) has been measured.
- If resistance is above 1 kohms this indicates open circuit/high contact resistance somewhere in the circuit.
- If resistance is below 55 ohms this indicates short-circuiting/contact resistance between the CAN-lines somewhere in the circuit.

Hint: For LS-CAN (Low Speed), terminating resistors are located in Upper electronic module (UEM) and Rear electronic module (REM).

Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the

resistance changes to detect intermittent short-circuits or open circuit.

Note! Resistance measurement measures only main lines in the CAN-net (in circuit where both terminating resistors are found), not branches to certain control modules. See wiring diagram for vehicle model in question. Open circuit on branching without a terminating resistor cannot be detected with this measurement. However, short-circuiting on a branch can be detected. To measure resistance in the CAN-net to control modules located in a branching of their own, the measurement shall be done against the CAN-net at that control module. The values shall be as above.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy as necessary.

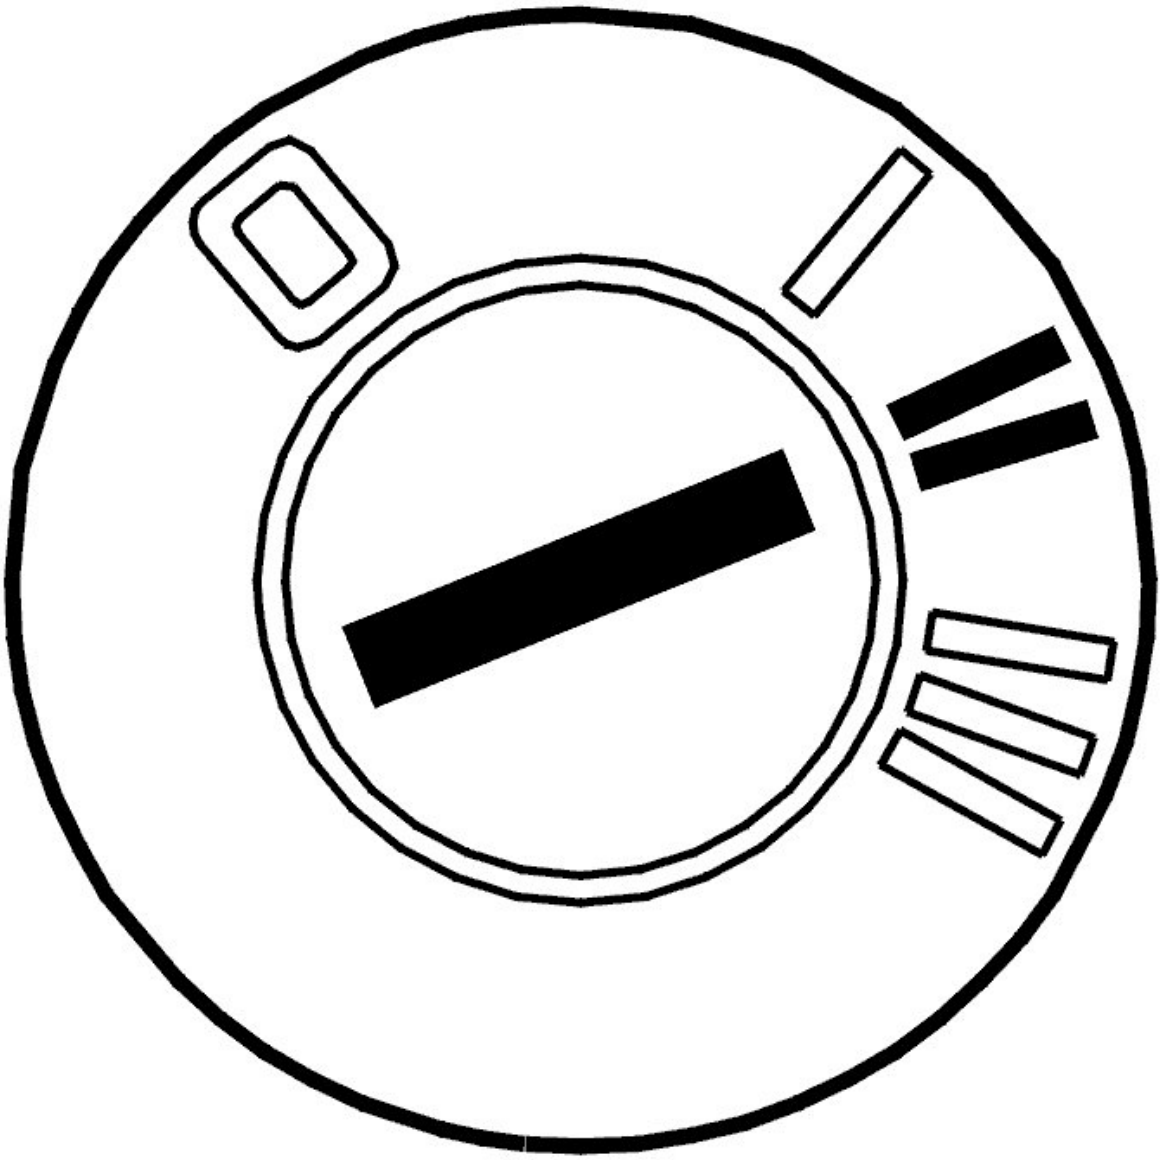
Was a fault detected?

Yes - Verification

No - Checking short-circuiting to ground/voltage in CAN-net

Checking the amount of traffic on the LS-CAN



- Connect the battery
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
Faults in the CAN network may be due to a control module sending faulty messages that disrupt normal communication. When messages are sent incorrectly, this results in a considerable increase in the amount of traffic on the CAN network. The load can be checked by reading the average value of the voltage on the CAN cables in relation to ground.
For further information, see the wiring diagram.
Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #3 and #4 (ground). The voltage should be approx: 2,8 - 3,2 V.
- #11 and #4 (ground). The voltage should be approx: 1,8 - 2,2 V.
- #3 and #11. The voltage shall be between approx. 0.55-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Hint: DiCE Error Frame Finder can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools: **951 3010** (memory card) as well as associated TJ 20402.

- Ignition on.
- Connect DiCE Error Frame Finder to the diagnostics socket.
- Note the blue LED-indicator. The indicator flashes to show detection of fault messages.

Note! Certain interference may occur without any real fault!

Cable fault

- Shake the cables lightly and pull lightly on the connections during the check to locate any fault. Note the blue LED-indicator.

"Chatting" control modules

- "Chatting" control modules may be difficult to find and troubleshooting may take time. Let the vehicle stand with DiCE connected for an extended time period. Afterwards, activate functions to provoke a malfunction. It may take up to several hours before the fault messages are sent. When the indicator starts to flash, remove the fuse for one control module at a time until the indicator stops flashing. When the indicator stops flashing, restore the fuse for the relevant control module and check that the indicator starts to flash again. Then it is likely that the problem is identified.

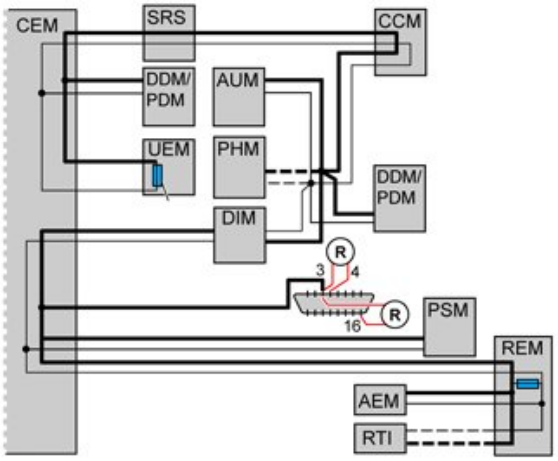
Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

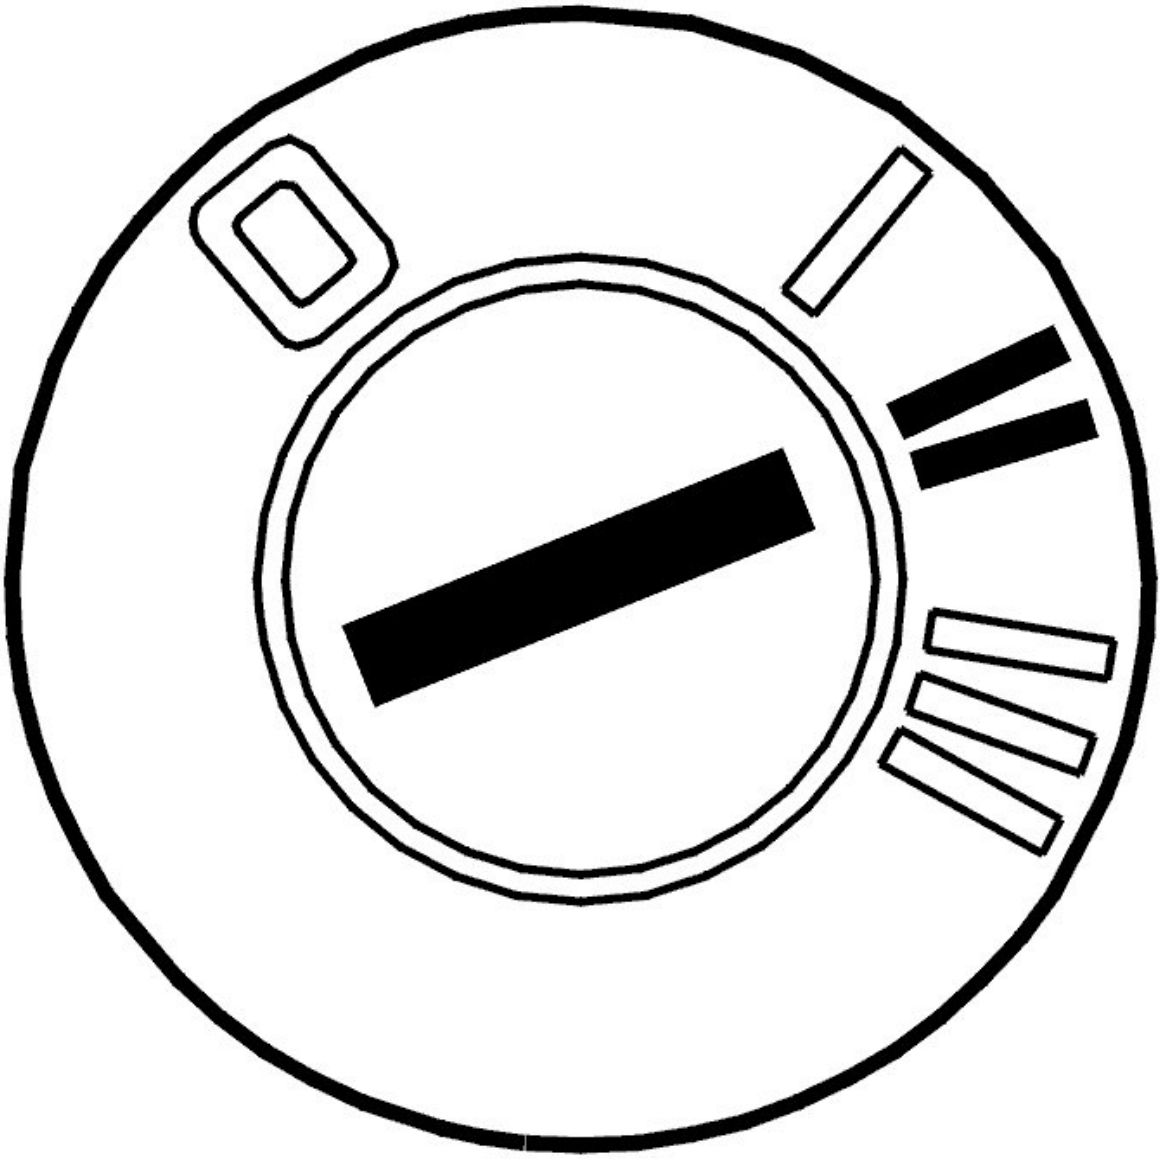


Was a fault detected?

Yes - Verification

No - Checking the amount of traffic on the LS-CAN

Checking voltage-drop in cable for CAN-H and CAN-L, respectively



- Connect the battery.
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

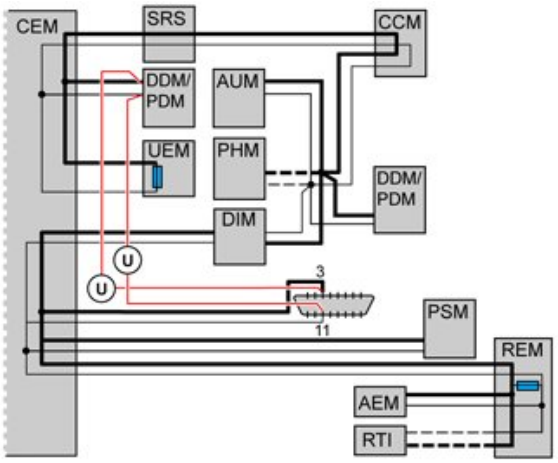
In principle, the voltage measured in each cable in the CAN-net shall be the same at each control module in the network. This means that the voltage-drop in the cable for CAN-H and CAN-L, respectively, between the control modules should be very low. If there is a voltage-difference in the CAN-lines between the diagnostics socket/Central electronic module (CEM) and a control module due to, e.g., contact resistance in a connector or branching, communication may be lost/interfered with. Check if there is voltage-drop in the cable for CAN-H and CAN-L between the diagnostics socket/Central electronic module (CEM) and the control module where there is problem with communication.
Carry out the following:
Measure voltage between the following connections on the OBDII-box/diagnostics socket.
- #3 and corresponding connection on relevant control module for CAN-H. The voltage shall be lower than 50 mV.
- #11 and corresponding connection on relevant control module for CAN-L. The voltage shall be lower than 50 mV.

If voltage is too high, this indicates too high contact resistance in cable, connector, or branching. Check the circuit between the diagnostics socket and control module in question for contact resistance and oxidation.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy wiring as necessary.

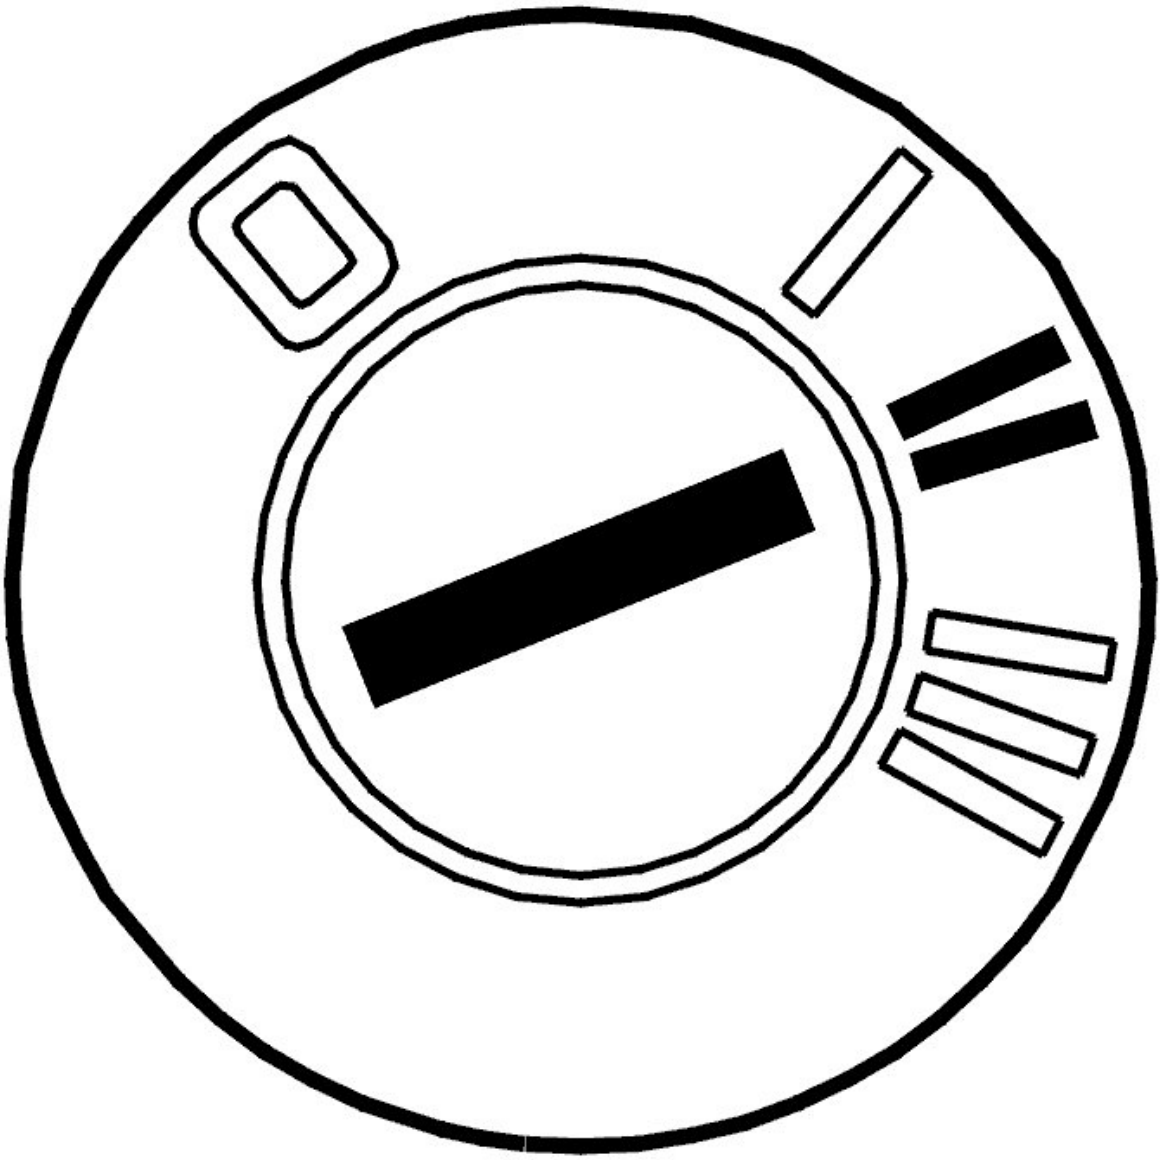
Other information
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

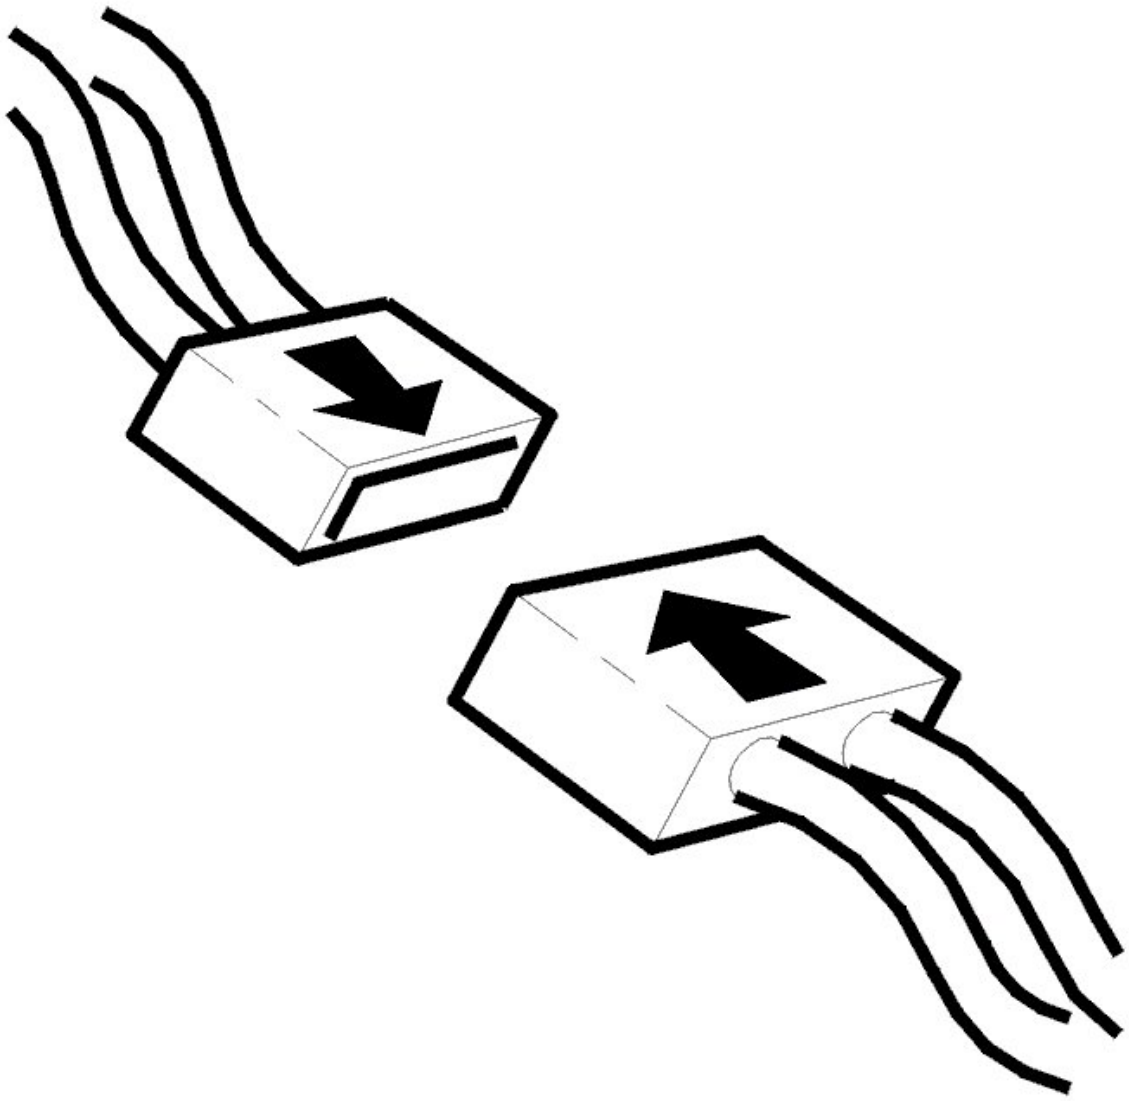


Continue - Verification

Checking the differential electronic module (DEM)

Hint: After carrying out the repair, check that the fault has been remedied.





- Ignition off
- Reconnect the connectors. Reinstall the components
- Ignition on for at least 10 seconds.

Read off the control module ID from the differential electronic module (DEM) by clicking on the VCT2000 symbol.

Could the control module ID be read off?

Yes - Fault Found

No - Fault-tracing information

Fault-tracing information

Information

Fault-tracing information

The fault should have been detected and remedied. As this is not the case fault-tracing has failed.
Exit fault-tracing for this diagnostic trouble code (DTC) or make another attempt.

Do you want to exit fault-tracing?

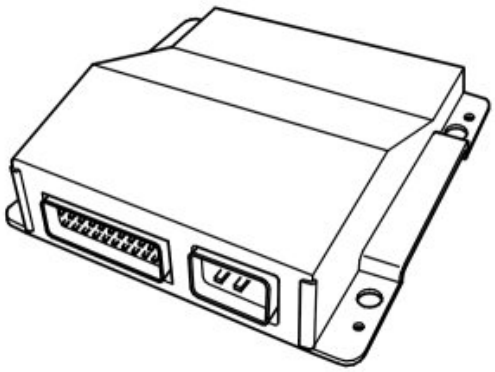
FAULT-TRACING FAILED - FAULT-TRACING FAILED

Attempt New Test - Checking the power supply and ground for the differential electronic module (DEM)

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CEM-1A65

Condition



The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers that communication with the suspension module (SUM) is not operating.
The diagnostic trouble code (DTC) can be diagnosed when the ignition has been on for more than 10 seconds.

Note! If CEM-1A6X diagnostic trouble codes (DTCs) are stored, the central electronic module (CEM) must not be replaced as the diagnostic trouble code (DTC) indicates a communication fault in the Control area network!

Substitute value
- None.

Possible source
- No power supply to the suspension module (SUM)
- Open-circuit in the ground lead for the suspension module (SUM)
- Contact resistance in the terminals
- Open-circuit in the wiring for the CAN high speed network to the suspension module (SUM)
- The suspension module (SUM) is not intended for this vehicle, for example a used control module with different software/hardware.

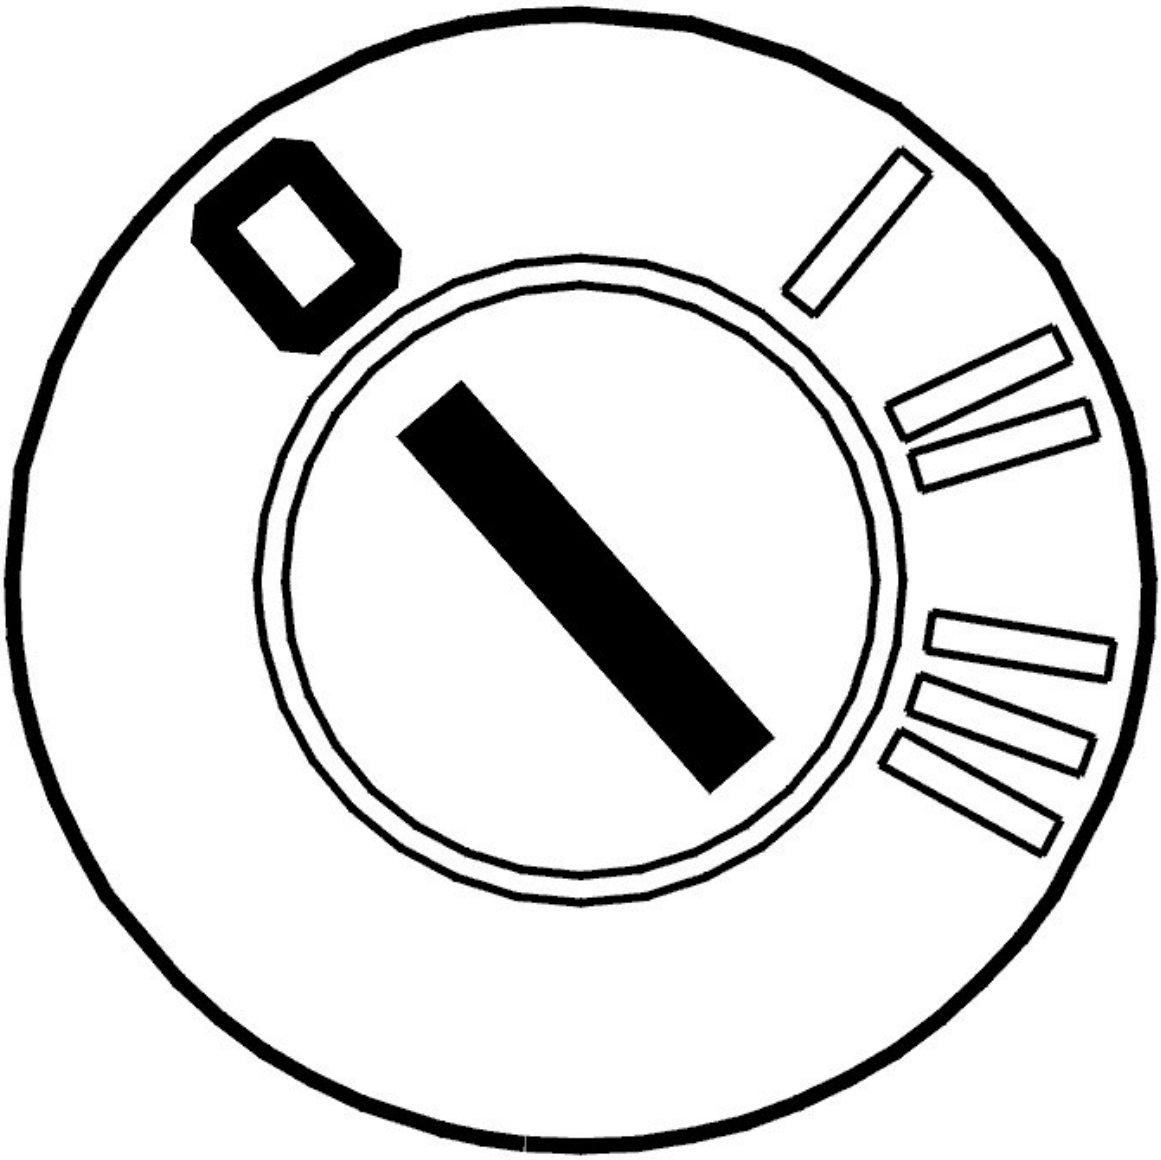
Hint: If several diagnostic trouble codes (DTCs) are stored in the central electronic module (CEM) for communication faults with other control modules in the high speed network, this indicates a common fault in the Control area network, see the wiring diagram.

Fault symptom[s]
- General warning lamp lit.
- Four-C (Continuously Controlled Chassis Concept) does not work.

Signal Missing

Signal missing

Checking the connectors



- Ignition off.

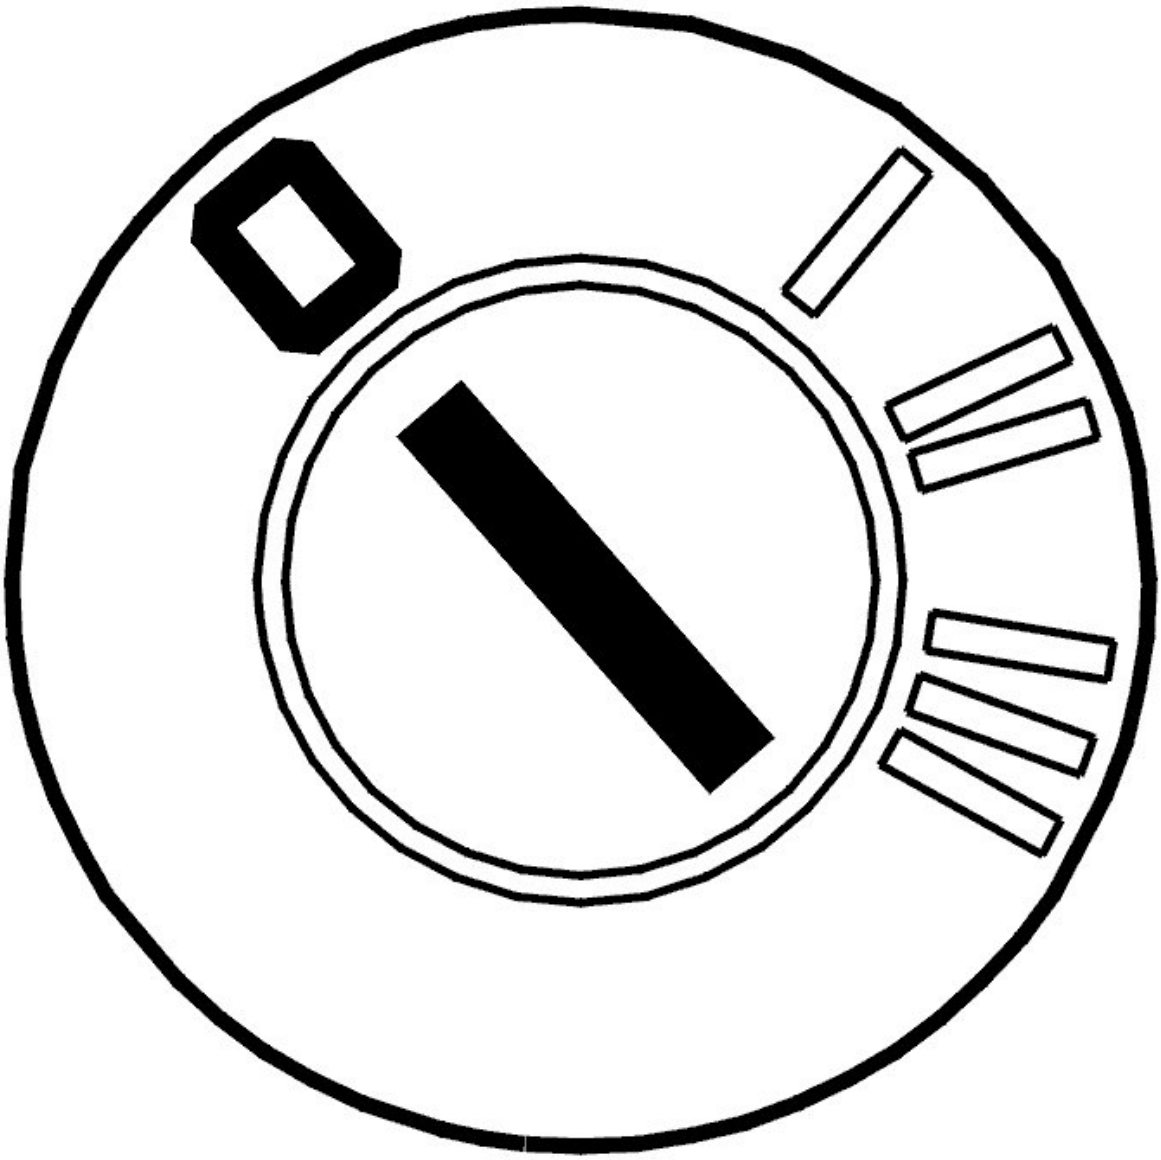
Check the connectors and wiring for the suspension module (SUM) and the cable harness. Check for contact resistance and oxidation. Check for loose connections.
Check for damage carefully.

Other information

- Suspension module (SUM), replacing See: Relays and Modules/Relays and Modules - Steering and Suspension/Relays and Modules - Suspension/Suspension Control Module/Service and Repair
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

Continue - Checking the components and wiring

Checking the components and wiring



- Ignition off.

Check that the fuses for the suspension module (SUM) are intact.
Check the relay for 15i power supply.

Hint: In the event of a fault in the 15i power supply relay, diagnostic trouble codes (DTCs) are stored in the central electronic module (CEM). If diagnostic trouble codes (DTCs) are stored for the relay, fault trace accordingly.

Check the cable between the fuse and 15i power supply relay terminal #3. Check for an open-circuit. Check for a short-circuit to ground.
Check the cable between 15i power supply relay terminal #1 and suspension module (SUM) terminal #C1 (#31). Check for an open-circuit. Check for a short-circuit to ground.
Check the cable between suspension module (SUM) terminal #C2 (#32) and ground. Check for an open-circuit. Check for a short-circuit to supply voltage.

Other information

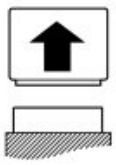
- For further information about fuses and relays, see the Wiring Diagram
- Connecting the breakout box See: Steering and Suspension/Suspension/Suspension Control (Automatic - Electronic Level)/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box, Suspension Module (SUM)
- Signal specification See: Steering and Suspension/Suspension/Suspension Control (Automatic - Electronic Level)/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Specification, Suspension Module (SUM)
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

Was a fault detected?

Yes - Verification

No - Checking the bus cable

Checking the bus cable



- Disconnect the suspension module (SUM) from the bus cable. Pull the connector out of the control module.
- To obtain the correct value, the battery must be disconnected during resistance readings.

Measure the resistance of the connectors across terminals #A15 and #A16.

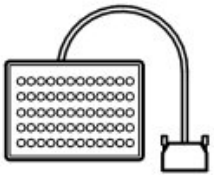
Note! Take care that you measure directly at the connector so that it is not damaged.

Hint: Only connect a breakout box to the connector, not to the control module. In this way, the direction of any faults in the bus cable can be established.

The resistance must be approximately 120 ohms. If another reading is given, there may be an open-circuit in the bus cable.

Other information

- Connecting the breakout box See: Steering and Suspension/Suspension/Suspension Control (Automatic - Electronic Level)/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box, Suspension Module (SUM)
- Signal specification See: Steering and Suspension/Suspension/Suspension Control (Automatic - Electronic Level)/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Specification, Suspension Module (SUM)
- Battery, disconnecting See: Starting and Charging/Battery/Service and Repair/Procedures/Battery, Disconnecting



Does the measuring instrument display a resistance of approximately 120 ohms?

Yes - Fault-tracing Information

No - Signal missing

Signal missing

General information

Note! Figures shown are only examples.

Hint: For general information about CAN-troubleshooting, see:

- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

General about CAN-related diagnostic trouble codes.
CEM-DF01 - DF17can only be stored in Central electronic module (CEM). These diagnostic trouble codes are stored when an electric fault is detected in CAN-lines. Start with these diagnostic trouble codes first.
CEM-1AXX only stored in Central electronic module (CEM). One diagnostic trouble code for every control module on the CAN-net. These diagnostic trouble codes indicate that Central electronic module (CEM) does not receive any reply from other control modules.
XXX-E000 (HS-CAN)/E001 (LS-CAN) can be stored in all CAN-connected control modules. These diagnostic trouble codes indicate that the control module has detected interference on the CAN-net.
XXX-E003 can be stored in all CAN-connected control modules except in Central electronic module (CEM). The control modules on the CAN-net listen for a message (identity number) that is sent out at regular intervals from Central electronic module (CEM). This diagnostic trouble code indicates that the control module has not received any identity number, or that the expected number is not correct. Interference on the CAN-net can also store this diagnostic trouble code.

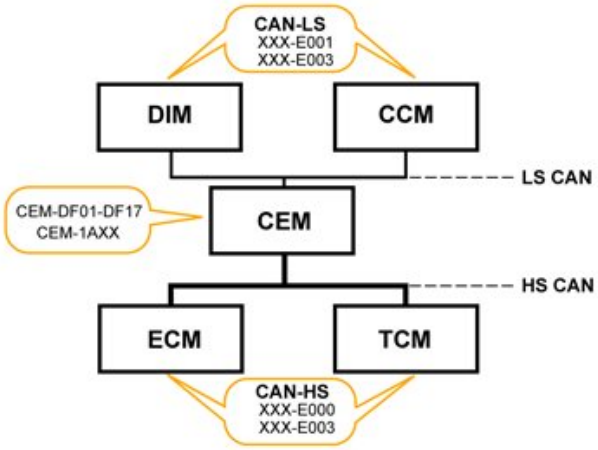
Note! In case of CAN-related faults, it is likely that a combination of above diagnostic trouble codes occur.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

If a communication diagnostic trouble code can be read from the control module, the malfunction is probably intermittent.
Intermittent fault in the voltage supply and ground to a control module on the CAN network results in the Central electronic module (CEM) storing a diagnostic trouble code (DTC) for an open-circuit in communication with the control module where the voltage supply does not work. There will probably not be a diagnostic trouble code (DTC) in the control module where the open-circuit in the voltage supply occurred as the control module cannot store a diagnostic trouble code (DTC) when it is not supplied with power.

Note! Central electronic module (CEM) should not be replaced in case of CAN-fault, unless troubleshooting reveals that Central electronic module (CEM) has an internal fault.

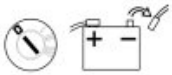
Caution! During this fault-tracing use the wiring diagram to provide support when taking readings.



Select "Continue".

Continue - Checking resistance in CAN-net

Checking resistance in CAN-net



- Ignition off
- Disconnect the battery negative lead
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #6 and #14. The resistance should be approx. 55 - 65 ohms.
- If resistance is approx. 120 ohms, this indicates open circuit in the circuit so that only one terminating resistor (120 ohms) has been measured.
- If resistance is above 1 kohms this indicates open circuit/high contact resistance somewhere in the circuit.
- If resistance is below 55 ohms this indicates short-circuiting/contact resistance between the CAN-lines somewhere in the circuit.

Hint: For HS-CAN (High Speed) the terminating resistors are located in Brake control module (BCM) and in Engine control module (ECM).

Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

Note! Resistance measurement measures only main lines in the CAN-net (in circuit where both terminating resistors are found), not branches to certain control modules. See wiring diagram for vehicle model in question.Open circuit on branching without a terminating resistor cannot be detected with this measurement. However, short-circuiting on a branch can be detected. To measure resistance in the CAN-net to control modules located in a branching of their own, the measurement shall be done against the CAN-net at that control module. The values shall be as above.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy wiring as necessary.

Other information

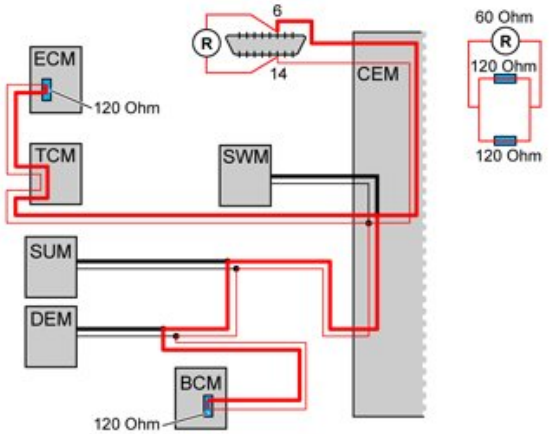
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

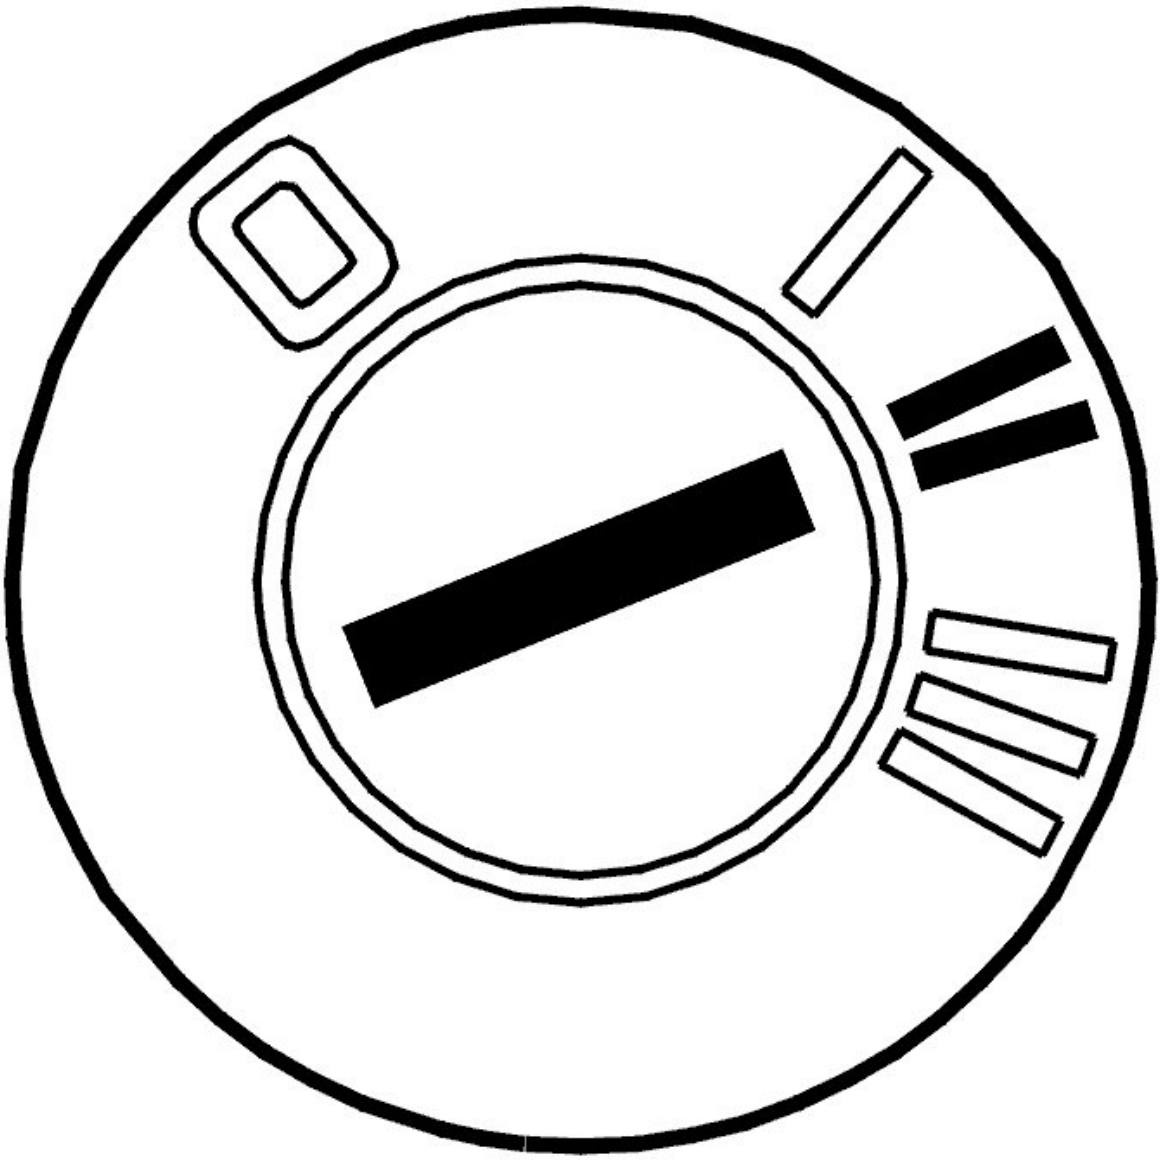


Was a fault detected?

Yes - Verification

No - Checking short-circuiting to ground/voltage in CAN-net

Checking the traffic load on the CAN cables



- Connect the battery
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Faults in the CAN network may be due to a control module sending faulty messages that disrupt normal communication. When messages are sent incorrectly, this results in a considerable increase in the amount of traffic on the CAN network. Check the load by measuring the average voltage value on the CAN cables in relation to ground.
For further information, see the wiring diagram.
Measure voltage between the following connections on the OBDII-box/diagnostics socket.
- #6 and #4 (ground). The voltage should be approx: 2,8 - 3,2 V.
- #14 and #4 (ground). The voltage should be approx: 1,8 - 2,2 V.
- #6 and #14. The voltage shall be between approx. 0.55-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Hint: DiCE Error Frame Finder can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools: **951 3010** (memory card) as well as associated TJ 20402.

- Ignition on.
- Connect DiCE Error Frame Finder to the diagnostics socket.
- Note the blue LED-indicator. The indicator flashes to show detection of fault messages.

Note! Certain interference may occur without any real fault!

Cable fault

- Shake the cables lightly and pull lightly on the connections during the check to locate any fault. Note the blue LED-indicator.

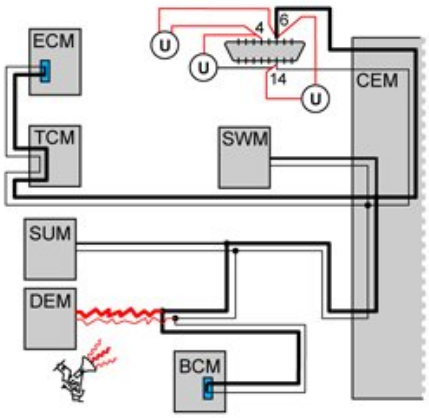
"Chatting" control modules

- "Chatting" control modules may be difficult to find and troubleshooting may take time. Let the vehicle stand with DiCE connected for an extended time period. Afterwards, activate functions to provoke a malfunction. It may take up to several hours before the fault messages are sent. When the indicator starts to flash, remove the fuse for one control module at a time until the indicator stops flashing. When the indicator stops flashing, restore the fuse for the relevant control module and check that the indicator starts to flash again. Then it is likely that the problem is identified.

Remedy wiring as necessary.

Other information

- Battery, disconnecting See: Starting and Charging/Battery/Service and Repair/Procedures/Battery, Disconnecting
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

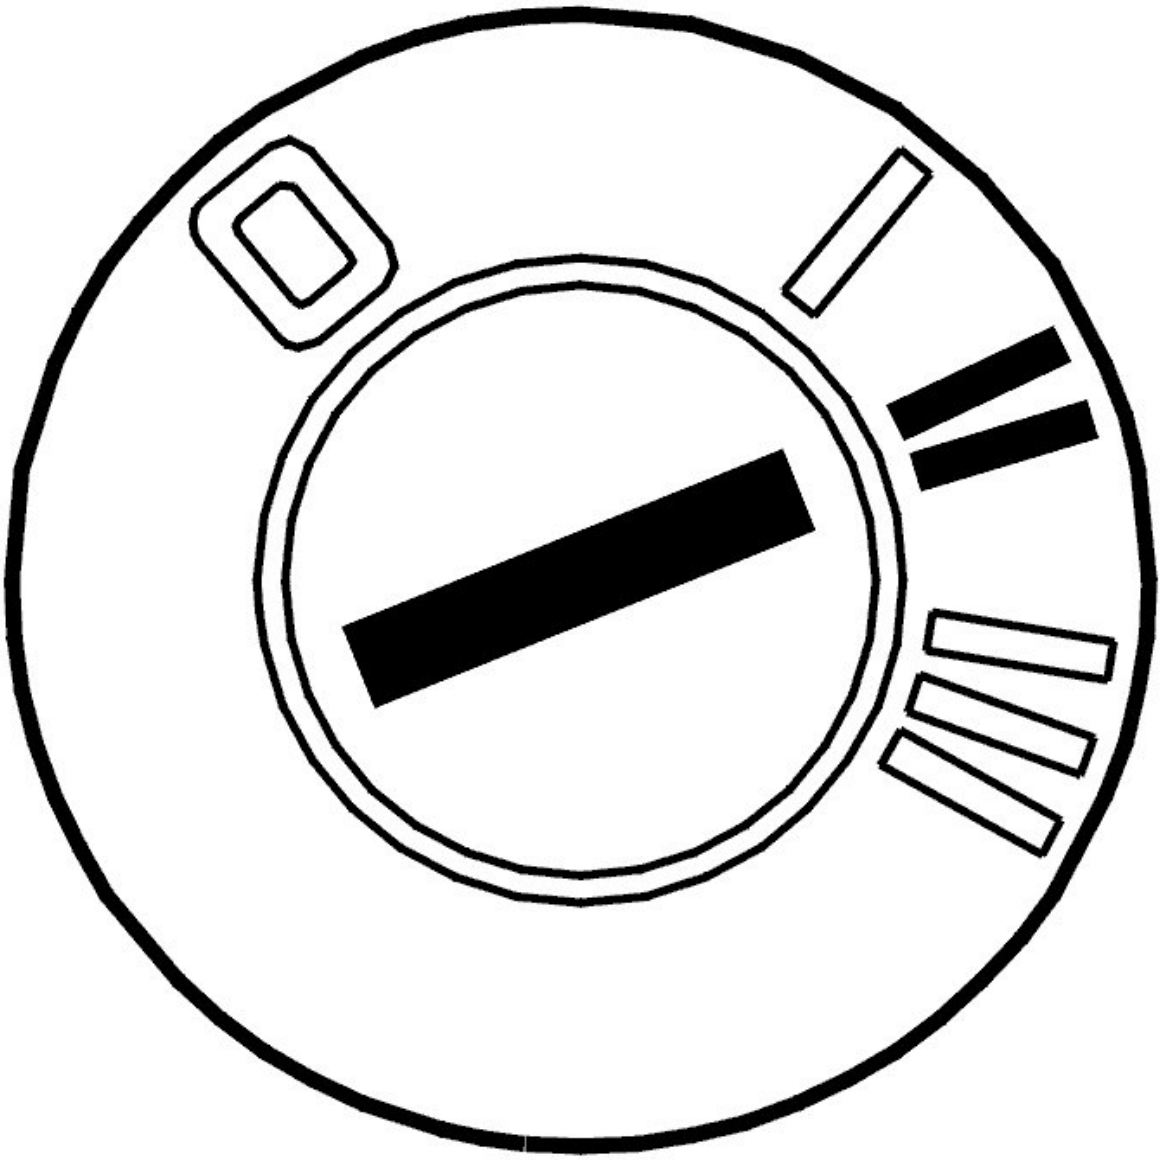


Was a fault detected?

Yes - Identifying a control module in the CAN network

No - respectively

Identifying a control module in the CAN network



Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:

- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Hint: DiCE Error Frame Finder can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools: **951 3010** (memory card) as well as associated TJ 20402.

If the load on the CAN network is too high, this may be due to a control module sending faulty messages on the CAN network (known as a disruptive control module). The fault may also be due to an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The faults can occur without a diagnostic trouble code (DTC) being stored by the control modules. The voltage can be measured between the CAN cables in order to check the load on the CAN network.

Note! It is not necessarily the control module(s) that stored the diagnostic trouble code (DTC) that is communicating faultily. Faulty messages can come from any control module in the same section of the CAN network. However, faulty communication in one network cannot affect the communication on the other network. In other words, faulty communication on the LS-CAN cannot disrupt communication on the HS-CAN and vice versa.

- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Check communication/load on CAN-net by measuring voltage between CAN-L and CAN-H. Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #6 and #14. The average value of the voltage must be approximately 0.6-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

In order to identify which control module has faulty communication, cut the power supply to one control module at a time. Check the voltage in the

CAN cables again. The easiest way to cut the power supply is to remove the fuse(s) for the relevant control module. Repeat until the voltage between the CAN wiring drops to the normal level.

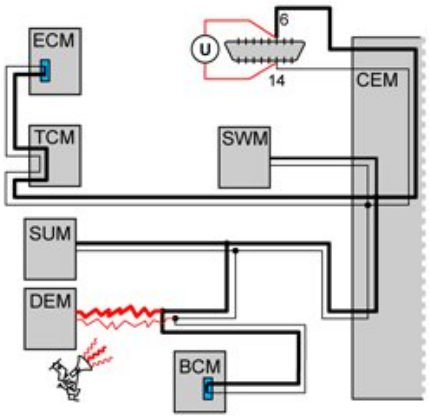
Note! When connecting and disconnecting individual control modules, other diagnostic trouble codes (DTCs) may be stored in certain control modules.

Hint: When the suspected defective control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the malfunction appears and disappears. Switch off the ignition between each check.

Note! Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.

A control module that is communicating incorrectly must be replaced. See Repairing and installing/Removing, replacing and installing.

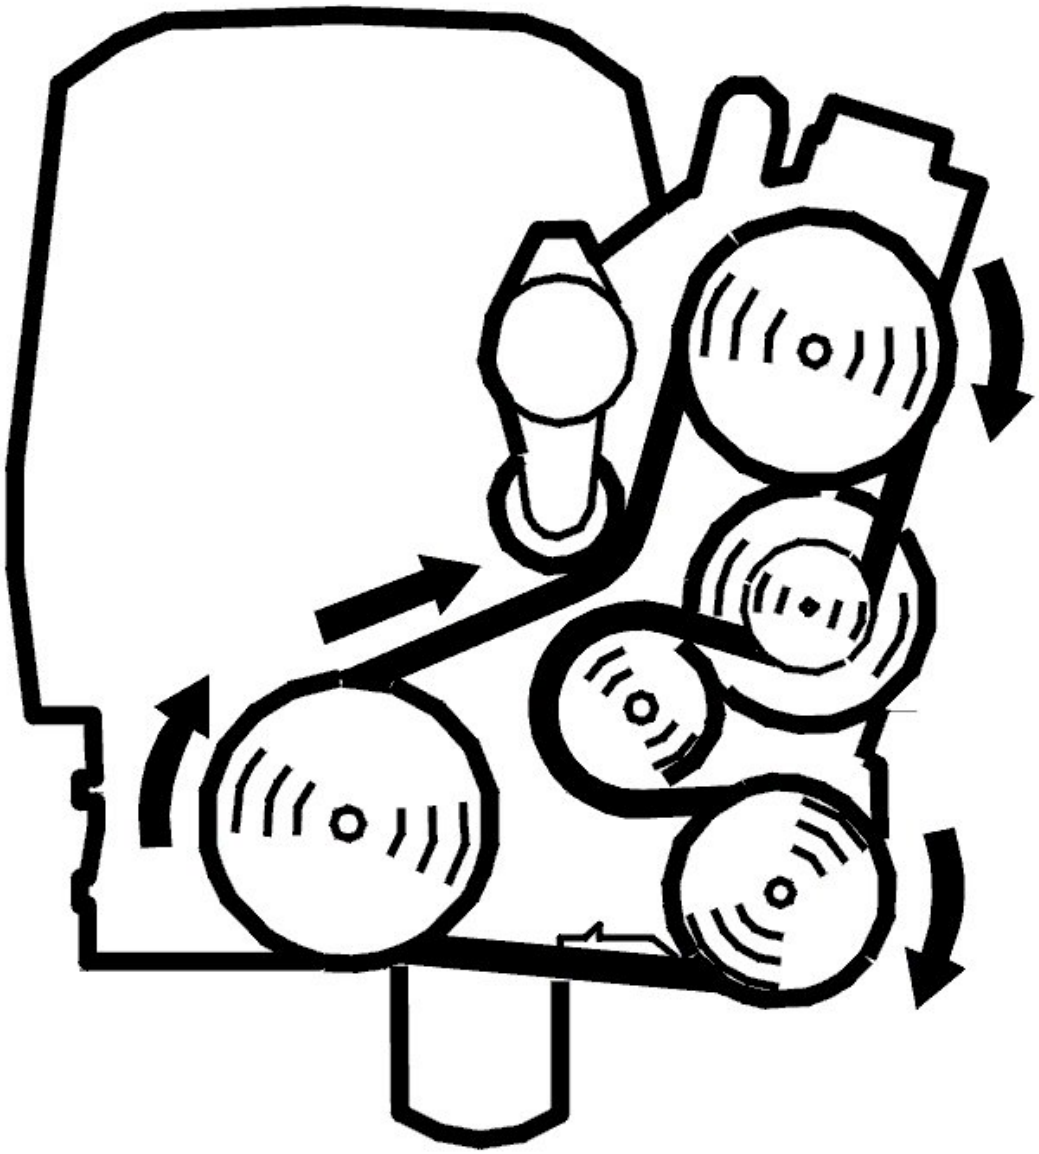
Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

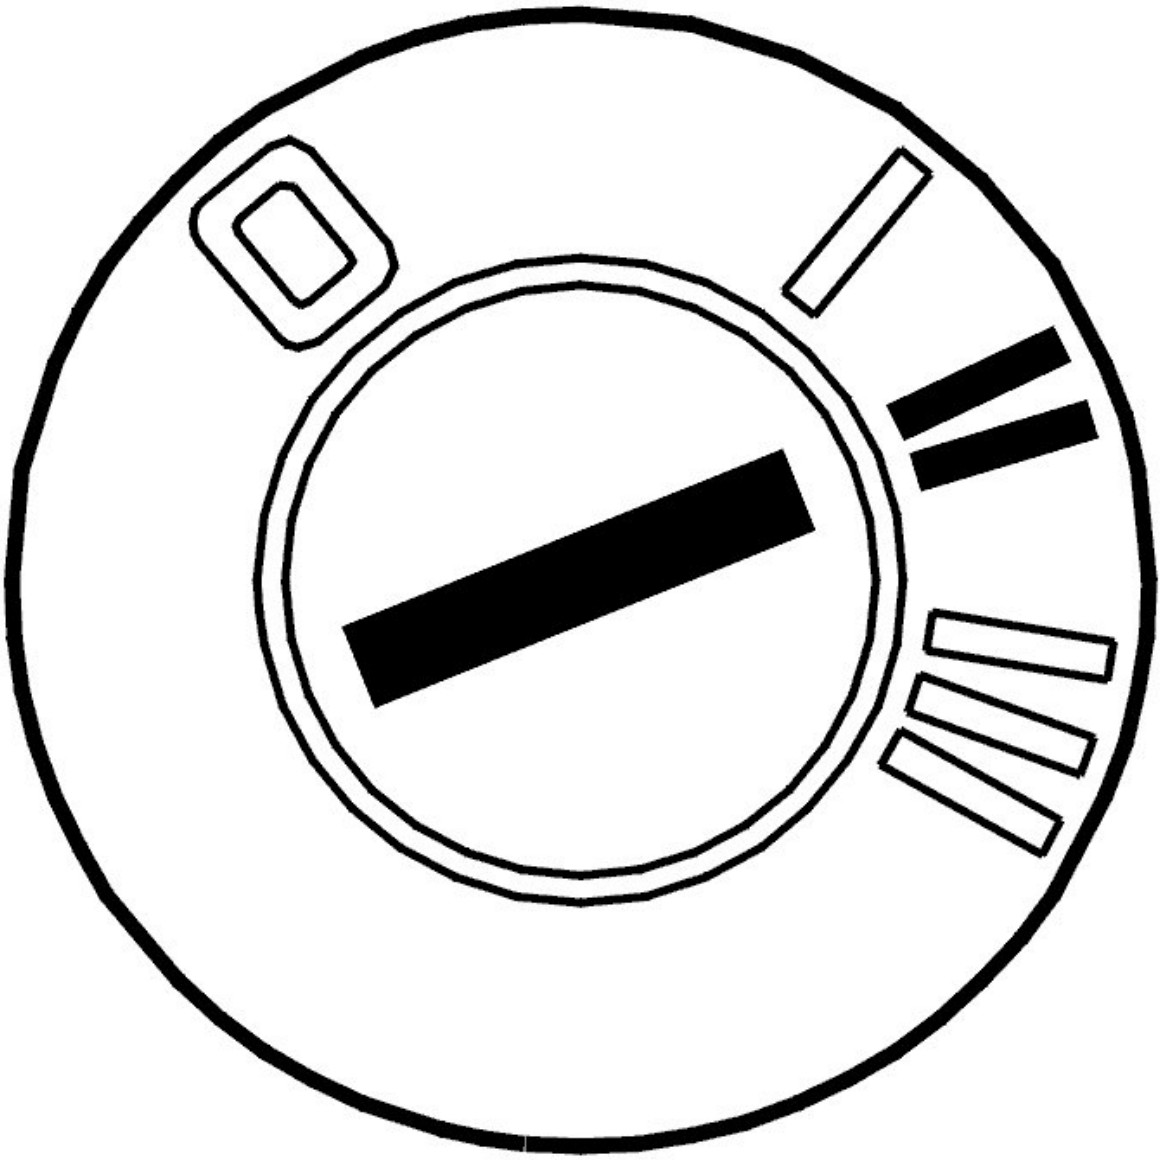


Continue - Verification

Verification

Hint: After rectifying a fault, a verification should be carried out.





- Reinstall the connectors, components etc.
- Ignition on.

Note! For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

- Erase diagnostic trouble codes (DTCs) in all control modules.
- Ignition off.
- Ignition on.
- Start the vehicle. Allow the vehicle to run for 10 minutes.
- Read out the diagnostic trouble codes in the vehicle via the DIAGNOSTICS tab.

Does the diagnostic trouble code (DTC) for faulty communication return?

Yes - Fault-tracing information

No - Fault Found

Fault-tracing information

Information

Fault-tracing information

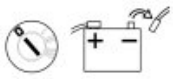
Checking short-circuiting to ground/voltage in CAN-net



- Ignition off.
- Disconnect the battery negative lead.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Checking for a short-circuit to ground

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #6 and #4 (ground). Measurement is shown in the figure. The resistance should be above 1 kohms.
- #14 and #4 (ground). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and ground.

Checking for a short-circuit to voltage

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #6 and #16 (voltage). Measurement is shown in the figure. The resistance should be above 1 kohms.
- #14 and #16 (voltage). The resistance should be above 1 kohms.

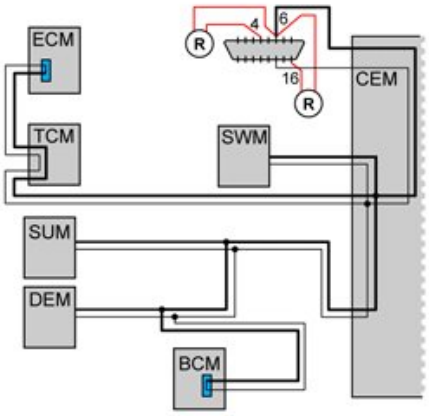
If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and voltage cable.
Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

Hint: Part the CAN-net at suitable points to decide where a short-circuit may be found.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy wiring as necessary.

Other information
- Battery, disconnecting See: Starting and Charging/Battery/Service and Repair/Procedures/Battery, Disconnecting
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

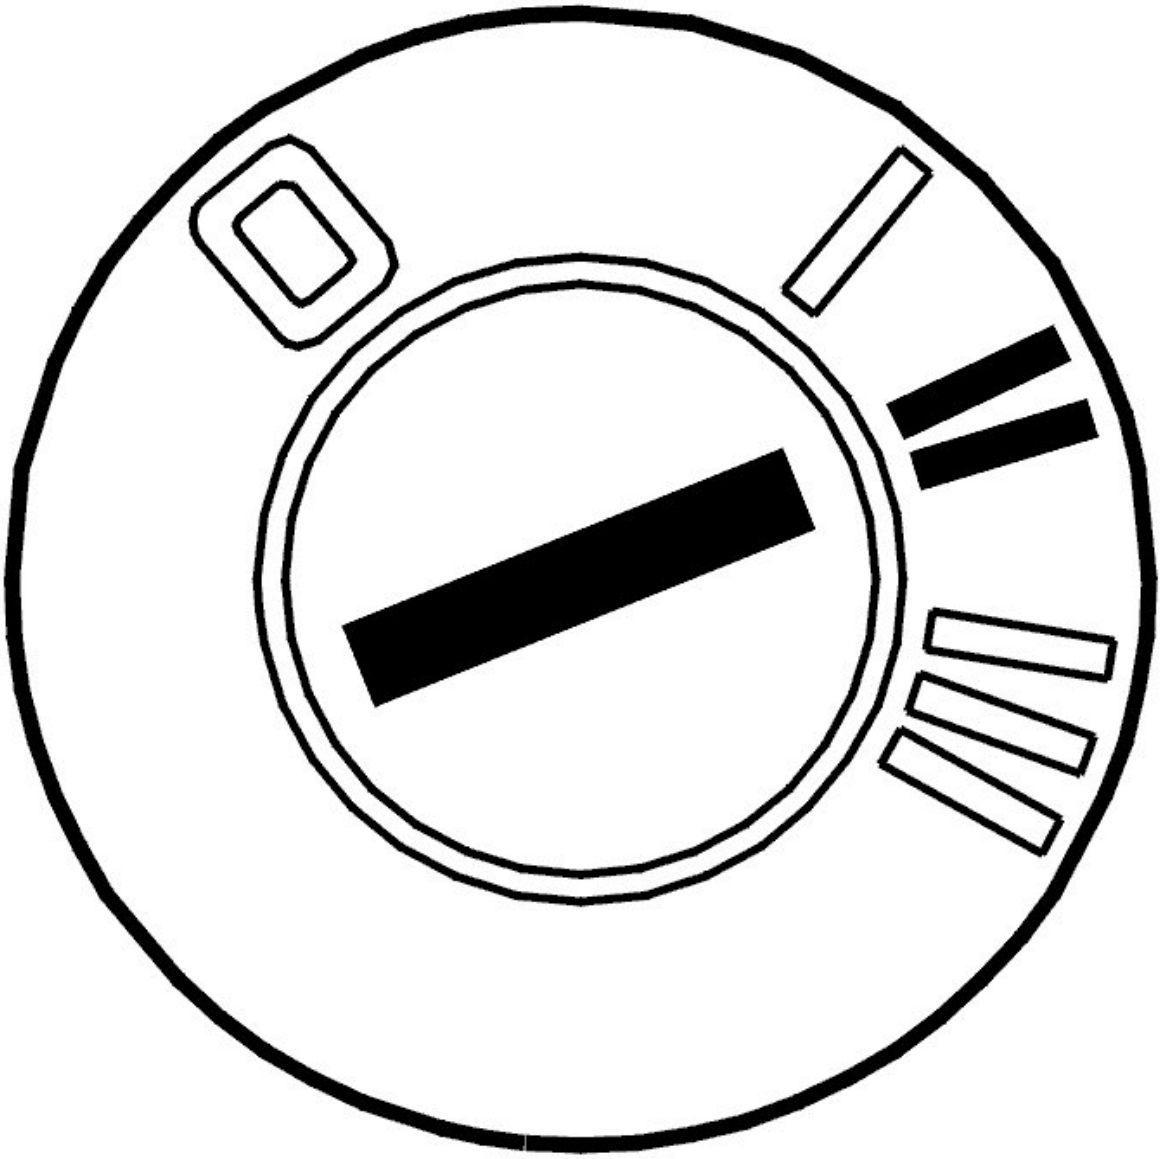


Was a fault detected?

Yes - Verification

No - Checking the traffic load on the CAN cables

Checking voltage-drop in cable for CAN-H and CAN-L, respectively



- Connect the battery.
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

In principle, the voltage measured in each cable in the CAN-net shall be the same at each control module in the network. This means that the voltage-drop in the cable for CAN-H and CAN-L, respectively, between the control modules should be very low. If there is a voltage-difference in the CAN-lines between the diagnostics socket/Central electronic module (CEM) and a control module due to, e.g., contact resistance in a connector or branching, communication may be lost/interfered with.
Check if there is voltage-drop in the cable for CAN-H and CAN-L between the diagnostics socket/Central electronic module (CEM) and the control module where there is problem with communication.
Carry out the following:
Measure voltage between the following connections on the OBDII-box/diagnostics socket.
- #6 and corresponding connection on relevant control module for CAN-H. The voltage shall be lower than 50 mV.
- #14 and corresponding connection on relevant control module for CAN-L. The voltage shall be lower than 50 mV.

If voltage is too high, this indicates too high contact resistance in cable, connector, or branching. Check the circuit between the diagnostics socket and control module in question for contact resistance and oxidation.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy wiring as necessary.

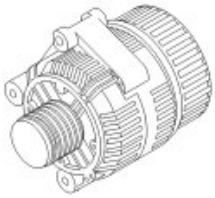
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CEM-1C0A

Condition



The central electronic module (CEM) continuously checks the charge status of the battery.
The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) detects excessive voltage (above 16 V).
The diagnostic trouble code (DTC) can be diagnosed at engine speeds (RPM) above 600 rpm.

Note! The voltage of the battery is measured by Rear electronic module (REM) and the voltage value is transmitted to Central electronic module (CEM) via CAN-net. This means that the diagnostic trouble code can be generated if the rear electronic module (REM) sends

incorrect data.

Substitute value
- None.

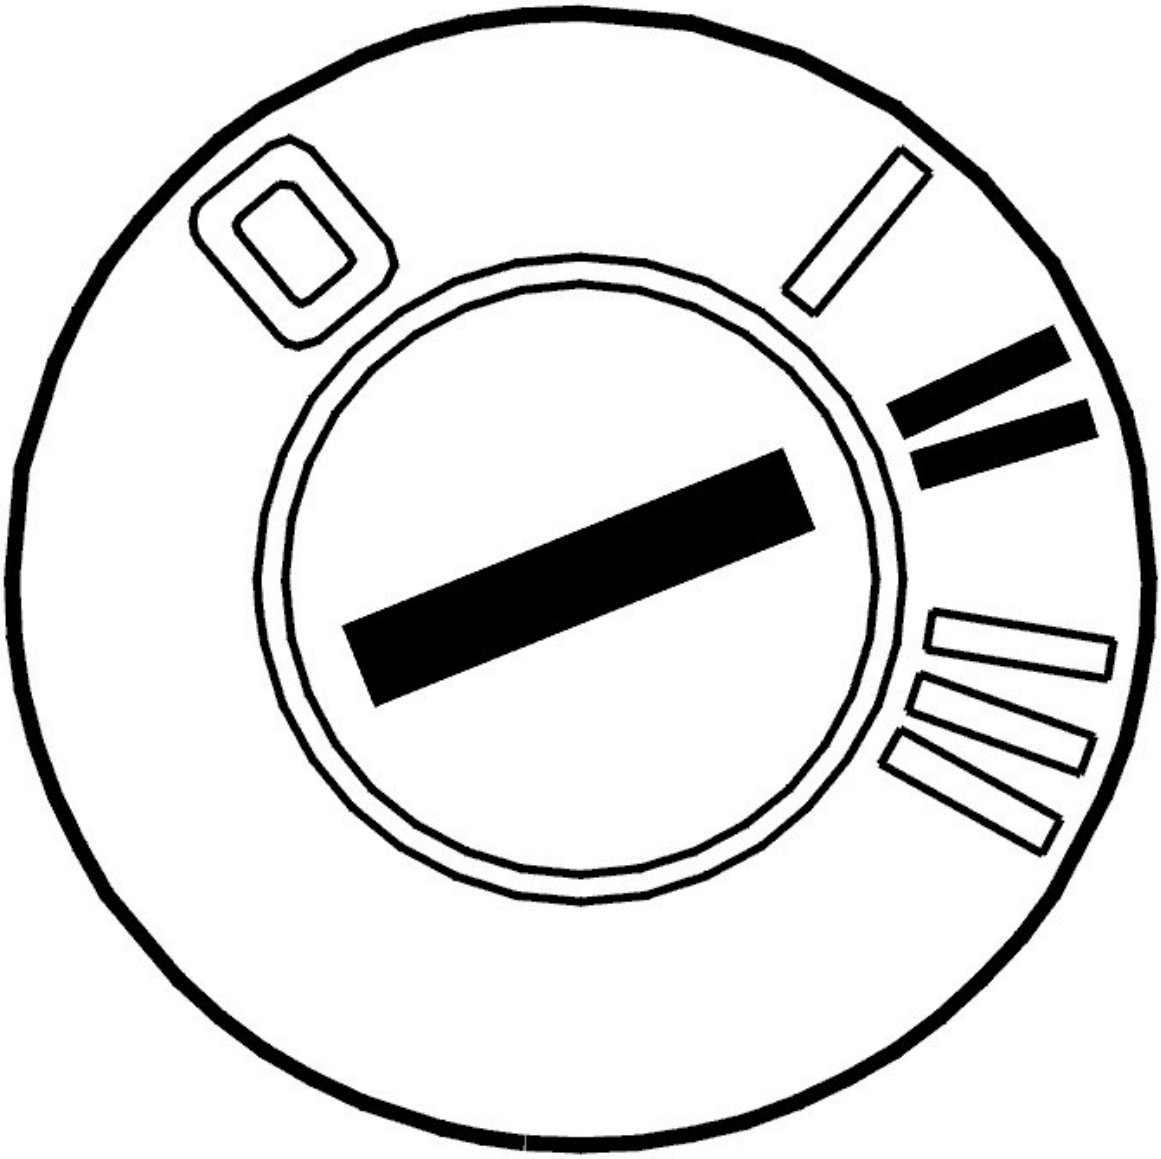
Possible source
- A battery charger with too high charge voltage has been connected previously
- Damaged alternator control module (ACM).

Fault symptom[s]
- The electrolyte in battery boils with the engine running
- The headlamp bulb blows.

Voltage Too High

Voltage too high

Checking the power supply



- Start the engine.
- Read off and compare the voltage feed to central electronic module (CEM) and Rear electronic module (REM) by clicking on the symbol for VCT2000.

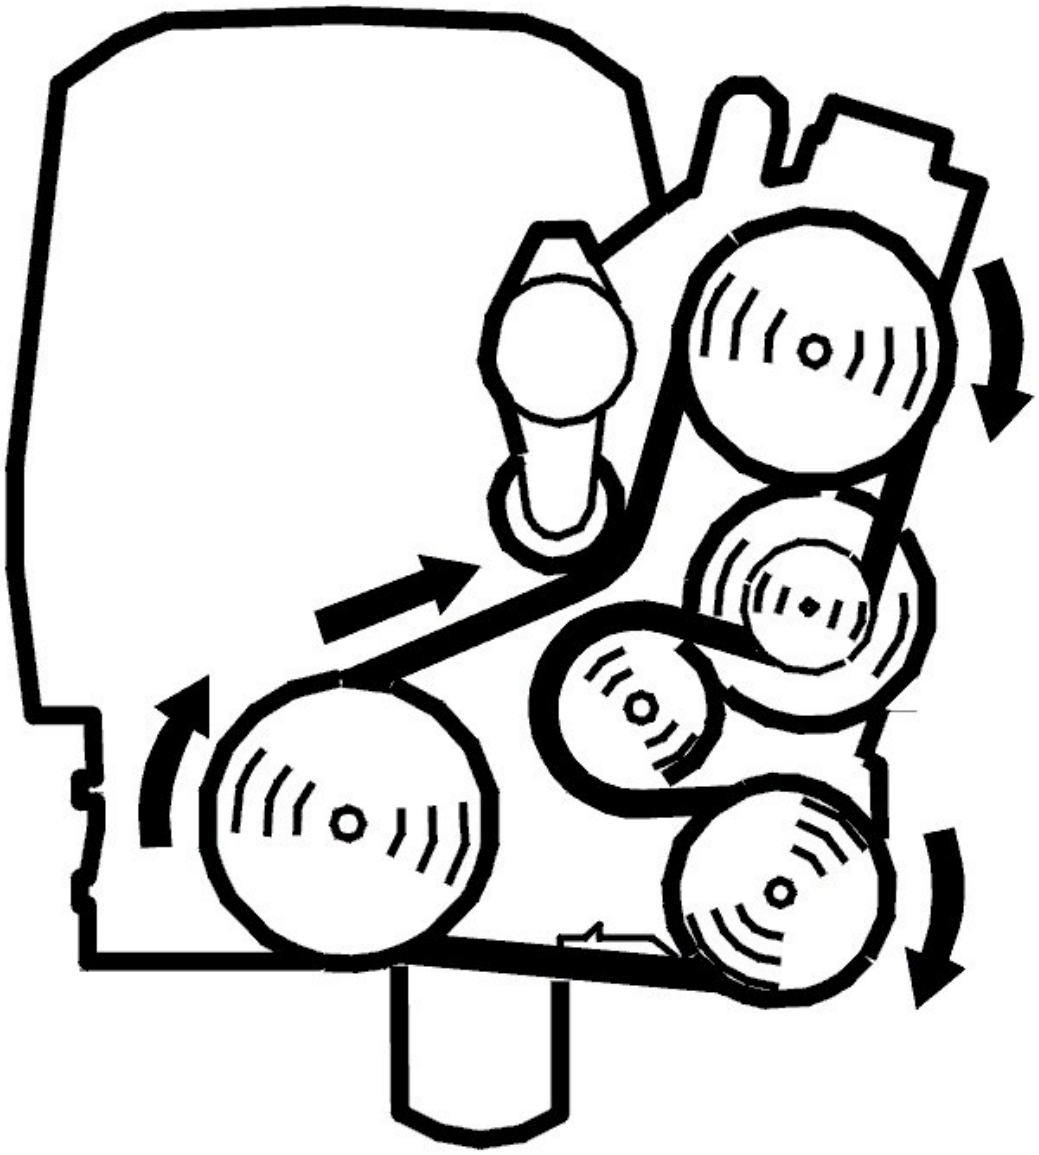
The voltage for Rear electronic module (REM) and the Central electronic module (CEM) should be approximately the same.
The tool also shows the value of the voltage the rear electronic module (REM) transmits on the CAN network.
The value should match other measurement values.

Is the power supply OK?

Yes - Checking battery voltage

No - Checking the power supply and ground at rear electronic module (REM)

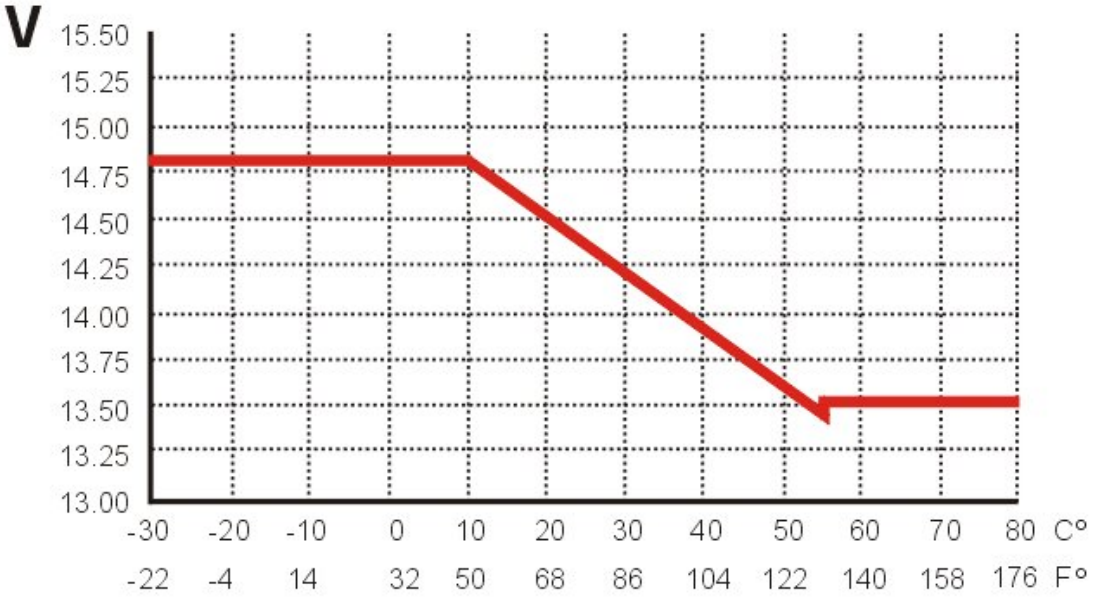
Checking battery voltage



- Start the engine
- Read off the battery voltage. The central electronic module (CEM) uses the prevailing outside temperature to calculate the voltage at which the battery should be charged
- Switch on a few major power consuming components, such as the blower fan.

Check that the voltage is within the limits of 13.5-14.9 V. Try at different engine speeds (RPM).
The fault is permanent if the voltage is outside the permitted range.
If the voltage is within the permitted range, the fault was present previously but is not active at the moment, i.e. an intermittent fault.

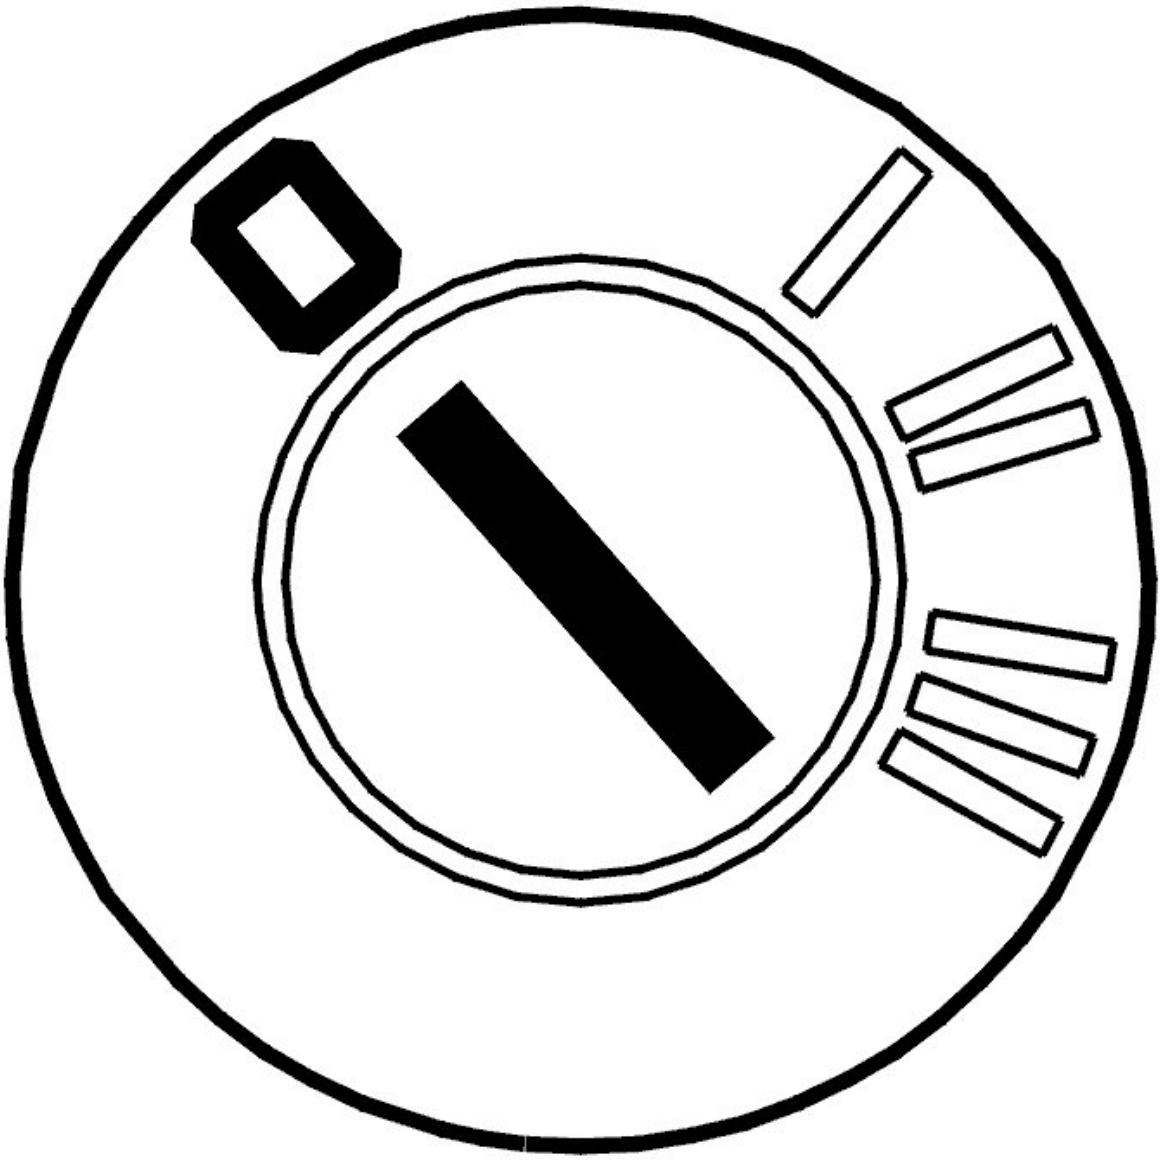
Note! This diagnostic trouble code can be stored if a battery charger with too high charge voltage has been connected.



Select Continue

Continue - Checking the component

Checking the component



- Ignition off.

Try a new alternator control module (ACM) (charge regulator).
Remedy as necessary.

Was a fault detected?

Yes - Verification

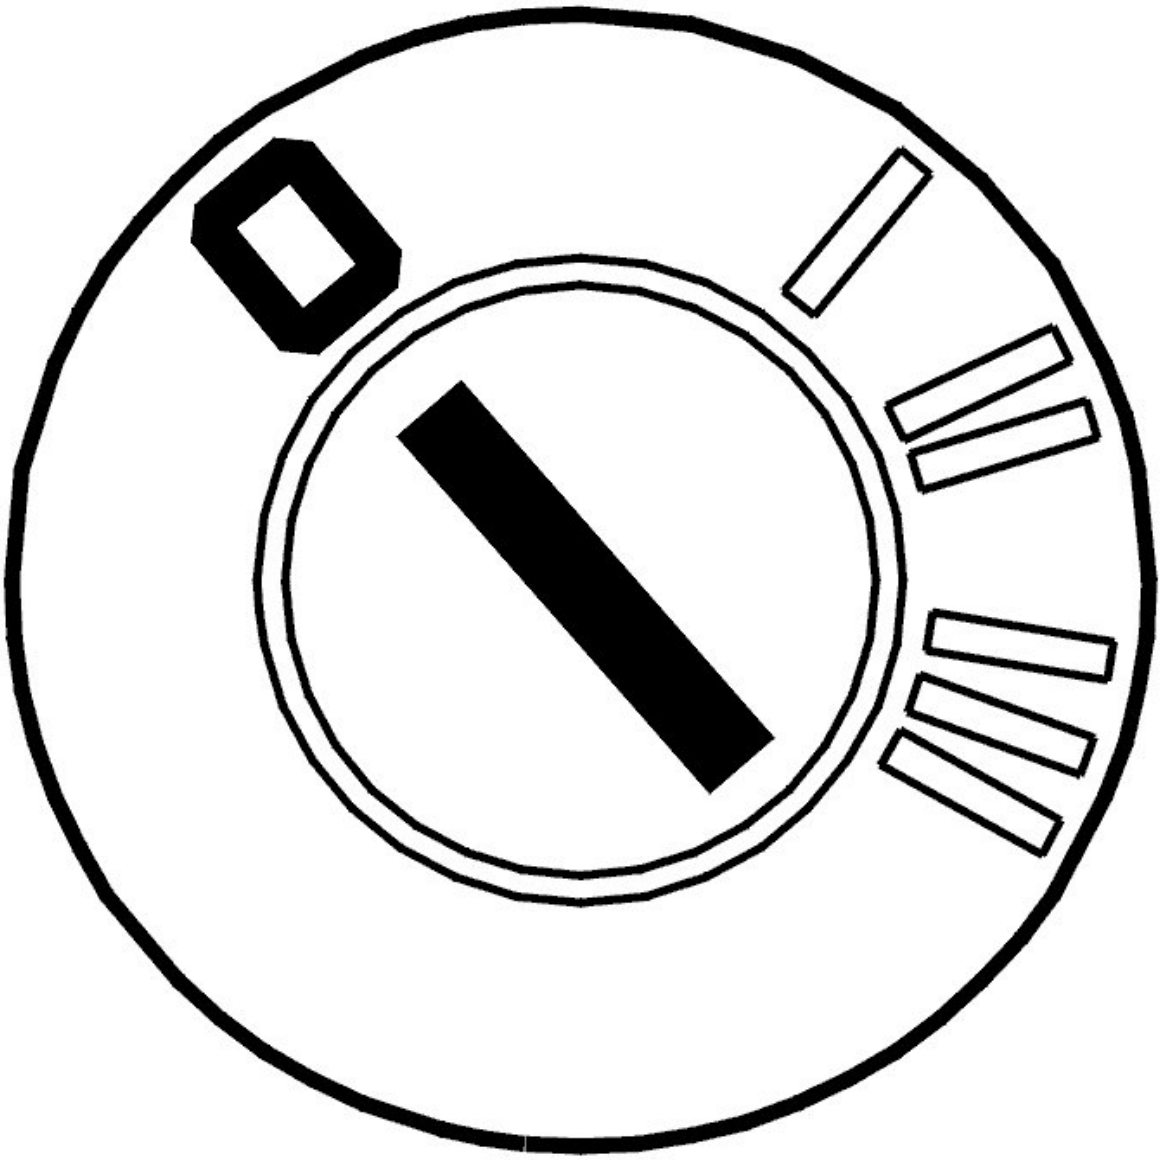
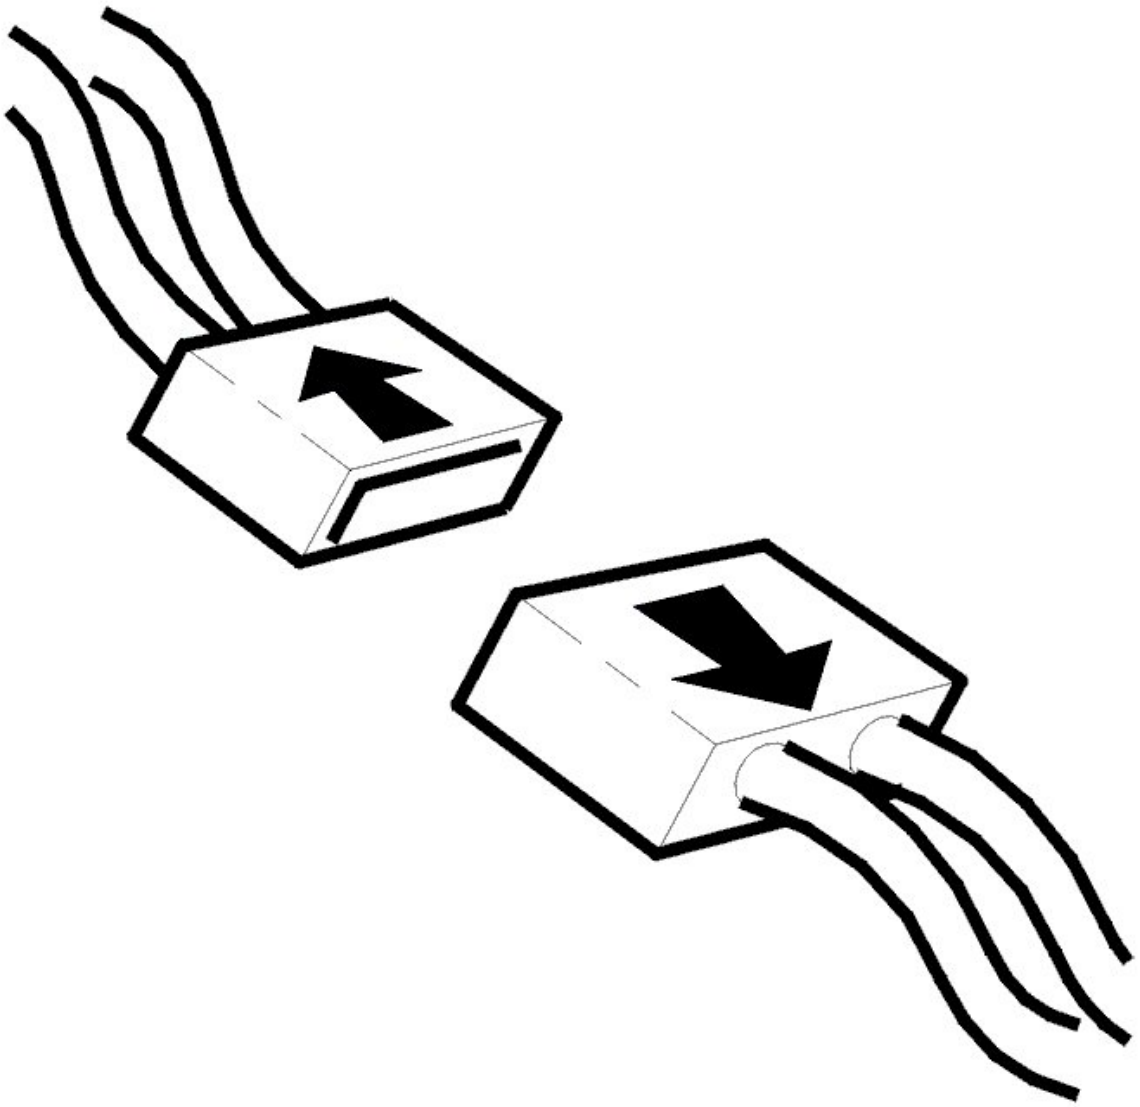
No - Checking the ground terminal

Checking the ground terminal





- Ignition off
- Disconnect central electronic module (CEM) connector D.

Check central electronic module (CEM) connector D. Check for contact resistance and oxidation. Check for damage carefully.
Check the ground lead between central electronic module (CEM) terminal #D6 (#6) and the ground terminal. Check for an open-circuit. Check for loose connections. Check for contact resistance and oxidation. With the ignition on, the drop in voltage between the ground connection for the central electronic module (CEM) and the ground terminal must not be greater than 0.5 V.
Remedy as necessary.

Other information

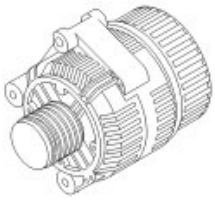
Attempt New Test - Checking the cable between the battery and generator (GEN)

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CEM-1C06

Condition



The central electronic module (CEM) communicates with the alternator control module (ACM).
The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) receives information from the alternator control module (ACM) indicating an electrical fault in the generator (GEN).
The diagnostic trouble code (DTC) can be diagnosed at engine speeds (RPM) above 600 rpm.

Substitute value
- None.

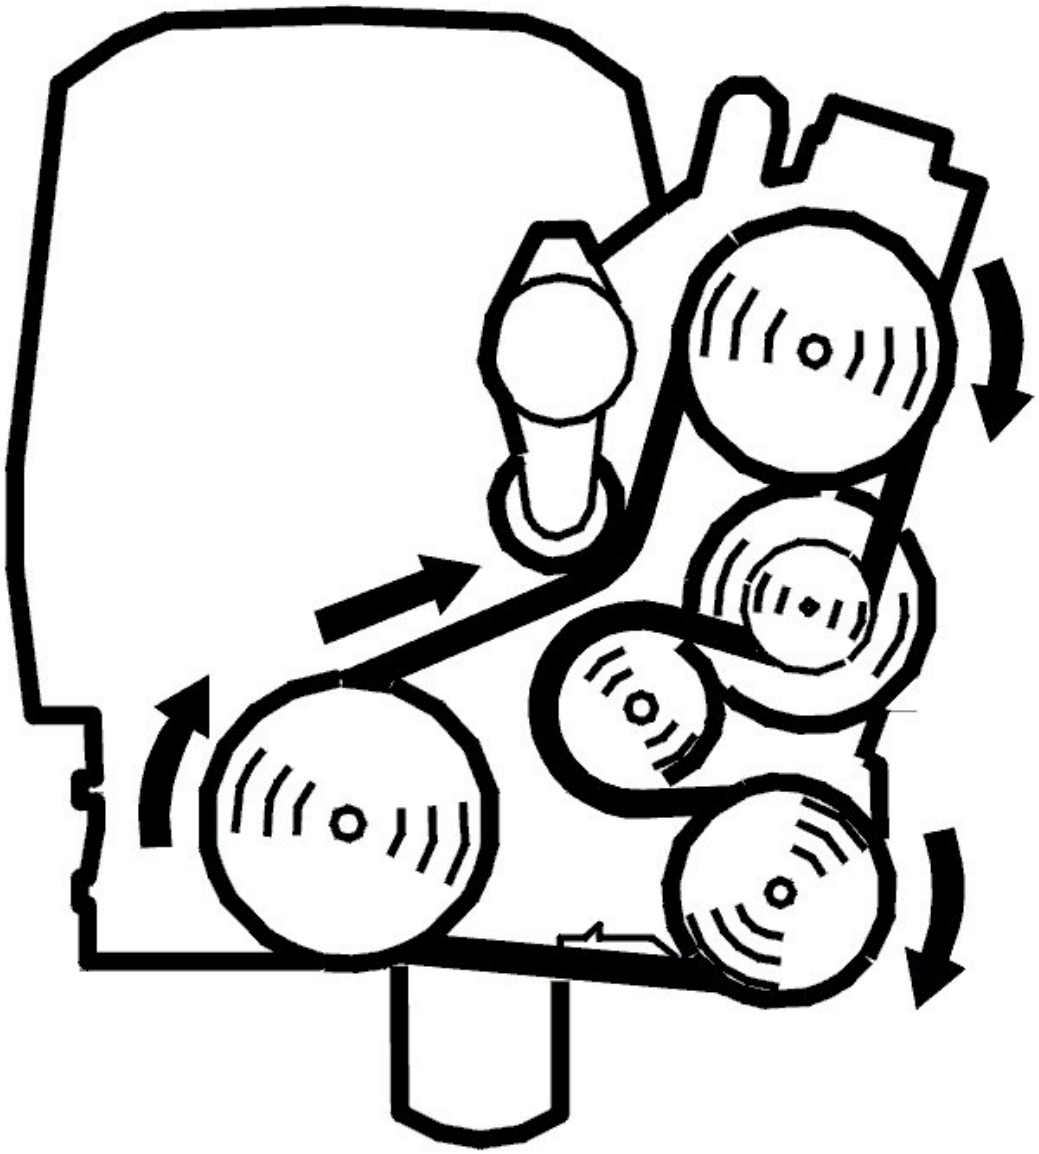
Possible source
- A battery charger with too high charge voltage has been connected previously
- Worn brushes (carbon)
- Damaged alternator control module (ACM)
- Damaged generator (GEN).

Fault symptom[s]
- The "Generator not charging" warning lamp is lit when the engine is running
- The battery discharges
- Low rotation speed in the starter motor
- The electrolyte in battery boils with the engine running
- The headlamp bulb blows.

Electrical Fault

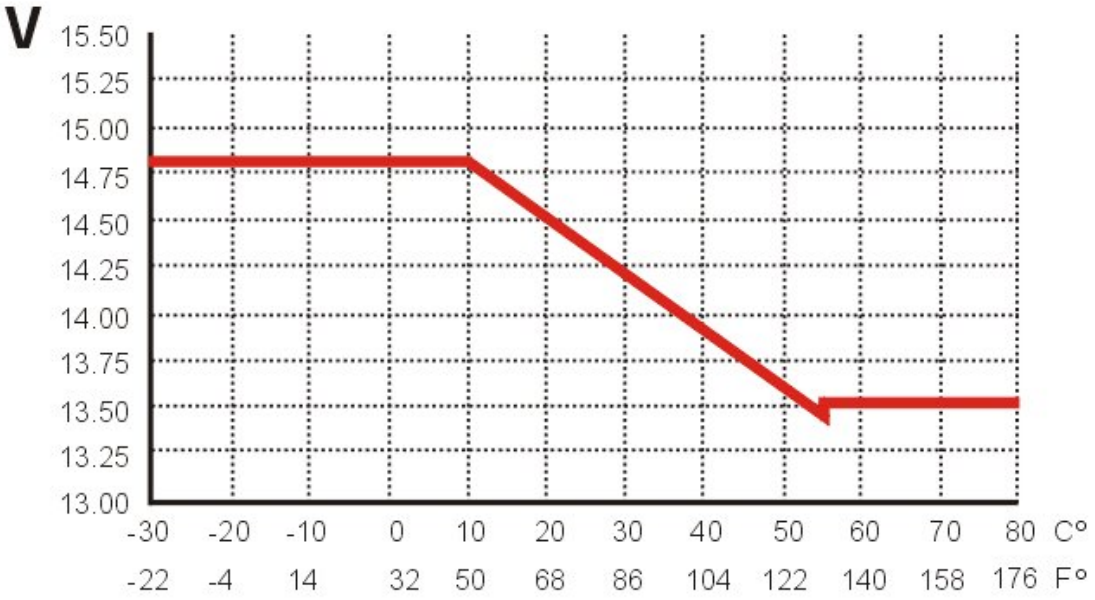
Electrical fault

Checking battery voltage



- Start the engine
- Read off the battery voltage. The central electronic module (CEM) uses the prevailing outside temperature to calculate the voltage at which the battery should be charged
- Switch on a few major power consuming components, such as the blower fan.

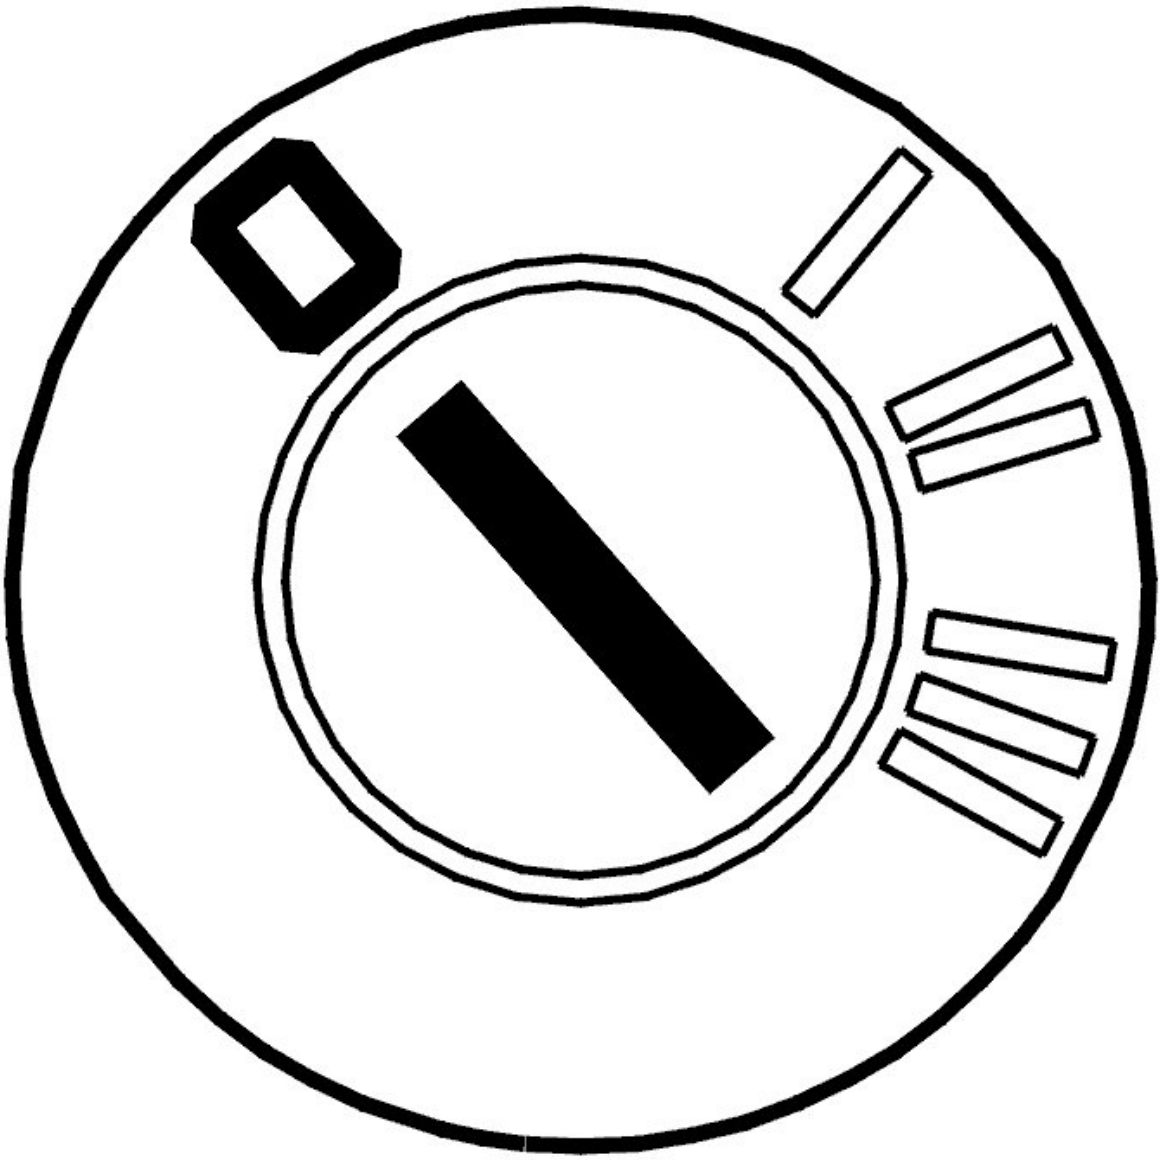
Check that the voltage is within the limits of 13.5-14.9 V. Try at different engine speeds (RPM).
The fault is permanent if the voltage is outside the permitted range.
If the voltage is within the permitted range, the fault was present previously but is not active at the moment, i.e. an intermittent fault.



Select Continue

Continue - Checking the component

Checking the component



- Ignition off.

Check the carbon brushes. If the brushes are worn, replace the alternator control module (ACM). Check that the brushes can move in the regulator housing. The brushes are lightly sprung. At the same time, check the slip rings. Replace the generator (GEN) if they are worn out.
If the brushes and slip rings appear to be OK, try a new alternator control module (ACM) (charge regulator). If this does not help, try a new generator (GEN).
Remedy as necessary.

Diagnostic Trouble Code (DTC) Information

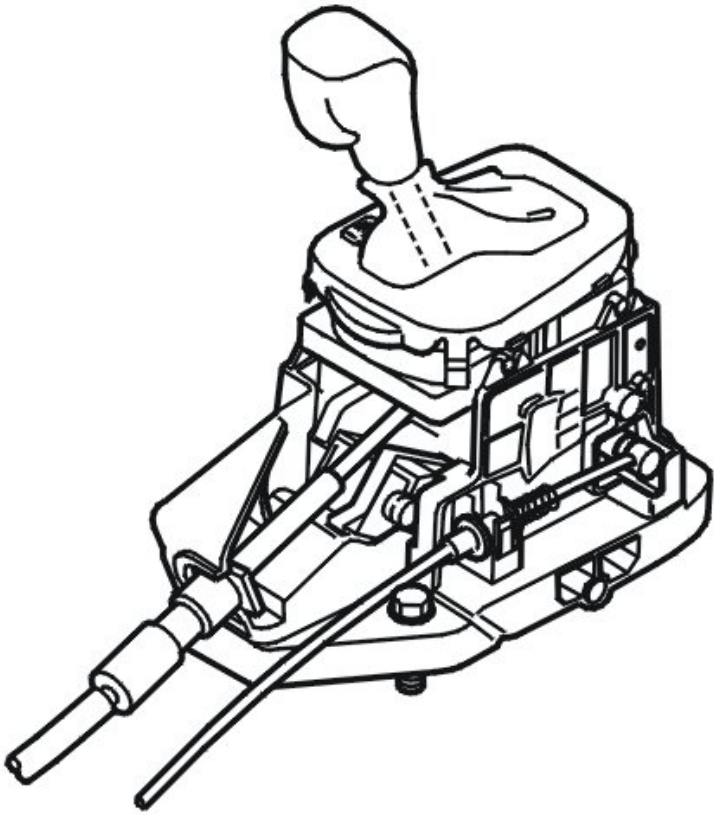
Diagnostic trouble code (DTC) information CEM-3F84

Condition



The central electronic module (CEM) receives information from the transmission on a hardwired cable indicating when park or neutral are engaged. This is achieved by grounding an input on the central electronic module (CEM). The central electronic module (CEM) also receives a signal indicating the position of the gear-shift position sensor from the transmission control module (TCM) via the controller area network (CAN).
The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) detects that the gear-shift selector lever is not in position P or N but the position received from the transmission control module (TCM) on the controller area network (CAN) indicates that it is.
The diagnostic trouble code (DTC) can be diagnosed at ignition switch position II.

Substitute value
- None.

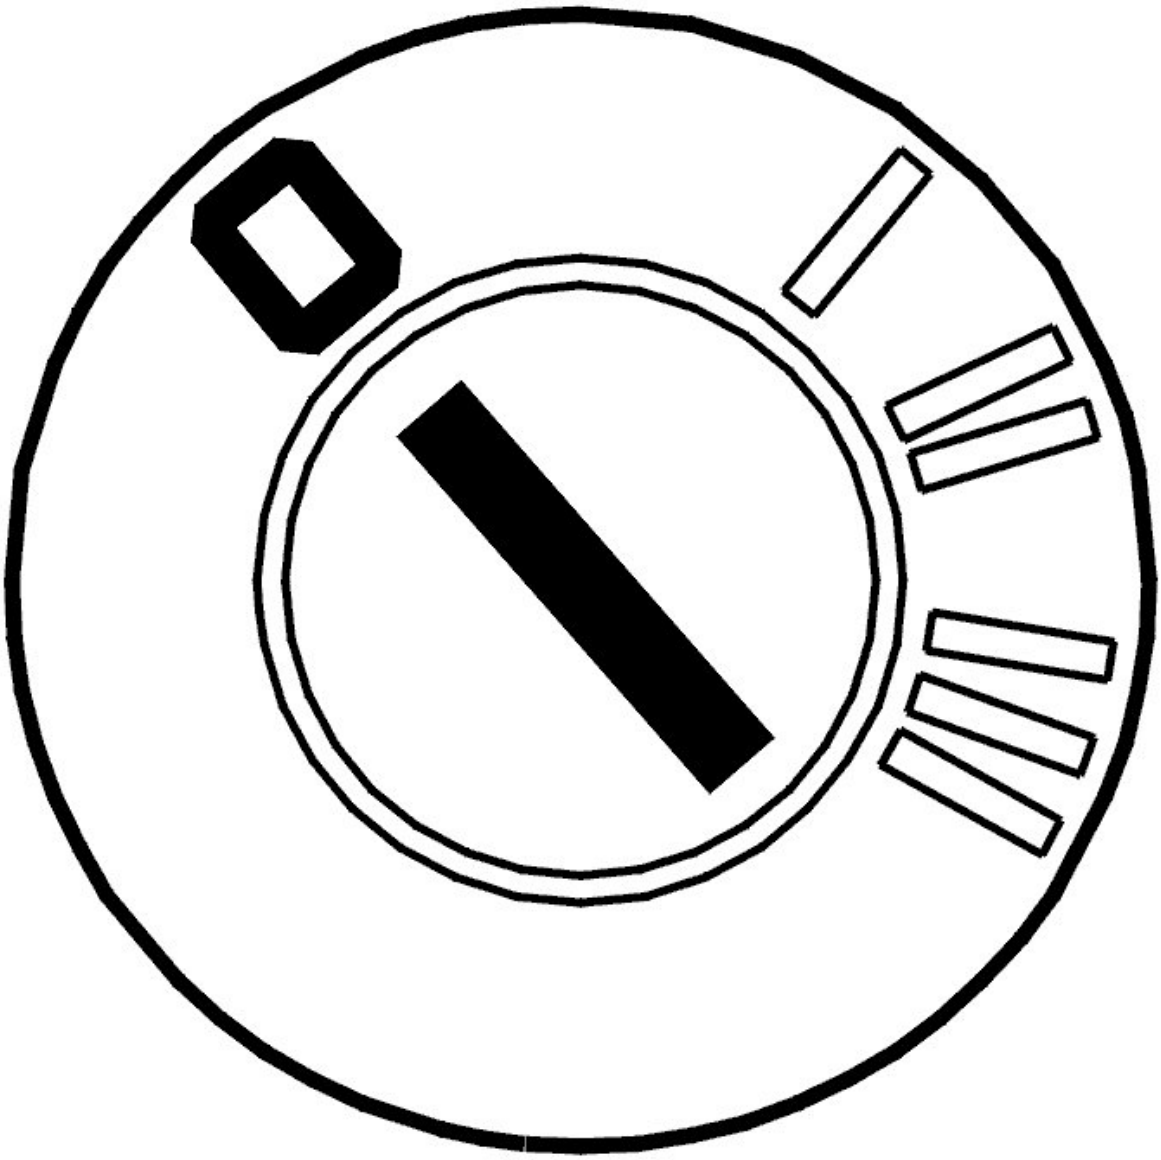
Possible source
- Open-circuit or short-circuit to supply voltage in the cable from the gear-shift position sensor.

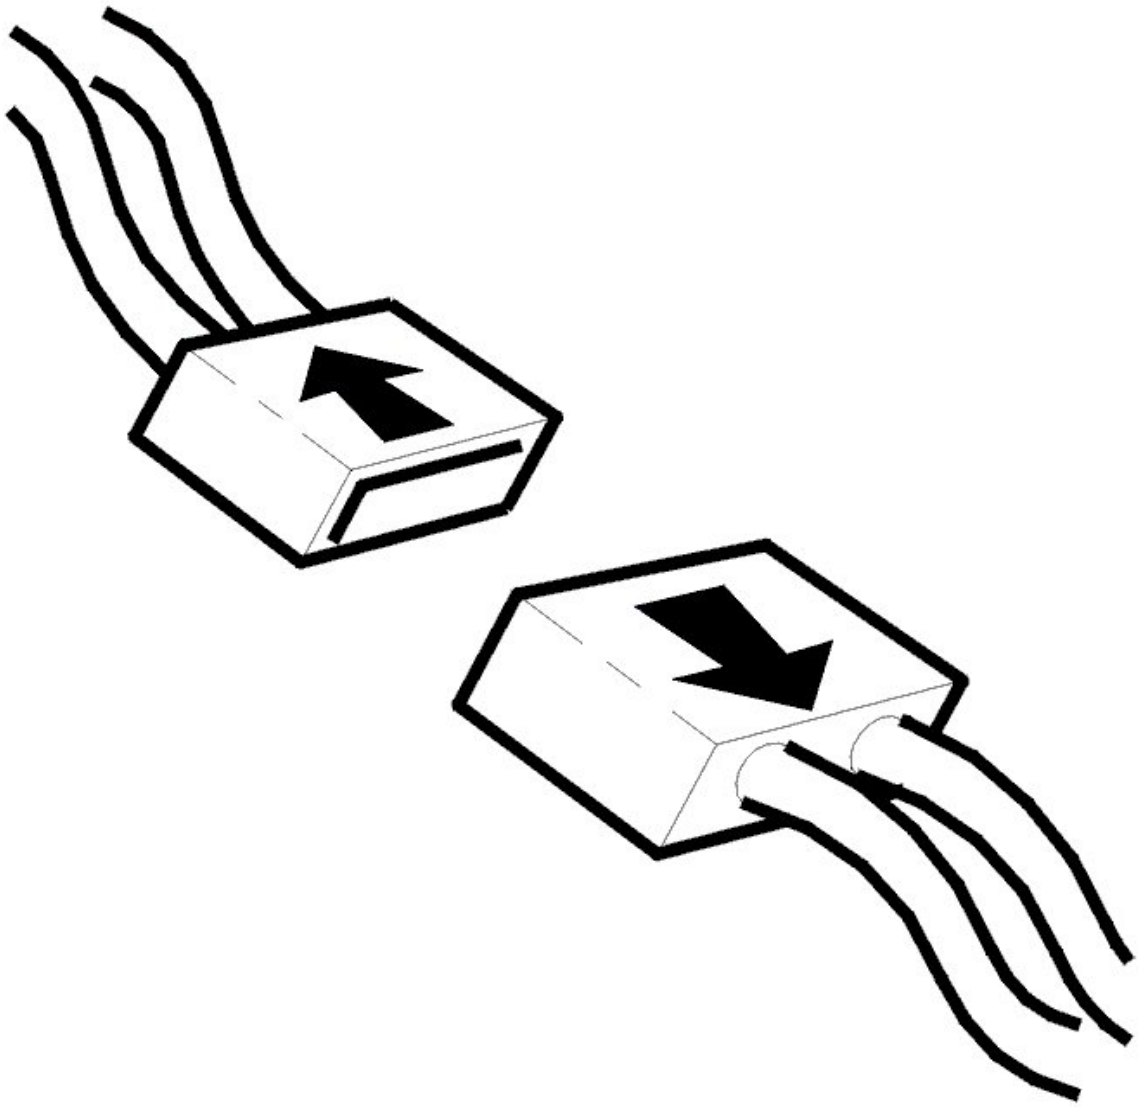
Fault symptom[s]
- The gear selector is jammed in position P.

Faulty Signal

Faulty signal

Checking the wiring





- Ignition off
- Disconnect central electronic module (CEM) connector C.

Check central electronic module (CEM) connector terminal C. Check for contact resistance. Check for oxidation. Check for damaged and loose connections.
Check the cable. Check for an open-circuit. Check for a short-circuit to the battery.
Take readings between:

- Central electronic module (CEM) terminal #C28 (28) and transmission control module (TCM) terminal #A44.

Remedy as necessary.

Other information

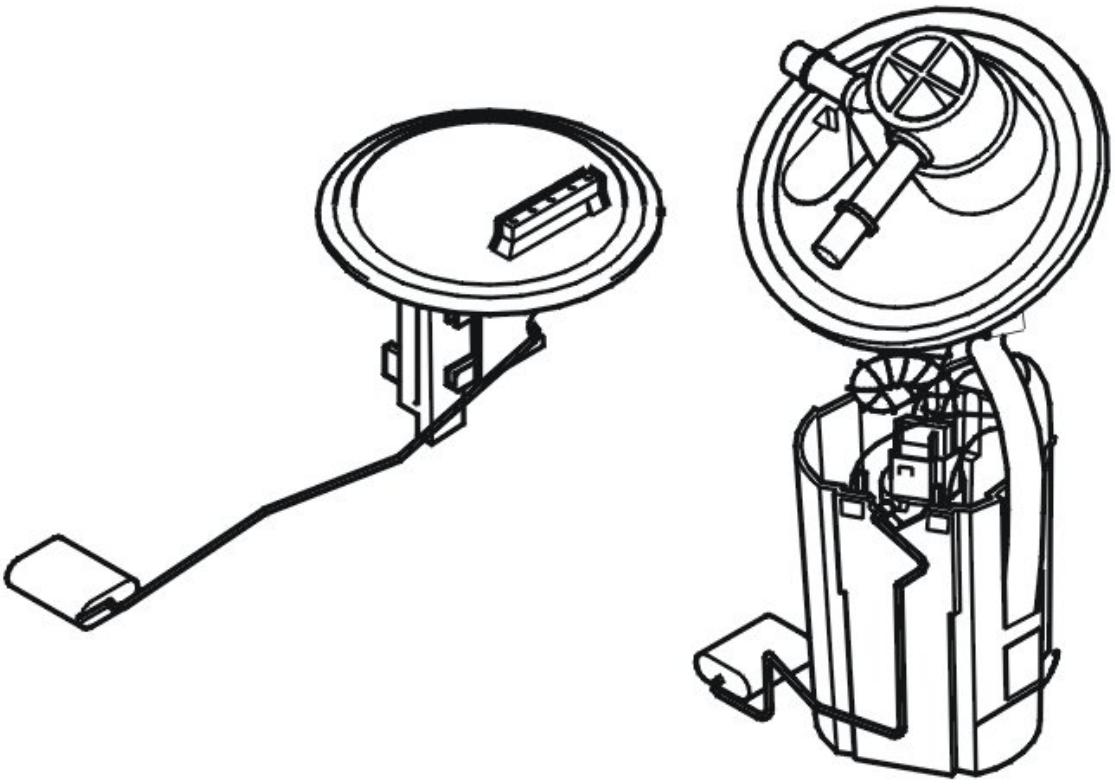
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CEM-3F90

Condition



Central electronic module (CEM) checks the fuel pump relay, and activates it, when an approved check has been made by the system for Immobilizer. The fuel pump relay is located internally in the Central electronic module (CEM). The fuel pump relay sends voltage feed to the fuel pump when the relay is activated.
If Central electronic module (CEM) detects that the voltage on the output to the fuel pump is too low, the diagnostic trouble code is generated.
The diagnostic trouble code (DTC) can be diagnosed when the fuel pump is activated.

Note! When troubleshooting, the fuel pump may not be supplied with voltage by an external power source without first disconnecting the connector to the Central electronic module (CEM). If the connector is not loosened and the fuel pump is supplied with voltage, this can lead to failure of an internal ground conductor in the Central electronic module (CEM). In turn, this can lead to a number of other malfunctions in the vehicle and that Central electronic module (CEM) must be replaced.

The following applies to vehicles with fuel pump module (PEM):

Central electronic module (CEM) checks the voltage feed to the fuel pump module. The Central electronic module (CEM) activates the voltage supply to the fuel pump control module after the checks carried out by the function for the immobilizer have been approved.
If Central electronic module (CEM) detects that the voltage on the output to the fuel pump module (PEM) is too low, the diagnostic trouble code is generated.
The diagnostic trouble code (DTC) can be diagnosed when the fuel pump is activated.

Substitute value

- None.

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

Possible source

- Damaged power supply fuse.
- Open circuit on cables for voltage feed between fuse box engine compartment and Central electronic module (CEM).
- The cable for voltage feed between Central electronic module (CEM) and fuel pump module (PEM)/fuel pump is short-circuited to ground.

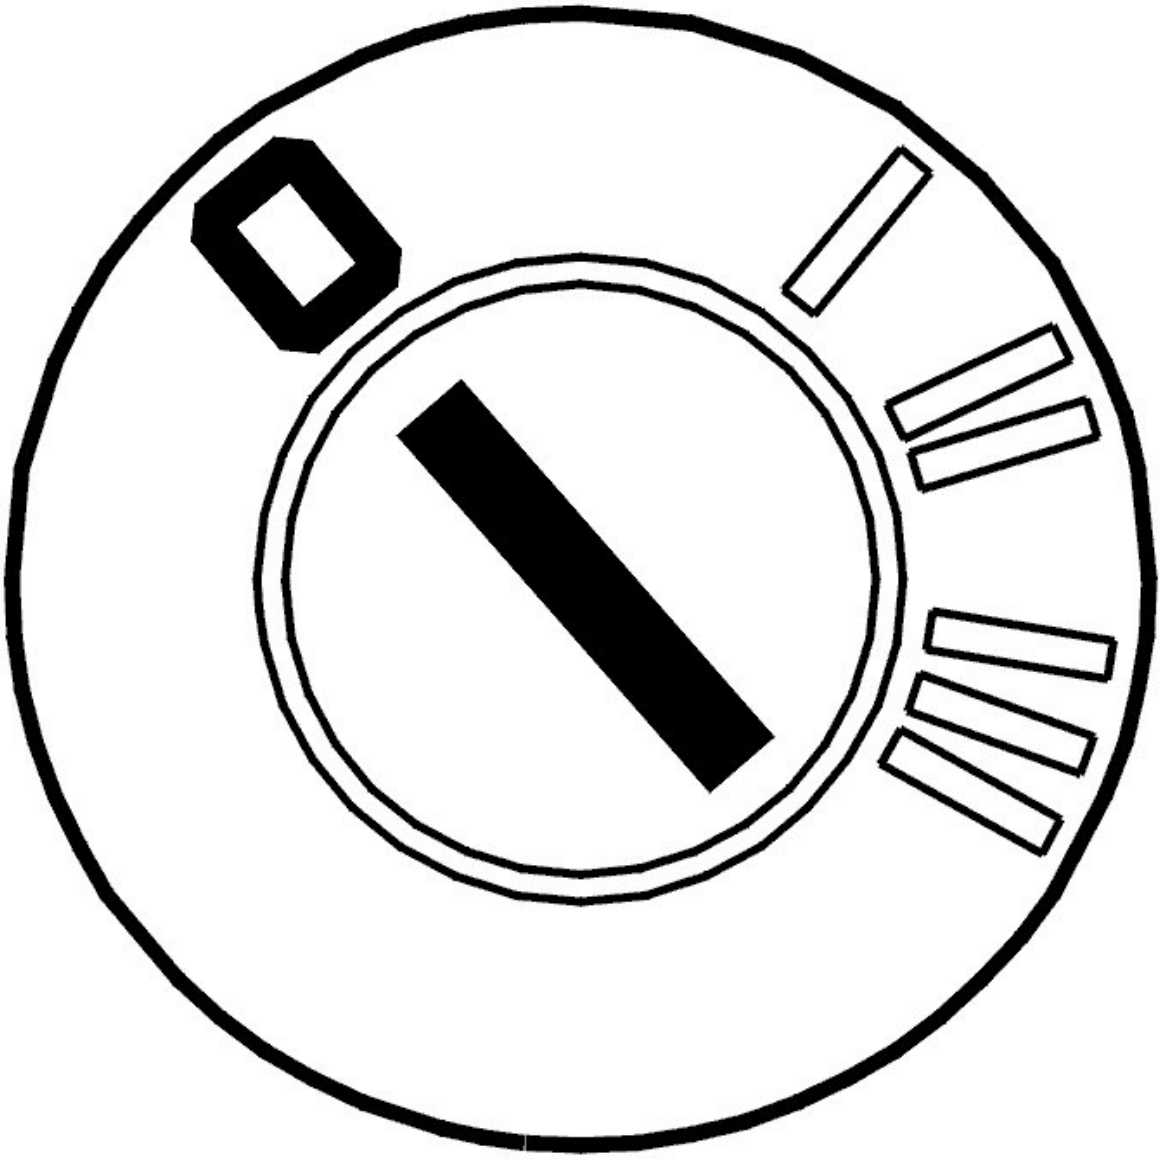
Fault symptom[s]

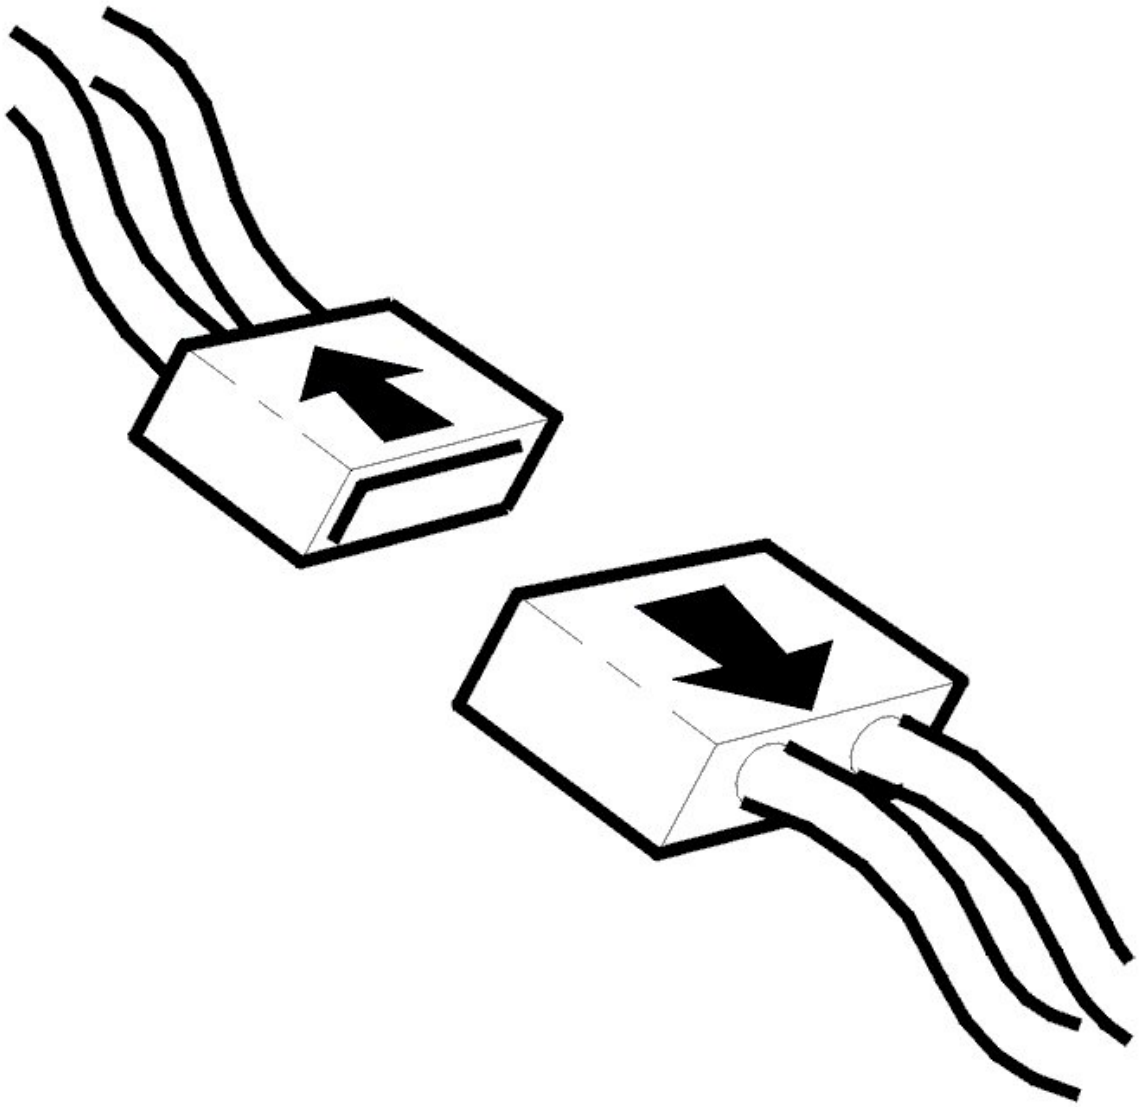
- The engine does not start.

Open-circuit or short-circuit to Ground

Open-circuit or short-circuit to ground

Checking the wiring





- Ignition off
- Check the fuse for voltage feed to fuel pump/fuel pump module.
- Disconnect central electronic module (CEM) connector A.

Check central electronic module (CEM) connector A and the connectors for the fuel pump (FP). Check for contact resistance. Check for oxidation. Check for damaged or loose connections.
Check the cable. Check for an open-circuit. Check for a short-circuit to ground.
Take readings between:

- Central electronic module (CEM) terminal #A16 (16) and fuel pump/fuel pump control module.

Remedy as necessary.

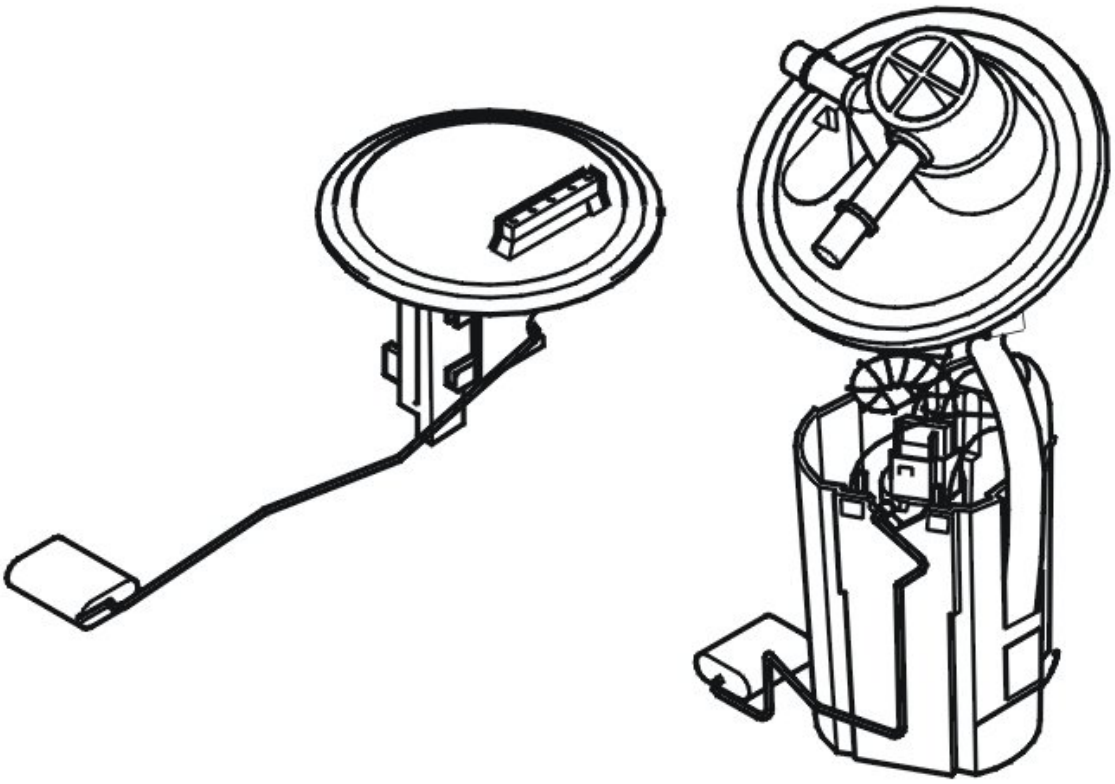
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CEM-3F91

Condition



Central electronic module (CEM) checks the fuel pump relay, and activates it, when an approved check has been made by the system for Immobilizer. The fuel pump relay is located internally in the Central electronic module (CEM). The fuel pump relay sends voltage feed to the fuel pump when the relay is activated.
If Central electronic module (CEM) detects that the output to the fuel pump is short-circuited to voltage, the diagnostic trouble code is generated. The diagnostic trouble code (DTC) can be diagnosed in ignition position II and if the fuel pump relay is activated at the same time.

Note!

Applies to vehicles to and incl. model year 2006

- When troubleshooting, the fuel pump may not be supplied with voltage by an external power source without first disconnecting the connector to the Central electronic module (CEM). If the connector is not loosened and the fuel pump is supplied with voltage, this can lead to failure of an internal ground conductor in the Central electronic module (CEM).

Applies to vehicles from and incl. model year 2007

- The case with the ground cable described above does not apply to Central electronic module (CEM) from and incl. model year 2006. This diagnostic trouble code can be generated if the cable for voltage feed to the fuel pump has an open circuit or if the fuel pump is not connected.

The following applies to vehicles with fuel pump module (PEM):

Central electronic module (CEM) checks the voltage feed to the fuel pump module. The Central electronic module (CEM) activates the voltage supply to the fuel pump control module after the checks carried out by the function for the immobilizer have been approved. The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers that the voltage in the signal cable is too high.

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

The diagnostic trouble code (DTC) can be diagnosed in ignition position II and if the relay for power supply to the fuel pump control module is not activated.

Substitute value
- None.

Possible source
- The cable for voltage feed to the fuel pump module is short-circuited to voltage.

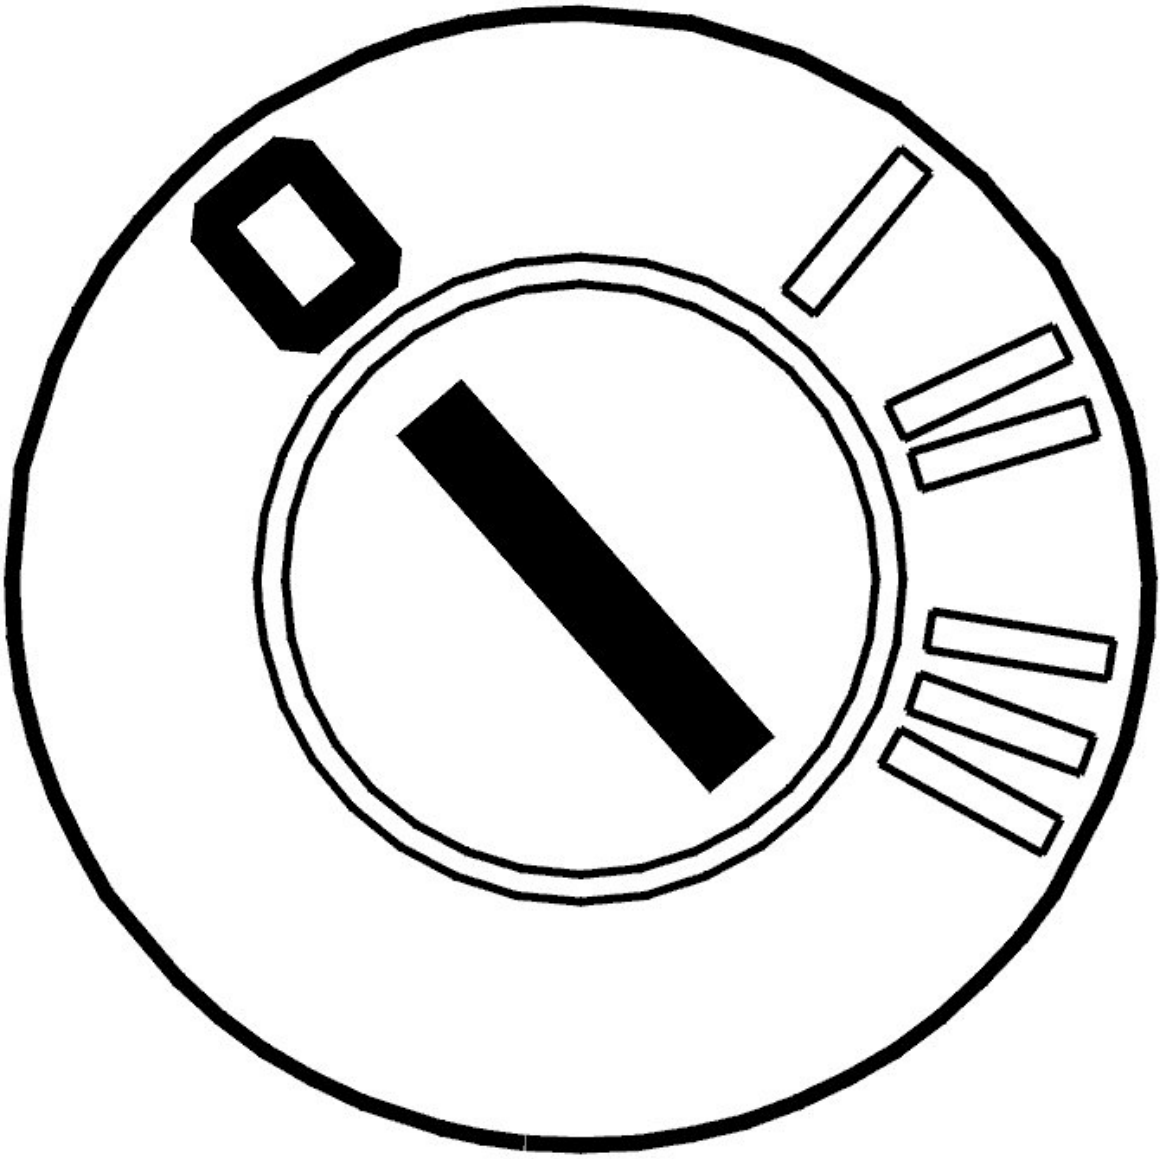
  Note! Applies to vehicles to and incl. model year 2006If the signal cable has been short-circuited to voltage, there is a risk of failure of an internal ground conductor on one of the circuit boards in the Central electronic module (CEM). This may lead to the relay for 15-feed, on Central electronic module (CEM), not working as intended. A result of incorrect function of 15-feed may be, e.g., that diagnostic trouble codes are generated for the seat heater in front seats and also that the communication with Brake control module (BCM) doe not work when the engine is on (BCM is not supplied with voltage when the 15-relay is not grounded). The malfunction may have different effects in different vehicles, depending on the vehicle's configuration (which units that are supplied via 15-feed), but also depends on where the ground conductor has failed.

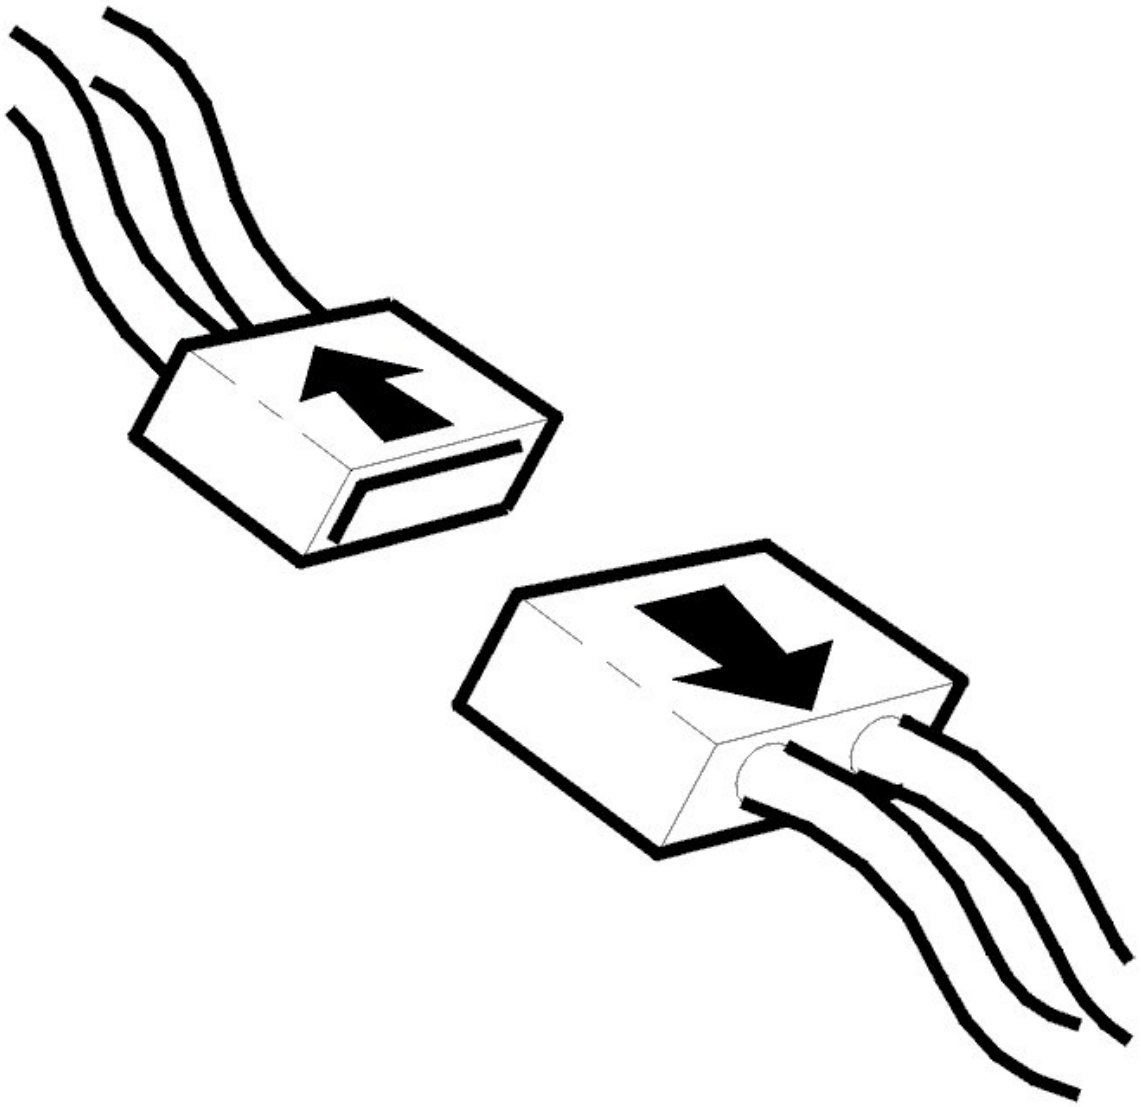
Fault symptom[s]
- Battery discharges

Short-circuit to Supply Voltage

Short-circuit to supply voltage

Checking the wiring





- Ignition off
- Disconnect central electronic module (CEM) connector A.

Check the cable for a short-circuit to supply voltage.
Take readings between:

- Central electronic module (CEM) terminal #A16 (16) and fuel pump/fuel pump control module.

Remedy as necessary.

Applies to vehicles to and incl. model year 2006

If the signal cable has been short-circuited to voltage, there is a risk of failure of an internal ground conductor on one of the circuit boards in the Central electronic module (CEM). This may lead to the relay for 15-feed, on Central electronic module (CEM), not working as intended. A result of incorrect function of 15-feed may be, e.g., that diagnostic trouble codes are generated for the seat heater in front seats and also that the communication with Brake control module (BCM) doe not work when the engine is on (BCM is not supplied with voltage when the 15-relay is not grounded). Continue - Verification

Replacing the component

Caution! A short-circuit to supply voltage may mean that the central electronic module (CEM) is damaged and must be replaced.

If the fault is intermittent, it has been registered previously but is no longer present. Intermittent faults can be caused by interference at start up of the central electronic module (CEM) or may be a different type of fault which occurs on different occasions. The fault is evaluated depending on how it occurs. Replace the central electronic module (CEM) if the fault recurs.
Replace the central electronic module (CEM) if the fault is permanent.
Remedy as necessary.

Substitute value
- None.

Possible source
- The reset button has been pressed in for more than 60 seconds
- The reset button has jammed in the pressed in position.

Fault symptom[s]
- The parking heater does not operate
- The reset button does not function.

Activated too long

Activated too long

Checking the control

The diagnostic trouble code (DTC) is stored when a button or switch has been depressed for a long time.
If the fault is intermittent, it has been registered previously but is no longer present. Intermittent faults can be caused by interference at start up or can be a different type of fault which occurs on different occasions. The fault is evaluated depending on how it occurs.
Check that the button or switch does not stick in the activated position.
Remedy as necessary.

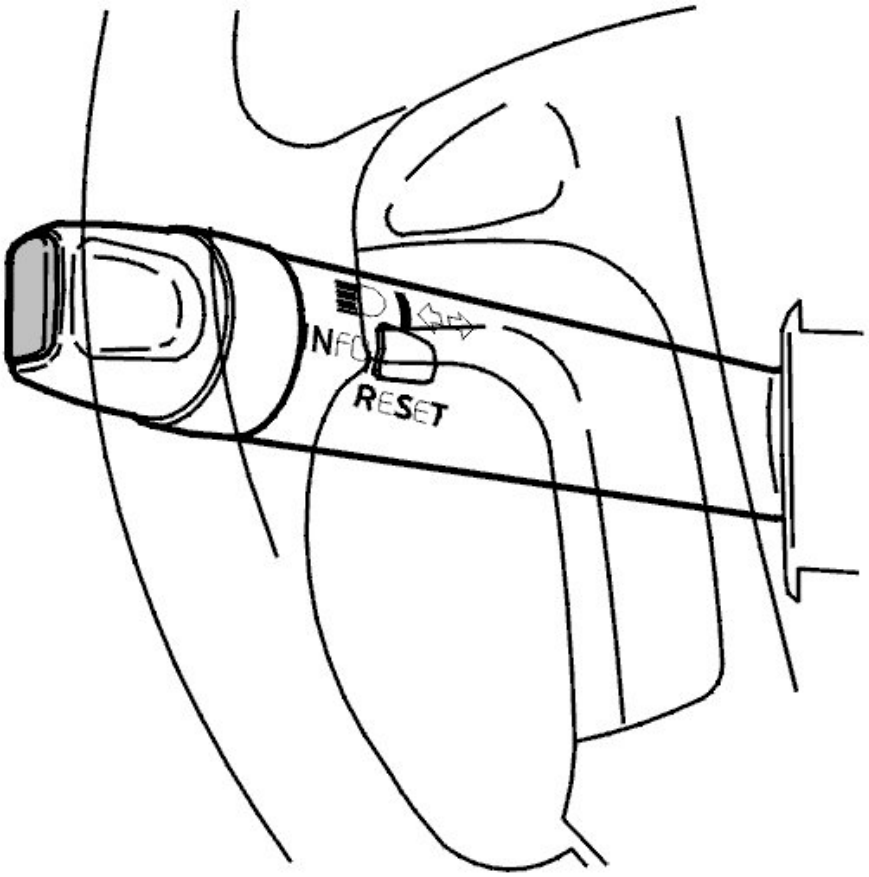
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CEM-4F01

Condition



The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers that the read button on the control stalk has been active for more than 60 seconds.
The diagnostic trouble code (DTC) can be diagnosed when the ignition is switched on.

Substitute value
- None.

Possible source
- The read button has been pressed in for more than 60 seconds
- The read button has jammed in the pressed in position.

Fault symptom[s]
- Text messages on the driver information module (DIM) cannot be erased.

Activated too long

Activated too long

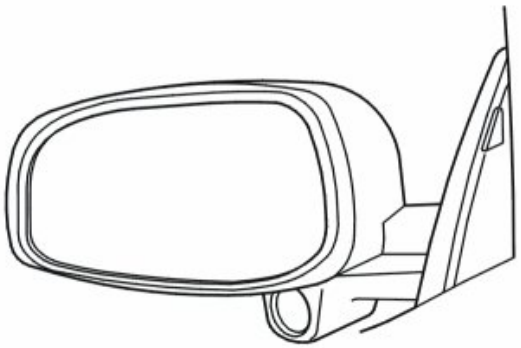
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CEM-4F41

Condition



The central electronic module (CEM) monitors communication between the blind spot indication system (BLIS) LEDs and camera modules.
If the central electronic module (CEM) detects that the signal from the left LED to the left camera module (LCM) is too low, a diagnostic trouble code is generated.
The diagnostic trouble code can be diagnosed when the ignition is on.

Substitute value
- Nothing.

Possible source
- The signal lead to the left LED is shorted to ground.

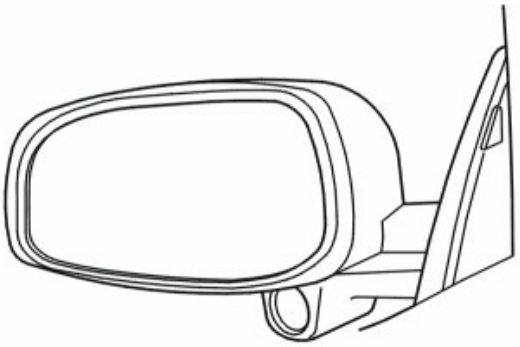
Fault symptom[s]
- The LED does not come on.

Signal Too Low

Signal too low

Checking the function

The LEDs should flash three times whenever the Blind Spot Indication System (BLIS) is activated.
Switch on the ignition to check the functionality of the left LED.

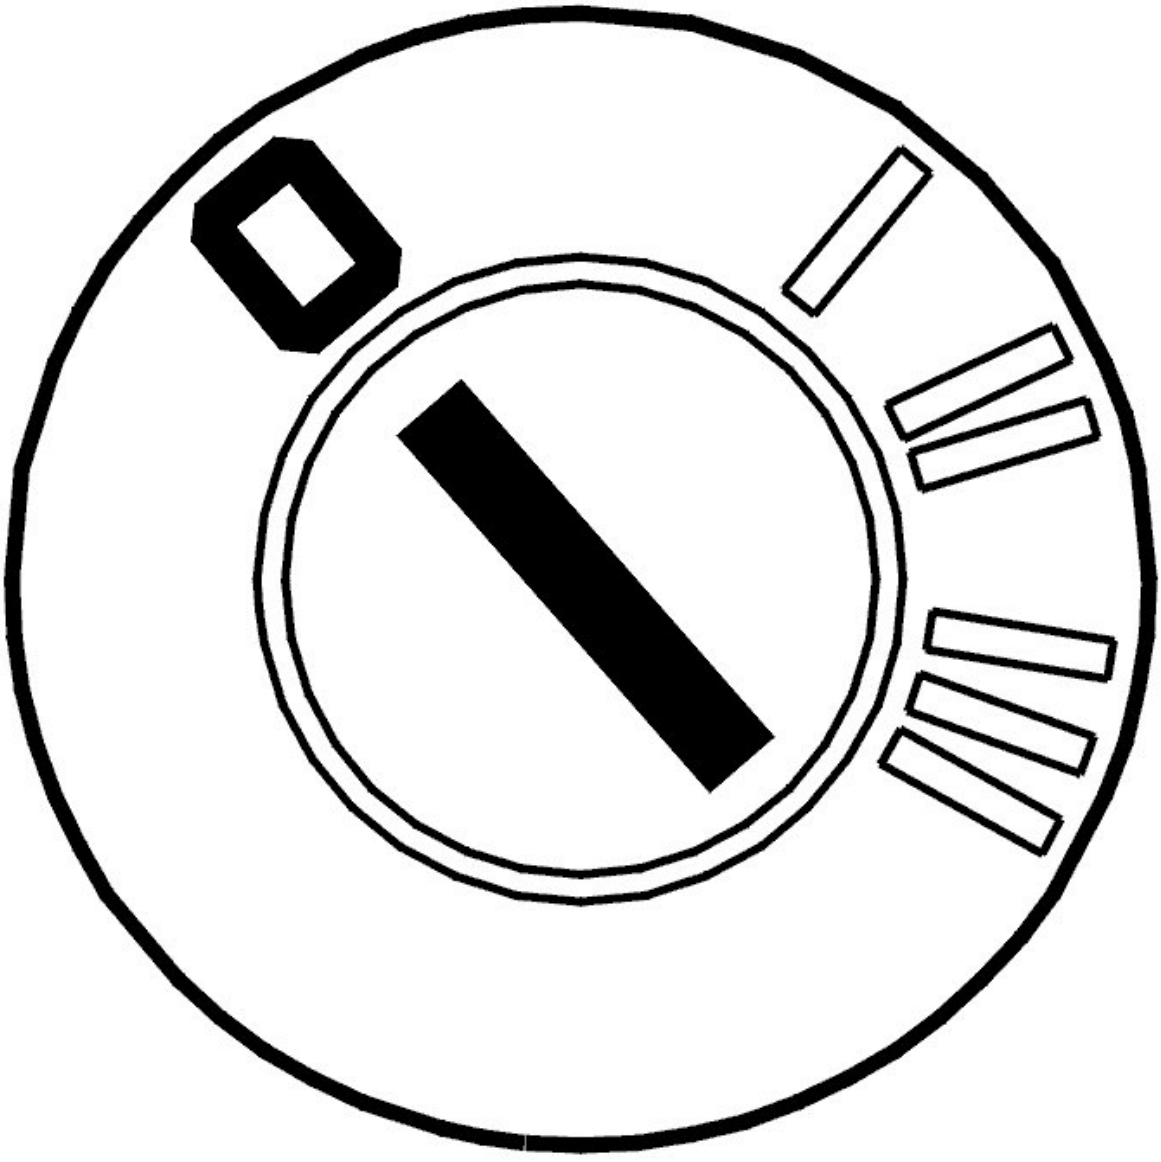


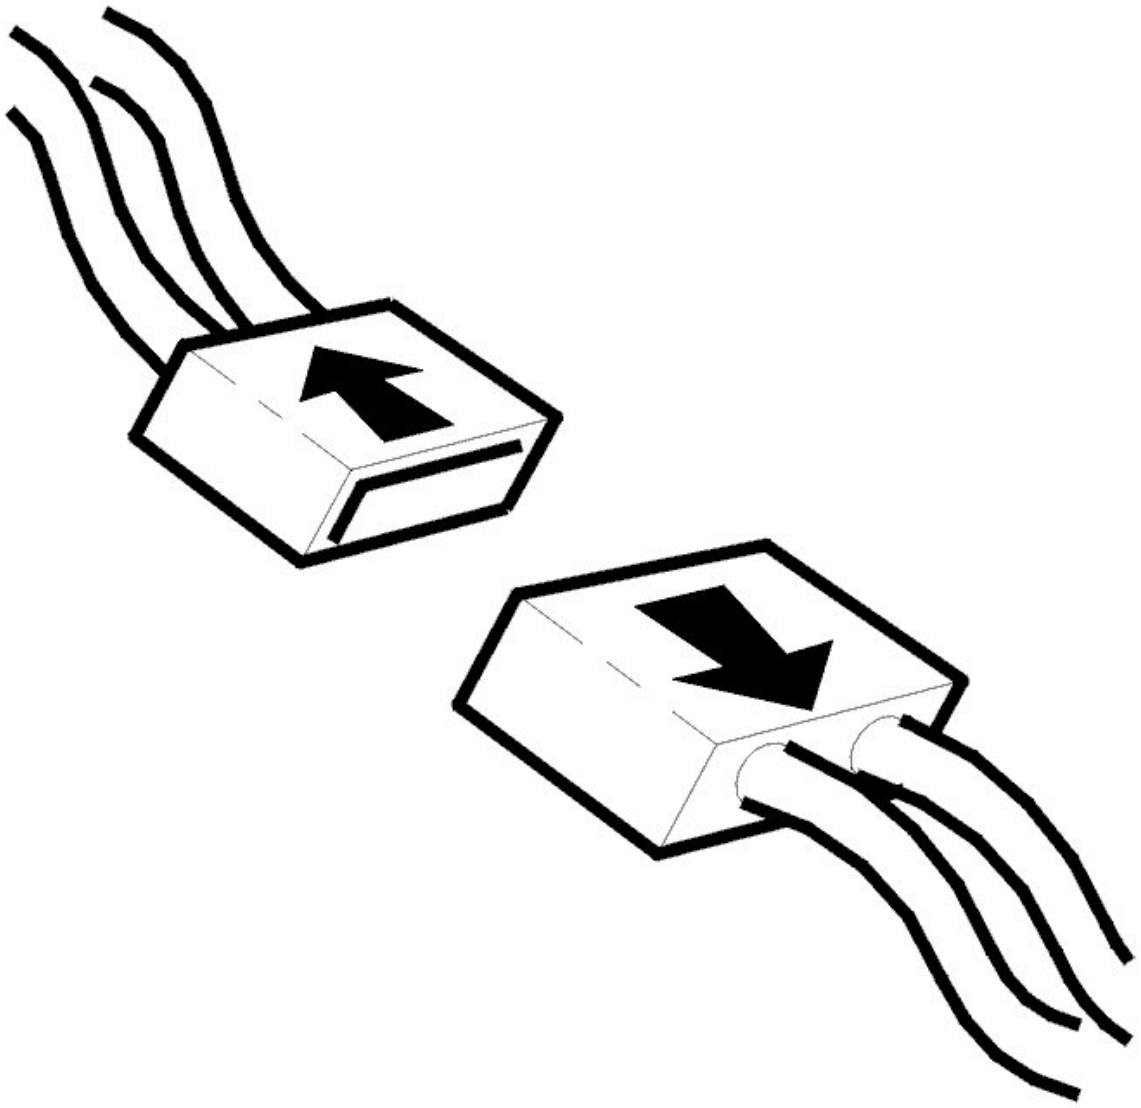
Did the LED flash three times?

Yes - Fault-tracing information

No - Checking the wiring

Checking the wiring





- Ignition off

Unplug the LED connector and check that the LED is intact. Also check the connector for contact resistance and corrosion.
Check the signal lead between the left camera module (LCM) and the #1 LED connector for shorting to ground.
Remedy as necessary.

Other information

Diagnostic Trouble Code (DTC) Information

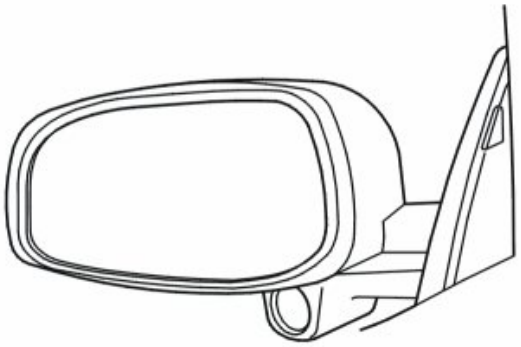
Diagnostic trouble code (DTC) information CEM-4F47

Condition



The central electronic module (CEM) controls communication with the blind spot indication system (BLIS) camera modules.
If the central electronic module (CEM) detects an internal fault on the left camera module (LCM) a diagnostic trouble code is generated.
The diagnostic trouble code can be diagnosed when the ignition is on.

Substitute value
- Nothing.

Possible source
- Dirty lens.
- Loose connection or oxidation in signal connections to Left Camera Module (LCM).
- Internal fault in left camera module (LCM).

Fault symptom[s]
- The LED does not come on.
- LED flashing rapidly.

Internal Fault

Internal fault

Replacing the component

A diagnostic trouble code will be generated if the central electronic module (CEM) detects an internal fault in the left camera module (LCM).
If the fault is intermittent it will have been registered earlier but no longer exists. Intermittent faults could be due to interference on starting up or to another type of fault than recurs at different times. The seriousness of the fault is determined from case to case.
Remedy as necessary.

Diagnostic Trouble Code (DTC) Information

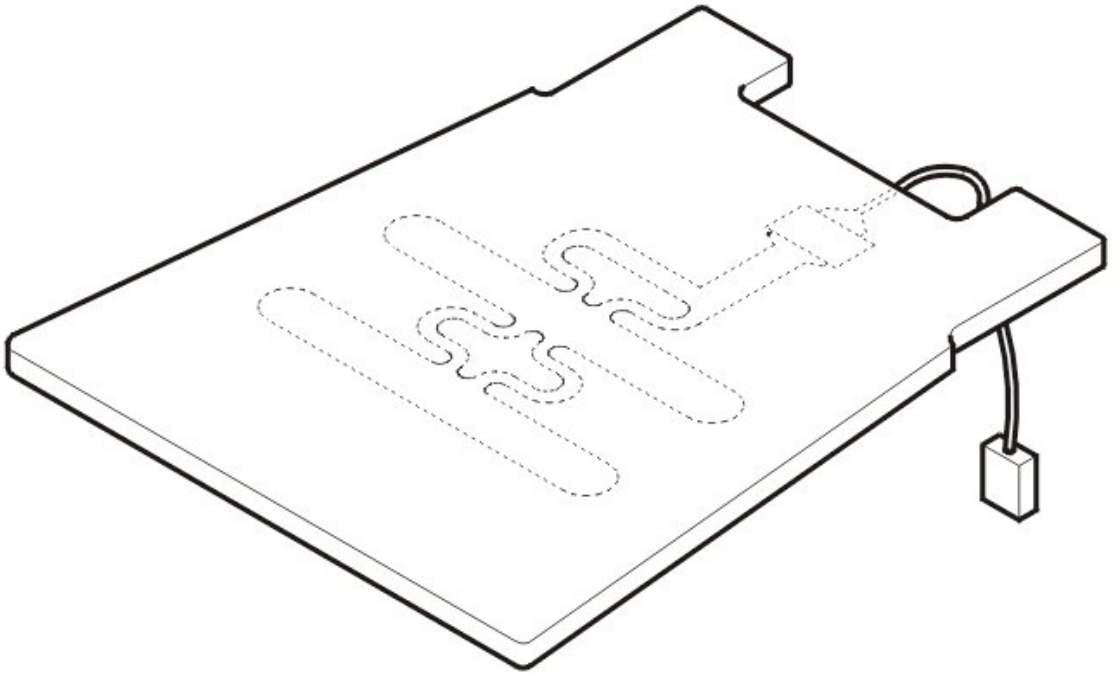
Diagnostic trouble code (DTC) information CEM-4F93

Condition



The central electronic module (CEM) checks the signal from the sensor for the seat belt reminder in the passenger seat.
The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers that the signal from the sensor is faulty.
The diagnostic trouble code (DTC) can be diagnosed with the ignition on and the battery voltage above 9 V.

Substitute value
- None.

Possible source
- Short-circuit between the signal cables
- Damaged sensor, seat belt reminder.

Fault symptom[s]
- General warning lamp lit.

Faulty Signal

Faulty signal

Checking components and wiring

Check the connectors on the central electronic module (CEM) and the sensor for the seat belt reminder. Check for contract resistance and oxidation. Check for damage or loose connections.
Check the signal cables between central electronic module (CEM) terminals D27 (#27) and D28 (#28) with the seat belt reminder sensor disconnected by measuring the resistance. Check for a short-circuit to each other. The resistance must be infinite.
Check the seat belt reminder sensor. Measure the resistance between terminals #1 and #2 in the sensor connector.

Hint: The resistance should be above 50 kohms with no passengers and below 50 kohms with passengers.

Remedy as necessary.

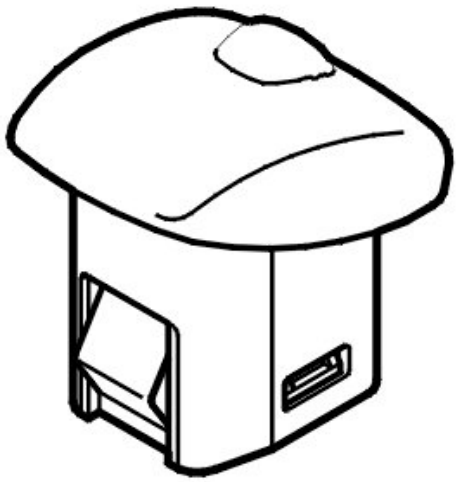
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CEM-5A00

Condition



The central electronic module (CEM) checks the signal from the sun sensor.
The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers that the signal from the sensor is too high.
The diagnostic trouble code (DTC) can be diagnosed when the ignition is switched on.

Substitute value
- The control module adopts a substitute value corresponding to approximately 20% (200 W/m2) of maximum solar heat.

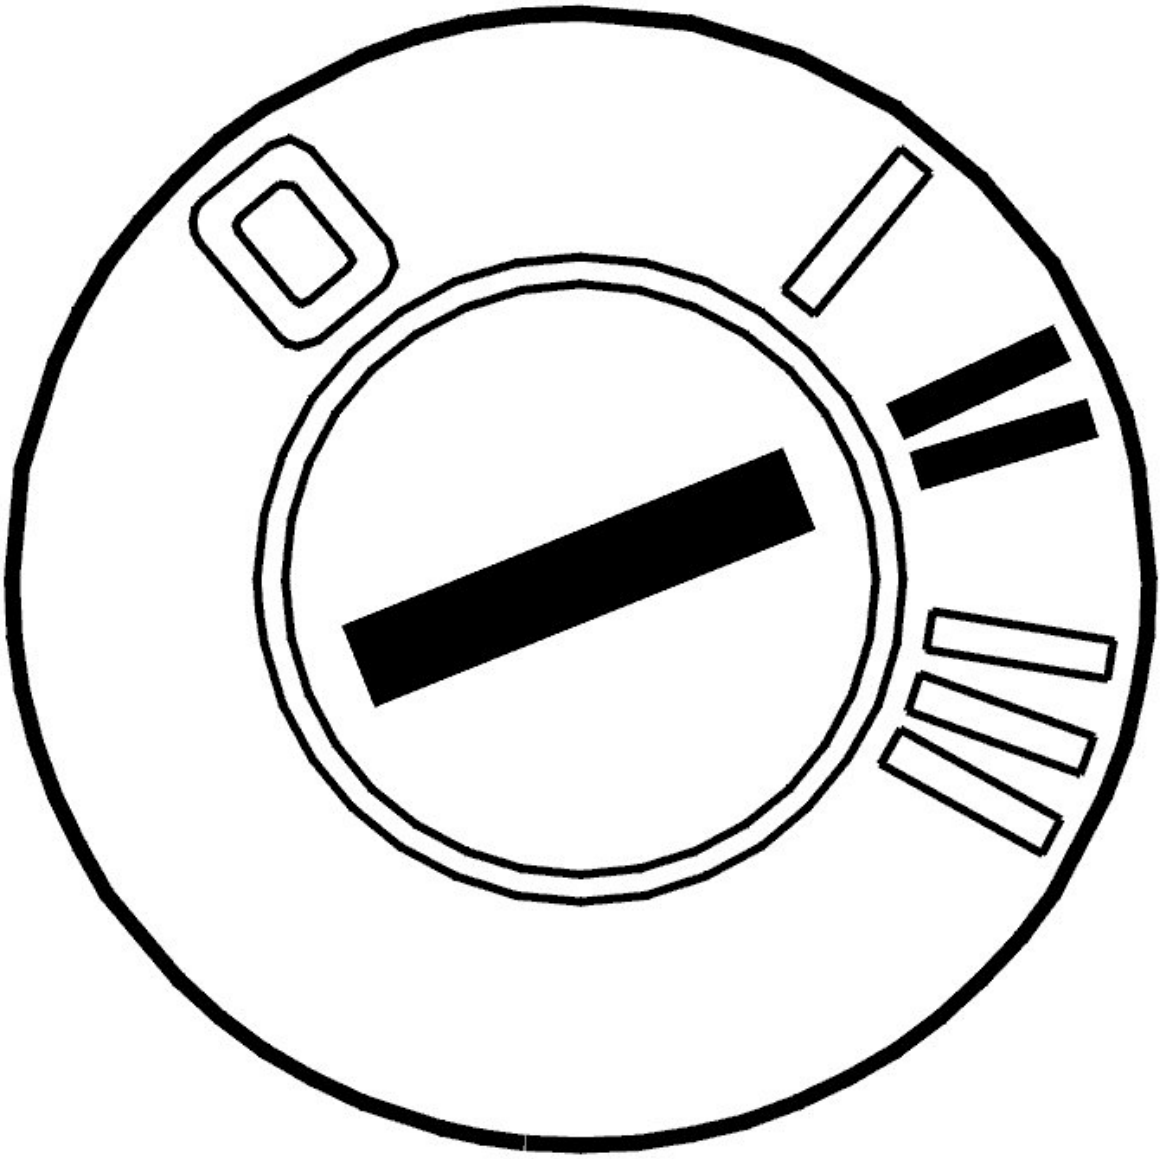
Possible source
- Short-circuit to supply voltage in the signal cable between the control module and the sun sensor
- Damaged sun sensor.

Fault symptom[s]
- The passenger compartment temperature does not drop when the sun intensity is high.

Signal Too High

Signal too high

Checking the component

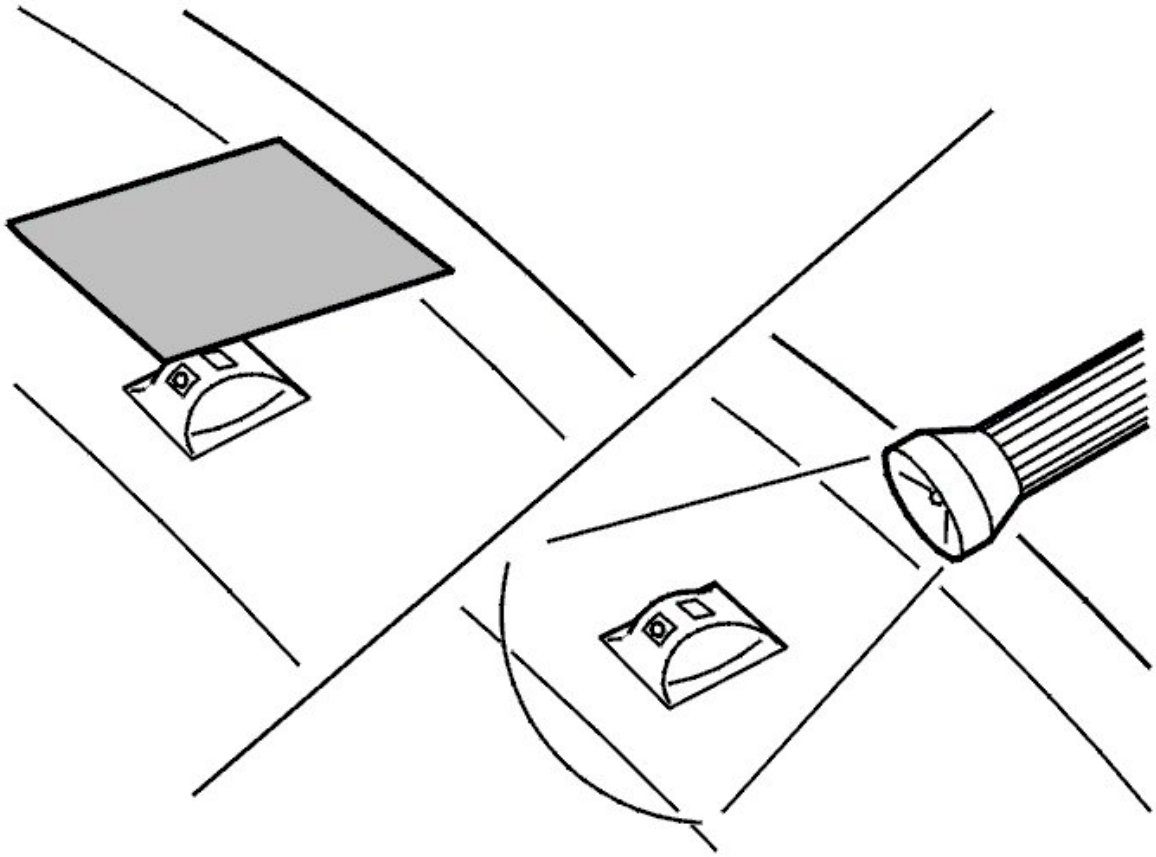


- Ignition on.

Check the sun sensor signal by varying the intensity of the light that it detects.
Cover the sun sensor with your hand to obtain the minimum signal, approximately 0.5 volts.
Then direct a strong light source (for example a flashlight) at the sun sensor from close range to increase the signal.

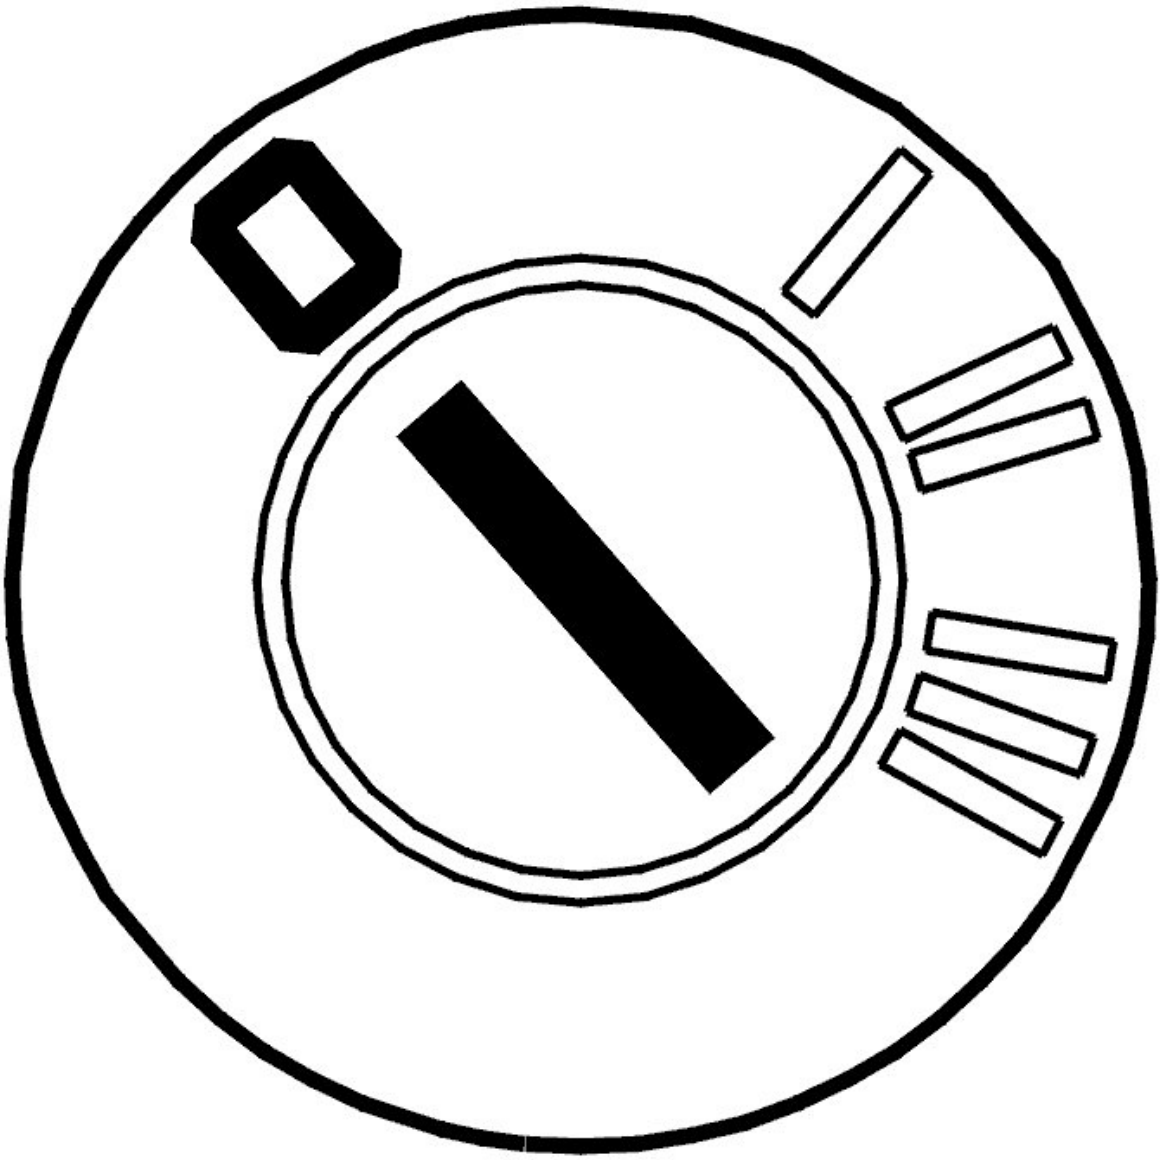
Hint: If the signal from the sun sensor is constantly above 4.85 volts, there is either an open-circuit in the cable or the sun sensor is defective.

Note! The illustration only shows the method. The appearance of the sun sensor can vary between different models.



Continue - Checking the wiring

Checking the wiring



- Ignition off.

Check the signal cable between the central electronic module (CEM) and the sun sensor. Check for an open-circuit. Check for a short-circuit to supply voltage.

Take readings between:

- Central electronic module (CEM) terminal #D30 (#30) and sun sensor terminal #1
- Central electronic module (CEM) terminal #D42 (#42) and sun sensor terminal #5.

Remedy as necessary.

Other information

- Connecting the breakout box See: Body and Frame/Body Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box/Connecting the Breakout Box, Central Electronic Module (CEM)

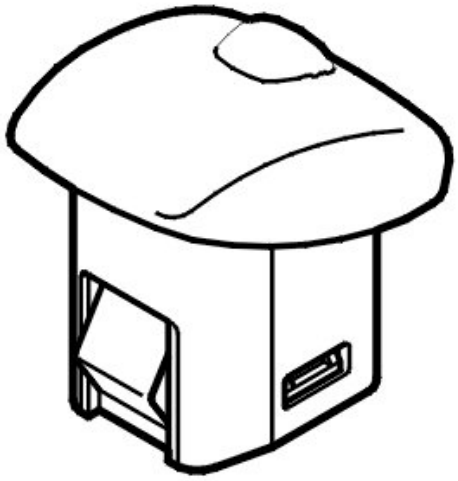
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CEM-5A01

Condition



The central electronic module (CEM) checks the signal from the sun sensor.
The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers that the signal from the sensor is too low.
The diagnostic trouble code (DTC) can be diagnosed when the ignition is switched on.

Substitute value
- The control module adopts a substitute value corresponding to approximately 20% (200 W/m2) of maximum solar heat.

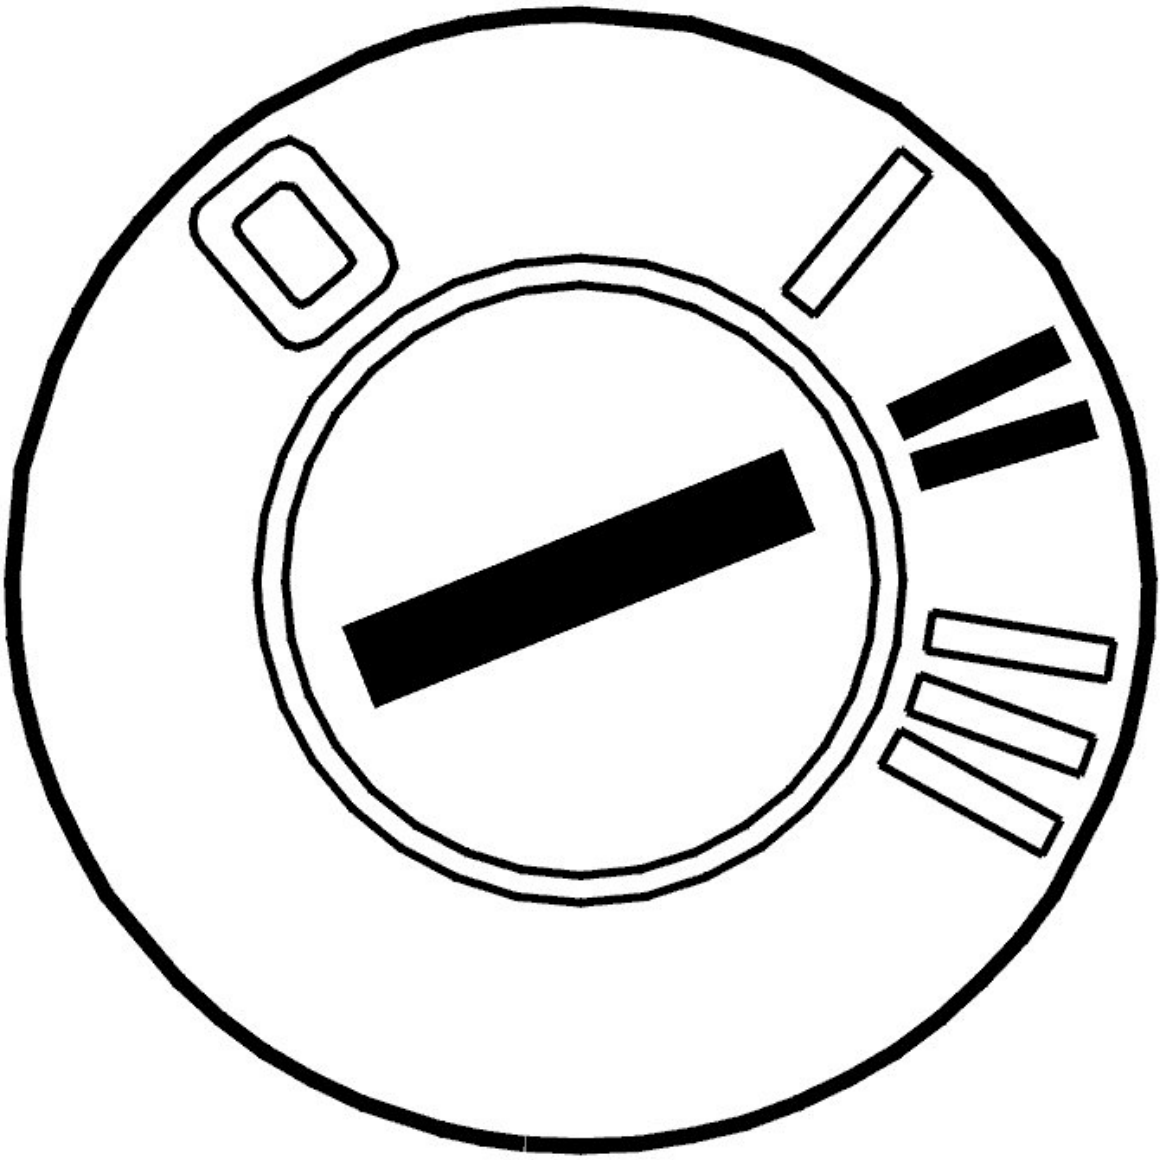
Possible source
- Short-circuit to ground in the signal cable between the control module and the sun sensor
- Damaged sun sensor.

Fault symptom[s]
- The passenger compartment temperature does not drop when the sun intensity is high.

Signal Too Low

Signal too low

Checking the component



- Ignition on.

If the fault is intermittent, it has been registered previously but is no longer present. Intermittent faults can be caused by interference at start up of the central electronic module (CEM) or may be a different type of fault which occurs on different occasions. The fault is evaluated depending on how it occurs.
Vary the light intensity. Read off the signal from the sun sensor.
Cover the sun sensor with your hand to obtain the minimum signal, approximately 0.5 volts.
Then direct a strong light source (for example a flashlight) at the sun sensor from close range to increase the signal.

Hint: The value must vary between approximately 0.5 and 4.85 V.

Do you want to exit fault-tracing?

Yes - FAULT-TRACING FAILED

No - Attempt New Test

FAULT-TRACING FAILED - FAULT-TRACING FAILED

Attempt New Test - Checking the function of the fuel pump (FP)

Checking components and wiring

Check the cable between combustion preheater module (CPM) terminal #13 and fuel pump (FP) terminal 2. Check for a short-circuit to supply voltage.
With the ignition on and the fuel pump (FP) connector disconnected, the voltage between fuel pump (FP) terminal 2 (control module side) and ground must be 0 V.
The fuel pump (FP) must be replaced if no faults are found in the cable.
Remedy as necessary.

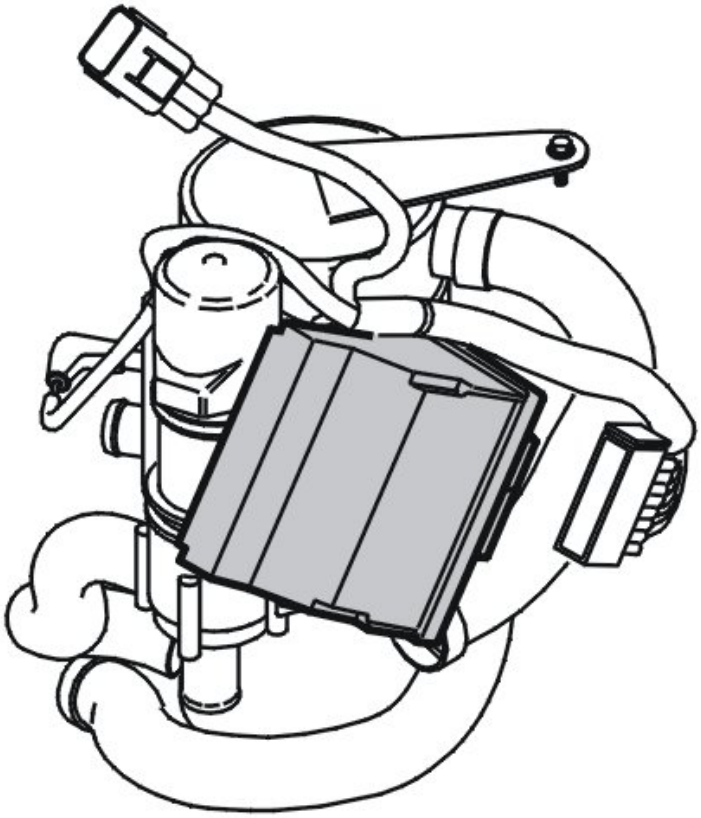
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CEM-5F4C

Condition



The central electronic module (CEM) checks the communication with the combustion preheater module (CPM).
The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers that the power supply to the combustion preheater module (CPM) is below 10.5 V.
The diagnostic trouble code (DTC) can be diagnosed when the heater is activated.

Substitute value
- None.

Possible source
- Poor battery
- Contact resistance in the control module terminals
- Damaged generator (GEN).

Fault symptom[s]
- Poor heating in the passenger compartment.

Signal Too Low

Signal too low

Checking the supply

Check the power supply to combustion preheater module (CPM) terminal #9. Check for contact resistance and oxidation. Check for loose connections. Also check the fuse in the engine compartment. Voltage should be 12 V.
Check the cable between terminal #1 on the Ext-X relay (2/29) and terminal #15 on the combustion preheater module (CPM). Check for contact resistance and oxidation. Check for loose connections. Check the relay, the power supply to the relay and the passenger compartment fuse.
If no fault is found, the fault may have been intermittent.
Remedy as necessary.

Other information

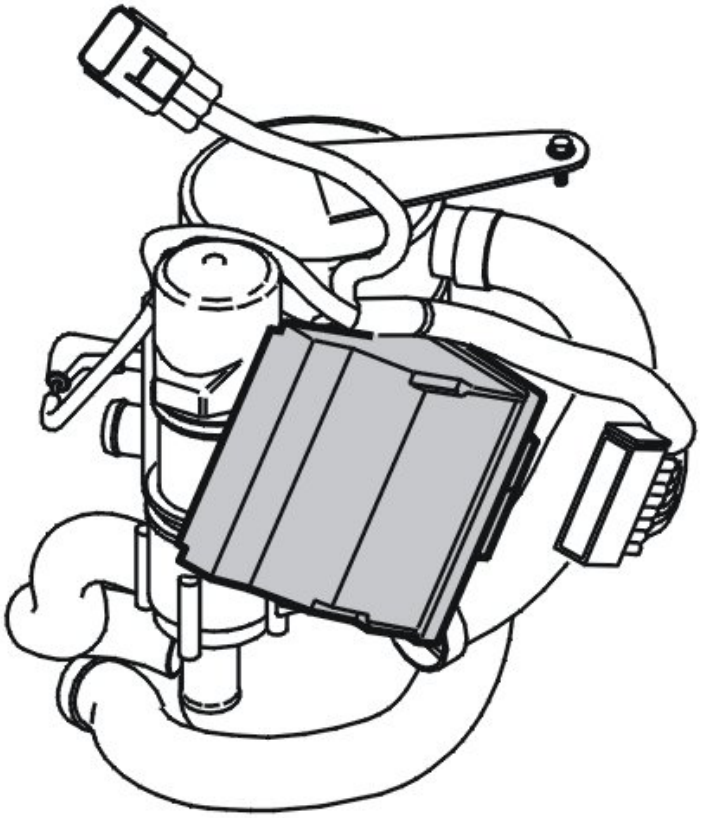
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CEM-5F4D

Condition



The central electronic module (CEM) checks the communication with the combustion preheater module (CPM).
The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers that the internal diagnostics in the combustion preheater module (CPM) do not respond within a certain time.
The diagnostic trouble code (DTC) can be diagnosed when the heater is activated.

Substitute value
- None.

Possible source
- Contact resistance in the terminals.
- Open-circuit in the communication cable.
- Short-circuit to ground in the communication cable.
- Short-circuit to supply voltage in the communication cable.

Fault symptom[s]
- Poor heating in the passenger compartment.

Too long time

Too long time

Checking communication

Check whether the communication is working. Read off the combustion preheater module (CPM) P/N in the VIDA communication input for example.
Test whether the fault is only limited to the combustion preheater module (CPM) or if there are communication faults with other nodes as well. The fault has been localized if the only problem is in establishing contact with the combustion preheater module (CPM).
If the communication works and the P/N can be read off, the fault is intermittent.

Continue - Checking communication

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CEM-5F4F

Condition

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

The central electronic module (CEM) checks the function and status parking heater.
During activation, the heater tries to start. If the heater does not start, it will try again a few times.
The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) receives a signal from the heater indicating that it has tried to start but failed.
The diagnostic trouble code (DTC) can be diagnosed when the heater is activated.

Substitute value
- The heater is not activated.

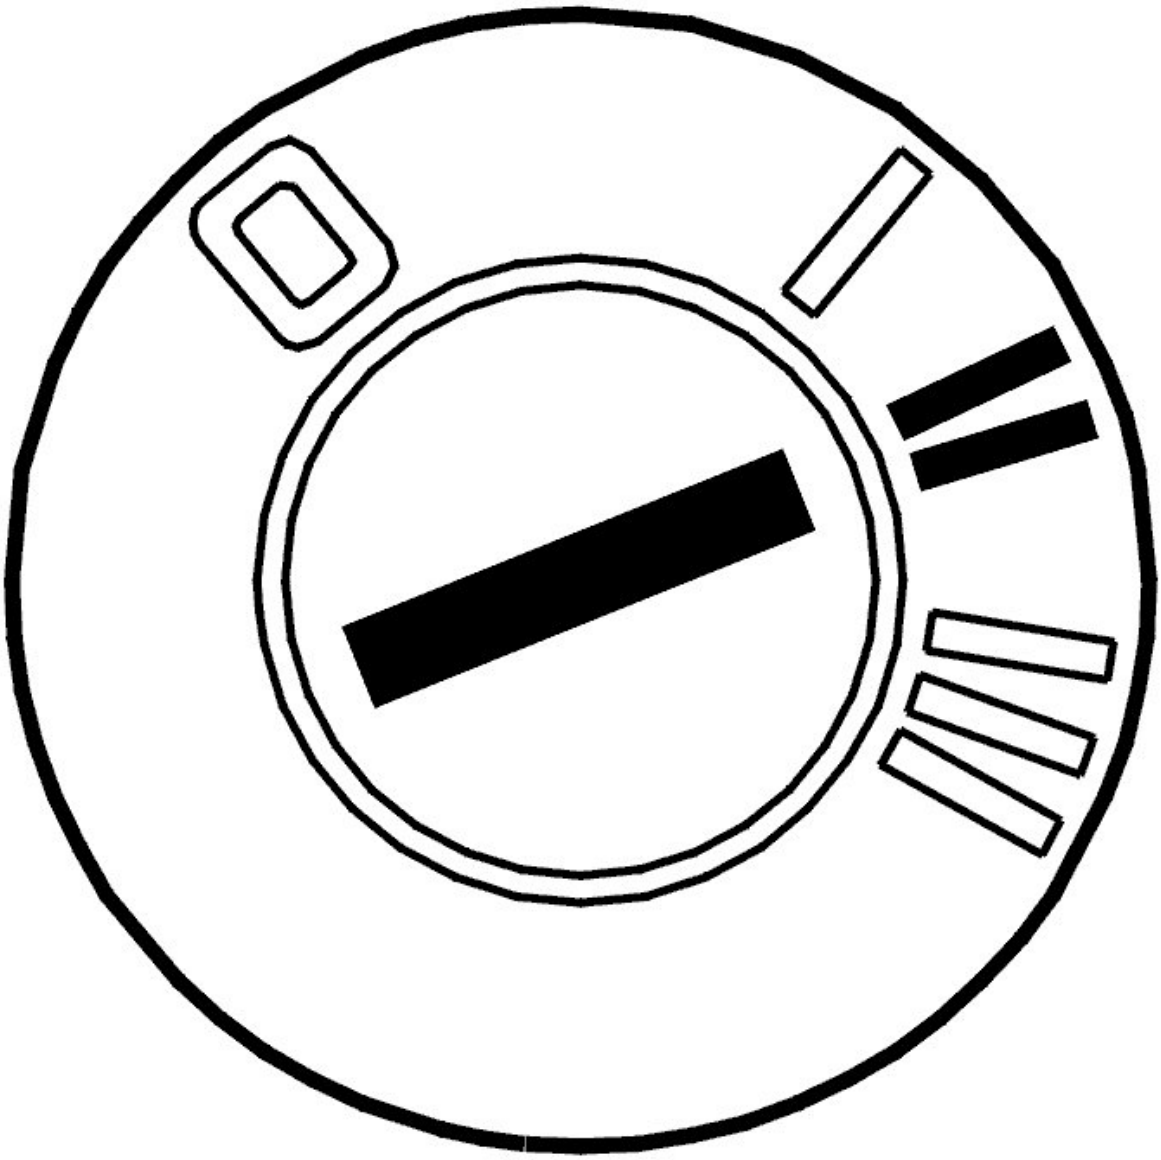
Possible source
- Fault in the fuel supply to the parking heater
- Flame sensor clogged with soot
- Blocked combustion air intake
- Contact resistance in the control module connectors
- Open-circuit or short-circuit to supply voltage in the control signal cable for the flame sensor
- Flame sensor not functioning.
- Fault in the power supply for the parking heater

Fault symptom[s]
- Poor heating in the passenger compartment.

Too Many Unsuccessful Attempts

Too many unsuccessful attempts

Checking the quantity of fuel and voltage



- If the quantity of fuel in the fuel tank is below 6 liters the heater is not permitted to start. If the battery voltage is poor the heater is not permitted to start. The combustion preheater module (CPM) interprets 3 or more failed start attempts as a fault in the heater. The heater cannot then be started until the diagnostic trouble codes (DTCs) have been erased
- Ignition on.

Note! The heater must be switched off when reading off!

Read off the values.
The fuel level status must be OK and the voltage to the heater must be normal.

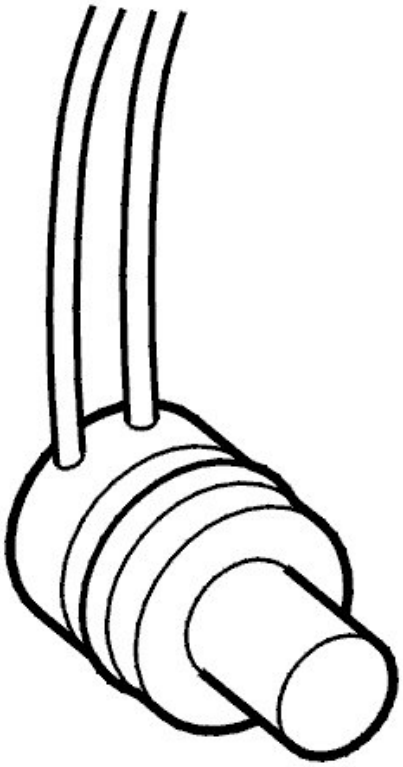
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CEM-5F31

Condition



The central electronic module (CEM) checks the communication with the combustion preheater module (CPM).
If Central electronic module (CEM) registers open circuit or short-circuiting to voltage on the circuit for the water temperature sensor, the diagnostic trouble code is generated.
The diagnostic trouble code (DTC) can be diagnosed when the heater is activated.

Substitute value
- None.

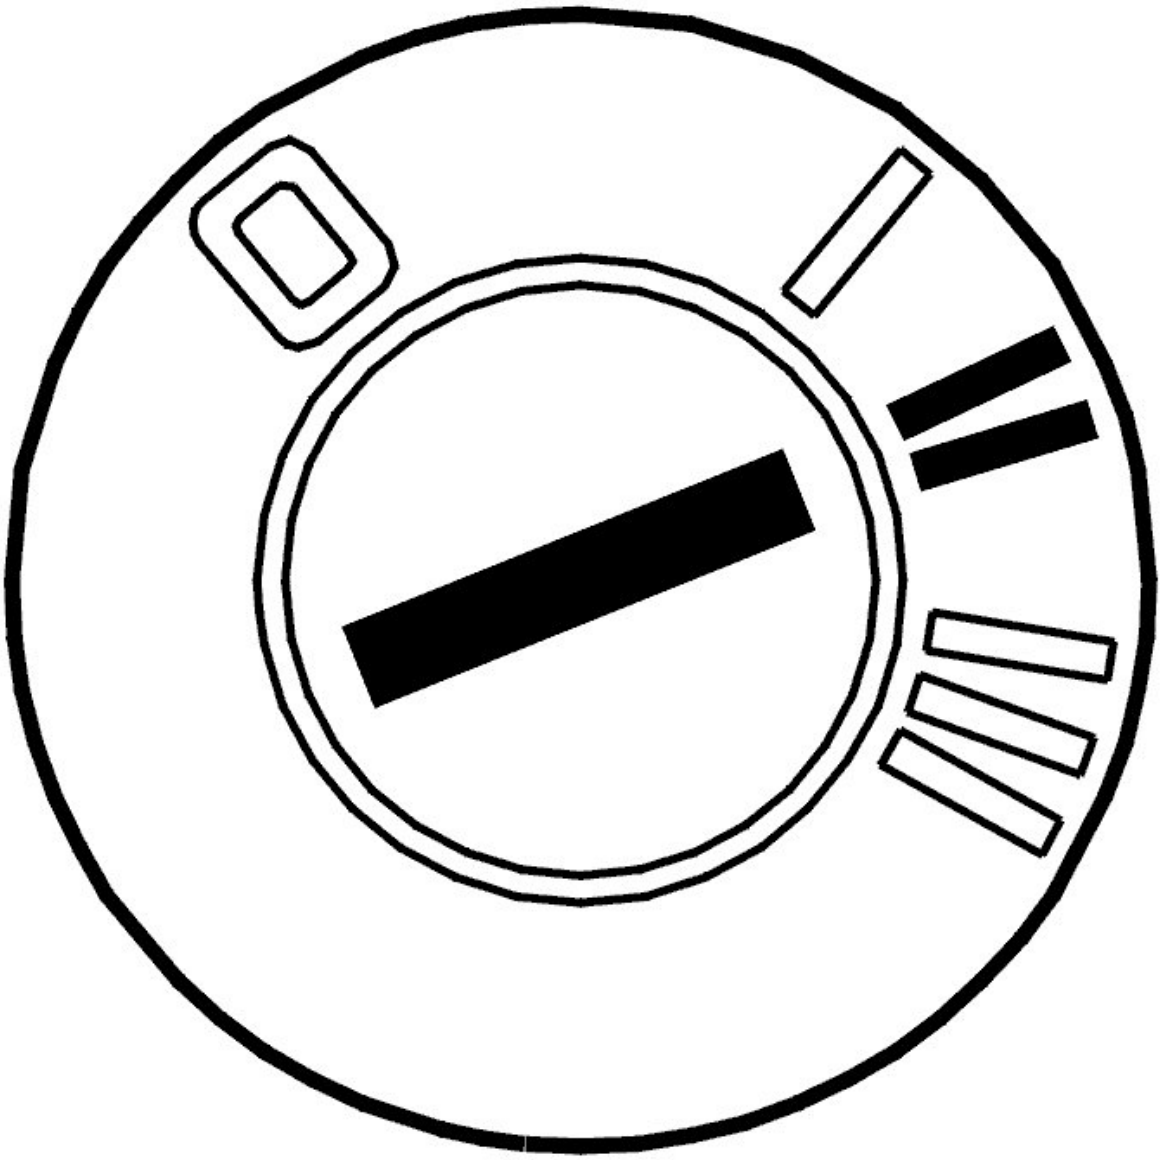
Possible source
- Open-circuit in the signal cable.
- Short-circuit to supply voltage in the signal cable
- Damaged engine coolant temperature (ECT) sensor.

Fault symptom[s]
- Poor heating in the passenger compartment.

Open Circuit or Short-Circuit to Voltage

Open circuit or short-circuit to voltage

Checking the function of the engine coolant temperature sensor



- Ignition on.

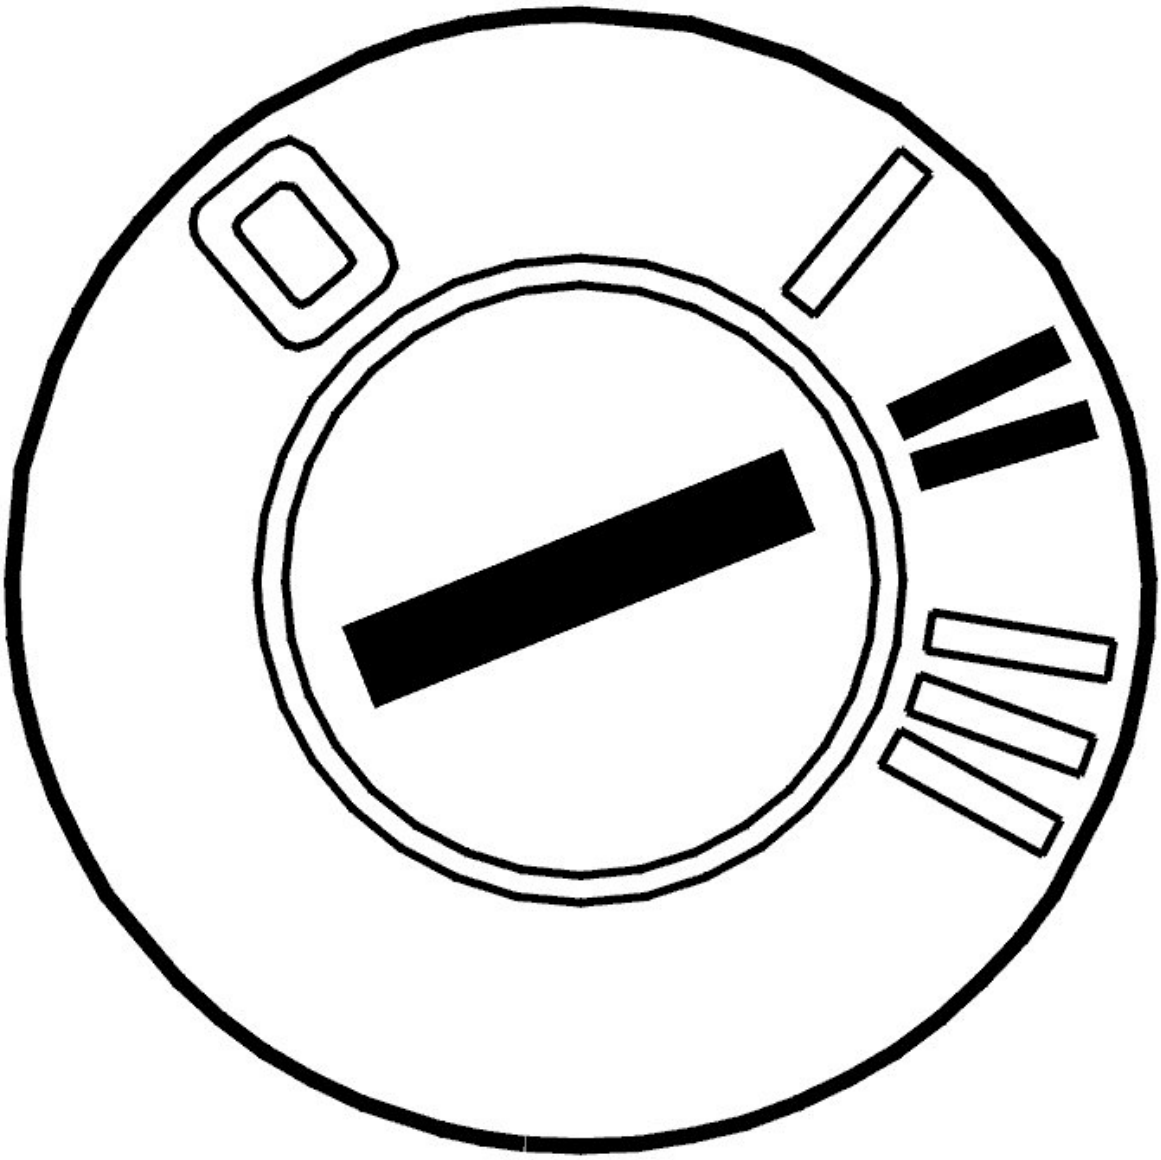
Read off the engine coolant temperature.
Check that the engine coolant temperature (ECT) reading is correct. Compare with the actual coolant temperature of the engine.

Is the temperature reading OK?

Yes - Checking components and wiring

No - Checking the connectors

Checking the connectors



- Ignition off.

Check the combustion preheater module (CPM) connectors. Check for contact resistance and oxidation. Remedy if necessary.

- Reinstall the components, reconnect the connectors etc.
- Ignition on
- Read off the engine coolant temperature.

Check that the engine coolant temperature (ECT) reading is correct. Compare with the actual coolant temperature of the engine.
If the temperature reading is now OK, the fault was probably caused by poor contact in the connector.

Other information

Checking components and wiring

Check the cable between central electronic module (CEM) terminal #8 and the signal cable for the flame sensor. Check for a short-circuit to supply voltage. Check for an open-circuit.

Hint: It is difficult to differentiate between the ground lead for the flame sensor and the signal cable. Take readings on one cable at a time to check for a plausible value on either of them.

Replace the flame sensor if no fault is found in the cable.
Remedy as necessary.

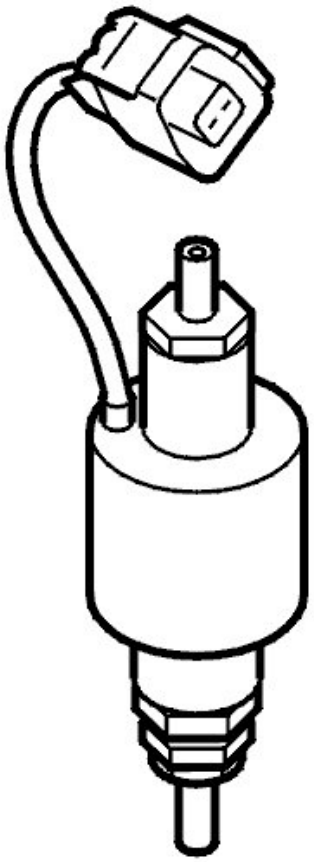
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CEM-5F40

Condition



The central electronic module (CEM) checks the communication with the combustion preheater module (CPM).
The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers that the signal in the circuit for the fuel pump (FP) is too low.
The diagnostic trouble code (DTC) can be diagnosed when the heater is activated.

Substitute value
- None.

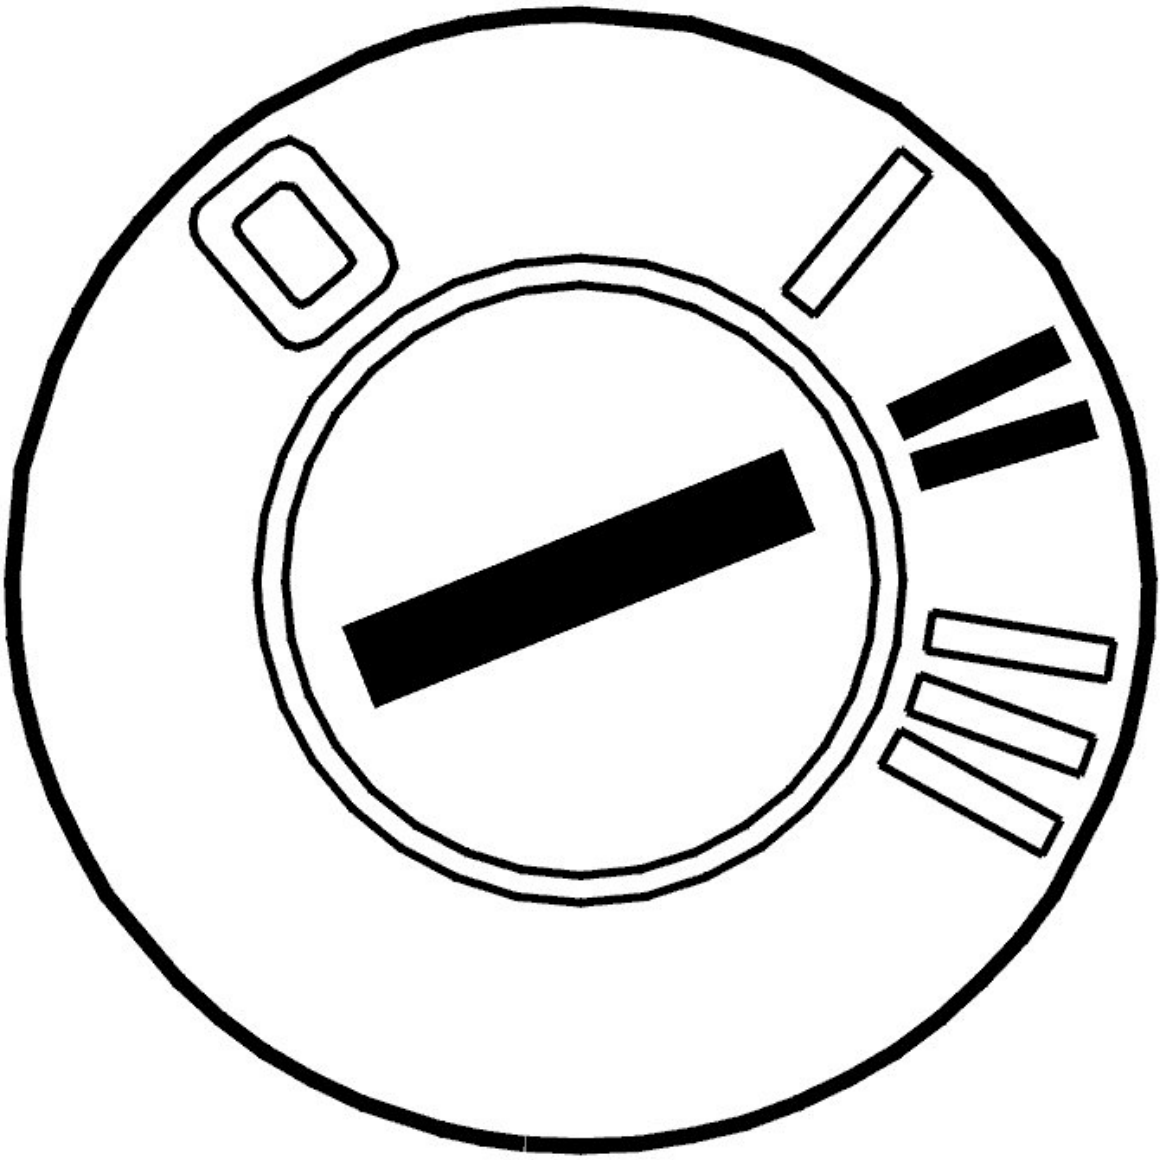
Possible source
- Contact resistance in the control module or fuel pump connectors
- Short-circuit to ground in the signal cable
- Open-circuit in the signal cable
- Open-circuit in the power cable
- Damaged overheat protection thermostat
- Damaged fuel pump.

Fault symptom[s]
- Poor heating in the passenger compartment.

Signal Too Low

Signal too low

Checking the function of the fuel pump (FP)



- Ignition on.

Note! It is important that only the ignition is on in order for the heater to start.

- Activate the heater.

Listen for a buzzing sound which indicates that the heater is running.
Check the heater function.

Other information

- Engine coolant heater, test running See: Heating and Air Conditioning/Auxiliary Cabin Heater/Testing and Inspection/Component Tests and General Diagnostics

Is the heater working?

Yes - Checking components and wiring

No - Checking components and wiring

Checking components and wiring

Check the fuel pump (FP) and combustion preheater module (CPM) connectors. Check for contact resistance and oxidation.

Check the cable between combustion preheater module (CPM) terminal #13 and fuel pump (FP) terminal 2. Check for an intermittent open-circuit. Check for an intermittent short-circuit to ground.
Check the cable between combustion preheater module (CPM) terminal #11 and water pump terminal 1. Check for an intermittent open-circuit. Remedy as necessary.

Other information

- Connecting the breakout box See: Heating and Air Conditioning/Auxiliary Cabin Heater/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box

Continue - Verification

Checking components and wiring

Check the fuel pump (FP) and combustion preheater module (CPM) connectors. Check for contact resistance and oxidation. Remedy as necessary Check for damage in particular.
Measure between the overheat protection thermostat terminals using an ohmmeter. The resistance must be approximately 0 ohms.
The overheat protection thermostat must be replaced if the value is not correct.
Check the cable between combustion preheater module (CPM) terminal #13 and fuel pump (FP) terminal 2. Check for an open-circuit. Check for an short-circuit to ground.
Check the cable between combustion preheater module (CPM) terminal #11 and fuel pump terminal 1. Check for an open-circuit.
The fuel pump (FP) must be replaced if no faults are found in the cable.

Note! Diagnostic trouble code (DTC) CEM-5F3B and/or diagnostic trouble code (DTC) CEM-5F3D may also be stored if there is a fault in the power cable.

Remedy as necessary.

Other information

- Connecting the breakout box See: Heating and Air Conditioning/Auxiliary Cabin Heater/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box

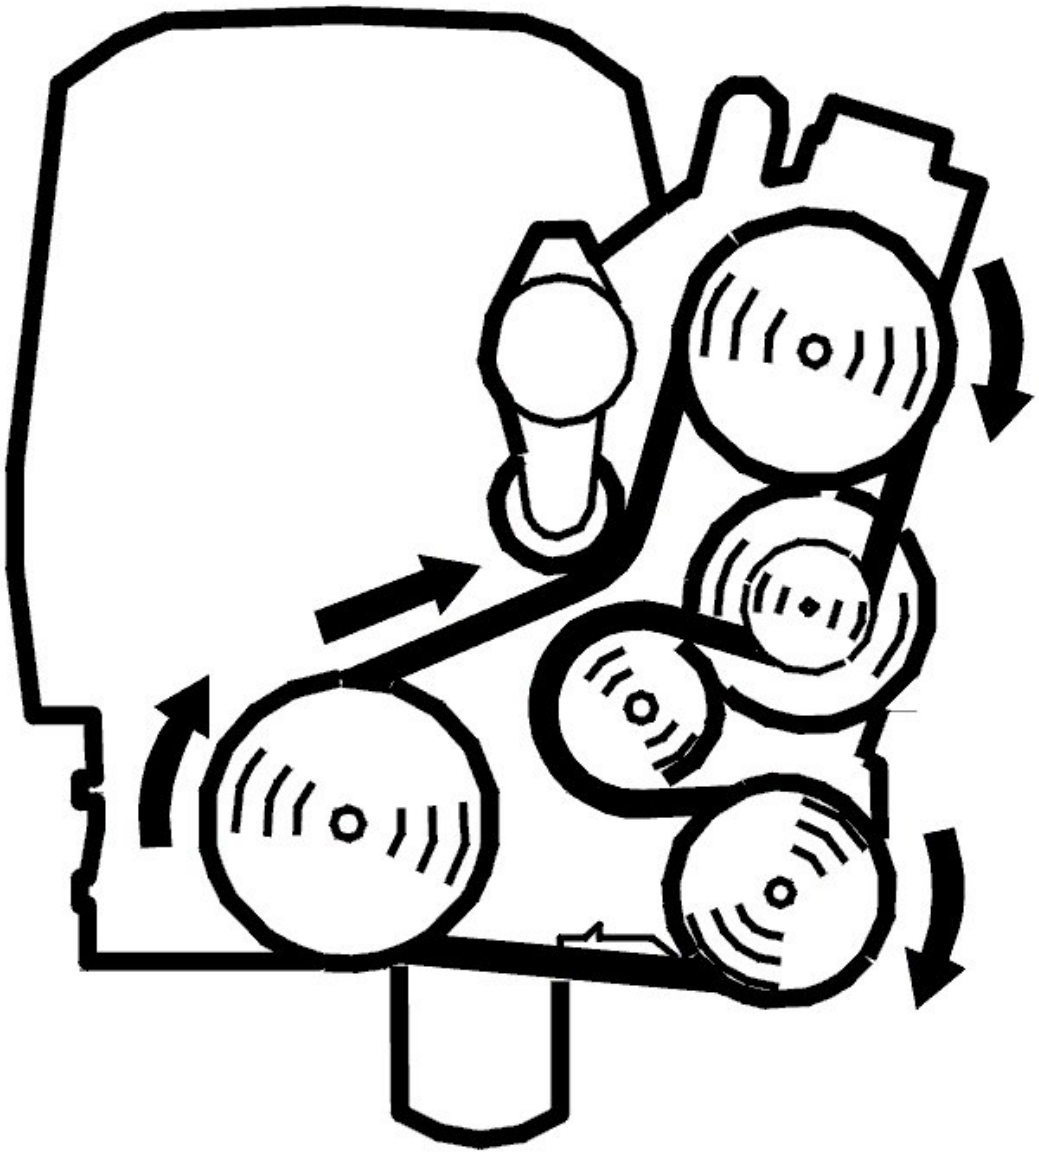
Checking the engine coolant temperature sensor



- Start the engine
- Read off the coolant temperature in the heater.

Check that the engine coolant temperature (ECT) reading is correct. Compare with the actual coolant temperature of the engine.

Is the temperature reading OK?

Yes - Checking components and wiring

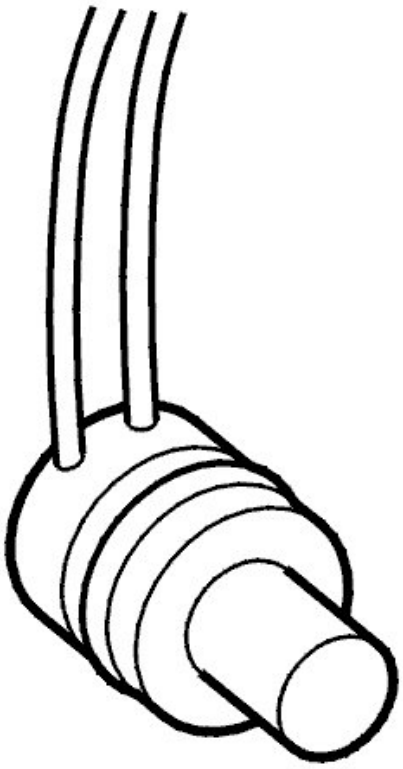
No - Checking components and wiring

Checking components and wiring

Check the resistance of the engine coolant temperature sensor.
Remedy as necessary.

Other information:

- Signal specification See: Heating and Air Conditioning/Auxiliary Cabin Heater/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Specification
- Components resistance values See: Heating and Air Conditioning/Auxiliary Cabin Heater/Specifications
- Overheat protection thermostat / flame sensor / engine coolant temperature sensor, replacing See: Heating and Air Conditioning/Auxiliary Cabin Heater/Auxiliary Cabin Heater Overheat Sensor / Switch/Service and Repair



Continue - Verification

Checking components and wiring

Check the fuel pump (FP) and combustion preheater module (CPM) connectors. Check for contact resistance and oxidation.
Check the cable between combustion preheater module (CPM) terminal #13 and fuel pump terminal 1. Check for an intermittent open-circuit.
Check the cable between combustion preheater module (CPM) terminal #11 and fuel pump terminal 2. Check for an intermittent open-circuit.

Note! Diagnostic trouble code (DTC) CEM-5F3B and/or diagnostic trouble code (DTC) CEM-5F3D may also be stored if there is a fault in the power cable.

Remedy as necessary.

Other information:

- Connecting the breakout box See: Heating and Air Conditioning/Auxiliary Cabin Heater/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box
- Fuel pump auxiliary heater, replacing See: Heating and Air Conditioning/Auxiliary Cabin Heater/Auxiliary Cabin Heater Fuel Pump/Service and Repair
- Overheat protection thermostat / flame sensor / engine coolant temperature sensor, replacing See: Heating and Air Conditioning/Auxiliary Cabin Heater/Auxiliary Cabin Heater Overheat Sensor / Switch/Service and Repair
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

Verification

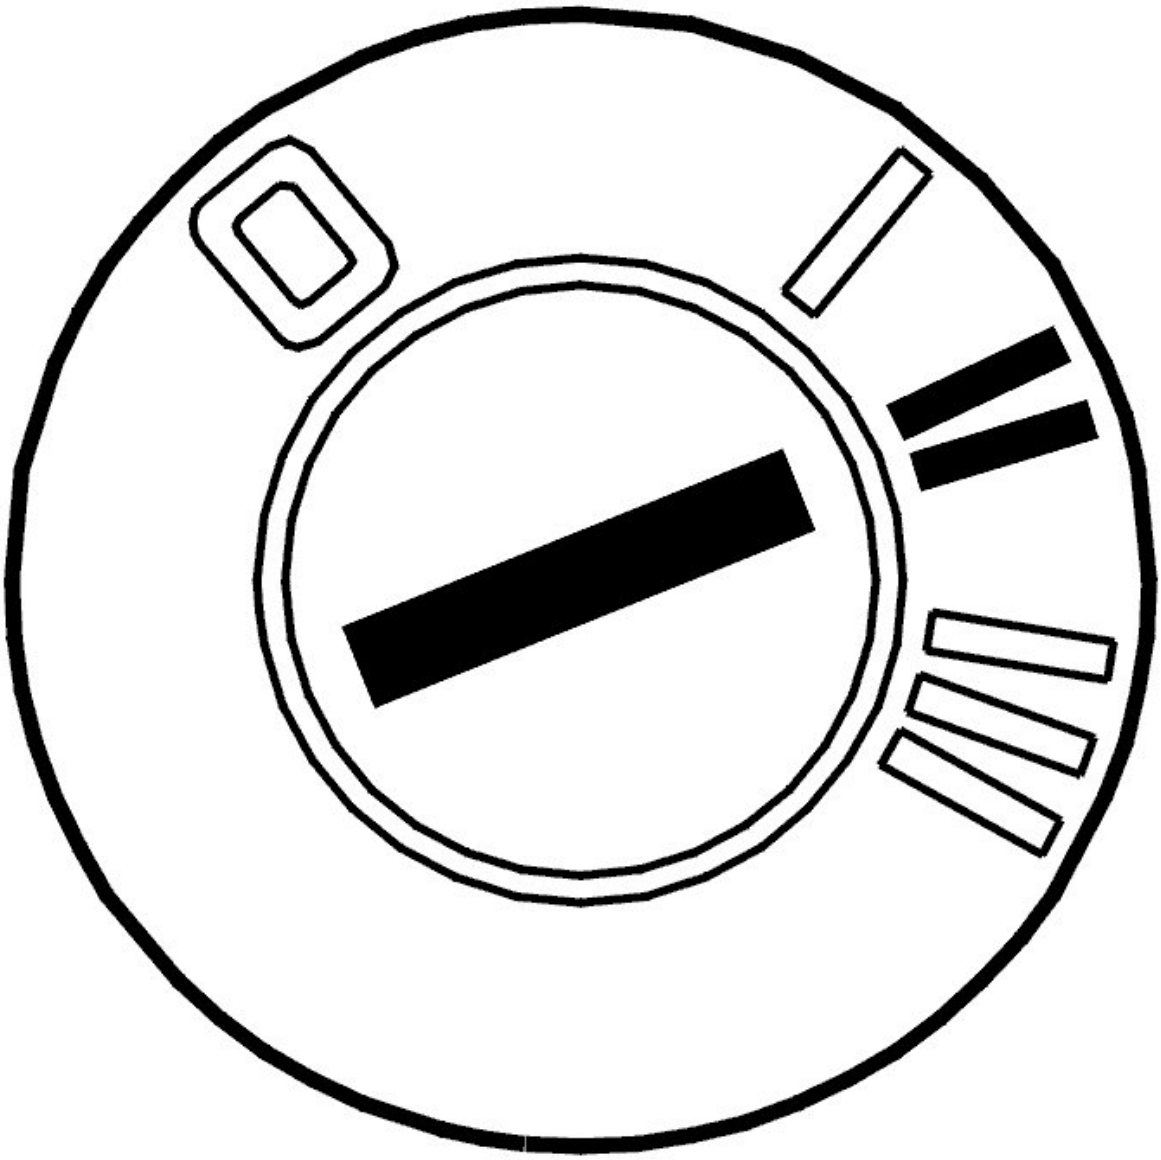
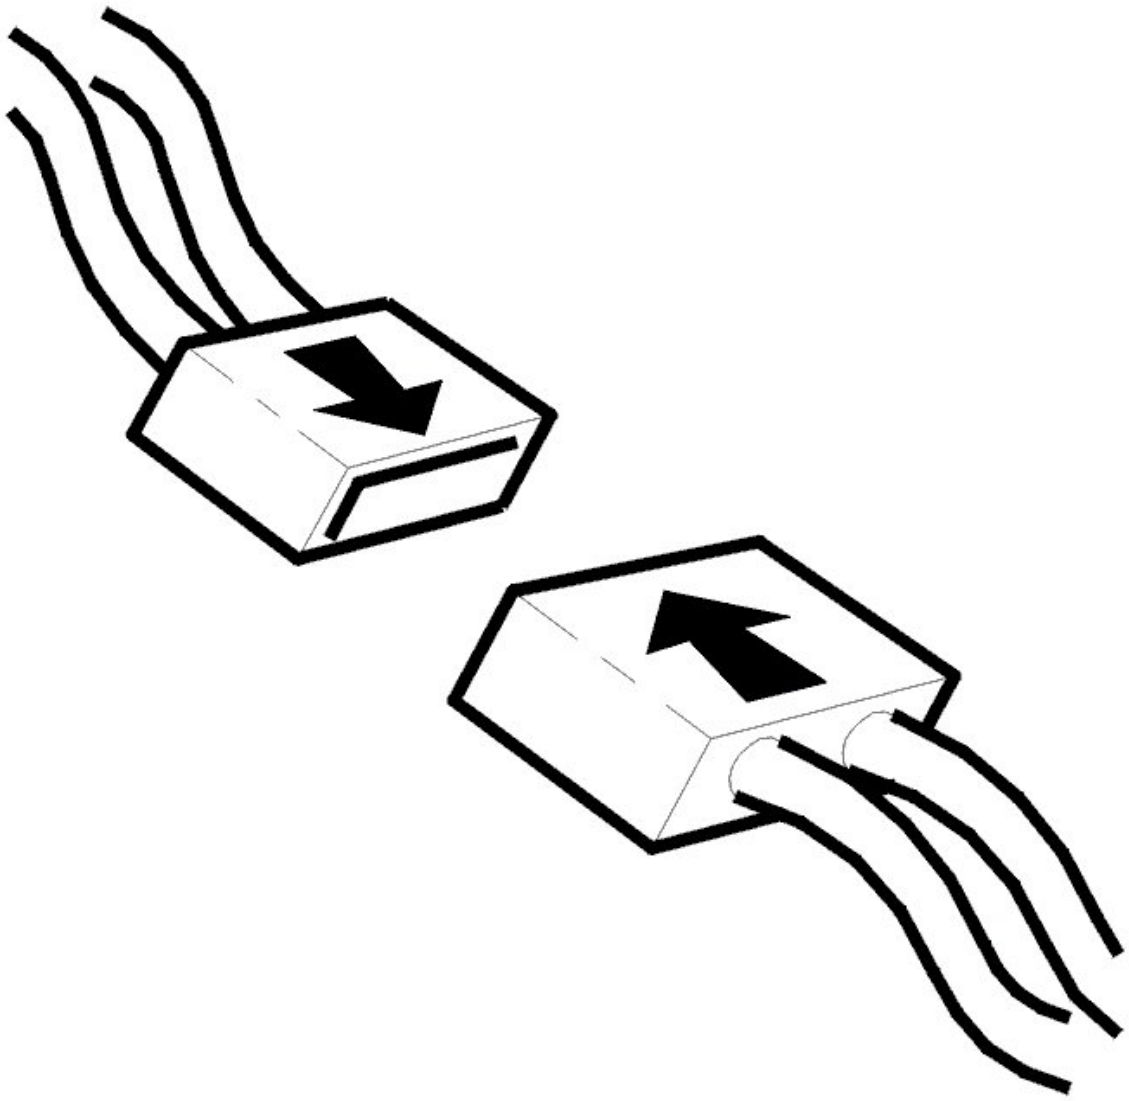
Hint: After carrying out the repair, check that the fault has been remedied.





- Ignition off
- Reinstall the connectors, components etc.
- Ignition on
- Read off the engine coolant temperature.

Note! It is important that only the ignition is on in order for the heater to start.

- Activate the heater.

Hint: After repair, the voltage of the flame sensor can be checked. The voltage must be a maximum of 1.0 V.

Check the heater function.

Caution! In order for to enable start of the heater itself, the battery voltage must be normal, coolant temperature must be lower than +96 °C and the heater's after-run/stop sequence must be finished. There must also be enough fuel in the tank.

Caution! If the heater or other components are not activated, try closing down the activation window and then starting the activation again with the symbol for VCT2000.

Diagnostic Trouble Code (DTC) Information

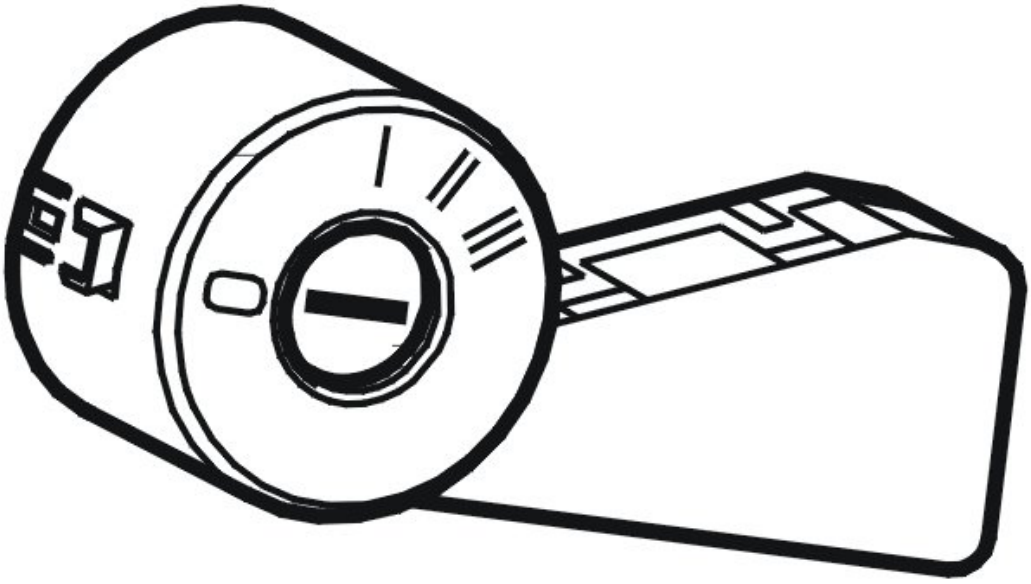
Diagnostic trouble code (DTC) information CEM-6C45

Condition



The central electronic module (CEM) checks the communication with the immobilizer antenna unit (IAU). The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers a fault in the communication with the immobilizer antenna unit (IAU).
The diagnostic trouble code (DTC) can be detected with the ignition on and if diagnostic trouble codes (DTCs) CEM-6C41 - CEM-6C44 are not stored during communication with the immobilizer antenna unit (IAU).

Substitute value
- None.

Possible source
- Temporary interference in the communication with the immobilizer antenna unit (IAU)
- Immobilizer antenna unit (IAU) not working.

Fault symptom[s]

- The starter motor does not turn.

Communication Fault

Communication fault

Replacing the antenna unit

The antenna unit has registered an internal fault.
If the fault is intermittent, it has been registered previously but is no longer present. Intermittent faults can be caused by interference at start up of the antenna module (ATM) or can be a different type of fault which occurs on different occasions. The fault is evaluated depending on how it occurs. If the fault recurs, replace the antenna unit.

Hint: The diagnostic trouble code (DTC) can also be stored by temporary interference in the communication with the antenna unit. If this is the case the antenna unit need not be replaced and the diagnostic trouble code (DTC) can be erased.

Antenna unit immobilizer, replacing See: Accessories and Optional Equipment/Antenna/Antitheft Antenna/Service and Repair
Remedy as necessary.

FAULT FOUND - DONE

Diagnostic Trouble Code (DTC) Information

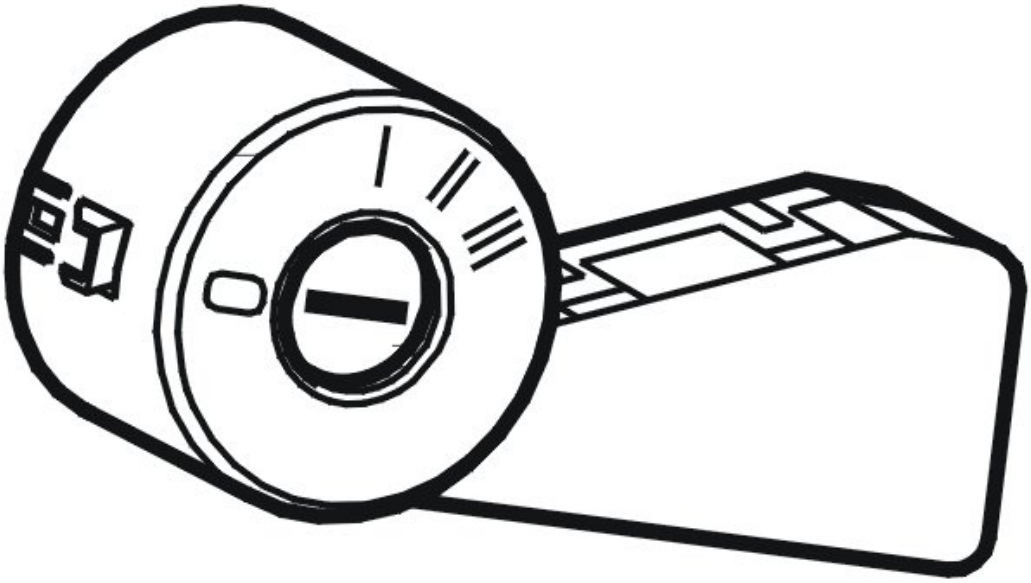
Diagnostic trouble code (DTC) information CEM-6C48

Condition



With the ignition on the central electronic module (CEM) reads the transponder signal. The diagnostic trouble code (DTC) is stored if the transponder responds with an unknown transponder, a non-approved code (not stored in the memory), no transponder code at all or an unknown

communication format.

Note! This diagnostic trouble code (DTC) may be stored for example if there are several ignition keys on the same key ring and one of them is inserted in the ignition switch.

Substitute value
- None.

Possible source
- The ignition key has a damaged transponder
- The ignition key is of the wrong type. It has no transponder
- The ignition key has previously belonged to the vehicle but has been erased from the memory for the central electronic module (CEM)
- The ignition key is a new key and has not yet been programmed into the memory for the central electronic module (CEM)
- Several keys are too close to each other during the read off
- An electronic door key was too close to the antenna unit during the read off
- An automatic road toll transponder is installed too close to the antenna unit
- EMC interference (strong electrical field) during the communication phase (when starting the engine)
- The ignition key is a Volvo key but for a different model
- The ignition key belongs to another Volvo of the same type, i.e. it has a different transponder code
- The ignition key is for another make of car and therefore does not have the same type of transponder.

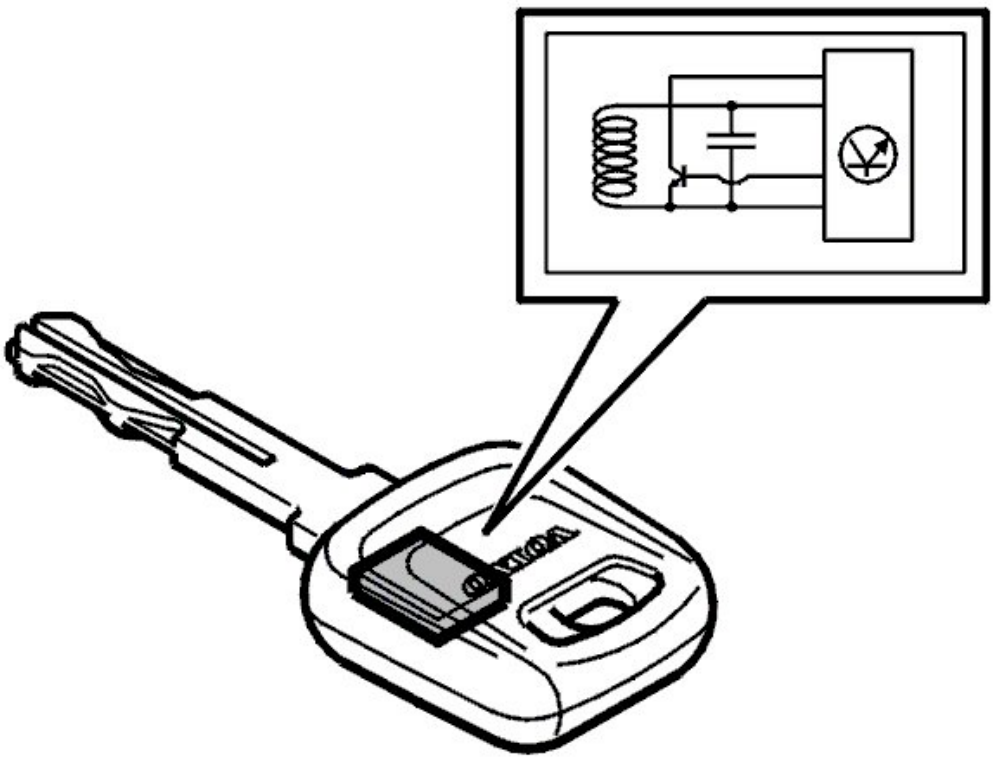
Fault symptom[s]
- The starter motor does not turn.

Faulty Signal

Faulty signal

Checking the key type

Visually check to see if the key in the ignition switch is the correct type. See the illustration.
Check that the color marking (a small semi-circular plastic marking positioned on the head of the key nearest one of the short sides of the metal section) is the correct color: The correct color is gray or red.
The key is for another type of Volvo if the colour marking is black or blue.
If the color is not correct, replace the key with the color marking as above. Insert the key in the ignition switch. If there is no key the correct color, order a new key and program it.
Key, add / remove See: Body and Frame/Locks/Key/Testing and Inspection/Add or Remove Key

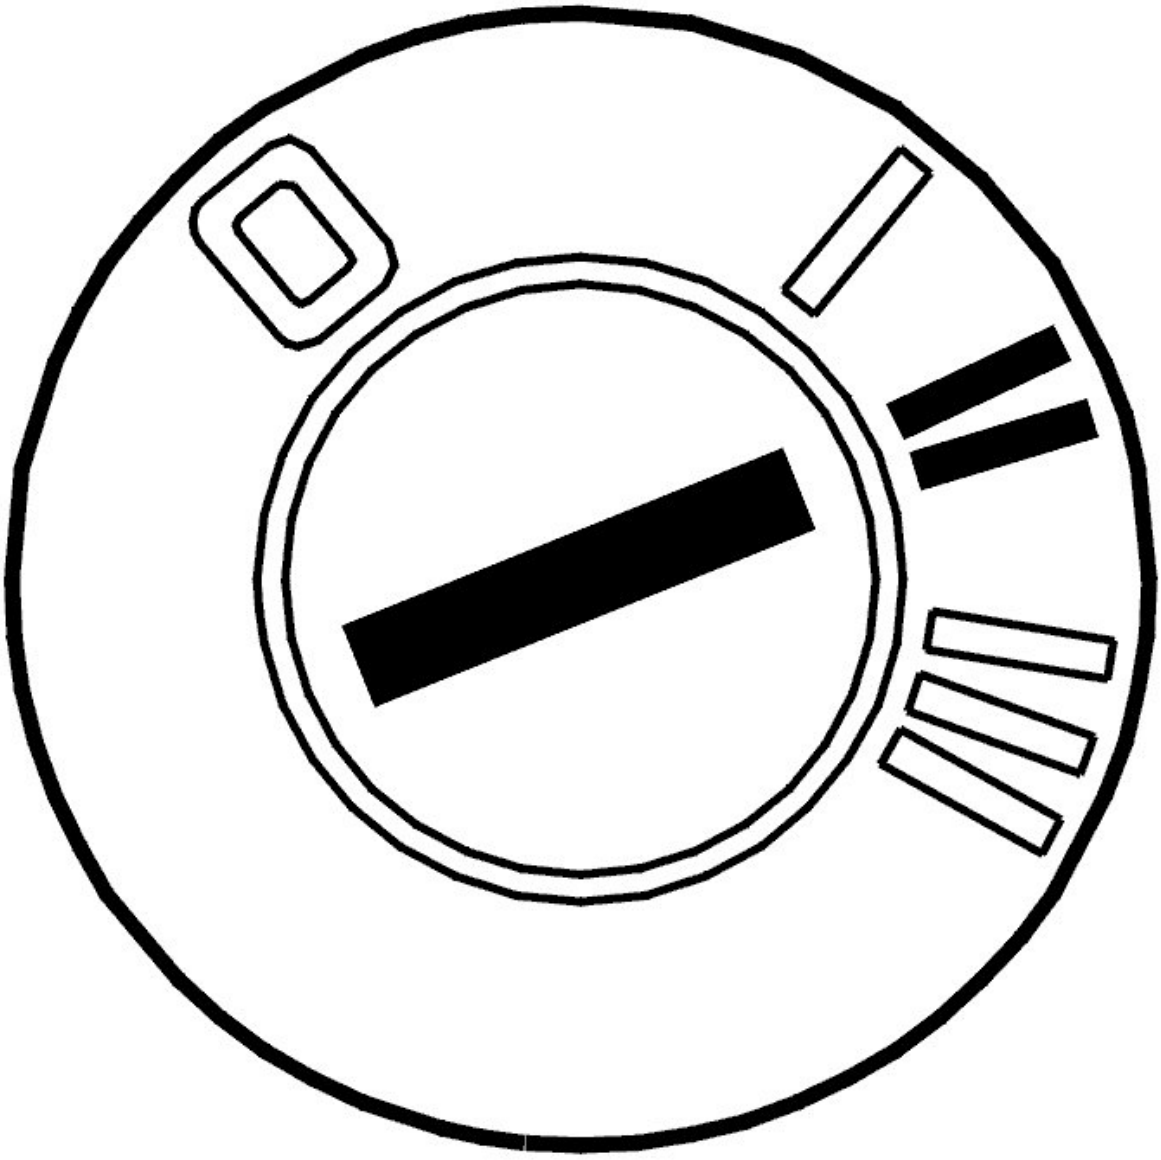


Continue - Checking the key code

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

Checking the key code

Note! Check to see if there are several keys (with transponders) on the same key ring. These keys should be separate so that they do not touch the key being used. Also check that no other transponder, such as an electronic door key or an identity card with an integrated transponder, is near by.If there is an automatic toll road transponder in the car, this should be positioned as far from the antenna unit as possible.



- Ignition on

Read off the CODE RECEIVED parameter to see if the key code has been received by the central electronic module (CEM).
If the code has been received Yes is shown.

Has the code been received?

Yes - Checking the stored code

No - Damaged transponder

Damaged transponder

The key has a damaged transponder.
Order new key(s) and software.

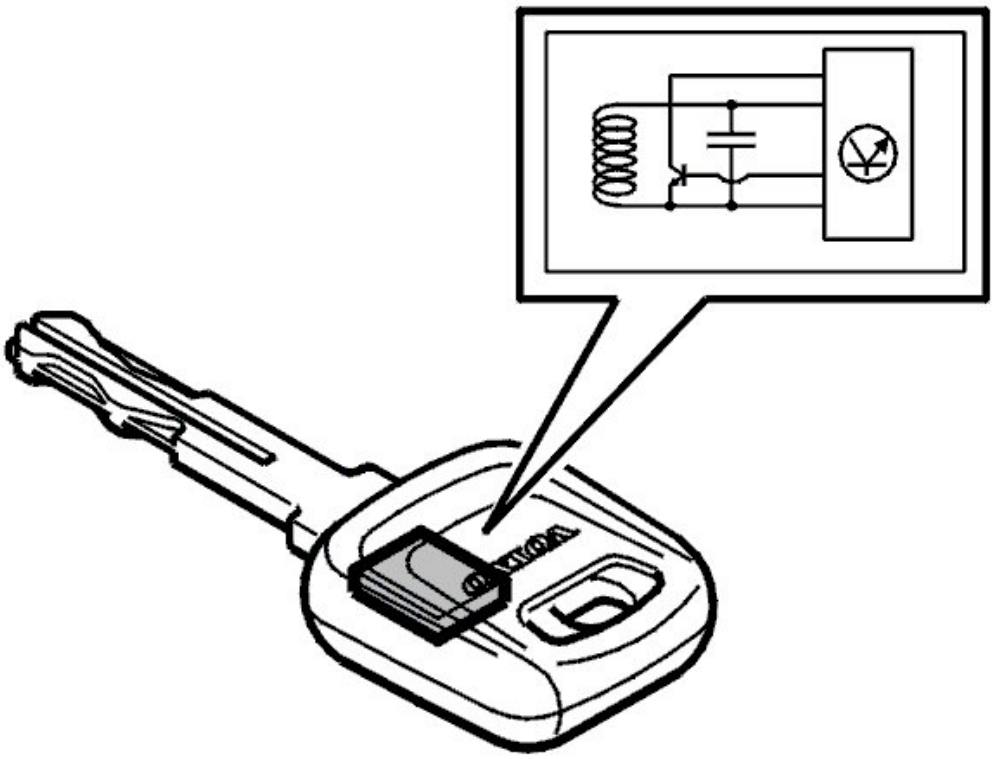
Visually check to see if the key in the ignition switch is the correct type. See the illustration.
Check that the color marking (a small semi-circular plastic marking positioned on the head of the key nearest one of the short sides of the metal section) is the correct color: The correct color is gray or red.
The key is for another type of Volvo if the color marking is black or blue.
If the color is not correct, replace the key with the color marking as above. Insert the key in the ignition switch. If there is no key the correct color, order a new key and program it.
Key, add / remove See: Body and Frame/Locks/Key/Testing and Inspection/Add or Remove Key



Continue - Checking start

Checking start

Use the same key which previously could not start the engine. Carry out three more start attempts.

Hint: If the start attempts are carried out in quick succession, remove the key from the ignition switch for at least two seconds between each start attempt. Otherwise a new transponder check will not be carried out. (If the key is left in the ignition switch between each start attempt, a new transponder check will not occur until the ignition has been switched off for approximately 30 seconds.).

One of the following may occur:
1. The engine starts every time

2. The engine starts at least once
3. The engine does not start.

Select one of the above response options.

1 - Communication

2 - Damaged transponder

3 - Incorrect key

Communication

Hint: The fault was caused by a temporary interruption in the communication between the transponder and the central electronic module (CEM).

Continue - Verification

Damaged transponder

The key has a damaged transponder.
Order new key(s) and software.
Key, add / remove See: Body and Frame/Locks/Key/Testing and Inspection/Add or Remove Key

Continue - Verification

Incorrect key

The key belongs to another vehicle. The transponder code and the mechanical key code (the key fits in the ignition switch) correspond but the security code for the key does not correspond with the security code of the car.
Order new key(s) and software.
Key, add / remove See: Body and Frame/Locks/Key/Testing and Inspection/Add or Remove Key

Diagnostic Trouble Code (DTC) Information

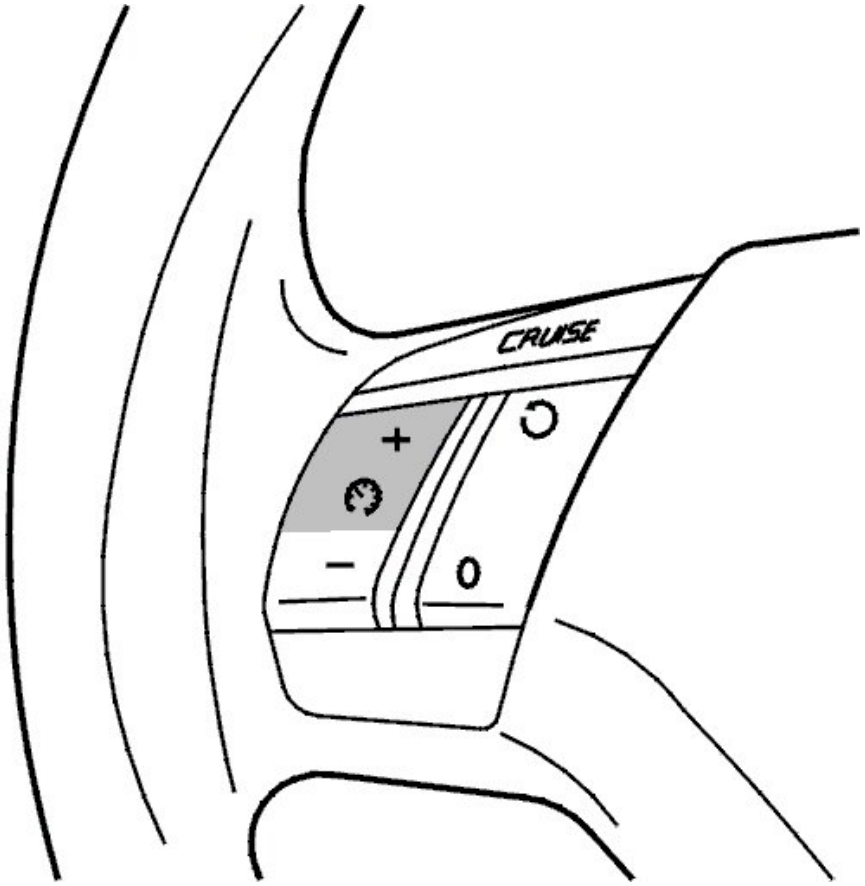
Diagnostic trouble code (DTC) information CEM-6F02

Condition



The central electronic module (CEM) checks the signal from the Set+ button for the cruise control.
The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers that the Set+ button has been active for more than 3 minutes.
The diagnostic trouble code (DTC) can be diagnosed when the ignition is switched on.

Substitute value
- None.

Possible source
- The Set+ button is jammed in the pressed in position
- Damaged Set+ button.

Fault symptom[s]
- Cruise control does not function at all.

Activated too long

Activated too long

Checking the control

The diagnostic trouble code (DTC) is stored when a button or switch has been depressed for a long time.
If the fault is intermittent, it has been registered previously but is no longer present. Intermittent faults can be caused by interference at start up of the central electronic module (CEM) or may be a different type of fault which occurs on different occasions. The fault is evaluated depending on how it occurs.
Check that the button or switch does not stick in the activated position.
Remedy as necessary.

Other information

The central electronic module (CEM) checks the signal from the right button.
The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers that the right button has been active for more than 1 minute.
The diagnostic trouble code (DTC) can be diagnosed when the ignition is switched on.

Substitute value
- None.

Possible source
- The right button has jammed in the pressed in position
- Damaged right button.

Fault symptom[s]
- The RTI buttons on the steering wheel do not function
- The navigation buttons on the steering wheel do not function.

Activated too long

Activated too long

Checking the control

The diagnostic trouble code (DTC) is stored when a button or switch has been depressed for a long time.
If the fault is intermittent, it has been registered previously but is no longer present. Intermittent faults can be caused by interference at start up of the central electronic module (CEM) or may be a different type of fault which occurs on different occasions. The fault is evaluated depending on how it occurs.
Check that the button or switch does not stick in the activated position.
Remedy as necessary.

Diagnostic Trouble Code (DTC) Information

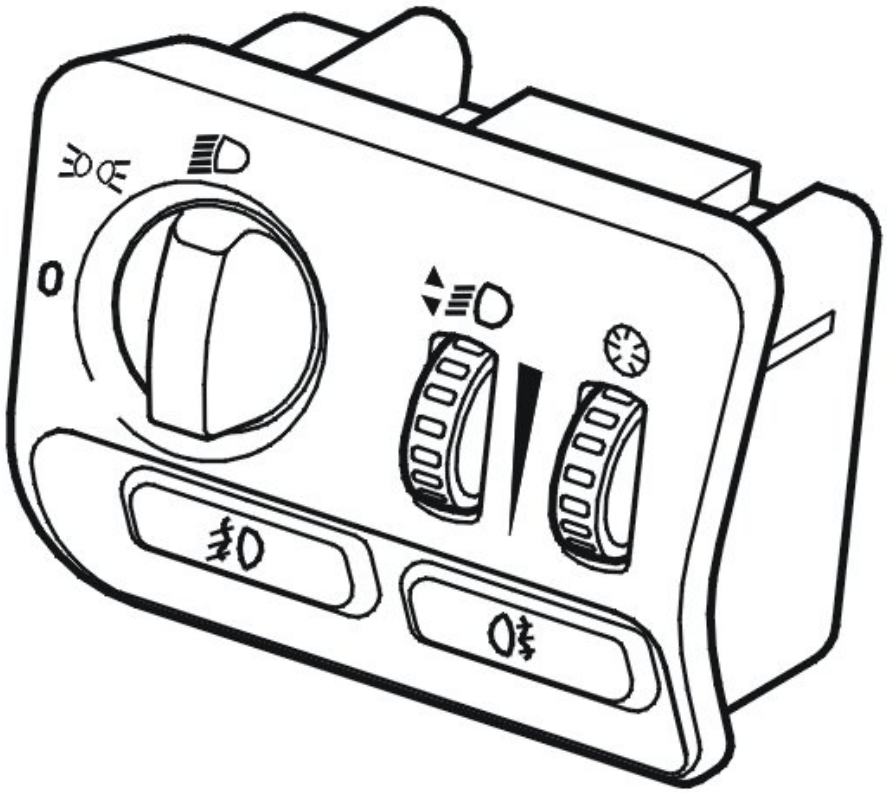
Diagnostic trouble code (DTC) information CEM-8A01

Condition



The central electronic module (CEM) communicates with the light switch module (LSM).
The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) receives information from the light switch module (LSM) that the light switch is not in an approved position. For example it is in-between the position for parking lamps and low beam.
The voltage in the central electronic module (CEM) must exceed 10 V for at least 1 second in order for the diagnostic trouble code (DTC) to be detected.
The diagnostic trouble code (DTC) can be diagnosed at ignition switch position II.

Substitute value
- Low beam always on.

Possible source
- Fault in the communication with the light switch module (LSM)
- Damaged light switch module (LSM).

Fault symptom[s]
- The low beam is constantly lit.

Faulty position

Faulty position

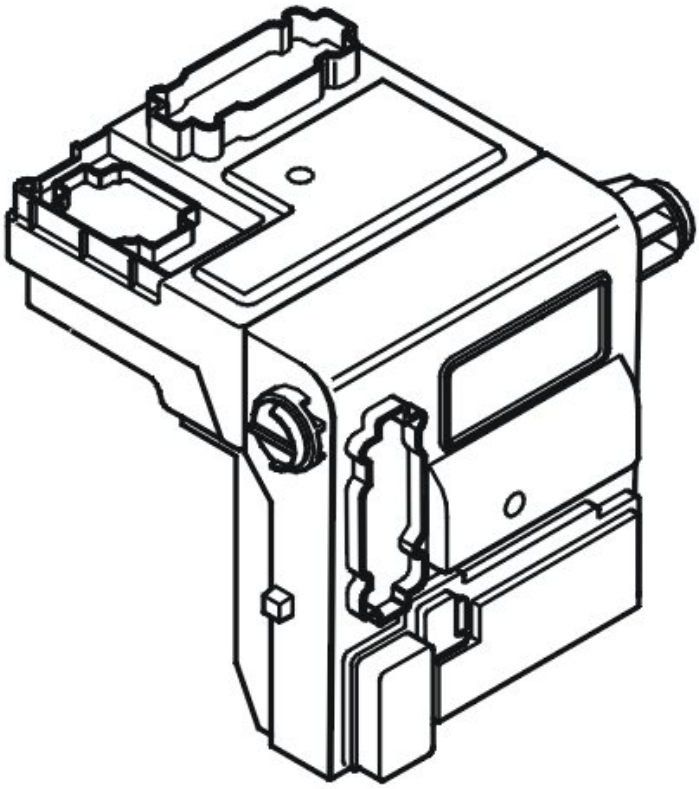
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CEM-8A20

Condition



The central electronic module (CEM) powers the left-hand low beam directly via an output. The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers that the power consumption for the output is too high.
The diagnostic trouble code (DTC) can be diagnosed when the ignition has been on for more than 40 seconds.

Substitute value
- None.

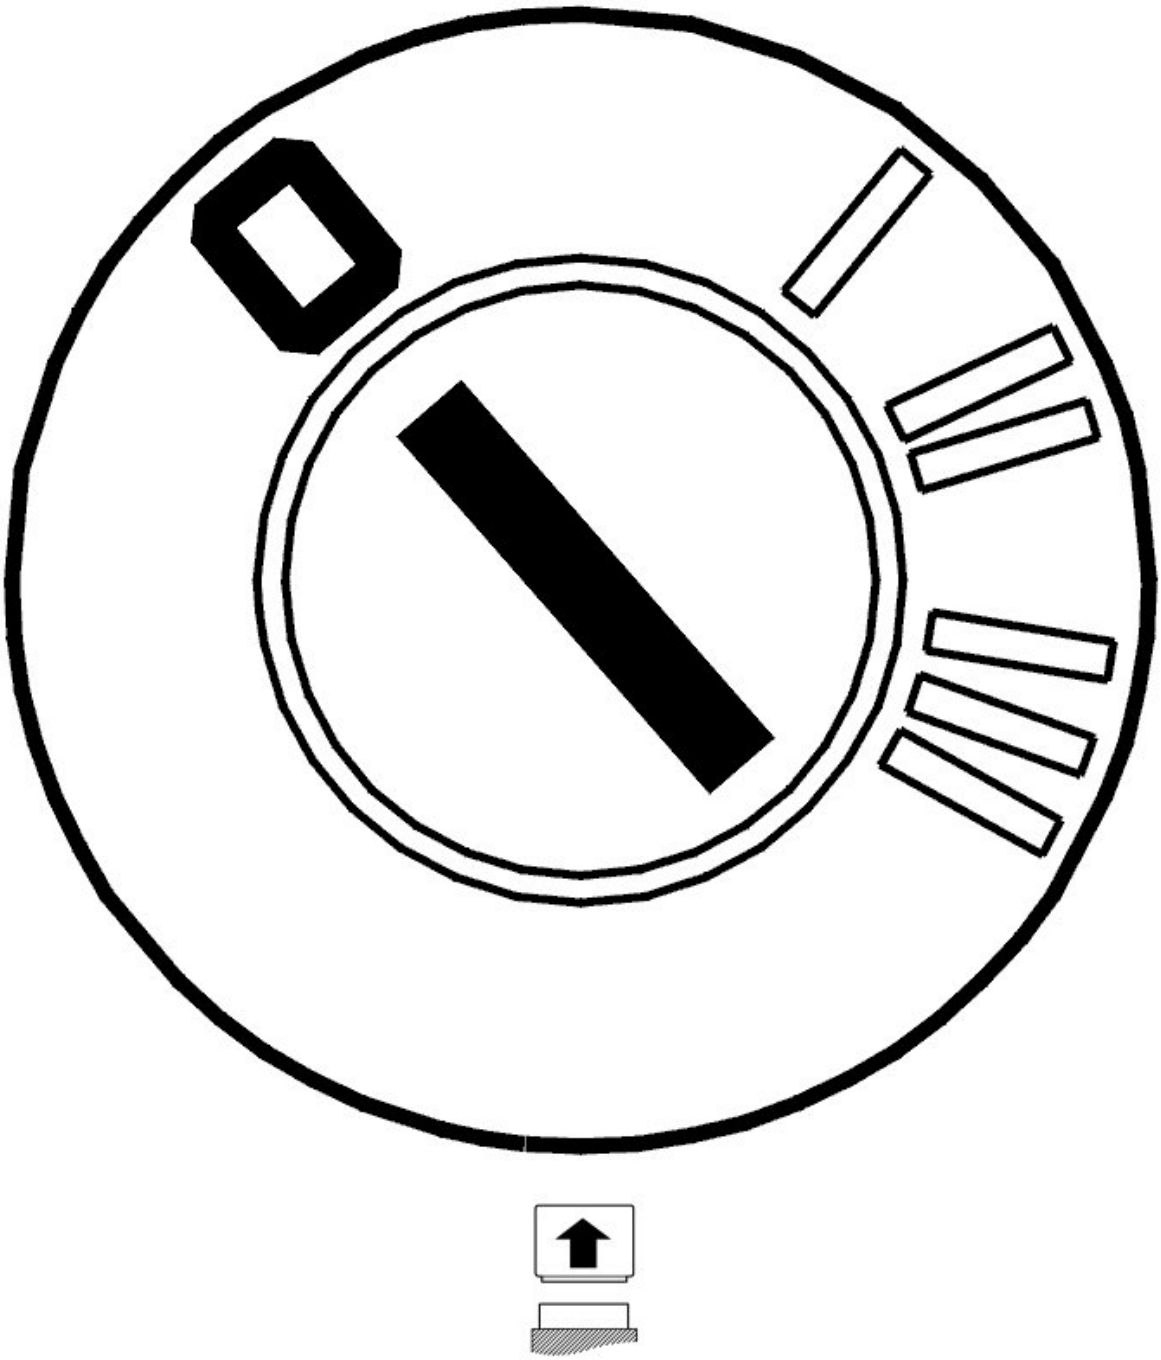
Possible source
- Short-circuit to ground in the low beam signal cable.

Fault symptom[s]
- Low beam does not work.

Signal Too Low

Signal too low

Checking the wiring



- Ignition off
- Disconnect central electronic module (CEM) connector B.

Check the power cable for a short-circuit to ground.

For S60, V70, S80 with Bi-Xenon and XC90

Take readings between:

- Central electronic module (CEM) terminal #B7 (#B7) and left-hand lamp housing connector terminal #A2.

For S80 without Bi-Xenon

Take readings between:

- Central electronic module (CEM) terminal #B7 (#B7) and left-hand stop lamp connector terminal #A3.

Remedy as necessary.

Diagnostic Trouble Code (DTC) Information

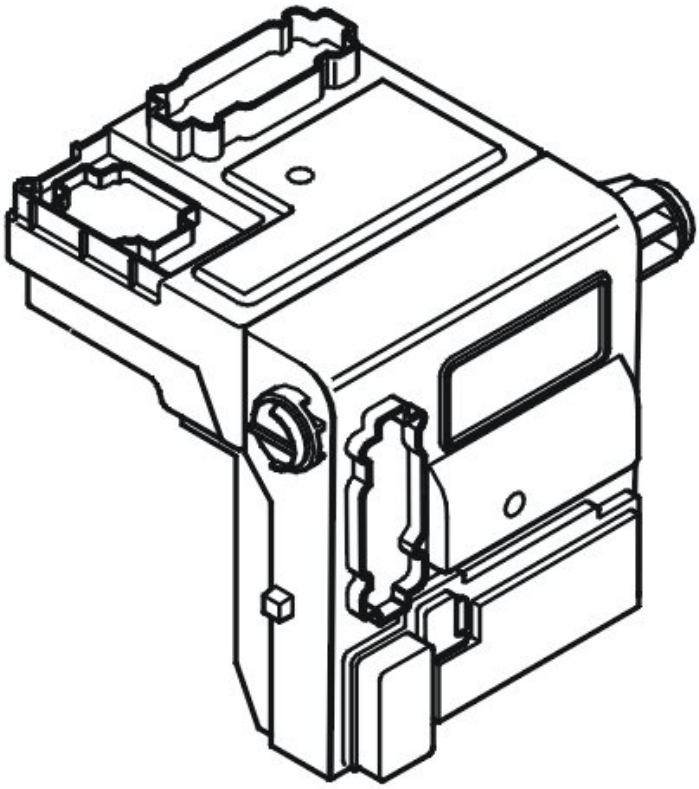
Diagnostic trouble code (DTC) information CEM-8D01

Condition



The central electronic module (CEM) checks the stop lamps.
The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers that the signal from the stop lamps is too low.
The diagnostic trouble code (DTC) can be diagnosed when the stop lamp is active.

Substitute value
- None.

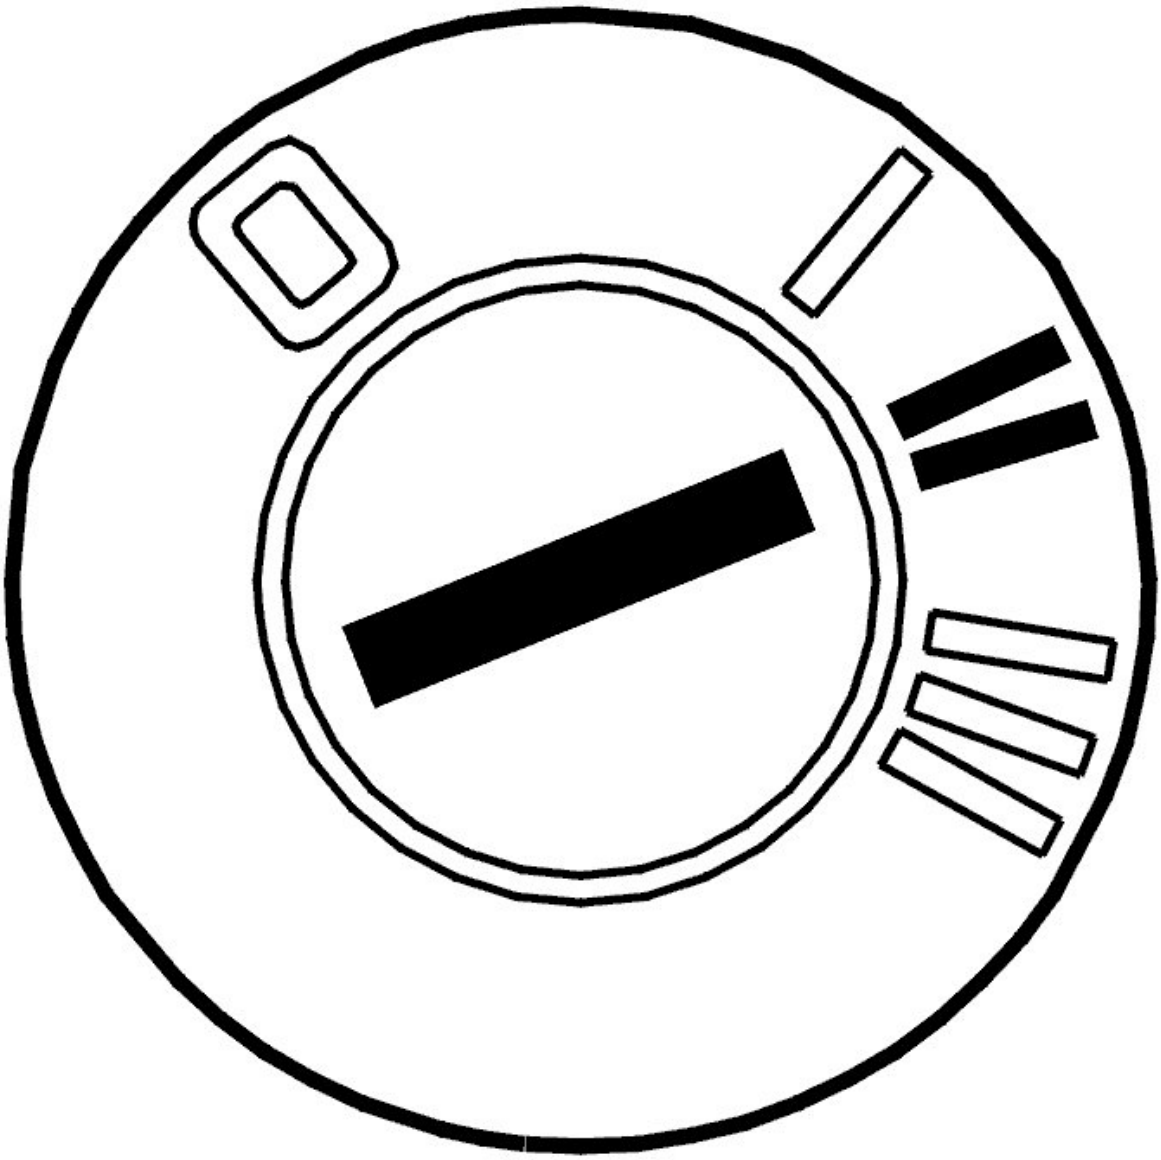
Possible source
- Short-circuit to ground in the circuit for the stop lamps.

Fault symptom[s]
- The stop lamp does not light when the brake pedal is depressed.

Signal Too Low

Signal too low

Checking the status



- Ignition on.

Activate the stop lamp.
Check if the fault is permanent or intermittent.
The stop lamp must light on activation.
The fault is permanent if the stop lamp does not activate.
If the stop lamp is activated, this is an indication that the fault was present previously but that it is not active at the moment, i.e. the fault is intermittent.

Continue - Checking components and wiring

Checking components and wiring

Check the voltage between the left and right-hand stop lamps and the output on the rear electronic module (REM). The voltage must be approximately 12 V when the stop lamp is activated.
Check the control signal cable. Check for a short-circuit to ground.
Take readings between:
S60

- Rear electronic module (REM) terminal #B3 (#3) and stop lamp terminal #B4.

S80

- Rear electronic module (REM) terminal #D18 (#18) and stop lamp terminal #7.

V70/XC70

- Rear electronic module (REM) terminal #B3 (#3) and stop lamp terminal #B2.

XC90

- Rear electronic module (REM) terminal #B3 (#3) and stop lamp terminal #A5.

Check the cable between central electronic module (CEM) terminal #A15 (15) and rear electronic module (REM) terminal #A18 (18). Check for a short-circuit to ground.
Remedy as necessary.

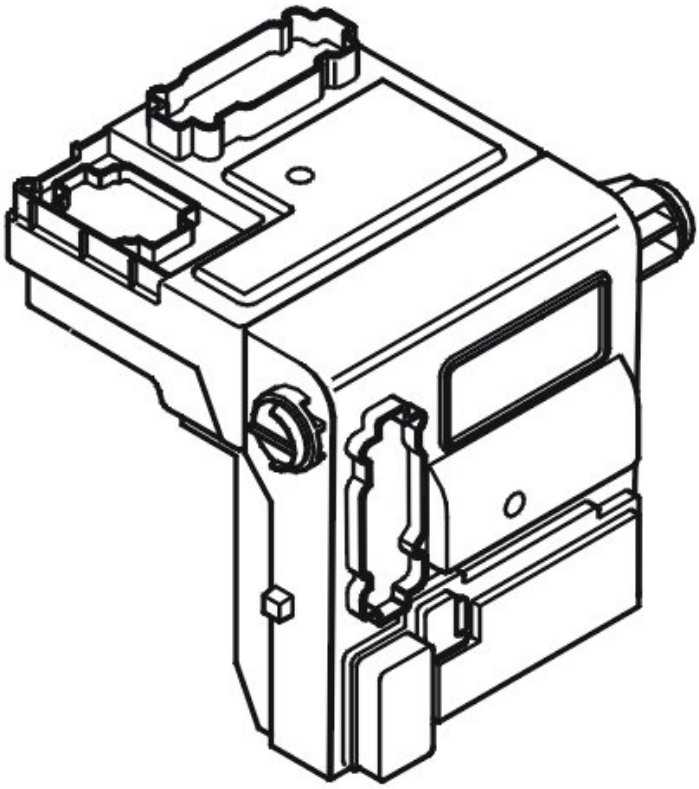
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CEM-8D02

Condition



The central electronic module (CEM) checks the stop lamps.
The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers that the signal from the stop lamps is faulty.
The diagnostic trouble code (DTC) can be diagnosed when the stop lamp is active.

Substitute value
- None.

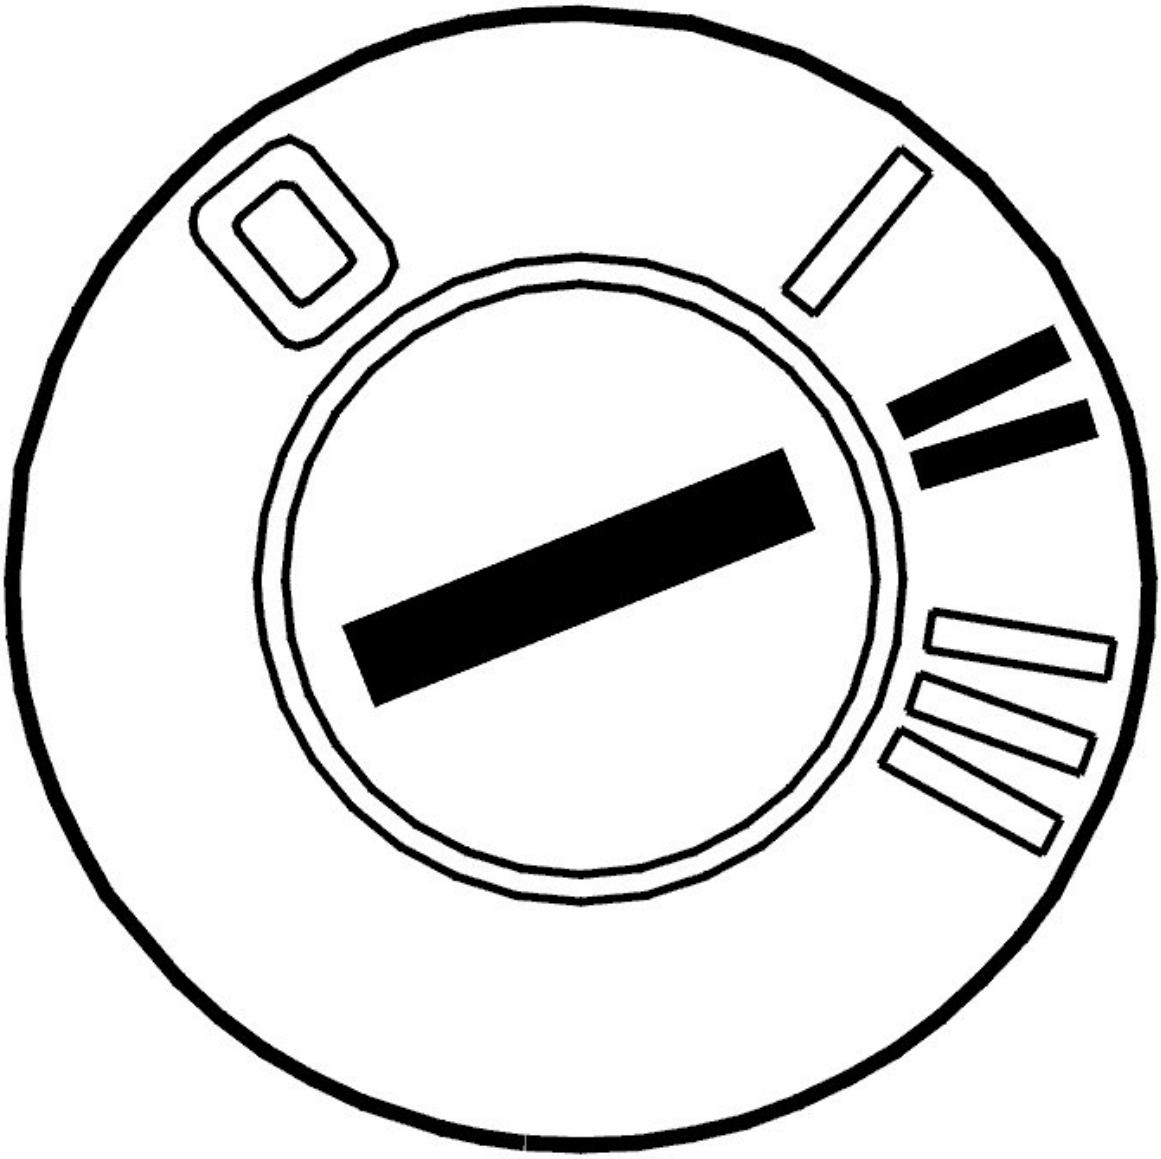
Possible source
- Open-circuit in the circuit for the stop lamps.

Fault symptom[s]
- The stop lamp does not light when the brake pedal is depressed.

Faulty Signal

Faulty signal

Checking the status



- Ignition on.

Activate the stop lamp.
Check if the fault is permanent or intermittent.
The stop lamp must light on activation.
The fault is permanent if the stop lamp does not activate.
If the stop lamp is activated, this is an indication that the fault was present previously but that it is not active at the moment, i.e. the fault is intermittent.

Continue - Checking components and wiring

Checking components and wiring

Check the voltage between the left and right-hand stop lamps and the output on the rear electronic module (REM). The voltage must be approximately 12 V when the stop lamp is activated.

Check the control signal cable. Check for an open-circuit. Check for a short-circuit to supply voltage.
Take readings between:

S60

- Rear electronic module (REM) terminal #B3 (#3) and stop lamp terminal #B4.

S80

- Rear electronic module (REM) terminal #D18 (#18) and stop lamp terminal #7.

V70/XC70

- Rear electronic module (REM) terminal #B3 (#3) and stop lamp terminal #B2.

XC90

- Rear electronic module (REM) terminal #B3 (#3) and stop lamp terminal #A5.

Check the cable between central electronic module (CEM) terminal #A15 (15) and rear electronic module (REM) terminal #A18 (18). Check for a short-circuit to supply voltage. Check for an open-circuit.
Remedy as necessary.

Other information

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CEM-8D03

Condition

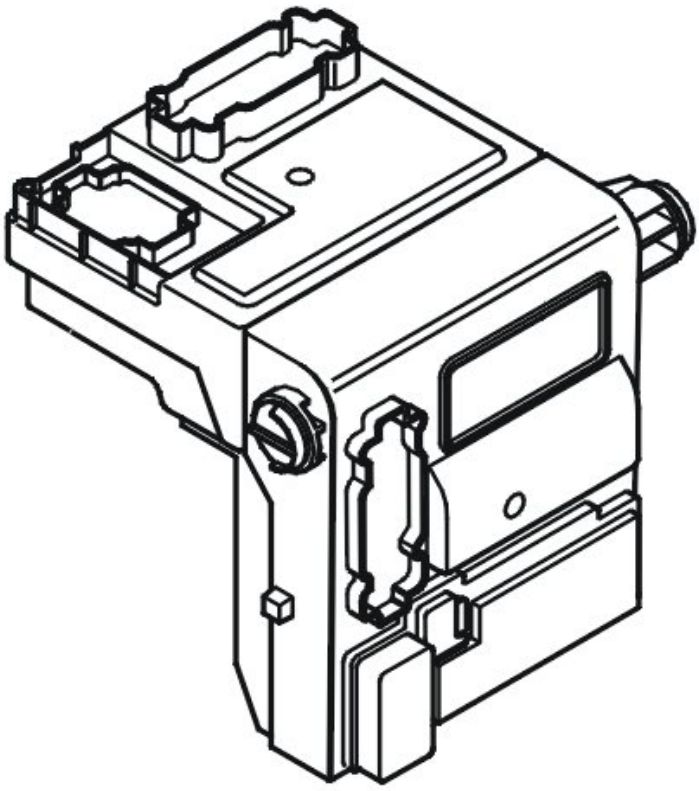
The central electronic module (CEM) checks the signal from the stop lamp switch.
The diagnostic trouble code (DTC) is stored if the control module detects that:

- Brake light is activated when Engine control module (ECM) informs that brake pedal is not depressed, and no internal error has been detected of Central electronic module (CEM).

The control module's test for the diagnostic trouble code (DTC) starts in the event of:

- Ignition position I and II, when HS-CAN is activated.

Note! The control module can only detect the fault once the test has been started and the diagnostic trouble code (DTC) is stored when the conditions are met.



Substitute value

- None.

Possible source
- Internal error in brake light switch or leads.

Fault symptom[s]
- Cruise control/Does not engage
- Cruise control/Disengagement does not work
- Cruise control/Does not remain at set speed/disengages
- Tail light/Brake lights constantly lit

Fault-tracing

Fault-tracing

Checking stop lamp switch status

Note! The following troubleshooting shall not be performed if no symptom (acc. to trouble code information) is noticed on the vehicle. Then the diagnostic trouble code shall be erased instead.

This diagnostic trouble code indicates that there is a defect in the brake light switch or the leads to the same.
Brake light switch is a switch that controls when the brake lights shall be activated/not activated.
Troubleshoot according to:
1. Check the brake light switch connector for contact resistance and oxidation.
2. Check that the brake light switch is supplied with voltage.
3. Check leads between Central electronic module (CEM) and brake light switch.
If no defect is detected, replace brake light switch.
Remedy as necessary.

Diagnostic Trouble Code (DTC) Information

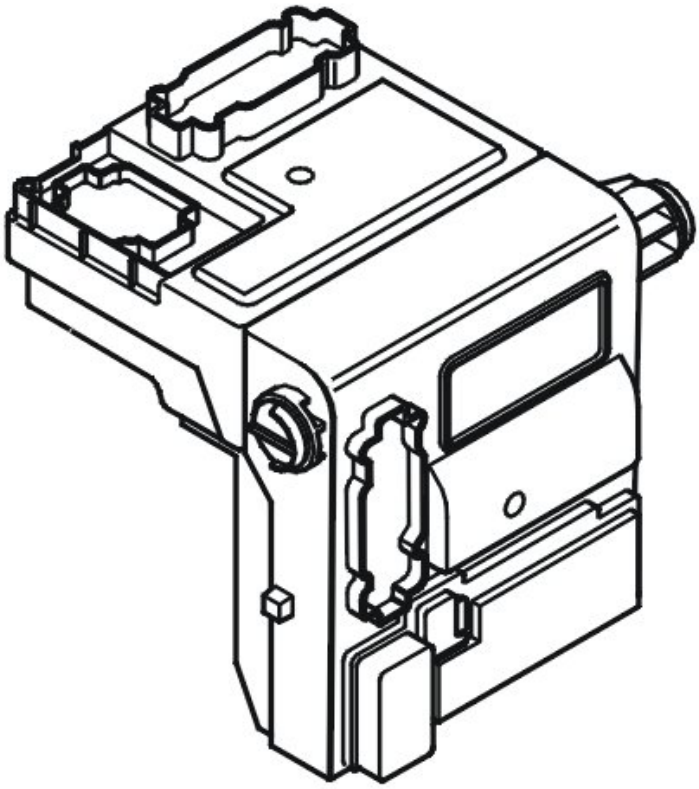
Diagnostic trouble code (DTC) information CEM-8D04

Condition

The central electronic module (CEM) checks the signal from the stop lamp switch.
The diagnostic trouble code (DTC) is stored if the control module detects that:
- Brake light is activated when Engine control module (ECM) informs that brake pedal is not depressed, and Central electronic module (CEM)

detects abnormal current to brake light.
The control module's test for the diagnostic trouble code (DTC) starts in the event of:
- Ignition position I and II, when HS-CAN is activated.

Note! The control module can only detect the fault once the test has been started and the diagnostic trouble code (DTC) is stored when the conditions are met.



Substitute value
- None.

Possible source
- Internal fault in the central electronic module (CEM).

Fault symptom[s]
- Tail light/Brake lights constantly lit

Fault-tracing

Fault-tracing

Replacing a component

The component has registered an internal fault.
Troubleshoot according to:
1. Check the brake light switch connector for contact resistance and oxidation.
2. Check that the brake light switch is supplied with voltage.
3. Check leads between Central electronic module (CEM) and brake light switch.
If no defect is found and the brake light is on constantly, change Central electronic module (CEM).

Note! Central electronic module (CEM) shall not be replaced if the brake lights work correctly. Then the diagnostic trouble code shall be erased instead.

Remedy as necessary.

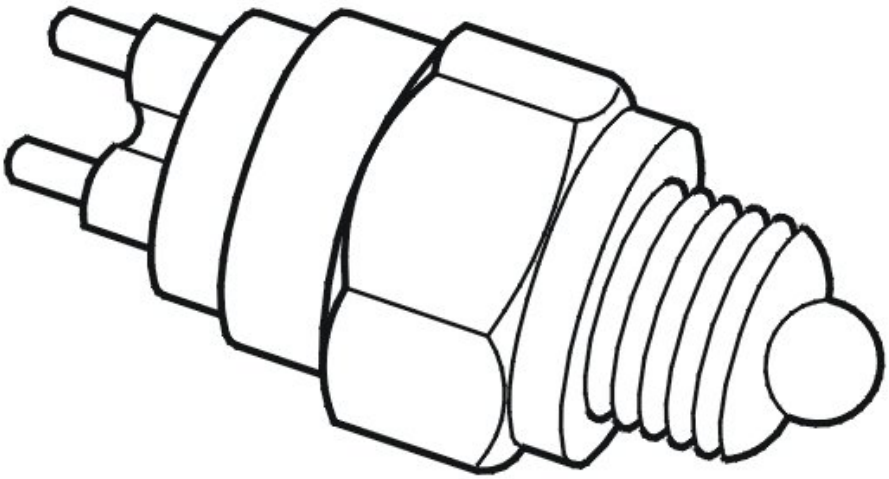
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CEM-8E01

Condition



The central electronic module (CEM) checks the back-up (reversing) lamp switch.
The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers that the signal in the circuit for the back-up (reversing) lamp switch is too low when gears 1 to 5 are selected and vehicle speed is above 80 km/h.
The diagnostic trouble code (DTC) can be diagnosed when the ignition is switched on.

Substitute value
- None.

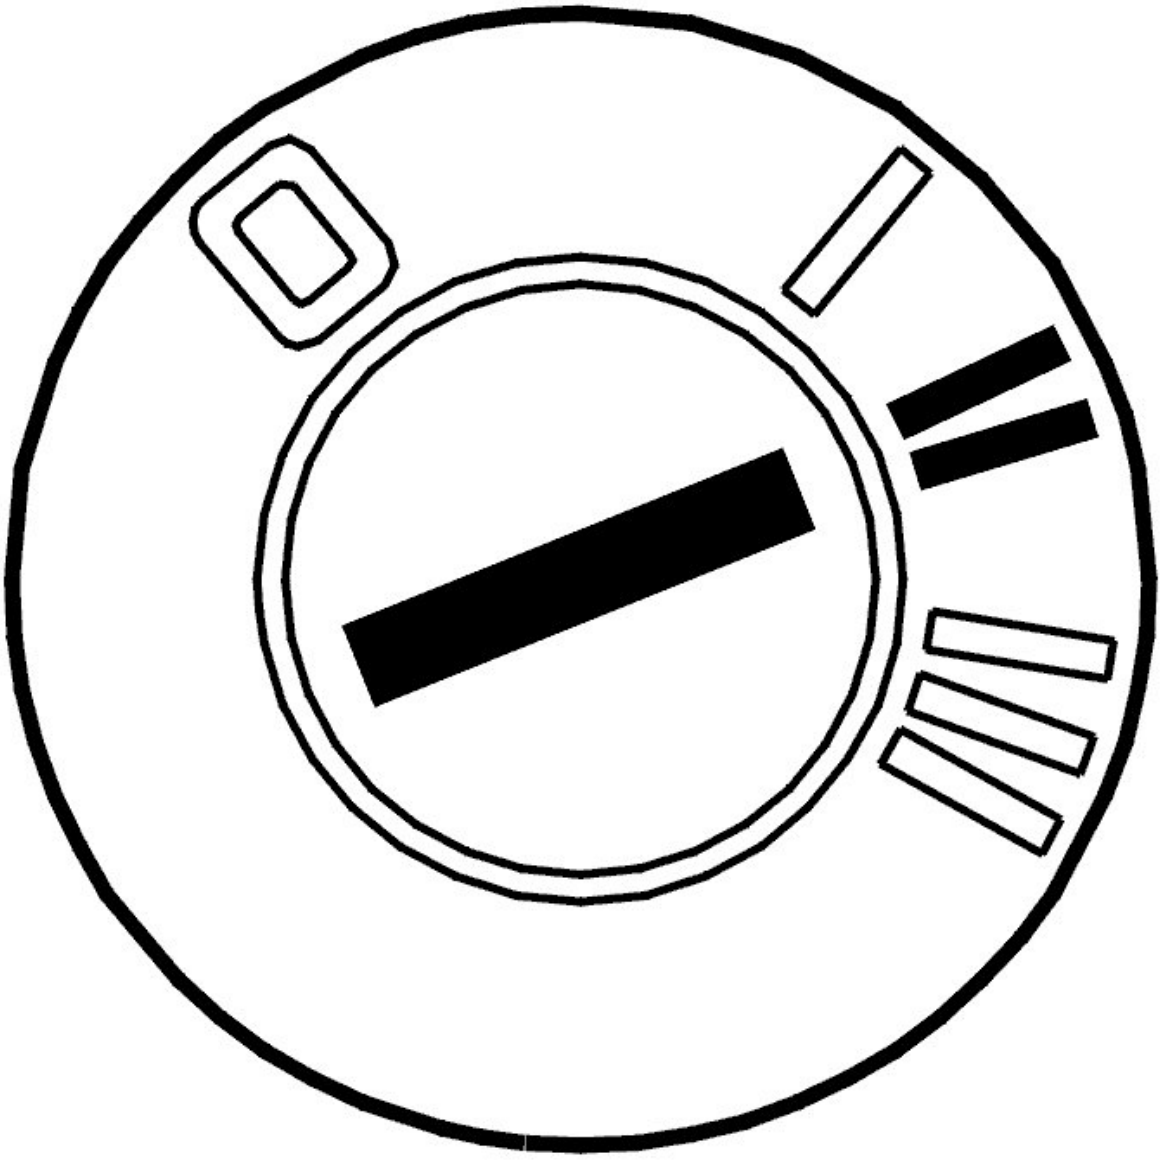
Possible source
- Damaged back-up (reversing) lamp switch
- Short-circuit to ground in the cable from the back-up (reversing) lamp switch.

Fault symptom[s]
- The back-up (reversing) lamp is constantly lit.

Faulty Signal

Faulty signal

Checking the component



- Ignition on.

Check that the back-up (reversing) lamp is only lit when back-up (reverse) gear is engaged.

Was a fault detected?

Yes - Checking components and wiring

No - Checking components and wiring

Checking components and wiring

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

Check the cable between the central electronic module (CEM) and the back-up (reversing) lamp switch. Check for an open-circuit. Check for a short-circuit to ground.
Take readings between:

- Central electronic module (CEM) terminal #C34 (34) and back-up (reversing) lamp switch terminal #1 (3/10).

Measure the resistance between back-up (reversing) lamp switch terminals #1 and #2 with gears 1 to 5 engaged. The resistance must be high.

Hint: The back-up (reverse) gear switch should be open in all gear positions except back-up (reverse).

Remedy as necessary.

Other information

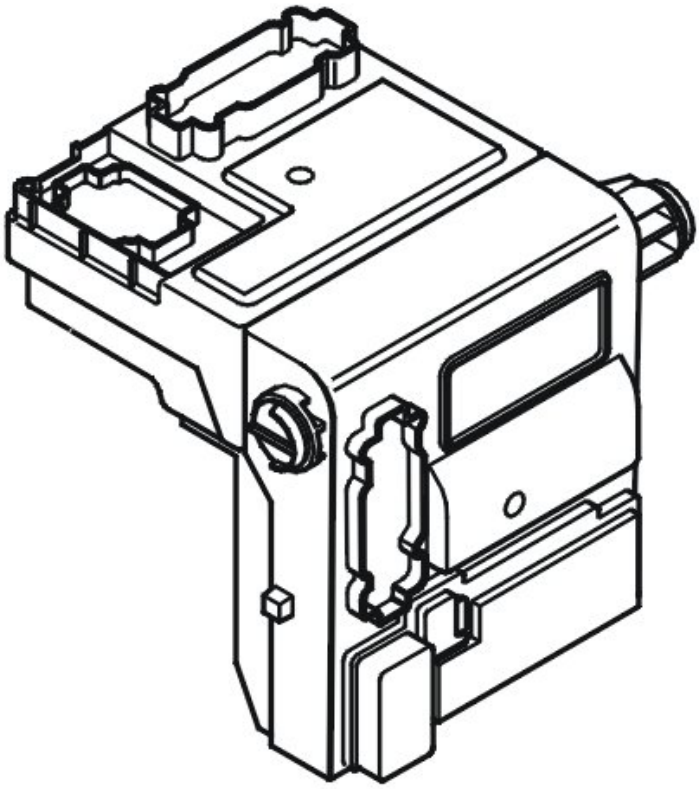
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CEM-8FF0

Condition



The central electronic module (CEM) checks the signal from the rain sensor button.
The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers that the rain sensor button has been active for more than 1 minute.
The diagnostic trouble code (DTC) can be diagnosed when the ignition is switched on.

Substitute value
- None.

Possible source
- The rain sensor button has jammed in the pressed in position
- Damaged rain sensor button.

Fault symptom[s]
- No rain sensor function.

Activated too long

Activated too long

Checking the control

The diagnostic trouble code (DTC) is stored when a button or switch has been depressed for a long time.
If the fault is intermittent, it has been registered previously but is no longer present. Intermittent faults can be caused by interference at start up or can be a different type of fault which occurs on different occasions. The fault is evaluated depending on how it occurs.
Check that the button or switch does not stick in the activated position.
Remedy as necessary.

Other information

Washer / wiper switch, replacing See: Sensors and Switches/Sensors and Switches - Wiper and Washer Systems/Wiper Switch/Service and Repair

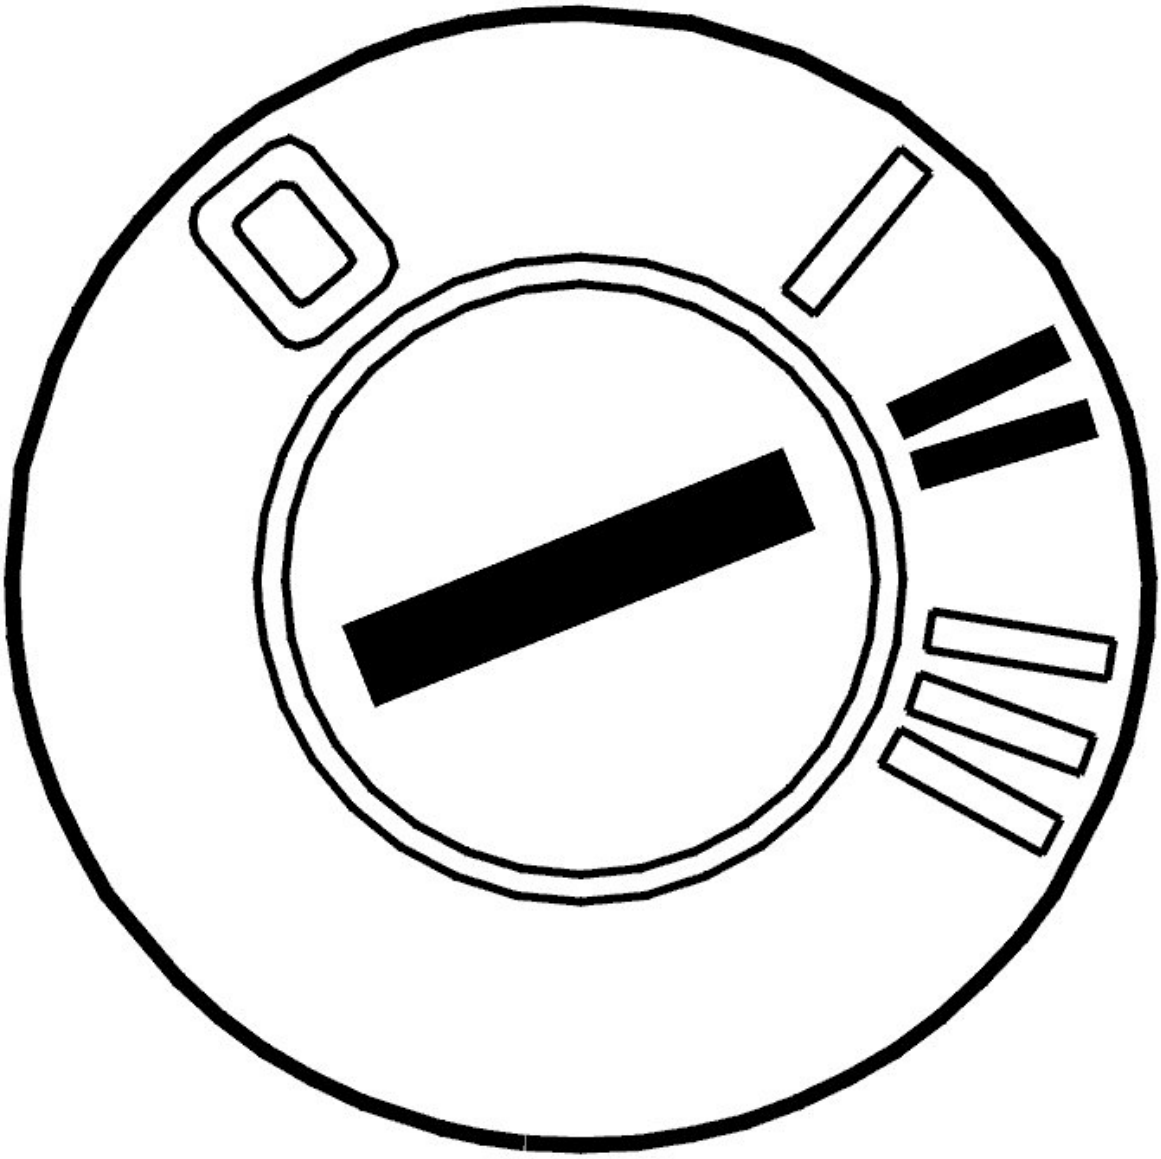
Continue - Verification

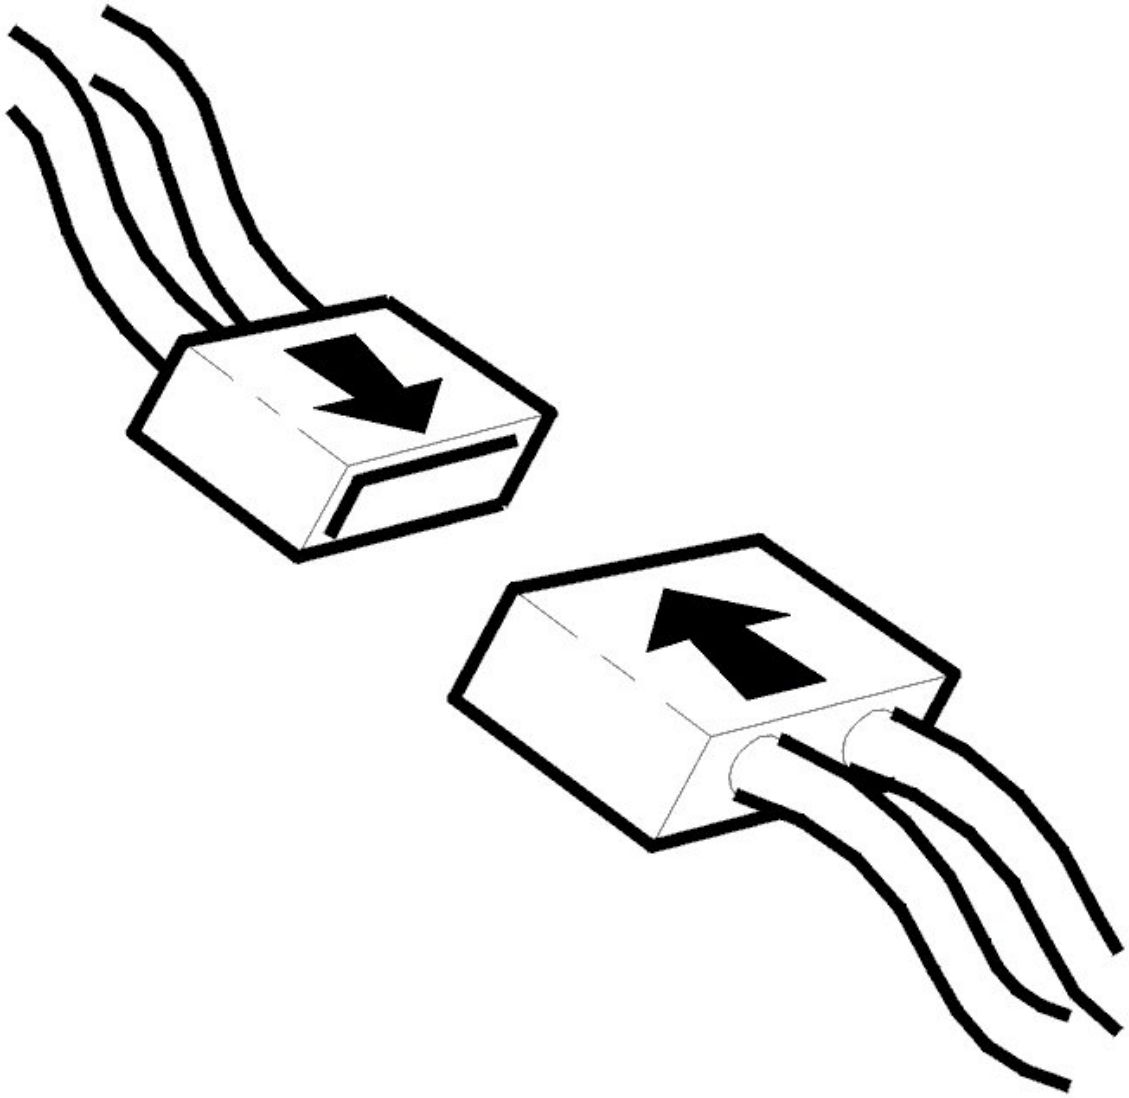
Verification

Verification

Verification

Hint: After carrying out the repair, check that the fault has been remedied.





- Ignition off
- Reinstall the connectors, components etc.
- Ignition on.

Activate the rain sensor.

Hint: The wiper blades make a reference stroke to determine the cleanliness and condition of the windshield when the rain sensor is activated. The rain sensor is deactivated when the ignition is switched off. To reactivate the rain sensor with the ignition on, move the lever to position 0 and then to intermittent wiping.

Spray water on the windshield where the rain sensor is positioned.
The wiper blades must now wipe the windshield clean.

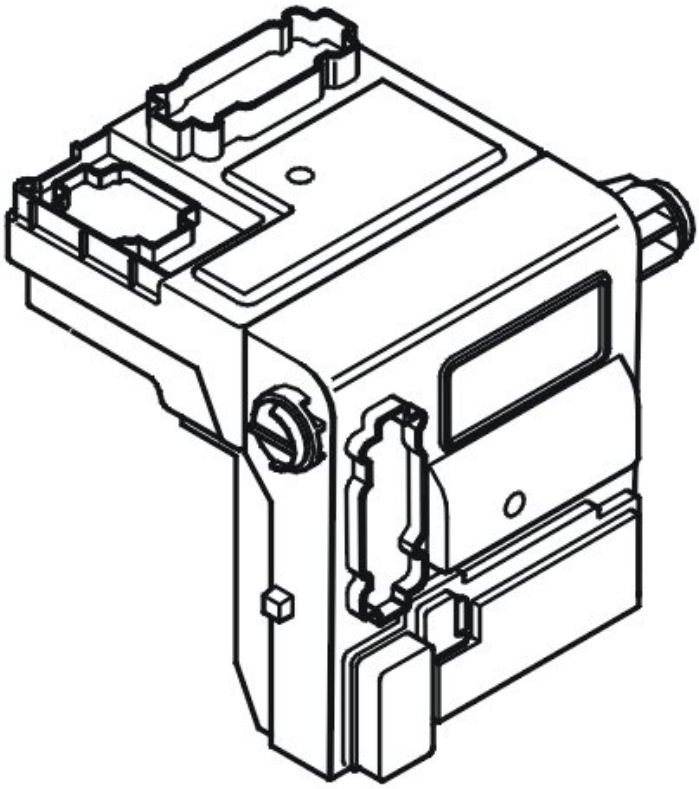
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CEM-8FF1

Condition



The central electronic module (CEM) checks the signal from the LED in the rain sensor button.
A diagnostic trouble code will be generated if the central electronic module (CEM) registers a signal from the LED in the rain sensor button that is too low.
The diagnostic trouble code can be diagnosed when the ignition is on.

Substitute value
- Nothing.

Possible source
- LED in rain sensor button short-circuited to ground.

Fault symptom[s]
- The LED does not come on.

Signal Too Low

Signal too low

Replacing the component

A diagnostic trouble code will be generated if the LED in the rain sensor button is shorted to ground.
If the fault is intermittent it will have been registered earlier but no longer exists. Intermittent faults could be due to interference on starting up or to another type of fault than recurs at different times. The seriousness of the fault is determined from case to case.
Remedy as necessary.

Other information

Washer / wiper switch, replacing See: Sensors and Switches/Sensors and Switches - Wiper and Washer Systems/Wiper Switch/Service and Repair

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CEM-8F1A

Condition

The central electronic module (CEM) checks the signal from the right-hand Xenon lamp.
The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers that the signal from the right-hand Xenon bulb is too low.
The diagnostic trouble code (DTC) can be diagnosed at ignition switch position II.

Substitute value
- Shortest headlamp range will be used.

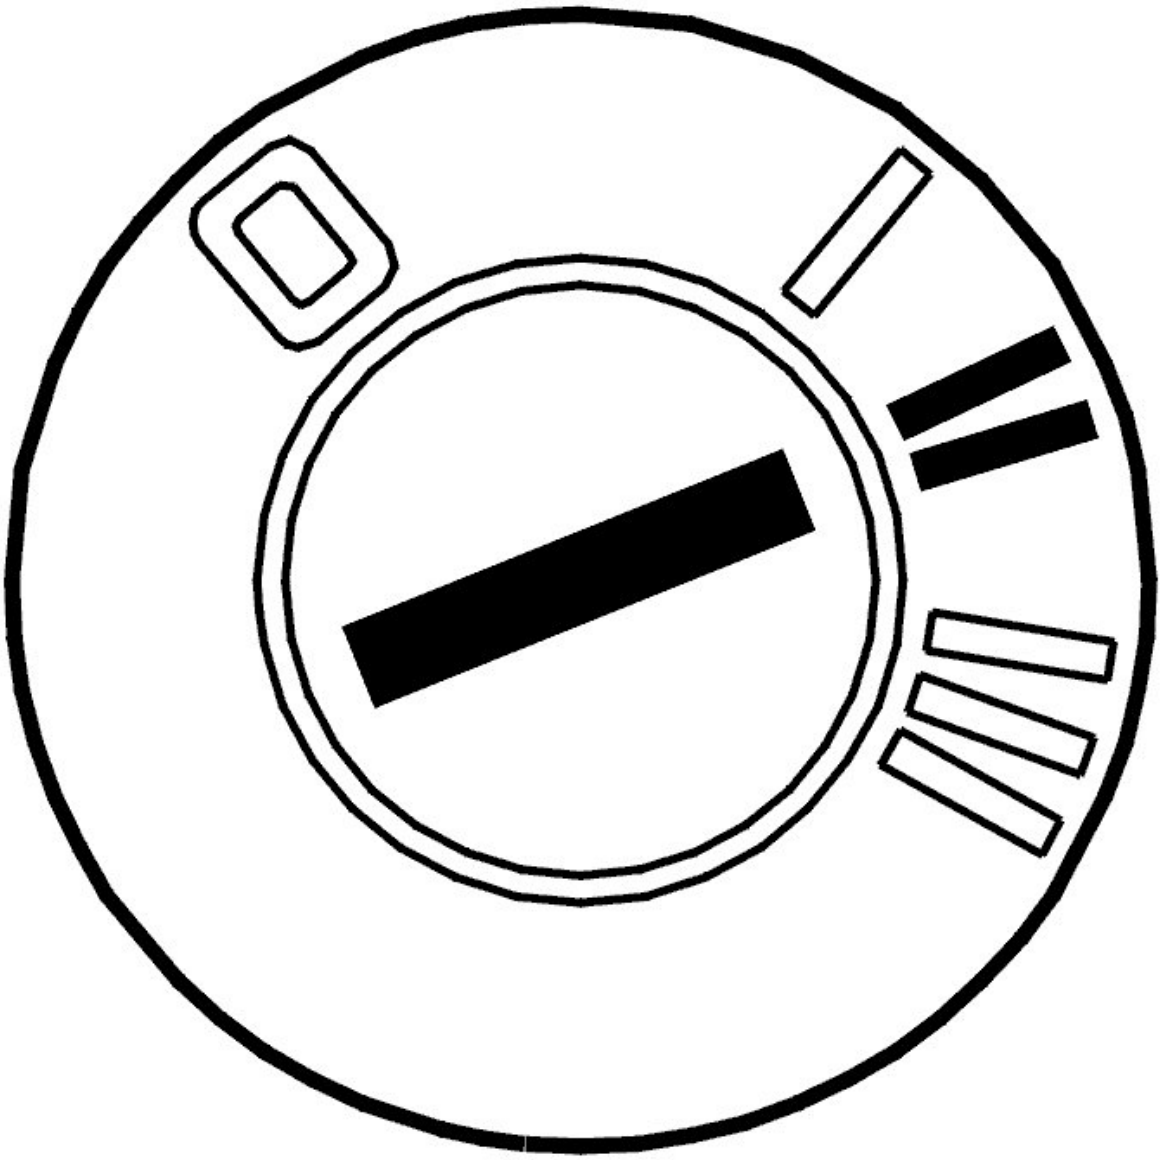
Possible source
- Short-circuit to ground in the signal cable
- The actuator motor in the xenon lamp housing has jammed
- Damaged actuator motor in the xenon lamp housing.

Fault symptom[s]
- The low beam is constantly lit
- The high beam is constantly lit
- The road surface is not illuminated.
- Headlights/Headlight aim is off

Signal Too Low

Signal too low

Checking the status



- Ignition on.
- Switch between high and low beam.

If the right-hand Xenon lamp does not switch between high and low beam, the fault is permanent.
If the right-hand xenon lamp switches between high and low beam, the fault was present previously but is no longer active, intermittent fault.

Continue - Checking components and wiring

Checking components and wiring

Check the signal cable between the central electronic module (CEM) and the actuating motor in the right Xenon headlamp for short circuit to ground.
For information about terminal numbers and cable routing, see signal description and corresponding wiring diagram.
If no fault is found, replace the right headlamp.
Remedy as necessary.

Condition

The central electronic module (CEM) checks the windshield wipers.
The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) detects that the windshield wiper is in "parking position" for longer than 5 seconds and the steering wheel module (SWM) indicates that the windshield wiper should be activated.
The diagnostic trouble code (DTC) can be diagnosed when the ignition is switched on.

Substitute value
- None.

Possible source
- Damaged windshield wiper motor
- Short-circuit to supply voltage in the power supply cable
- Open-circuit in the power supply cable.

Fault symptom[s]
- The windshield wipers are not working
- No rain sensor function.

Signal Too High

Signal too high

Checking the cable

Hint: The fault could also have been caused by the windshield wipers sticking.

If the fault is intermittent, it has been registered previously but is no longer present. Intermittent faults can be caused by interference at start up of the central electronic module (CEM) or may be a different type of fault which occurs on different occasions. The fault is evaluated depending on how it occurs.
Check the cable between the central electronic module (CEM) and the windshield wiper motor (6/1). Check for a short-circuit to supply voltage. Check for an open-circuit.
Take readings between Central electronic module (CEM) terminal #C31(#31) and the windshield wiper motor (6/1) #3.
Check the cable between the central electronic module (CEM) and the rain sensor (7/149). Check for a short-circuit to supply voltage. Check for an open-circuit.
Take readings between Central electronic module (CEM) terminal #D11 (#11) and rain sensor (7/149) #4.
Also check the connectors.

If no other faults are found try a new windshield wiper motor (6/1).
Remedy as necessary.

Diagnostic Trouble Code (DTC) Information

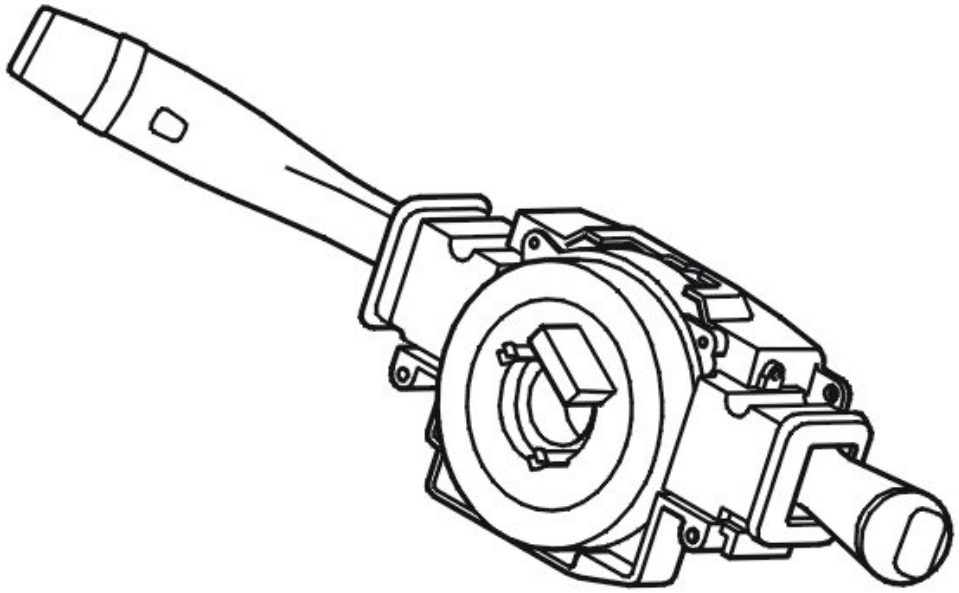
Diagnostic trouble code (DTC) information CEM-8F03

Condition



The central electronic module (CEM) checks the turn signal lamps.
The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers that there is no signal or a low signal in the circuit for the right-hand turn signal lamp.
The diagnostic trouble code (DTC) can be diagnosed when the ignition is switched on.

Substitute value
- None.

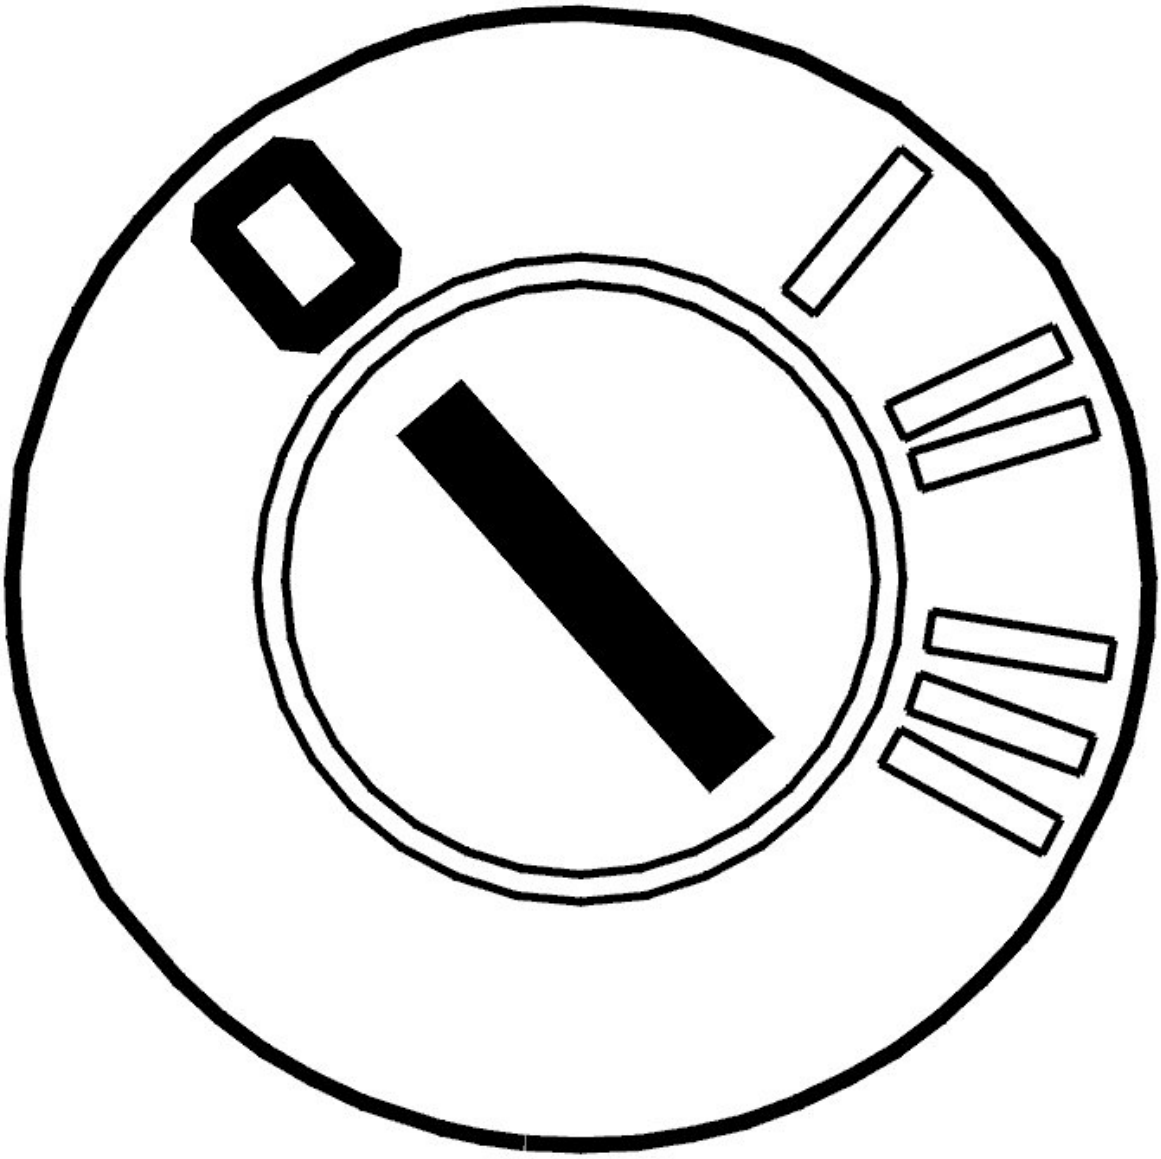
Possible source
- Short-circuit to ground in the circuit for the right-hand turn signal lamp
- Open-circuit in the circuit for the right-hand turn signal lamp.

Fault symptom[s]
- The turn signal lamps do not work.

Signal Too Low

Signal too low

Checking the wiring



- Ignition off.

Check the cable between the central electronic module (CEM) and the right-hand turn signal lamps. Check for an open-circuit. Check for a short-circuit to ground.
Also check the intermediate connectors.

For S60 and V70

Take readings between:

- Central electronic module (CEM) terminal #B32 (#32) and right front door turn signal lamp terminal #2
- Central electronic module (CEM) terminal #B32 (#32) and right-hand turn signal lamp terminal #1.

For S80

Take readings between:

- Central electronic module (CEM) terminal #B32 and right-hand front door turn signal lamp terminal #2
- Central electronic module (CEM) terminal #B32 and right-hand turn signal lamp terminal #2.

For the XC90

Take readings between:

Diagnostic Trouble Code (DTC) Information

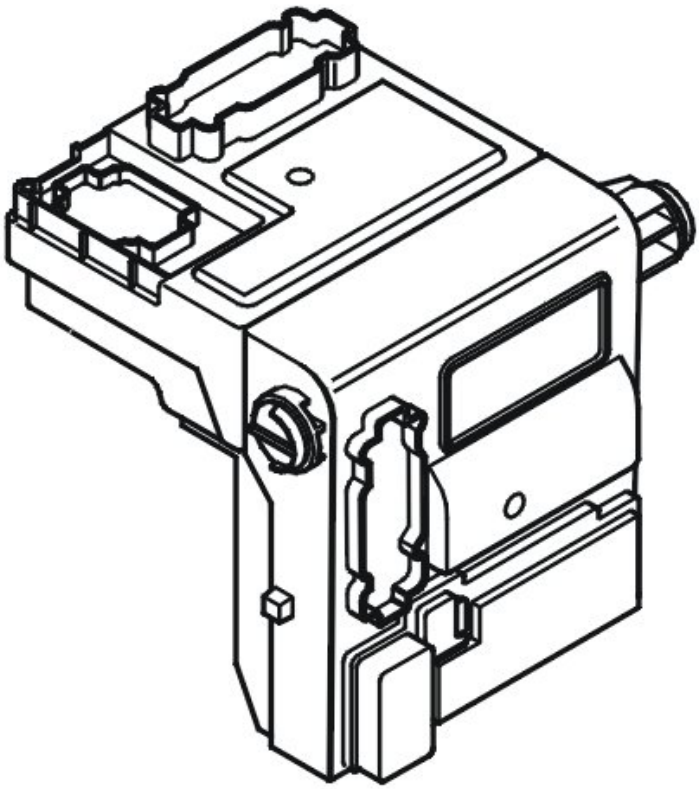
Diagnostic trouble code (DTC) information CEM-8F08

Condition



The central electronic module (CEM) checks the re-engagement signal from the driver circuit to the wake-up signal for the engine control module (ECM) and to the hazard warning signal flasher. Both functions are controlled by the same driver circuit in the central electronic module (CEM) but can only be re-engaged once.
The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers that the wake-up signal to the engine control module (ECM) is too low.

The diagnostic trouble code (DTC) can be detected when the ignition is on and when the lamp in the switch for the hazard warning signal flasher is not lit.

Substitute value
- None.

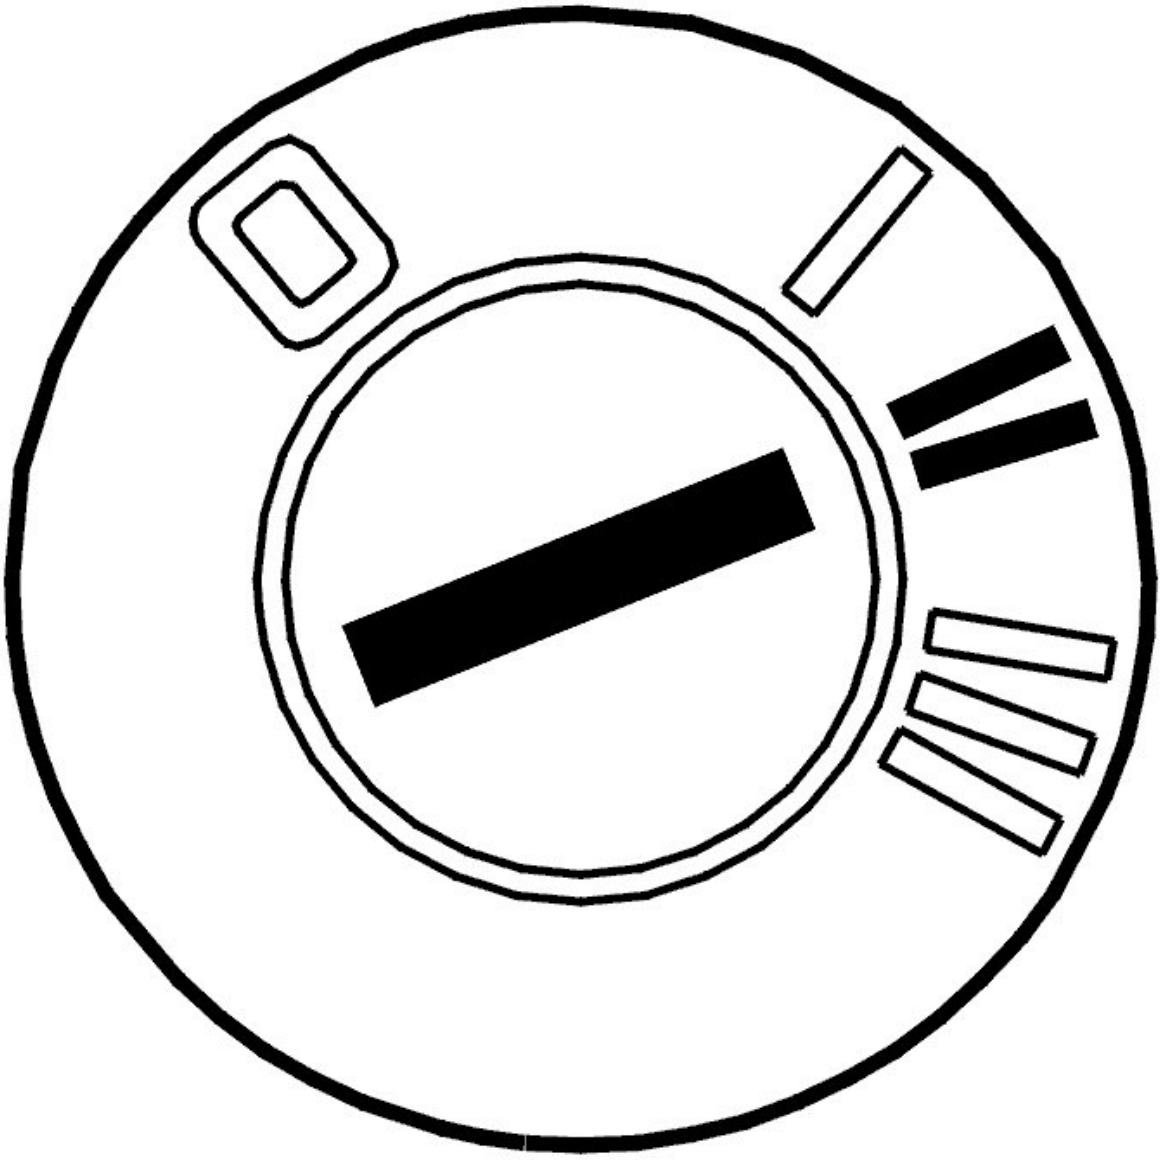
Possible source
- Short-circuit to ground in the signal cable for the wake-up signal to the engine control module (ECM).

Fault symptom[s]
- The starter motor turns but the engine does not start.

Signal Too Low

Signal too low

Checking the status

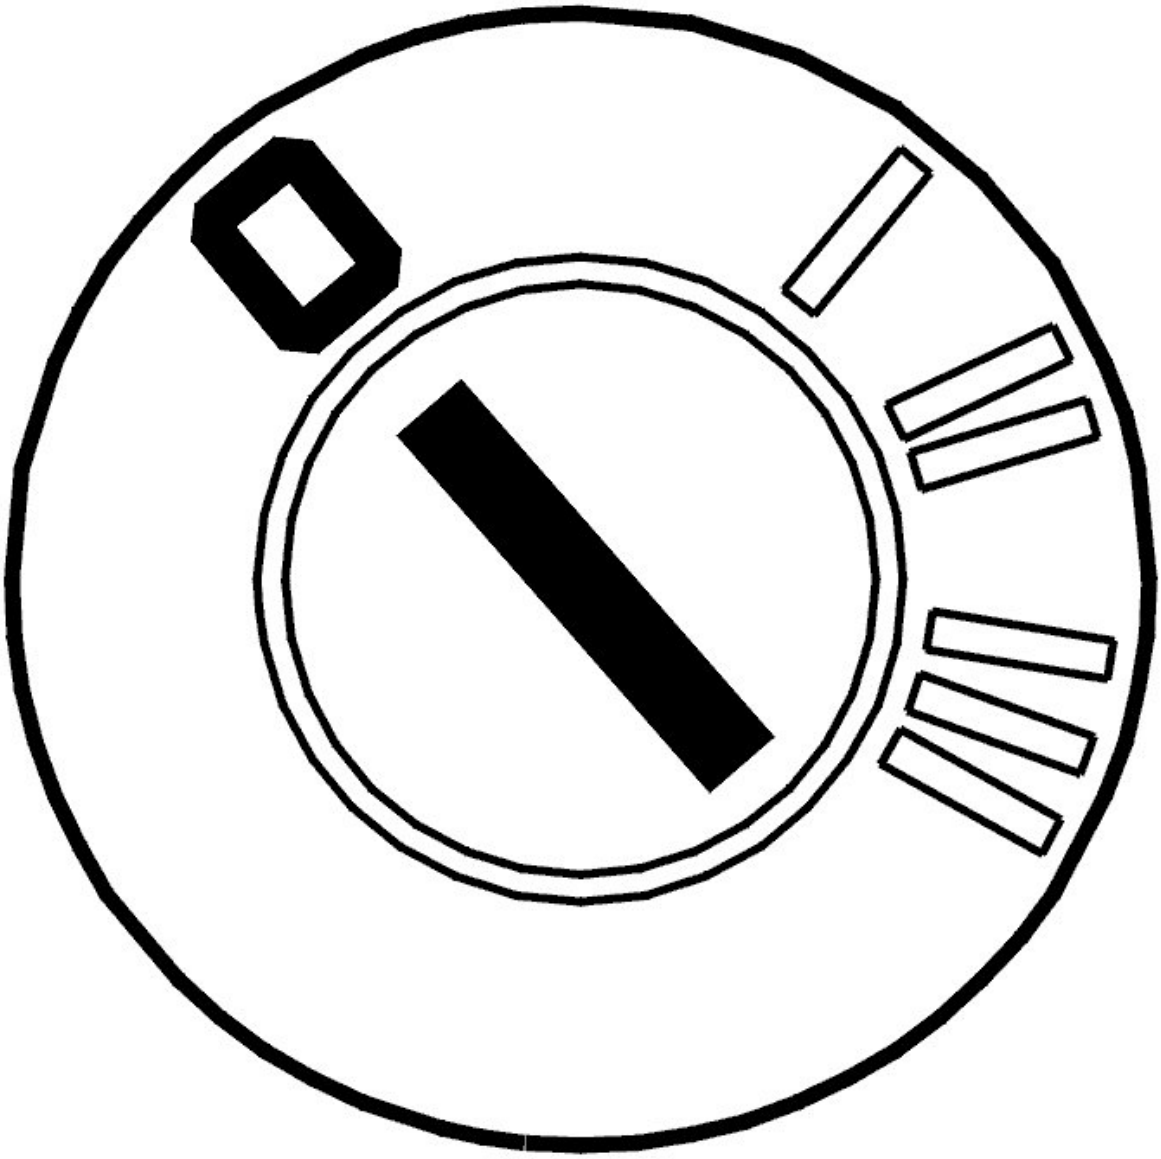


- Ignition on.

Read off the status of the waking signal for the engine control module (ECM).
Change the ignition key position from position I to II.
Check if the fault is permanent or intermittent.
The status of the wake-up signal for the engine control module (ECM) must change when changing the ignition key position.
If the status of the waking signal for the engine control module (ECM) does not change, the fault is permanent.
If the status of the waking signal for the engine control module (ECM) changes, this is an indication that the fault was present previously but that it is not active at the moment, i.e. the fault is intermittent.

Continue - Checking components and wiring

Checking components and wiring



- Ignition off.

Check central electronic module (CEM) connector terminal C and engine control module (ECM) connector B. Check for contact resistance. Check for oxidation. Check for damage. Check for loose connections. Also check the intermediate connectors.
Check the signal cable. Check for a short-circuit to ground.
Take readings between:

- Central electronic module (CEM) terminal #C15 (#15) and engine control module (ECM) terminal #B27.

Remedy as necessary.

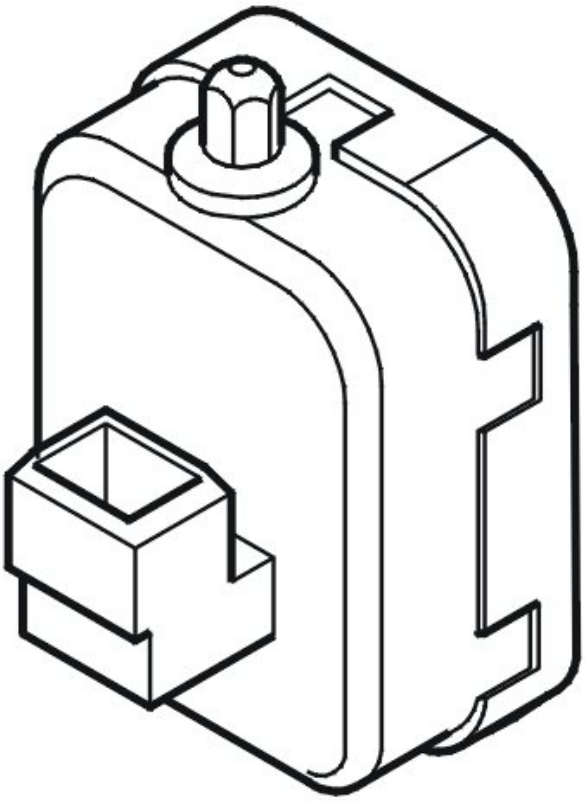
Diagnostic trouble code (DTC) information CEM-8F12

Condition



The central electronic module (CEM) checks the signal for the headlamp beam height control.
The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) detects that the voltage to the headlamp beam height control is below 10% of the supply voltage.
The diagnostic trouble code (DTC) can be diagnosed at ignition switch position II.

Substitute value
- None.

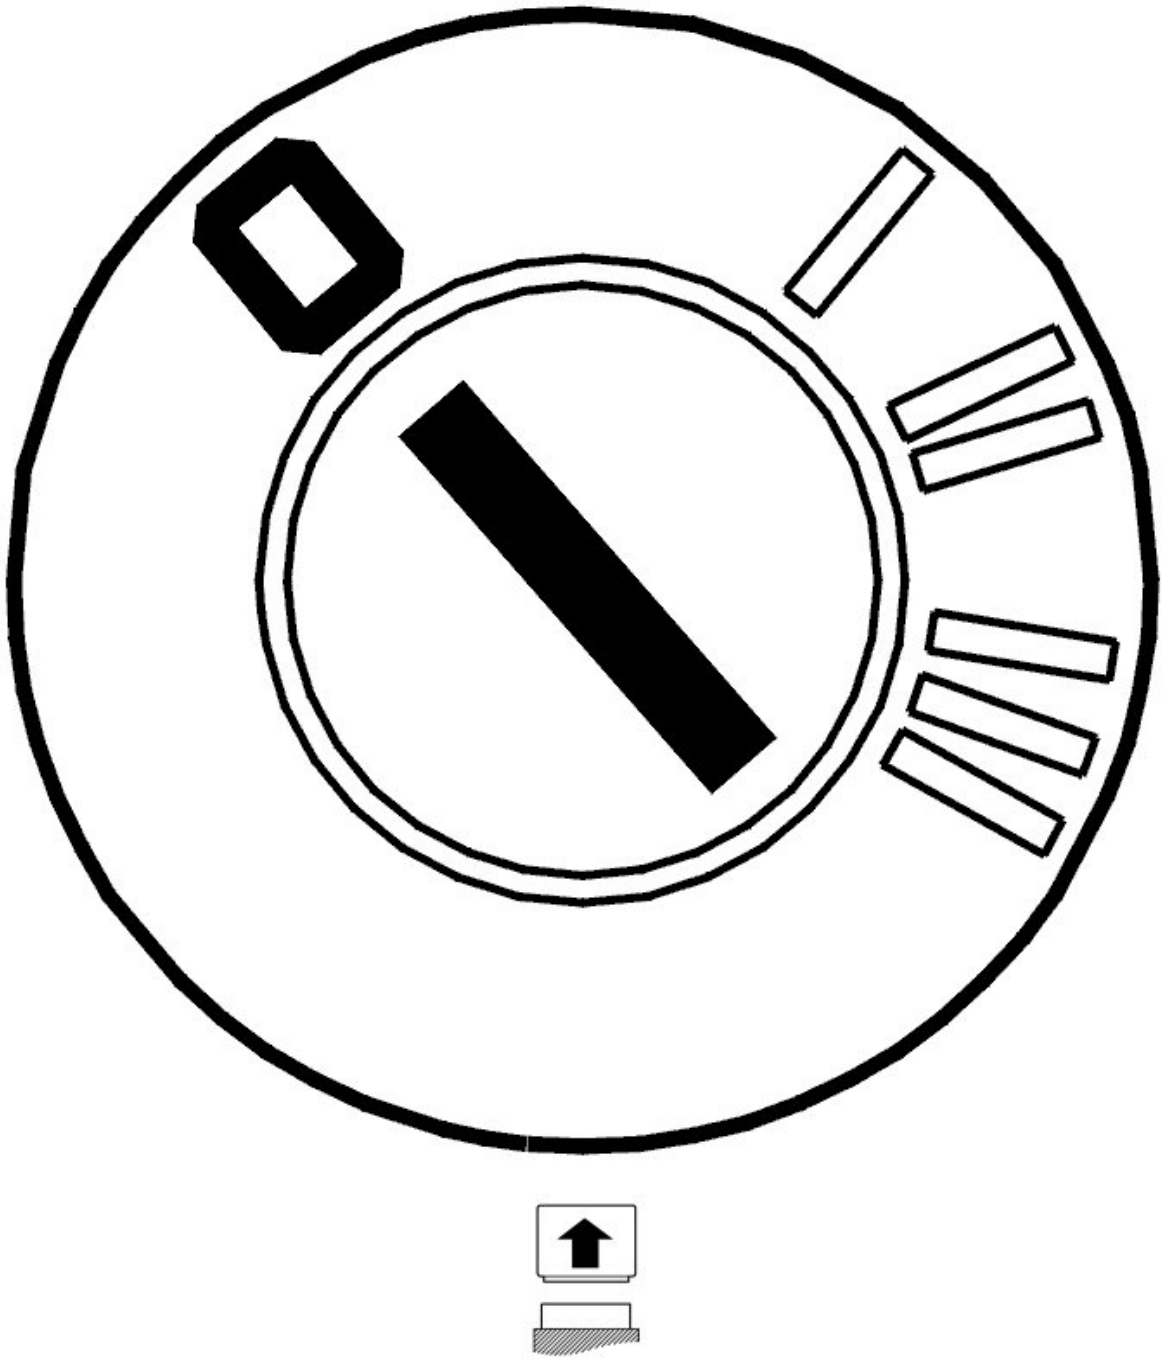
Possible source
- Damaged actuator motor for headlamp beam height control
- Open-circuit in the cable or short-circuit to ground.

Fault symptom[s]
- Incorrect setting for low beam.

Signal Too Low

Signal too low

Checking the wiring



- Ignition off
- Disconnect central electronic module (CEM) connector C.

Check the signal cable. Check for an open-circuit. Check for a short-circuit to ground.
Take readings between:

- Central electronic module (CEM) terminal #C12 (#12) and left headlamp alignment motor terminal #2
- Central electronic module (CEM) terminal #C11 (#11) and right headlamp alignment motor terminal #2.

If no fault was found, replace the actuator motor for headlamp beam height control.
Remedy as necessary.

Other information

- Connecting the breakout box See: Body and Frame/Body Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box/Connecting the Breakout Box, Central Electronic Module (CEM)

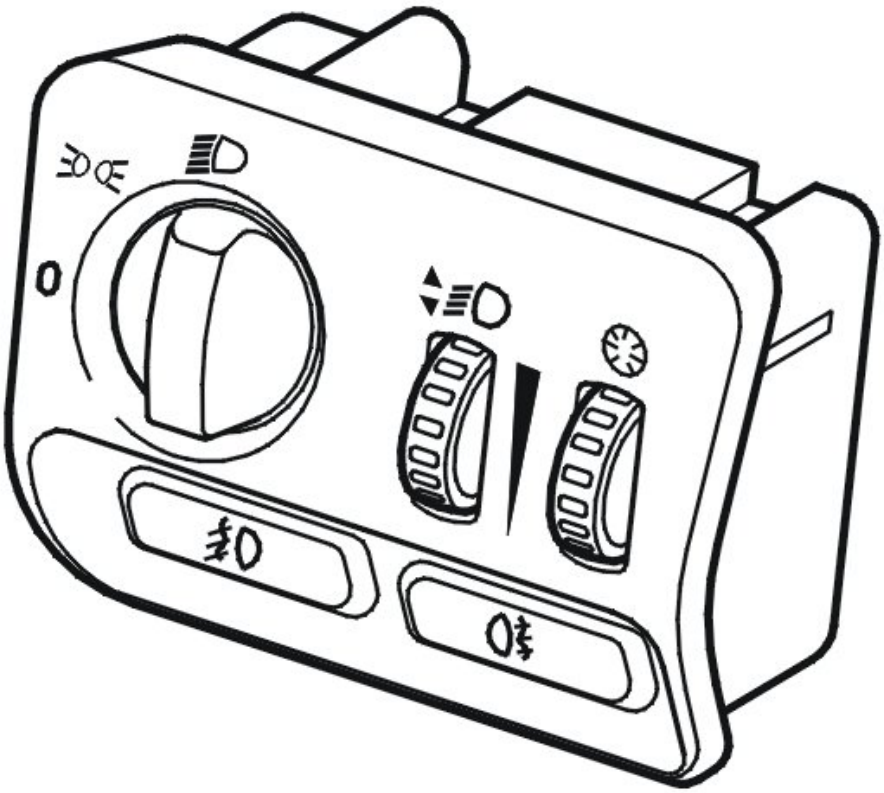
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CEM-8F13

Condition



The central electronic module (CEM) communicates with the light switch module (LSM).
The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) receives information from the light switch module (LSM) indicating that the signal from the headlamp beam height control is too high.
The diagnostic trouble code (DTC) can be diagnosed at ignition switch position II.

Substitute value
- None.

Possible source
- Damaged controller in the light switch module (LSM).

Fault symptom[s]
- Beam height control does not function.

Signal Too High

Signal too high

Replacing the component

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

The central electronic module (CEM) has registered an internal fault in the light switch module (LSM).
If the fault is intermittent, it has been registered previously but is no longer present. Intermittent faults can be caused by interference at start up of the central electronic module (CEM) or may be a different type of fault which occurs on different occasions. The fault is evaluated depending on how it occurs. If the fault recurs, replace the light switch module (LSM).
Switches lights, replacing See: Lighting and Horns/Headlamp/Headlamp Switch/Service and Repair
Remedy as necessary.

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CEM-8F15

Condition

The central electronic module (CEM) checks the signal from the left-hand Xenon lamp.
The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers a fault in the left-hand Xenon bulb.
The diagnostic trouble code (DTC) can be detected with the ignition on and when switching between low and high beam.
The diagnostic trouble code (DTC) can be diagnosed at ignition switch position II.

Substitute value

- Shortest headlamp range will be used.

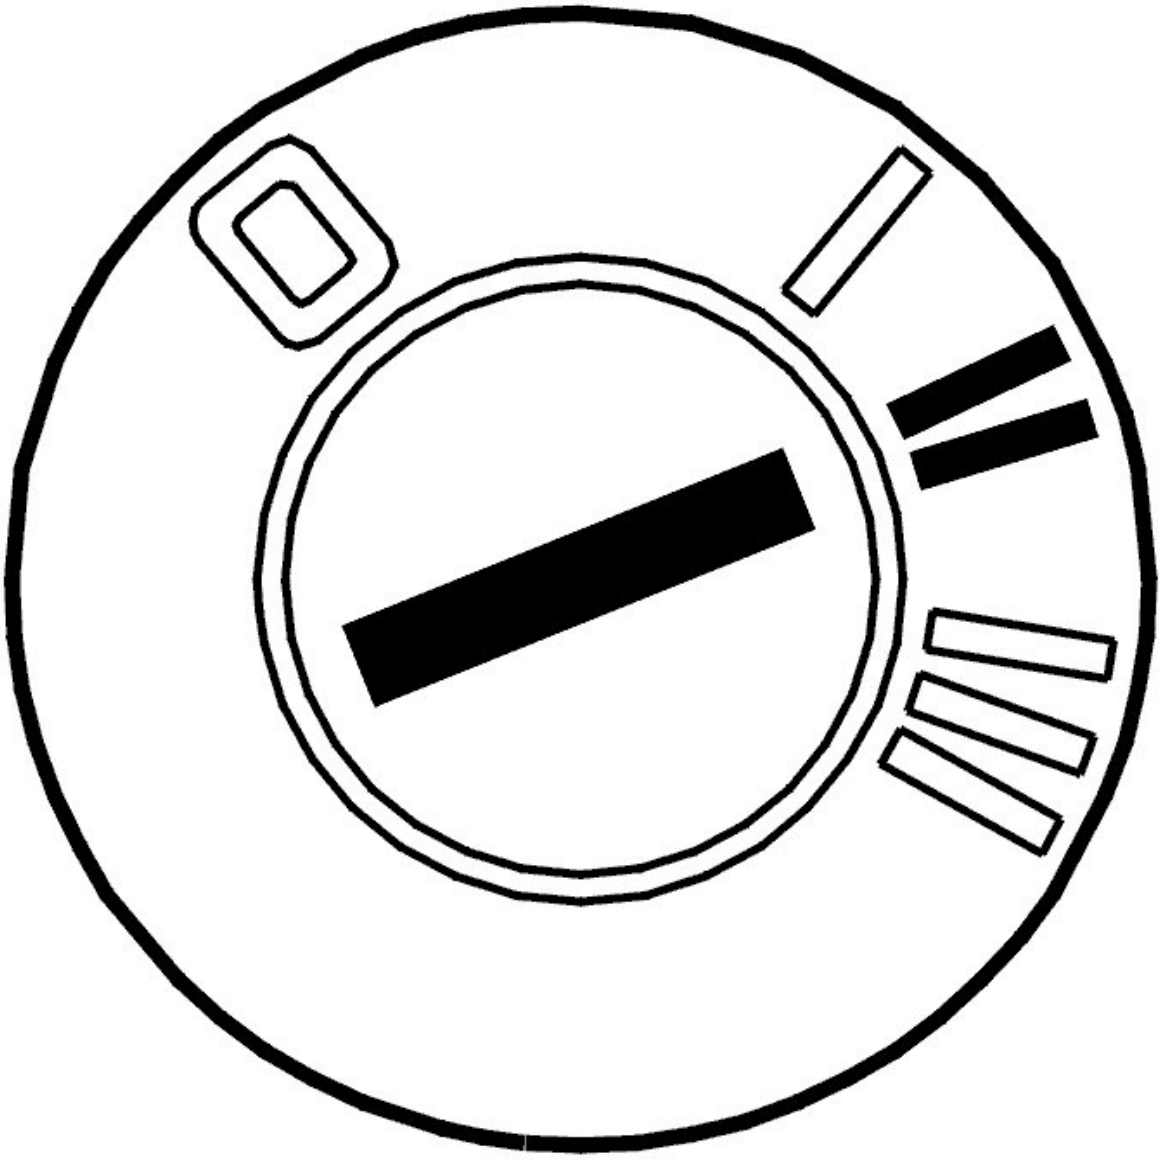
Possible source
- The actuator motor in the xenon lamp housing has jammed
- Damaged actuator motor in the xenon lamp housing.

Fault symptom[s]
- The low beam is constantly lit
- The high beam is constantly lit
- The road surface is not illuminated.
- Headlights/Headlight aim is off

Faulty Signal

Faulty signal

Checking the status



- Ignition on.
- Switch between high and low beam.

If the left-hand Xenon lamp does not switch between high and low beam, the fault is permanent.
If the left-hand Xenon lamp switches between high and low beam, the fault was present previously but is no longer active, intermittent fault.

Do the xenon lamps switch between high and low beam?

Yes - Fault Found

No - Replacing a component

Replacing a component

The diagnostic trouble code (DTC) indicates that the actuator motor in the left Xenon lamp is damaged.

Condition

The central electronic module (CEM) checks the windshield wipers.
The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers that the switch for single sweep and low speed wiping are active at the same time for more than 2.5 seconds.
The diagnostic trouble code (DTC) can be diagnosed when the ignition is switched on.

Substitute value
- The windshield wipers only operate at lowest speed.

Possible source
- Damaged windshield wiper lever.

Fault symptom[s]
- The windshield wipers only operate at lowest speed.

Faulty Signal

Faulty signal

Replacing the windshield wiper switch

If the fault is intermittent, it has been registered previously but is no longer present. Intermittent faults can be caused by interference at start up or can be a different type of fault which occurs on different occasions. The fault is evaluated depending on how it occurs.
If the fault is permanent, replace the windshield wiper switch because an internal fault has occurred.

Diagnostic Trouble Code (DTC) Information

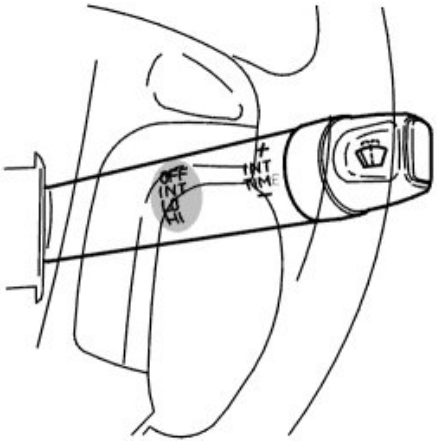
Diagnostic trouble code (DTC) information CEM-8F41

Condition



The central electronic module (CEM) checks the windshield wipers.
The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers that the signal from the relay circuit for the rear washer motor is too high.
The diagnostic trouble code (DTC) can be diagnosed when the ignition is switched on.

Substitute value
- None.

Possible source
- Short-circuit to supply voltage in the relay circuit for the rear washer motor.
- Damaged fuse.

Fault symptom[s]
- Rear windshield washing does not work
- The rear windshield washer motor does not operate.

Signal Too High

Signal too high

Checking the wiring

If the fault is intermittent, it has been registered previously but is no longer present. Intermittent faults can be caused by interference at start up or can be a different type of fault which occurs on different occasions. The fault is evaluated depending on how it occurs.
Check the fuse for the washer motor, replace if necessary.
For further information about the fuses and relays, see the Wiring Diagram
Check the cable between the central electronic module (CEM) and the washer motor. Check for a short-circuit to supply voltage.
Take readings between:
- Central electronic module (CEM) terminal #B29 (#29) and washer motor terminal #2.

Replace the central electronic module (CEM) if no fault is found.

Diagnostic Trouble Code (DTC) Information

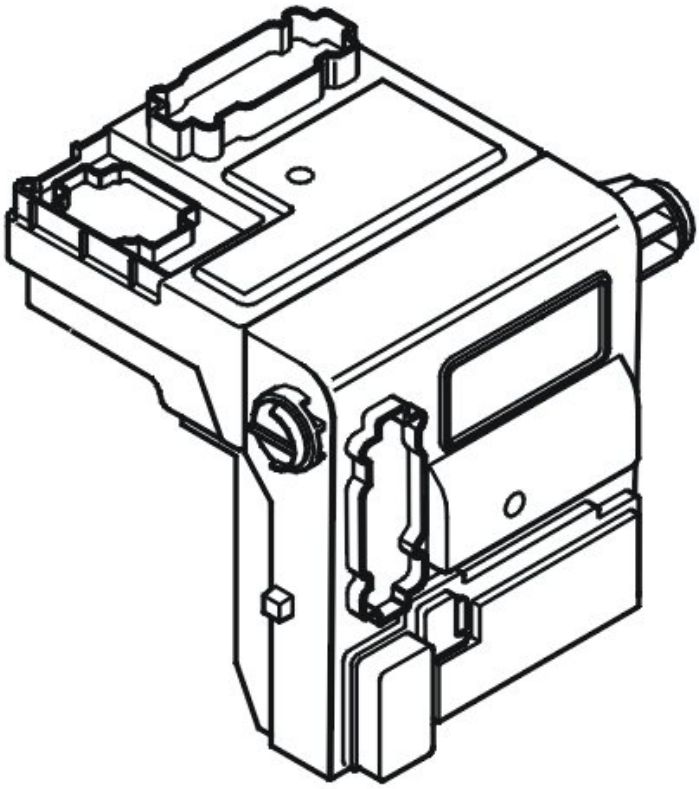
Diagnostic trouble code (DTC) information CEM-8F51

Condition



The central electronic module (CEM) checks the output signal to the relay coil for the headlamp wash/wipe.
The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) registers that the output signal to the relay coil is too high.
The diagnostic trouble code (DTC) can be diagnosed when the ignition is switched on.

Substitute value
- None.

Possible source
- Short-circuit to supply voltage in the signal cable
- Damaged relay.

Fault symptom[s]
- The headlamp washer motor does not operate.

Signal Too High

Signal too high

Checking the component

Replace relay 2/182.
Activate high-pressure cleaning by activating the windshield washer.

Hint: The washer must be activated for more than 0.3 seconds before high pressure cleaning will be activated. High-pressure cleaning is activated every fifth time the washers are activated if not more than 10 minutes have passed since the last activation.

If the function is OK, the cause of the fault was a damaged relay (short-circuit in the relay).

Other information:
- For further information about fuses and relays, see the relevant wiring diagram.

Was a fault detected?

Yes - Verification

No - Checking fusebox

Checking fusebox

Remove windshield wiper relay 2/182 from the fusebox base.
Check the relay coil driver circuit for a short-circuit to supply voltage. Take a voltmeter reading between terminal #2 and ground in the relay base.
The voltage between terminal #2 and ground must be approximately 0 V.
Remedy as necessary.

Other information
- For further information about fuses and relays, see the relevant wiring diagram
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

Checking the wiring

Check the cable between windshield wiper relay base terminal #2 and central electronic module (CEM) terminal #C25. Check for a short-circuit to supply voltage.
Remedy as necessary.
Replace the fusebox if no fault is found.

Other information

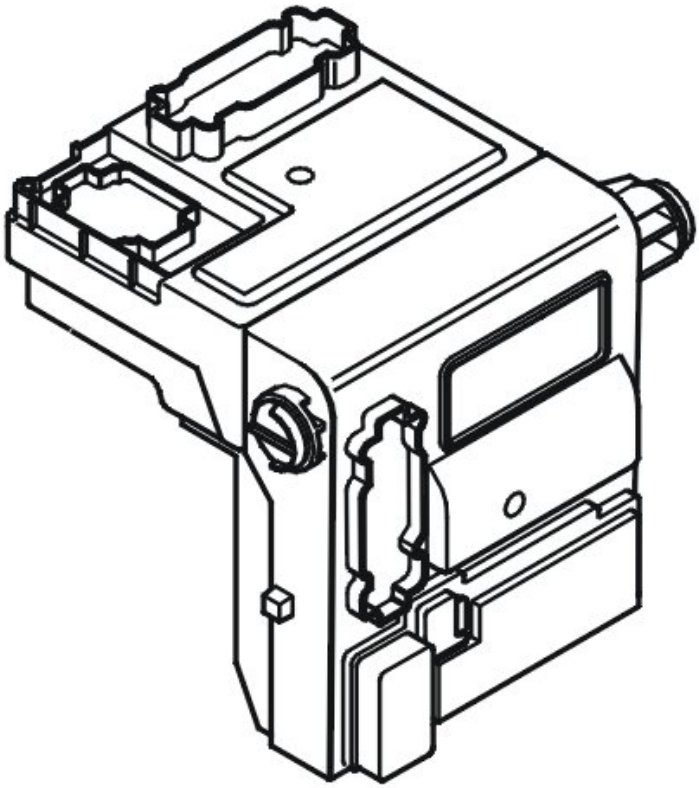
- For further information about fuses and relays, see the relevant wiring diagram
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

Continue - Verification

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CEM-8F52

Condition



The Central electronic module (CEM) checks the output signal to the relay winding for headlight cleaning.
If Central electronic module (CEM) registers that the output signal to the relay winding is missing or too low, the diagnostic trouble code is

generated.
The diagnostic trouble code (DTC) can be diagnosed when the ignition is switched on.

Substitute value
- None.

Possible source
- The washer pump's fuse has failed.
- Open-circuit or short-circuit to ground in the signal cable.
- Damaged relay.
- Short-circuiting in the pump for high-pressure washing.

Fault symptom[s]
- Headlight washer pump does not work

Signal Too Low or Signal Missing

Signal too low or signal missing

Checking fuses

Check that the fuse for the high-pressure washer is intact. Replace the fuse if necessary.
After changing fuse, erase trouble codes.
Activate ignition position II.
Try to activate the headlight washers with the lever.

Hint: The washer must be activated for more than 0.3 seconds for the high-pressure washer to be activated. The high-pressure washer is activated every fifth time that the washers are activated if not more than 10 minutes have passed since the last activation. Warning light for low washer fluid level may not be on.

If the trouble code does not return and the high-pressure washer works, no further action is needed.
If the fuse fails again, or if the trouble code returns, continue troubleshooting.

Do you wish to continue with fault tracing?

Yes - Checking the component

No - Verification

Checking the component

Replace relay 2/182.
Activate high-pressure washing by activating the washer for the windshield.

Hint: The washer must be activated for more than 0.3 seconds for the high-pressure washer to be activated. The high-pressure washer is activated every fifth time that the washers are activated if not more than 10 minutes have passed since the last activation.

If the function is OK, the cause of the fault was a damaged relay (short-circuit in the relay).

Other information:
- For further information about the fuses and relays, see the Wiring Diagram.

Do you wish to continue with fault tracing?

Yes - Checking high-pressure washer pump

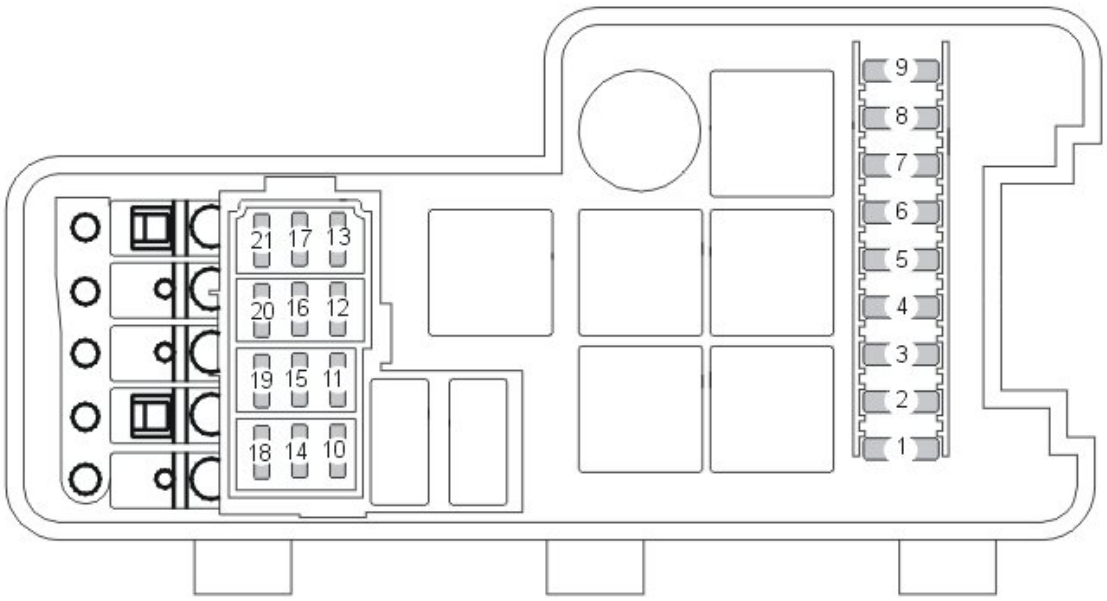
No - Verification

Checking fusebox

Remove headlight washer relay (2/182) from the fuse box socket.
Check the relay winding's drive circuit for short-circuiting to voltage by measuring voltage between #2 and ground in the relay socket.
Voltage between #2 and ground shall be battery voltage.
Remedy as necessary.

Other information:

- For further information about the fuses and relays, see the Wiring Diagram.
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals



Do you wish to continue with fault tracing?

Yes - Checking the wiring

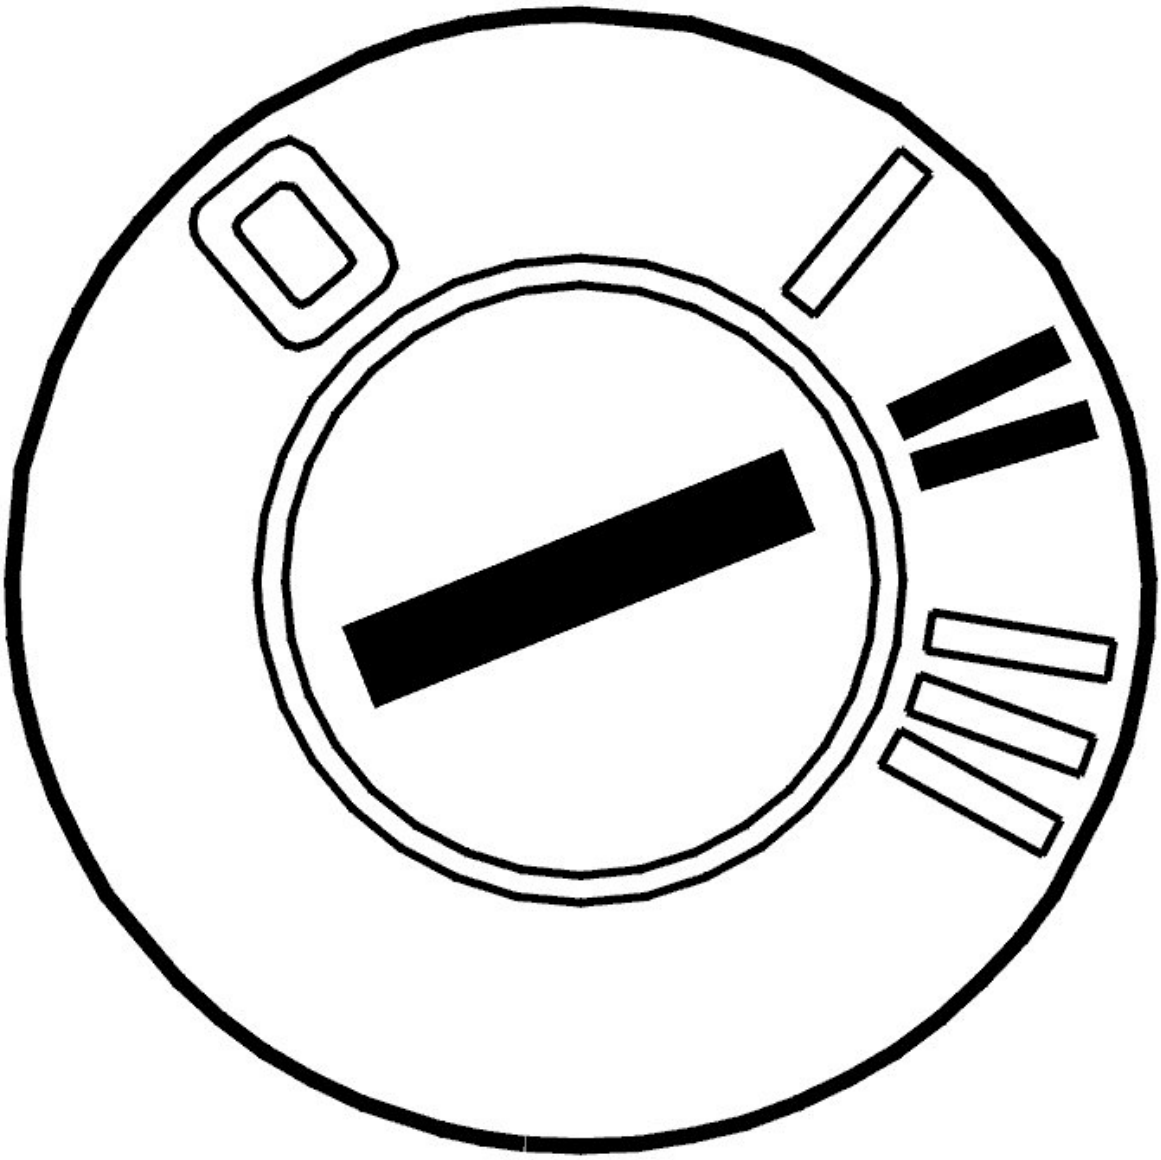
No - Verification

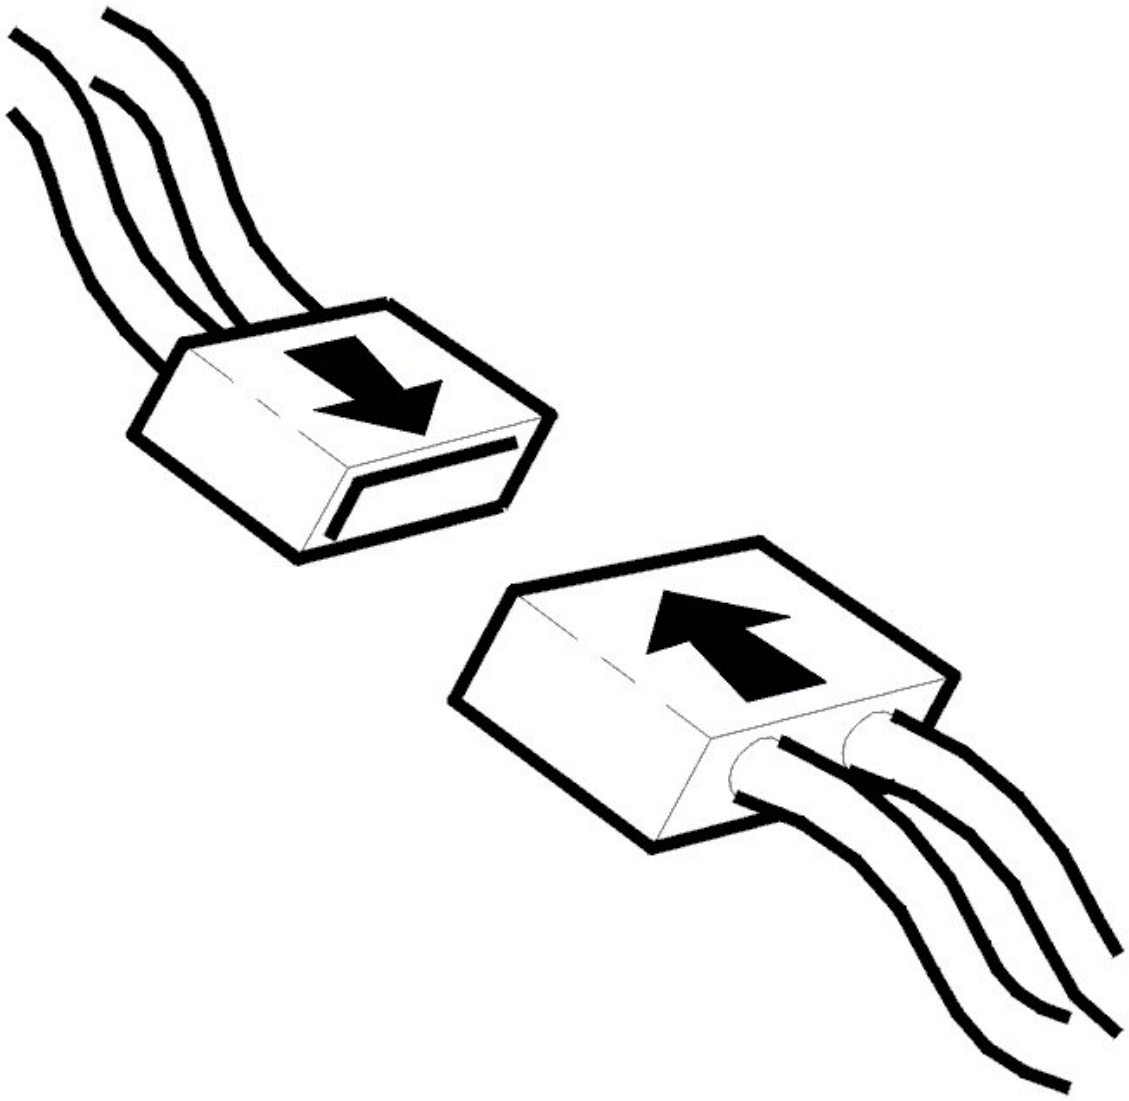
Verification

Verification

Verification

Hint: After carrying out the repair, check that the fault has been remedied.





- Ignition off
- Reinstall the connectors, components etc.
- Ignition on.

Activate high-pressure cleaning by activating the windshield washer.

Attempt New Test - Checking fuses

Checking the wiring

Check the cable between the headlight washer relay (2/182) #4 and central electronic module (CEM) #C25 for short circuits to ground and open circuits.
Disconnect washer pump and headlight washer relay (2/182). Check cable between connection #1 on the headlight washer relay (2/182) and ground for short-circuiting to ground.
Remedy as necessary.
Replace the fusebox if no fault is found.

Other information:

- For further information about the fuses and relays, see the Wiring Diagram.
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

Continue - Verification

Checking high-pressure washer pump

Check that the fuse for the high-pressure washer is intact.
Disconnect the pump for high-pressure washing from its connector.
Try to activate the headlight washers with the lever.
If the fuse does not fail when the washer pump is disconnected, the cause of the trouble code being set is probably an internal short circuit in the washer pump for the headlights. Try with changing high-pressure washer pump.
If the fuse fails, even if the pump is disconnected, the pump is probably okay. Continue troubleshooting.

Do you wish to continue with fault tracing?

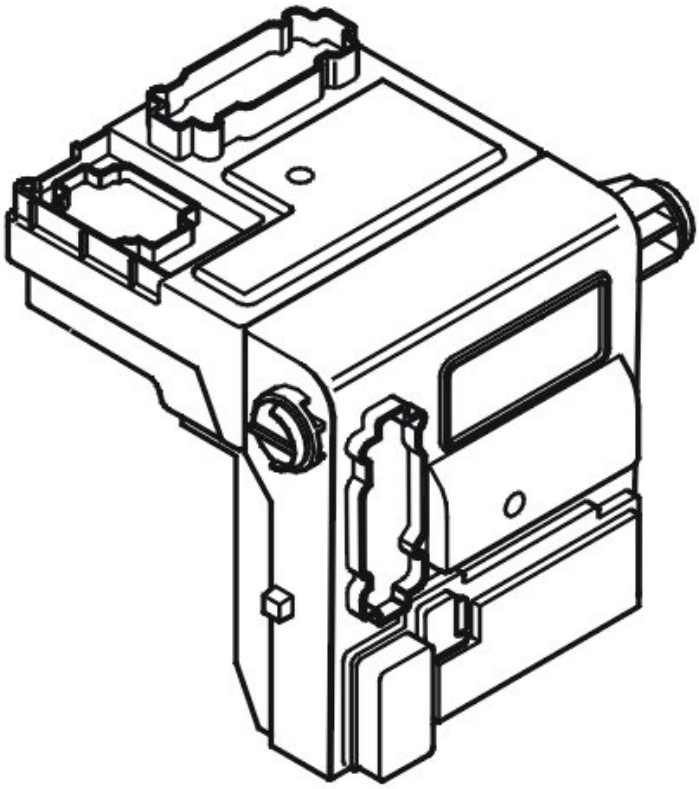
Yes - Checking fusebox

No - Verification

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CEM-9C01

Condition



The central electronic module (CEM) checks the glove compartment lighting.
The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) detects a short-circuit to ground in the power supply cable for the glove compartment lighting.
The diagnostic trouble code (DTC) can be diagnosed when the ignition is switched on.

Substitute value
- None.

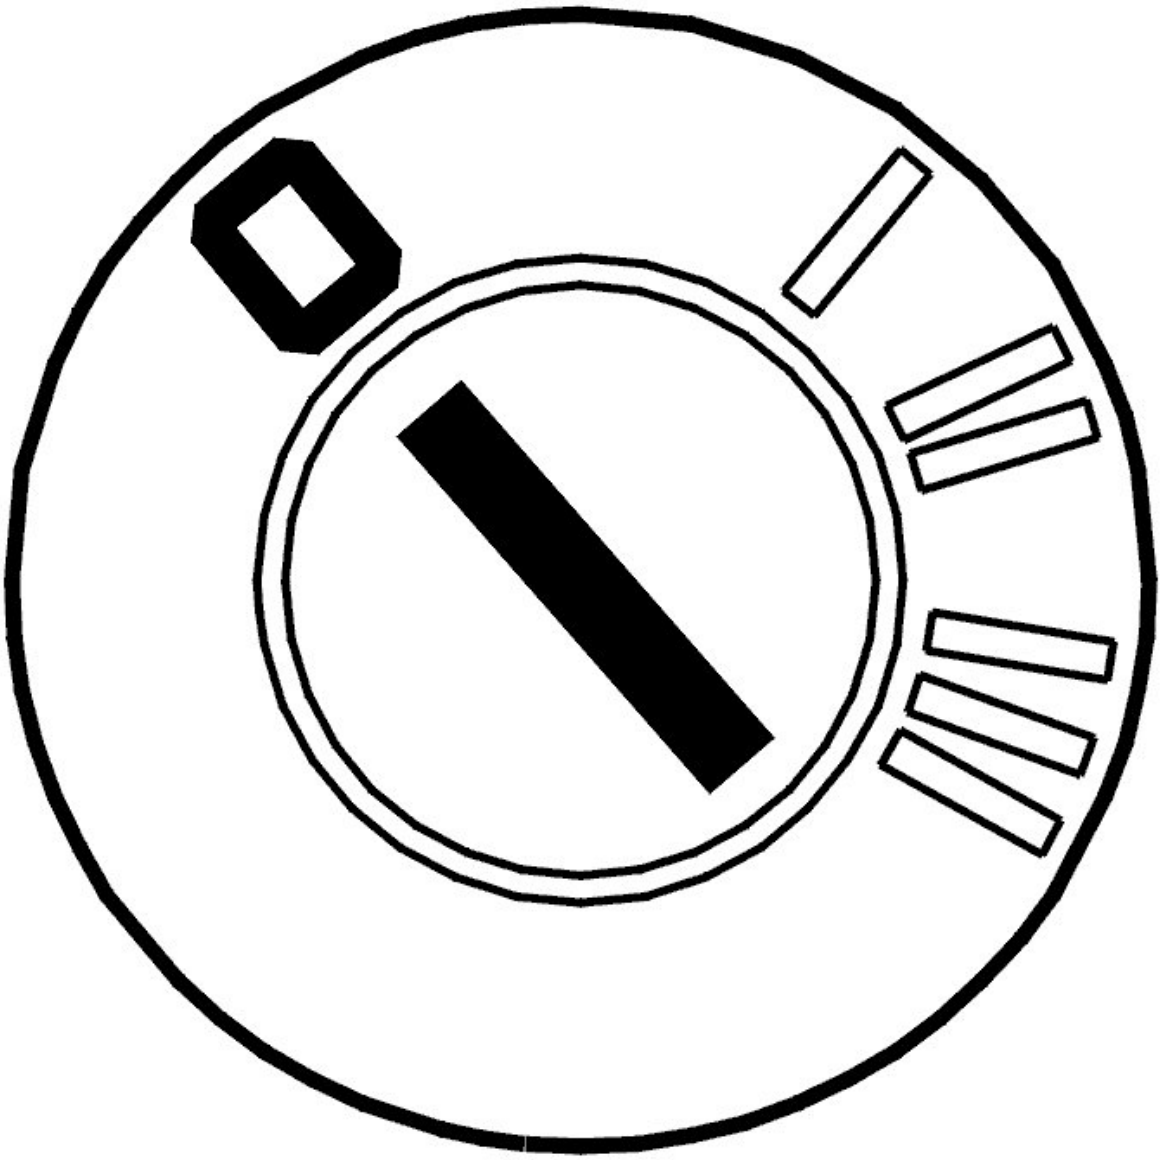
Possible source
- Short-circuit to ground in the cable to the glove compartment lighting.

Fault symptom[s]
- The glove compartment lighting is not working.

Signal Too Low

Signal too low

Checking the wiring



- Ignition off.

Check the power cable for a short-circuit to ground.
Take readings between:

- Central electronic module (CEM) #D9 and glove compartment lighting terminal #1.

Also check that the correct type of bulb is installed in the glove compartment lighting.

Checking the wiring

- Ignition off
- Disconnect central electronic module (CEM) connector D.

Check the signal cable. Check for a short-circuit to ground. Take readings between central electronic module (CEM) terminal #D29 (#29) and twilight sensor terminal #4.
For further information, see the wiring diagram.
Try a new twilight sensor if no fault was found.
Remedy as necessary.

Other information

- Connecting the breakout box See: Body and Frame/Body Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box/Connecting the Breakout Box, Central Electronic Module (CEM)
- Signal specification See: Body and Frame/Body Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters
- Location of components See: Body and Frame/Body Control Systems/Locations/Component Location, Central Electronic Module (CEM)
- Sun sensor / alarm LED, replacing See: Accessories and Optional Equipment/Antitheft and Alarm Systems/Security Lamp/Indicator/Service and Repair

- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

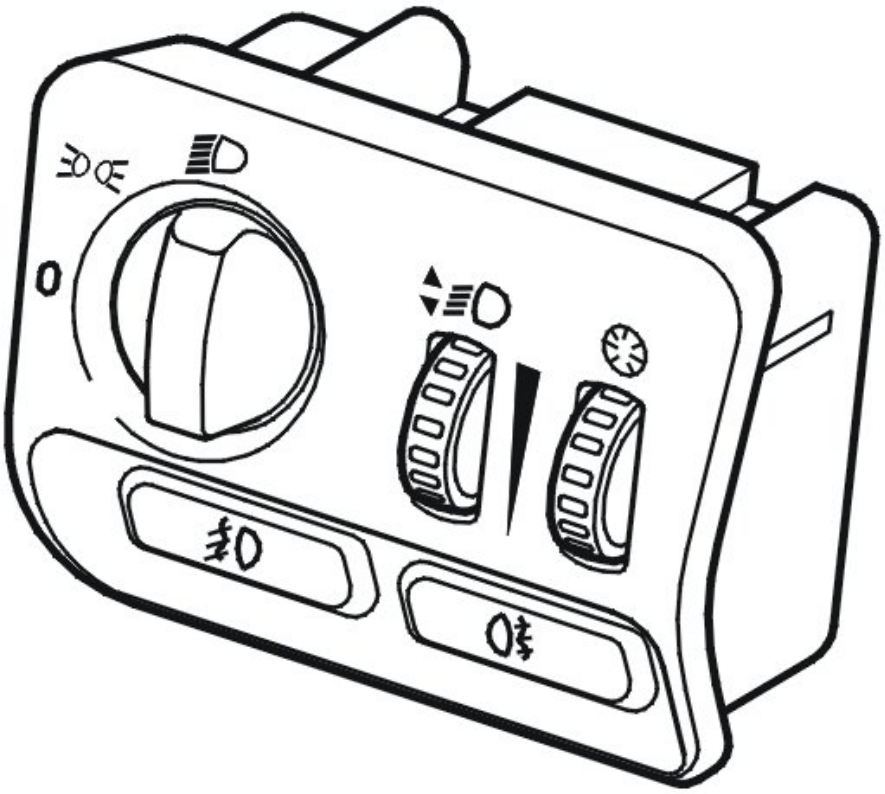
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information CEM-9F24

Condition



The central electronic module (CEM) communicates with the light switch module (LSM).
The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) receives information from the light switch module (LSM) indicating that the signal from the rheostat is too high.
The diagnostic trouble code (DTC) can be diagnosed at ignition switch position II.

Substitute value
- None.

Possible source
- Short-circuit to supply voltage in the rheostat
- Damaged light switch.

Fault symptom[s]

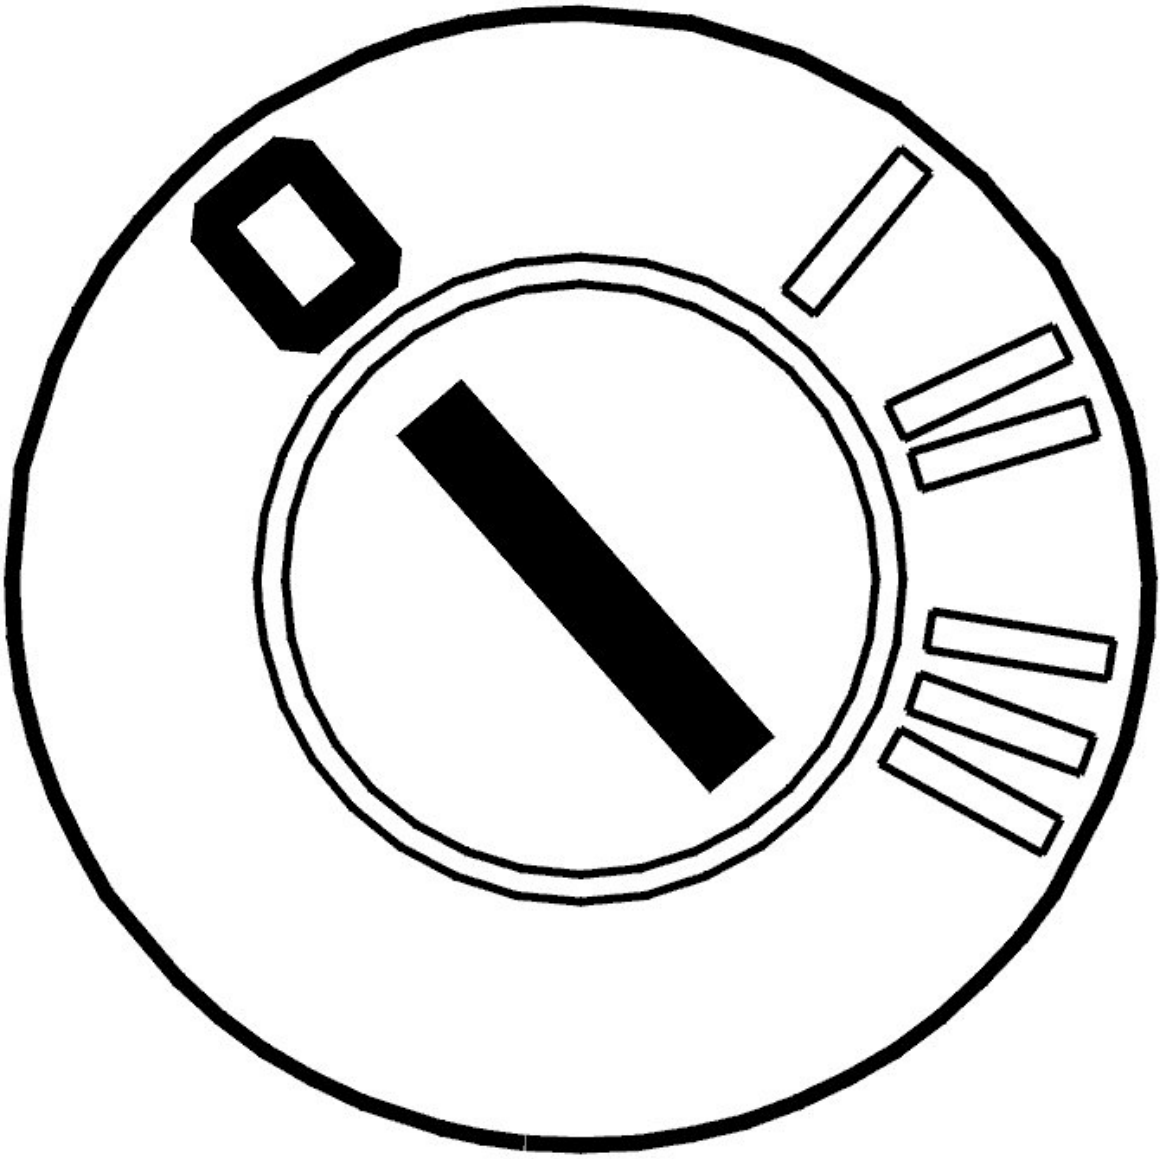
Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

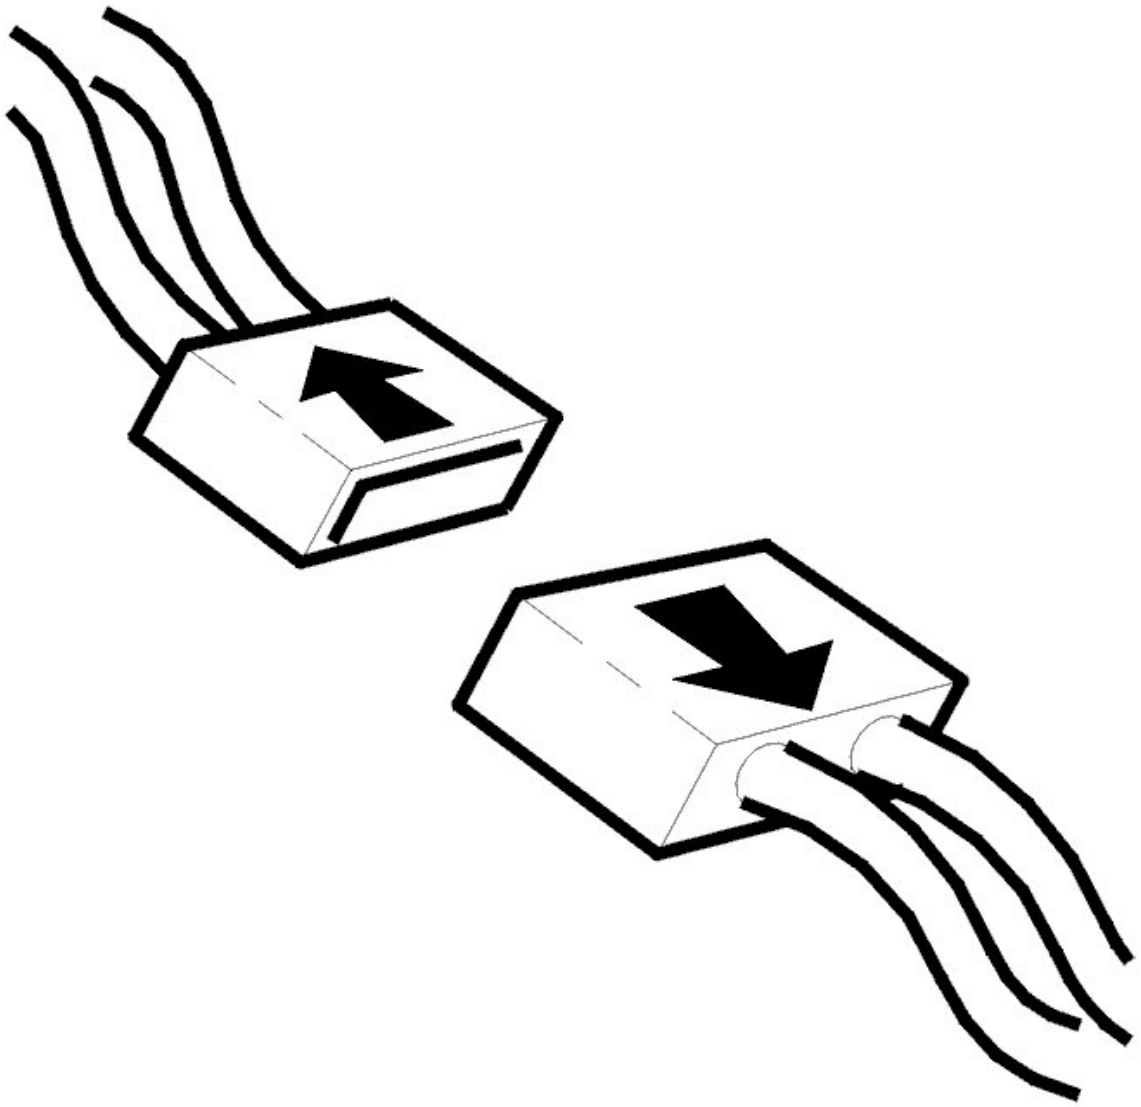
- The instrument lighting does not operate.

Signal Too High

Signal too high

Checking the wiring





- Ignition off
- Disconnect central electronic module (CEM) connector D.

Check the signal cable. Check for a short-circuit to supply voltage. Take readings between central electronic module (CEM) terminal #D41 (#D41) and light switch module (LSM) terminal #3.
Remedy as necessary.

Other information

- Connecting the breakout box See: Body and Frame/Body Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box/Connecting the Breakout Box, Central Electronic Module (CEM)
- Signal specification See: Body and Frame/Body Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters

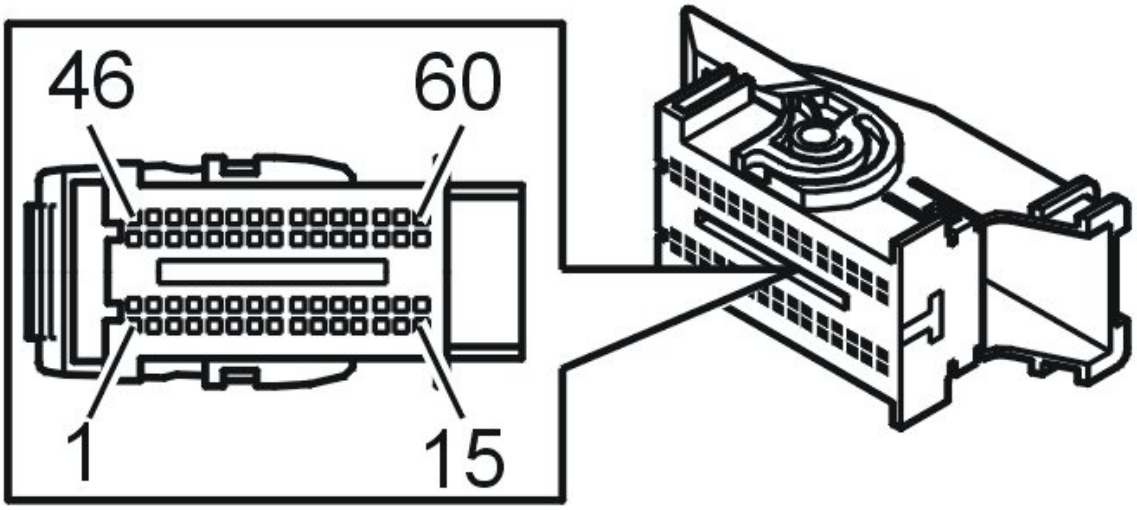
- Switches lights, replacing See: Lighting and Horns/Headlamp/Headlamp Switch/Service and Repair
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals



Was a fault detected?

Yes - Verification

No - Replacing the component

Replacing the component

The central electronic module (CEM) has registered an internal fault in the light switch module (LSM).
If the fault is intermittent, it has been registered previously but is no longer present. Intermittent faults can be caused by interference at start up of the central electronic module (CEM) or may be a different type of fault which occurs on different occasions. The fault is evaluated depending on how it occurs. If the fault recurs, replace the light switch module (LSM).
Switches lights, replacing See: Lighting and Horns/Headlamp/Headlamp Switch/Service and Repair
Remedy as necessary.

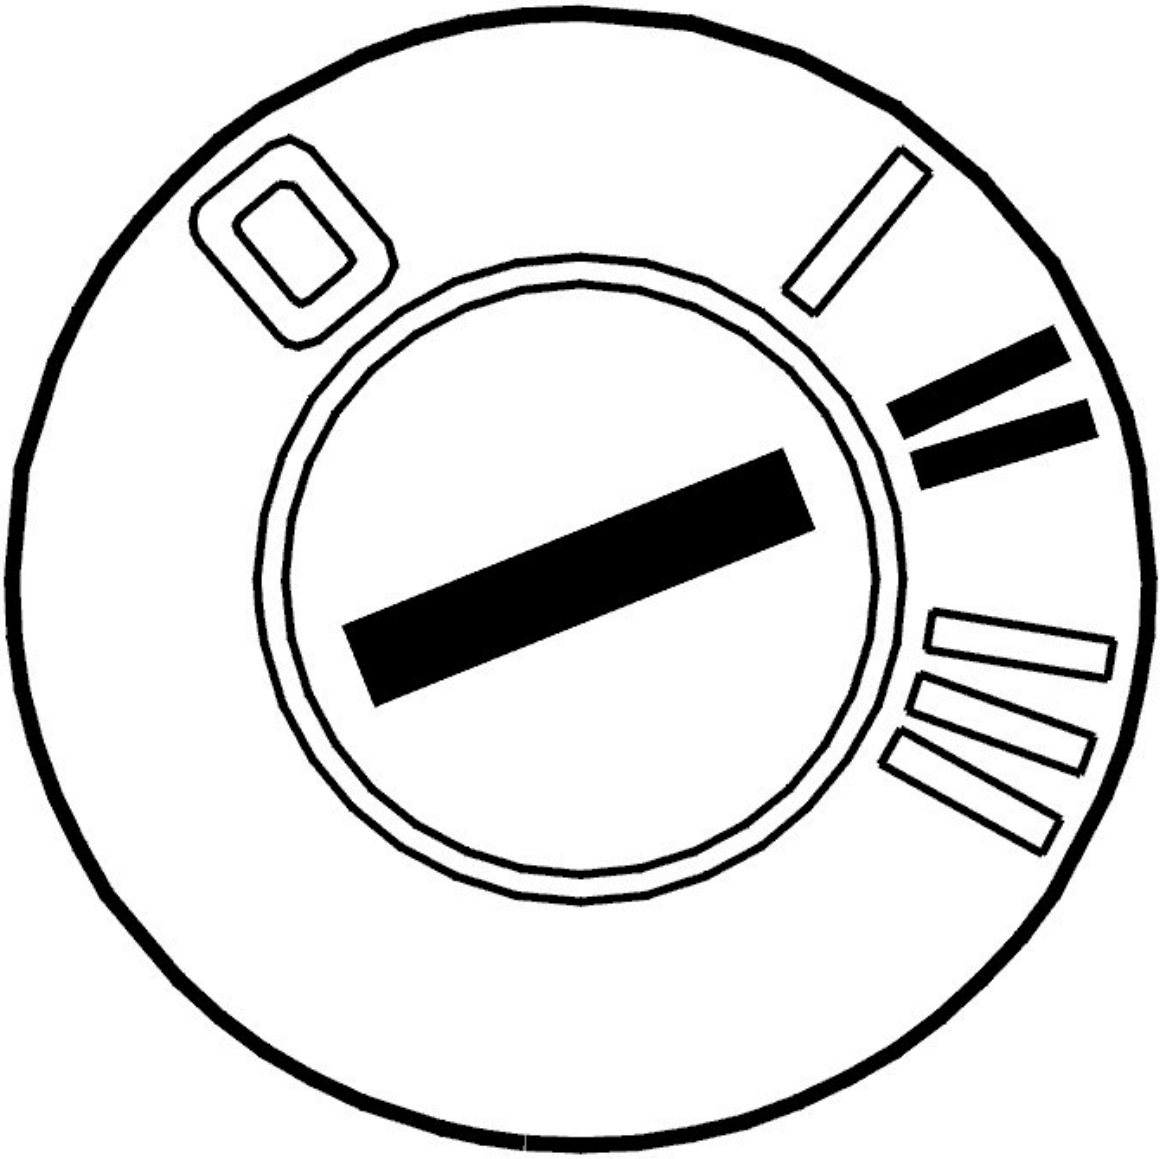
CEM-XXXX

Unknown diagnostic trouble code (DTC) for the current control module version

Reading off diagnostic trouble codes (DTCs)



- Ignition on.

Read off the diagnostic trouble code (DTC) that is stored in the car.
Make a note of the code. Report the code to VIDA customer support.

Continue - DONE

DDM-E001

Diagnostic trouble code (DTC) information DDM-E001

Condition

The control modules transmit and receive information via a standardized serial communication method - CAN (Controller Area Network). The diagnostic trouble code (DTC) is stored if the control module registers serious interference (CAN communication blocked).

Note! In the event of system communication problems, it is not possible to communicate with the control module. Therefore it will only be possible to read off the fault if it is intermittent.

Substitute value
- The control module shuts itself off ("bus-off").

  Hint: The control module will remain shut off until the power supply is broken (15, 30, X). When the power supply is connected the control module will make a new attempt to communicate.

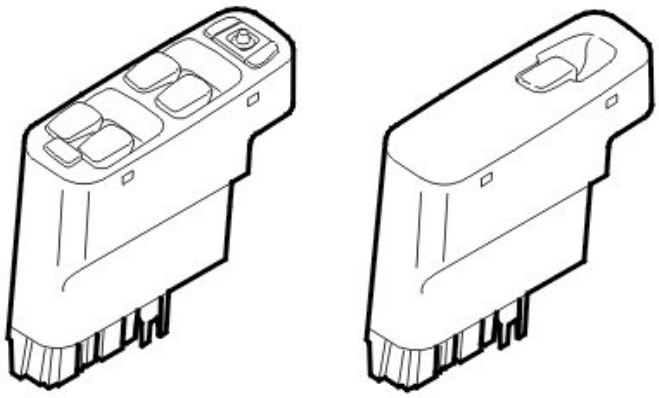
Possible source
- Short-circuit between the control area network (CAN) wiring
- Open-circuit in the control area network (CAN) wiring
- Internal fault in the control module
- Internal fault in another control module in the same part of the control area network (CAN).

Fault symptom[s]
- The switch panel for the driver's door does not work
- Automatic window closure does not function
- Cannot be controlled with the remote control.

DDM-E003

Diagnostic trouble code (DTC) information DDM-E003

Condition



The control module compares its configuration ID with the signal configuration transmitted on the control area network (CAN) by the central electronic module (CEM). If the configuration IDs do not correspond the fault code is stored. The diagnostic trouble code (DTC) is also stored if the communication between the control module and the central electronic module (CEM) is interrupted.

Note! In the event of open-circuit in both the control area network (CAN) cables, it is not possible to communicate with the control module. Therefore it will only be possible to read off the diagnostic trouble code (DTC) if this type of fault is intermittent. When the diagnostic trouble code (DTC) is stored, the control module responds to the diagnostic command, however normal control area network (CAN) communication does not work. ("Expulsion mode")

Substitute value
- None.

Possible source
- Faulty control area network (CAN) configuration ID. (The node is not intended for this car, for example a used control module with different

software/hardware.)
- Open-circuit in the control area network (CAN) wiring between the control module and the central electrical module (CEM).

Fault symptom[s]
- The switch panel for the driver's door does not work
- Automatic window closure does not function
- Cannot be controlled with the remote control.

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition

Diagnostic trouble code (DTC) DDM-001A is stored if the driver's door module registers a low signal in the lock signal cable (locking) for more than 10 seconds.

Substitute value
- None.

Possible source
- The lock has jammed in the locked position.
- Defective locking switch. (Short-circuit in the locking switch.)
- Short-circuit to ground in the lock signal cable (LK).

Fault symptom[s]
- Cannot be operated with a key from the driver's door.

Signal Too Low

Signal too low

Checking for permanent or intermittent faults

Check that the driver's door lock can be operated with the key.

Is the function OK?

Yes - Checking the cable

No - Checking the cable

Checking the cable

Check the cable between the door control module and the lock unit on the driver's door. Check for a short-circuit to ground.

DDM-0019 Central locking input (Unlocking)

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code information

Condition

If control unit registers that signal from temperature sensor is too low, diagnostic trouble code DDM-004B is displayed.

Substitute value
- Nothing.

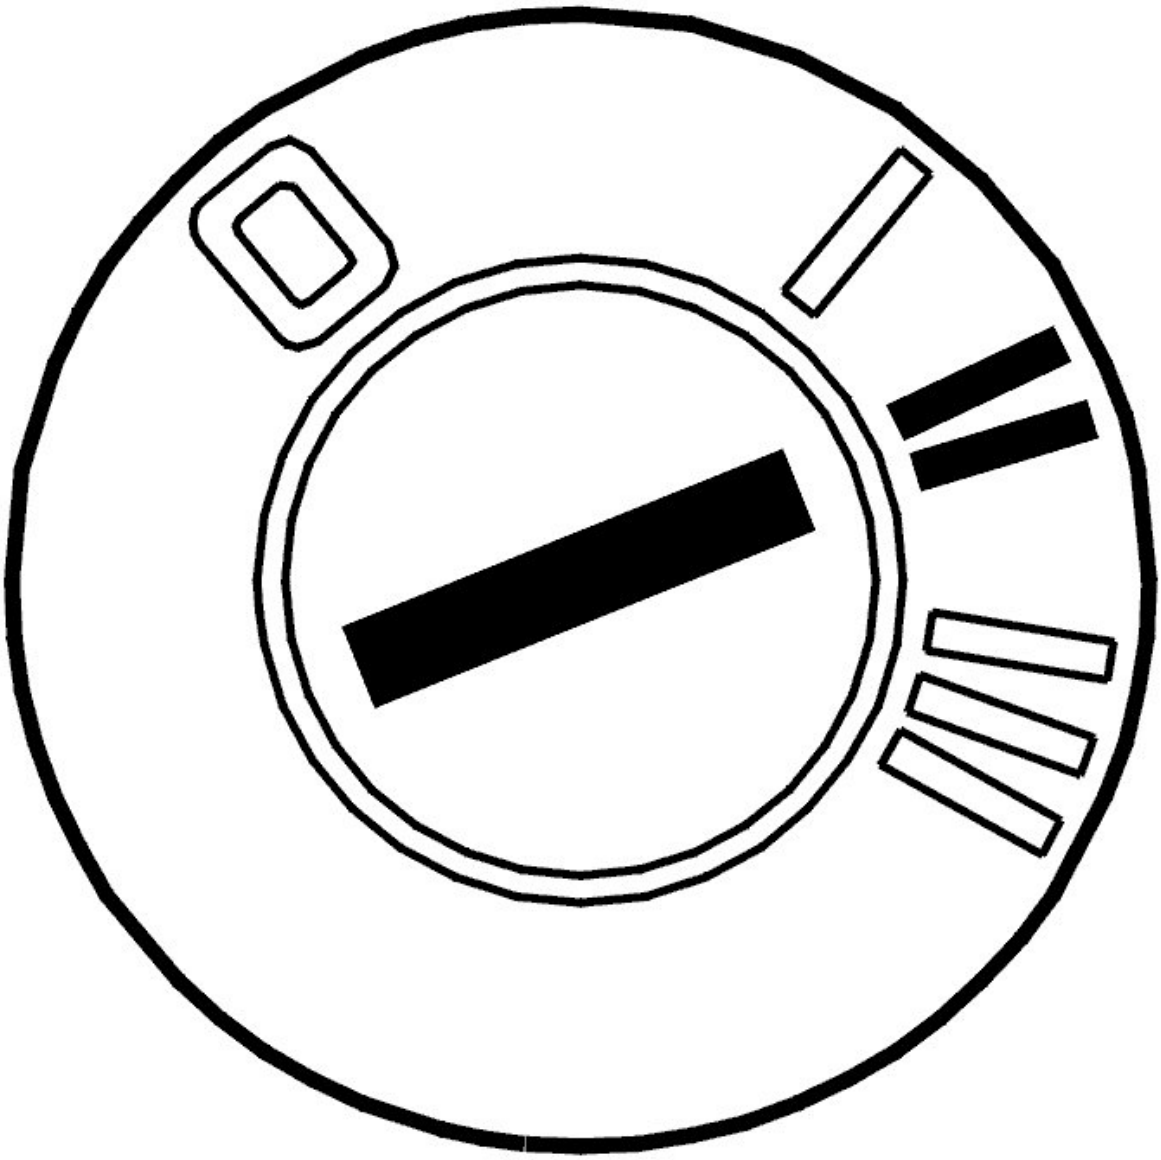
Possible source
- Signal wire short circuited to ground.

Fault symptom[s]
- Outside temperature sensor does not work.

Signal Missing

Signal missing

Checking faults



- Ignition on.

Check the outside temperature.

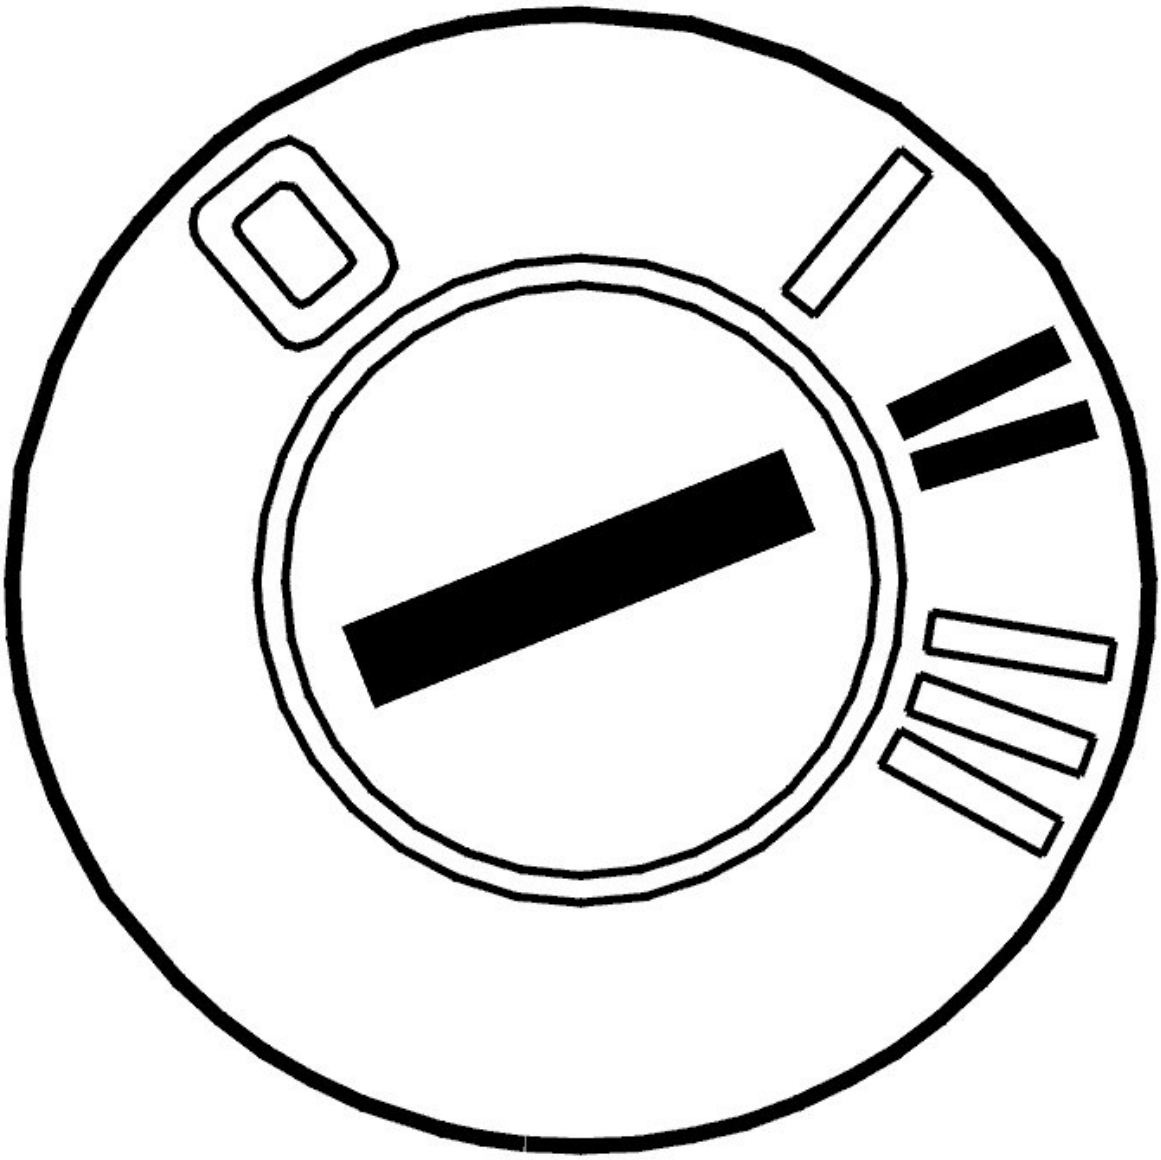
Note! The outside temperature sensor is always located in the right door mirror, irrespective of whether the car is left or right-hand drive.

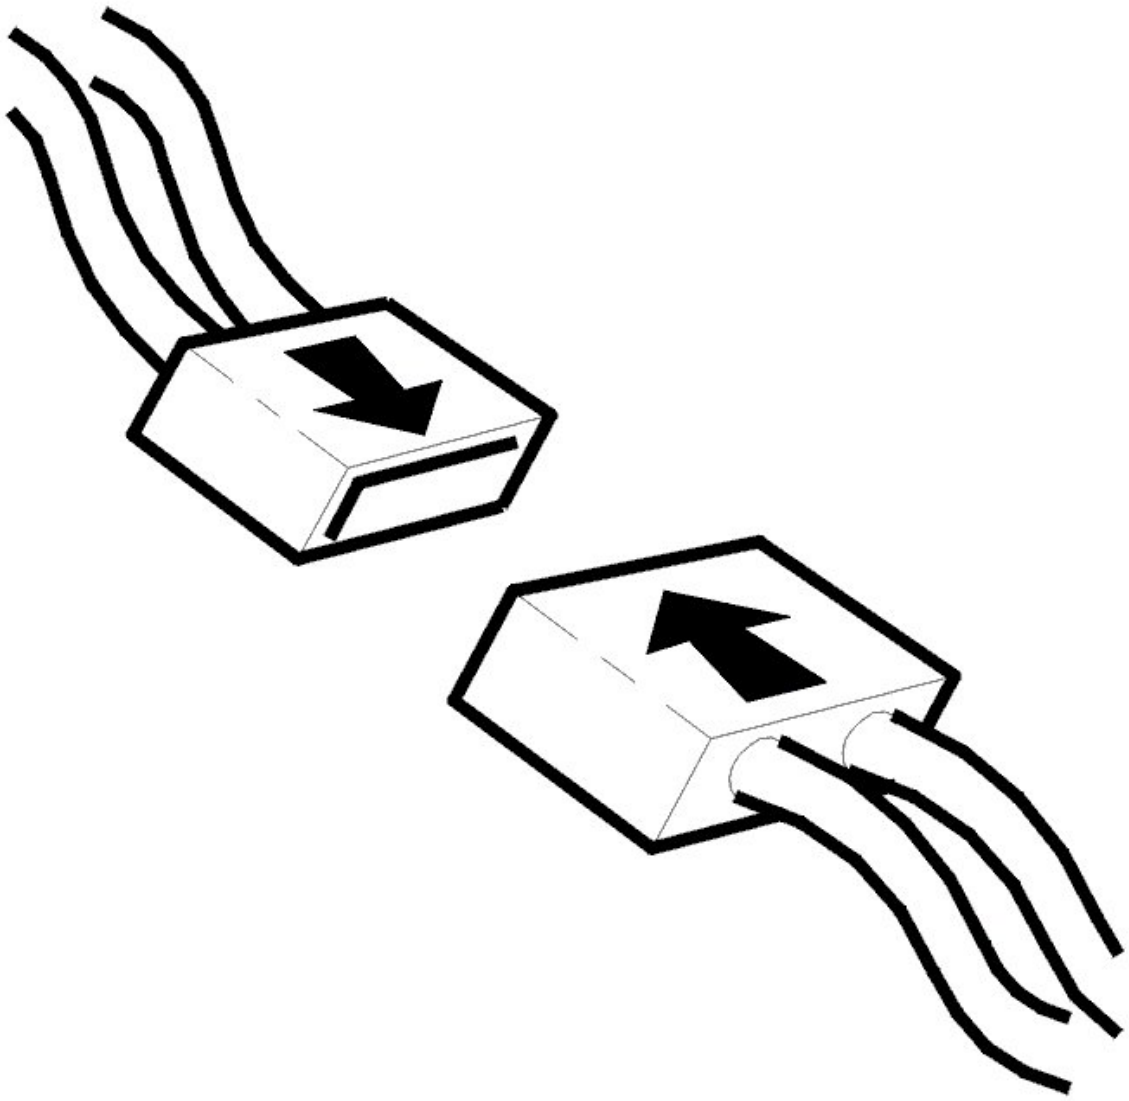
Is the temperature within its permitted range?

Yes - Intermittent fault

No - Checking the connectors

Checking the connectors





- Ignition off
- Check the power door mirror connector. Check for contact resistance and oxidation. Remedy if necessary. Check for damage carefully
- Reinstall the components, reconnect the connectors etc.
- Ignition on.

Check the outside temperature.

Note! The outside temperature sensor is always located in the right door mirror, irrespective of whether the car is left or right-hand drive.

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information DDM-0049

Condition

Diagnostic trouble code (DTC) DDM-0049 is stored if the control module registers that a signal has not been updated within the set period.

Substitute value
- The control module "Limp Home" program has been initiated.

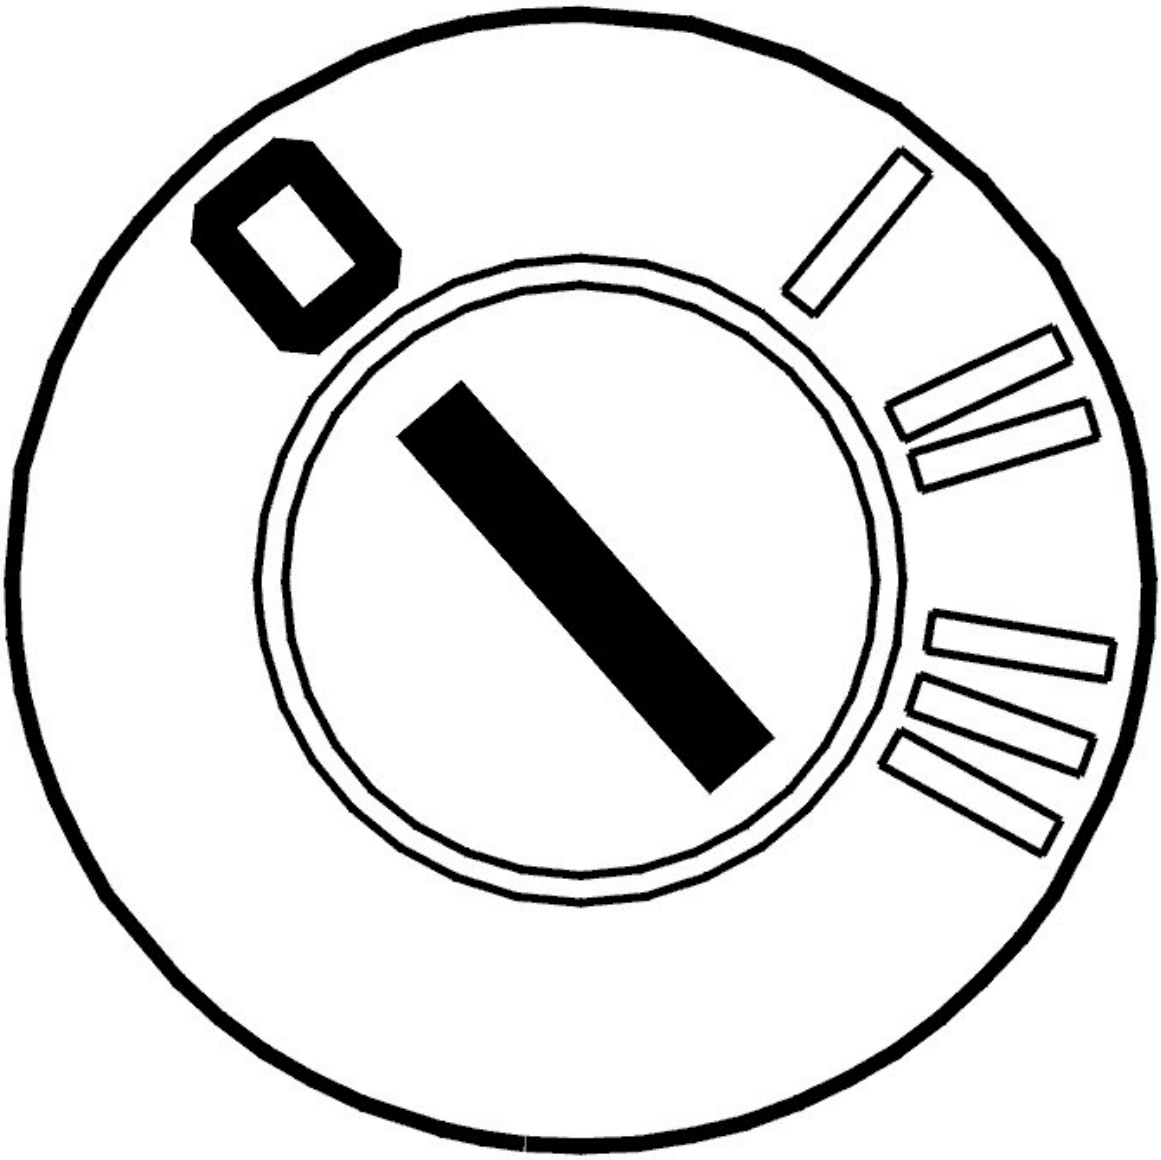
Possible source
- Internal fault.

Fault symptom[s]
- The power window mechanism does not operate
- Door mirror control does not function.

Internal Fault

Internal fault

Replacing the component



- Ignition off.

The driver door module (DDM) has registered an internal fault.

Note! A new control module is delivered without software. The control module must be programmed in order to function after replacement.

After replacing the control module the window position must be initialized.

- Ignition on.

Move the window to its upper limit position using manual control.
Initialize the window.
During initialization, the window will automatically go down to its lowest position and then go back up again.

Other information:

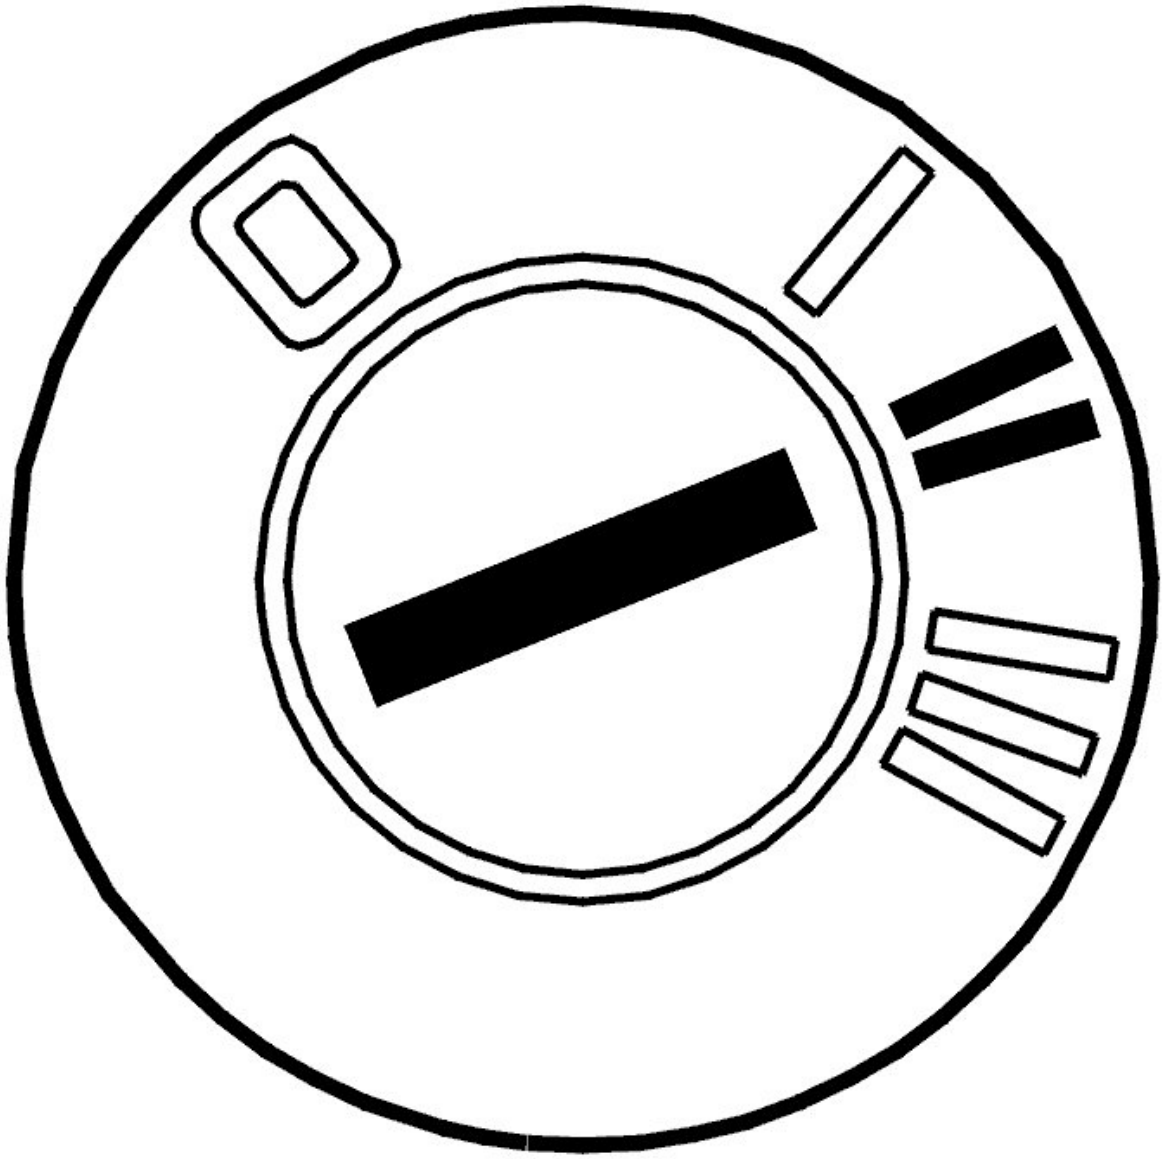
- For further information about programming and replacing the control module, see Driver's door module / passenger door module (DDM/PDM), replacing See: Body Control Module/Service and Repair/Driver's Door Module / Passenger Door Module (DDM/PDM), Replacing.

Continue - Fault Found

DDM-XXXX

Unknown diagnostic trouble code (DTC) for the current control module version

Reading off diagnostic trouble codes (DTCs)



- Ignition on.

Read off the diagnostic trouble code (DTC) that is stored in the car.
Make a note of the code. Report the code to VIDA customer support.

Continue - DONE

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information DDM/PDM-E010

Condition

The diagnostic trouble code (DTC) is generated if the voltage to the driver door/passenger door module (DDM/PDM) differs from the voltage to the central electronic module (CEM) by more than 2 V.
The driver door/passenger door module (DDM/PDM) receives information on voltage to the central electronic module (CEM) via the CAN network.

The diagnostic trouble code (DTC) can be diagnosed when the ignition is on.

Substitute value
- None.

Possible source
- Cable short-circuited to ground.
- Open-circuit on cable.
- Contact resistance.
- Half-blown fuse to driver door/passenger door module (DDM/PDM).

Fault symptom[s]
- Driver door/passenger door switch panel not working.

Internal Fault

Internal fault

Checking the power supply
- Ignition off
- Unplug connector B to the driver door/passenger door module (DDM/PDM).
- Ignition on.

Check the power supply to the driver door/passenger door module (DDM/PDM) by:
- Measuring the voltage between #B12 (#26) and #B5 (#19) on control module connector B.
- Measuring battery voltage.

If the difference between the control module supply voltage and battery voltage is greater than 2 V, the fault is in the supply cable or is due to contact resistance.
Also check the fuse of the driver door/passenger door module (DDM/PDM). A half-blown fuse can cause intermittent faults.
If the difference is less than 2 V, there could be an internal fault in the door control module.
Remedy as necessary.

Other information:
- Connecting the breakout box See: Body and Frame/Body Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box/Connecting the Breakout Box, Driver Door Module (DDM) / Passenger Door Module (PDM)
- Signal specification See: Body and Frame/Body Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition

Diagnostic trouble code (DTC) DDM/PDM-0001 is stored if the transmission control module (TCM) registers that the signal cable M+ or signal cable M- is too high.
Diagnostic Trouble Code (DTC) DDM/PDM-0001 can be diagnosed at terminal 15.

Substitute value
- None.

Possible source
- Short-circuit to supply voltage in the M+ or M- signal cables.

Fault symptom[s]
- The power window mechanism does not operate.

Signal Too High

Signal too high

Checking components and wiring

Check signal cable M+ between door control module connector terminal #B4 and central locking motor connector terminal #3. Check for a short-circuit to supply voltage.
Check signal cable M- between door control module connector terminal #B3 and central locking motor connector terminal #6. Check for a short-circuit to supply voltage.
Remedy as necessary.

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition

Diagnostic trouble code DDM/PDM-0005 is stored if the control module registers a low signal or open-circuit in the M+ signal cable or M- signal cable (the power supply wiring to the power window motor) when the window is operated upwards or downwards.
Diagnostic Trouble Code (DTC) DDM/PDM-0005 can be diagnosed when the power window motor is activated.

Substitute value
- None.

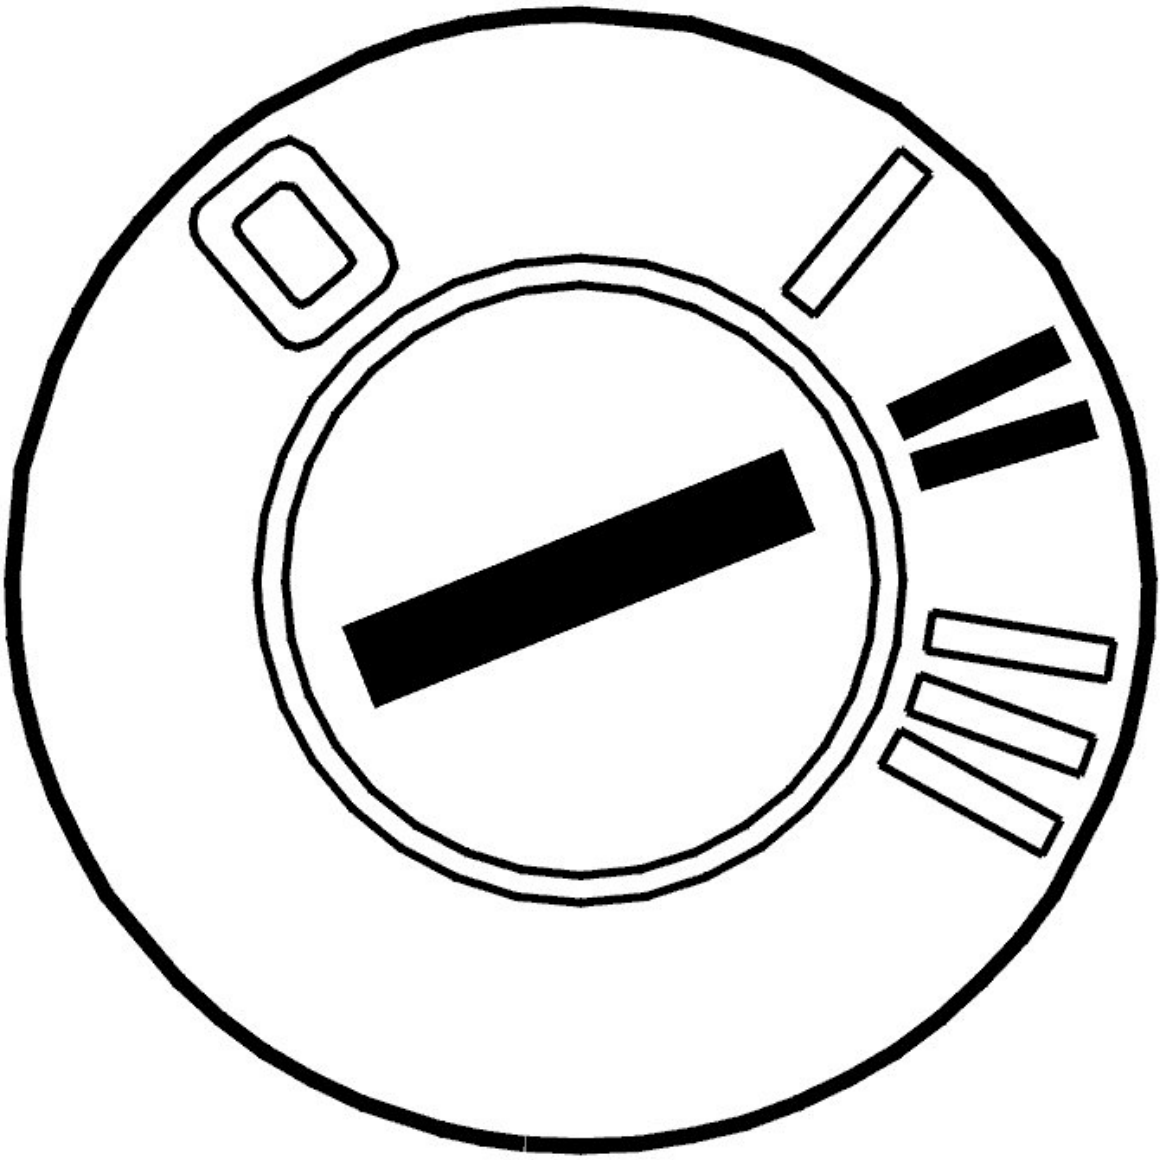
Possible source
- Short-circuit to ground in the M+ or M- signal cables
- Open-circuit in the M+ signal cable or M- signal cable
- Blown fuse.

Fault symptom[s]
- The power window mechanism does not operate.

Signal Too Low or Signal Missing

Signal too low or signal missing

Checking for permanent or intermittent faults



- Ignition on.

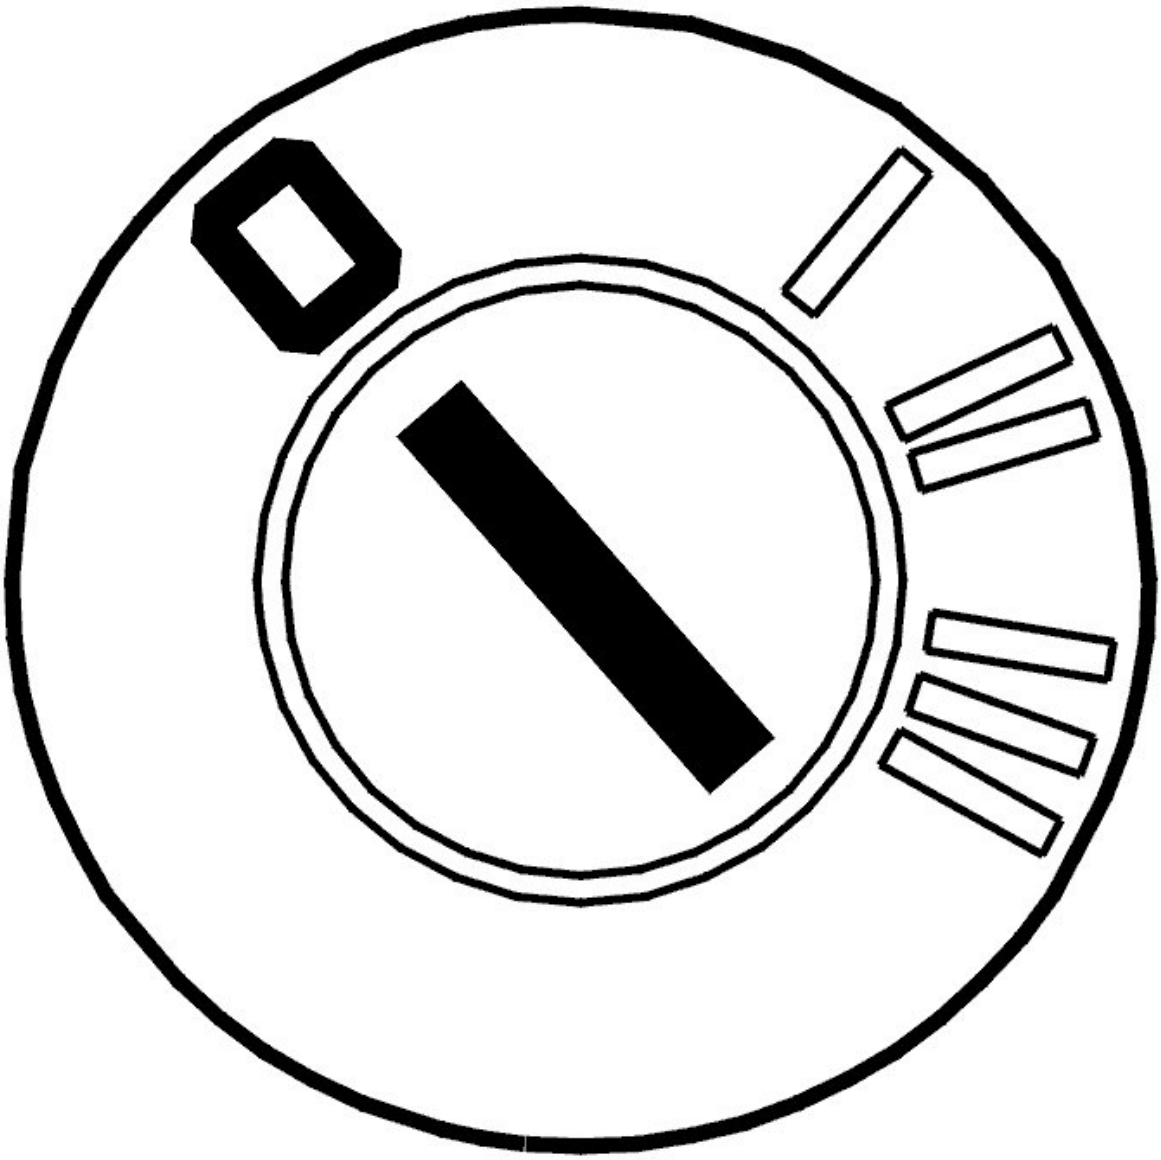
Press the switch for the power window to check the function of the power window mechanism.

Is the power window control operating correctly?

Yes - Intermittent fault

No - Checking the connectors

Checking the connectors



- Ignition off.

Check that the fuses are intact.
Check the control module and power window lift motor connectors. Check for contact resistance and oxidation.

Other information:

- For further information about the fuses and relays, see the Wiring Diagram
- Driver's door module / passenger door module (DDM/PDM), replacing See: Body Control Module/Service and Repair/Driver's Door Module / Passenger Door Module (DDM/PDM), Replacing
- Window lift mechanism front side door, replacing See: Body and Frame/Doors, Hood and Trunk/Doors/Front Door/Front Door Window Regulator/Service and Repair/Window Lift Mechanism Front Side Door, Replacing
- Checking the power supply and ground terminals See: Body and Frame/Body Control Systems/Testing and Inspection/Component Tests and General Diagnostics/Checking the Voltage/Ground Terminal, Driver Door Module (DDM)/ Passenger Door Module (PDM)
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

Continue - Checking the cable

Checking the cable

Check the cable between control module connector terminal #B4 and power window lift motor connector terminal #3. Check for an open-circuit. Check for a short-circuit to ground.
Check the cable between control module connector terminal #B3 and power window lift motor connector terminal #6. Check for an open-circuit. Check for a short-circuit to ground.
Remedy as necessary.

Other information:

- Connecting the breakout box See: Body and Frame/Body Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box

- Signal specification See: Body and Frame/Body Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters

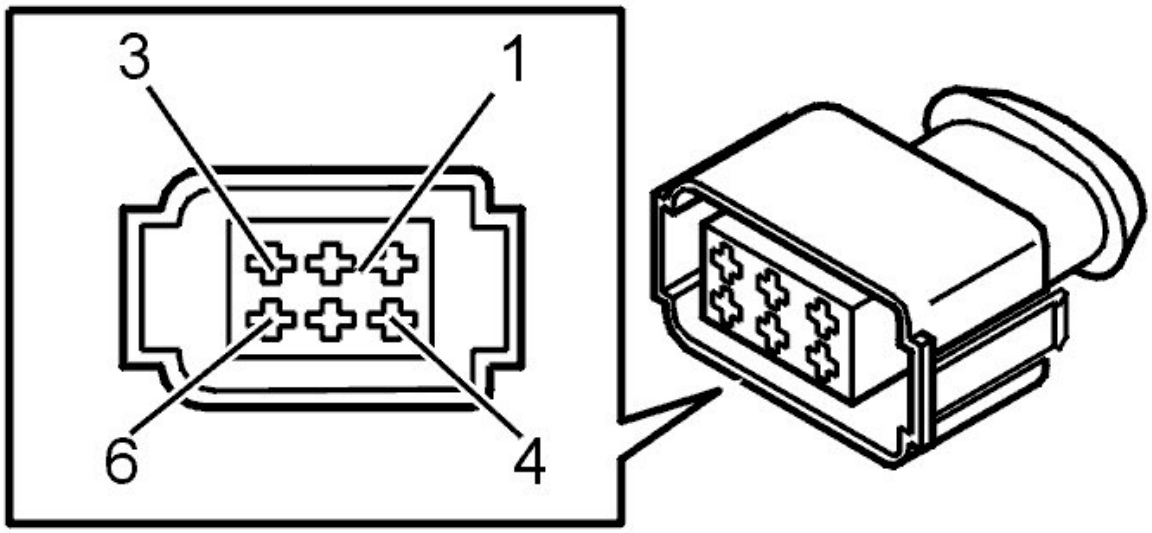
- Checking the power supply and ground terminals See: Body and Frame/Body Control Systems/Testing and Inspection/Component Tests and General Diagnostics/Checking the Voltage/Ground Terminal, Driver Door Module (DDM)/ Passenger Door Module (PDM)
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

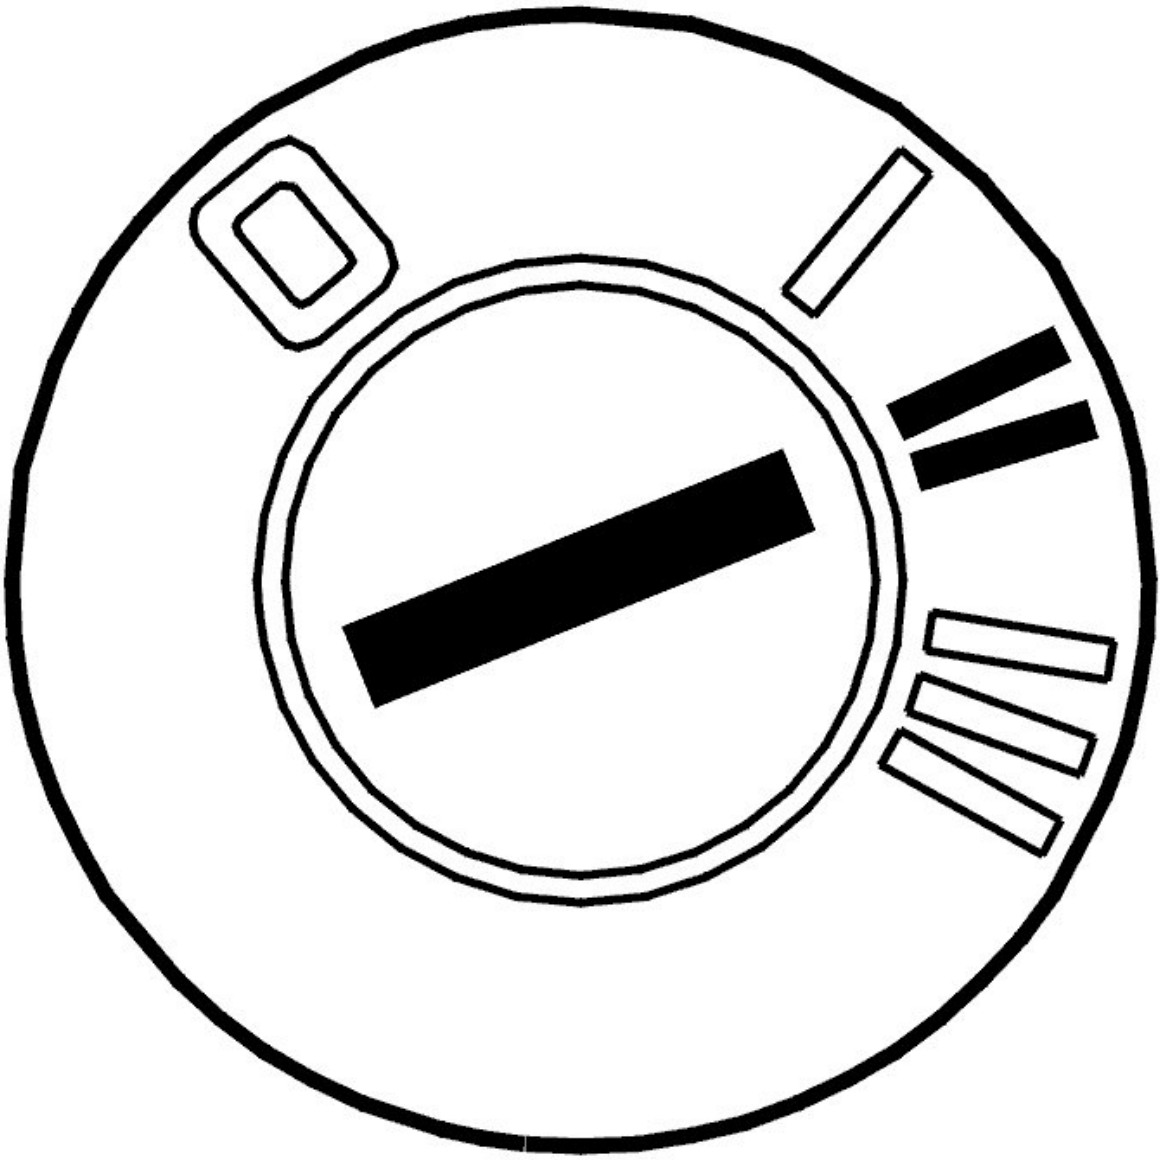


Was the cable OK?

Yes - Replacing the component

No - Verification

Replacing the component



Replace the window lift mechanism.

- Ignition on.

Move the window to its upper limit position using manual control.
Initialize the window.
During initialization, the window will automatically go down to its lowest position and then go back up again.

Other information

- Window lift mechanism front side door, replacing See: Body and Frame/Doors, Hood and Trunk/Doors/Front Door/Front Door Window Regulator/Service and Repair/Window Lift Mechanism Front Side Door, Replacing

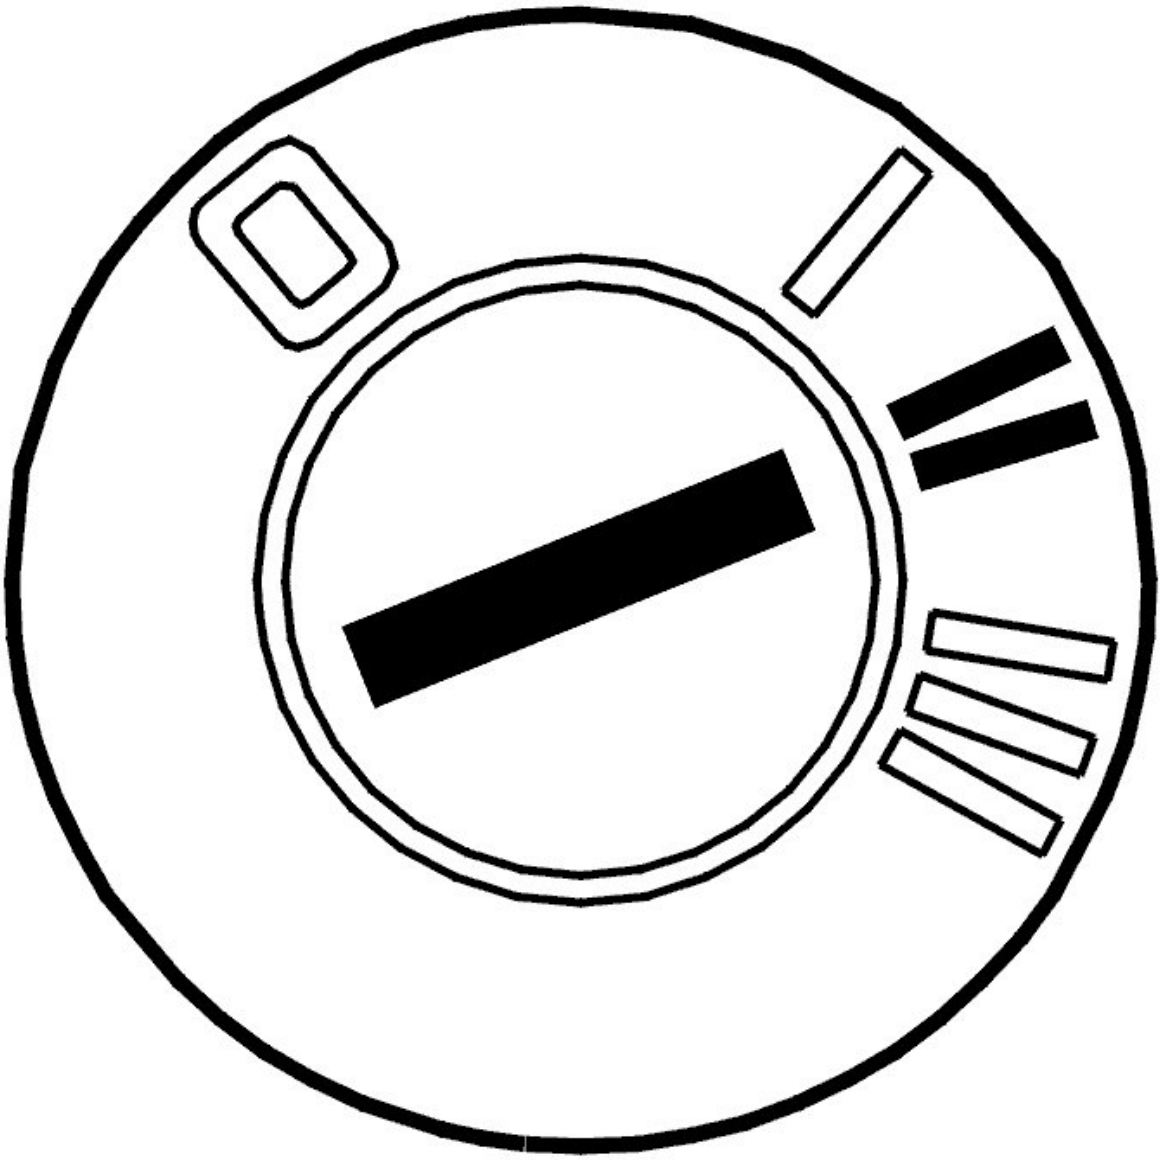
Continue - Verification

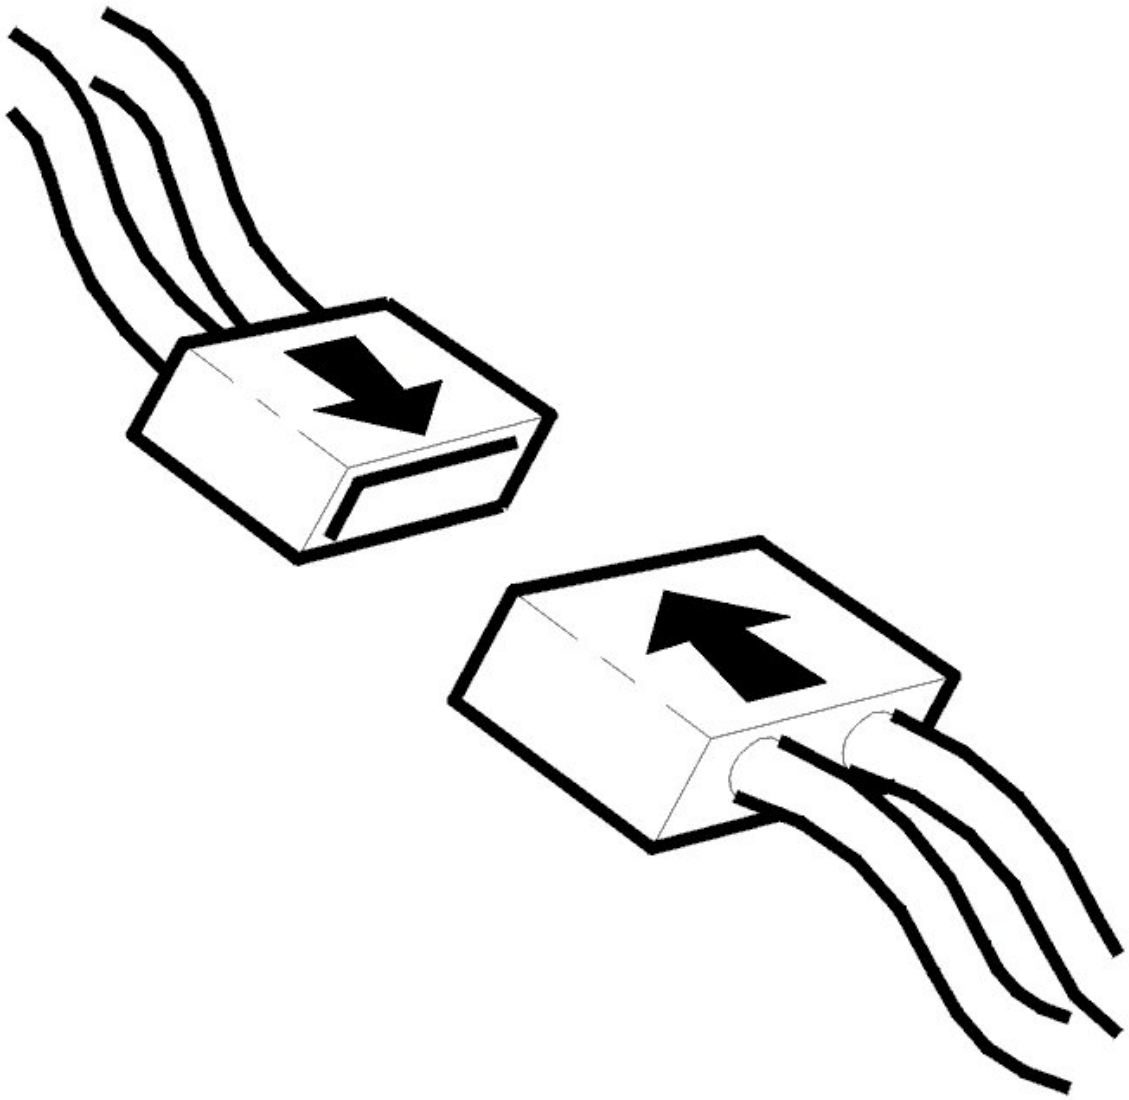
Verification

Verification

Verification

Hint: After the repair it is necessary to check that the fault has been rectified.





- Ignition off.
- Connect the connectors, install the components, etc.
- Ignition on.

Check that window operates by raising/lowering window to its end stops.

Does window operate?

Yes - VERIFIED

No - VERIFICATION FAILED

VERIFIED - Fault Found

VERIFICATION FAILED - Fault-tracing information

Intermittent fault

Check the connectors for the control module and power window lift motor. Check for contact resistance and oxidation. Check for loose connections.
Check the cable between control module connector terminal #B4 and power window lift motor connector terminal #3. Check for an intermittent open-circuit.
Check the cable between the control module connector terminal #3B and the power window lift motor connector terminal #6. Check for an intermittent open-circuit.

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition

Diagnostic trouble code (DTC) DDM/PDM-0010 is stored if the control module registers a short-circuit to ground in signal cable M1.
Diagnostic trouble code (DTC) DDM/PDM-0010 can be diagnosed when the central locking locks or unlocks.

Substitute value
- None.

Possible source
- Signal cable M1 is short-circuited to ground.

Fault symptom[s]
- The central locking system does not function at all.

Signal Too Low

Signal too low

Checking components and wiring

Check signal cable M1 between door control module connector terminal #B2 and central locking motor connector terminal #8. Check for a short-circuit to ground.
Remedy as necessary.

Other information:
- To connect the breakout box, see Connecting the breakout box See: Body and Frame/Body Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box
- To access and replace the door control module, see Driver's door module / passenger door module (DDM/PDM), replacing See: Body Control Module/Service and Repair/Driver's Door Module / Passenger Door Module (DDM/PDM), Replacing

Diagnostic trouble code (DTC) information

Condition

Diagnostic trouble code (DTC) DDM/PDM-0023 is stored if door mirror down is activated at the same time as the control module registers that there is voltage in the cable.

Substitute value
- None.

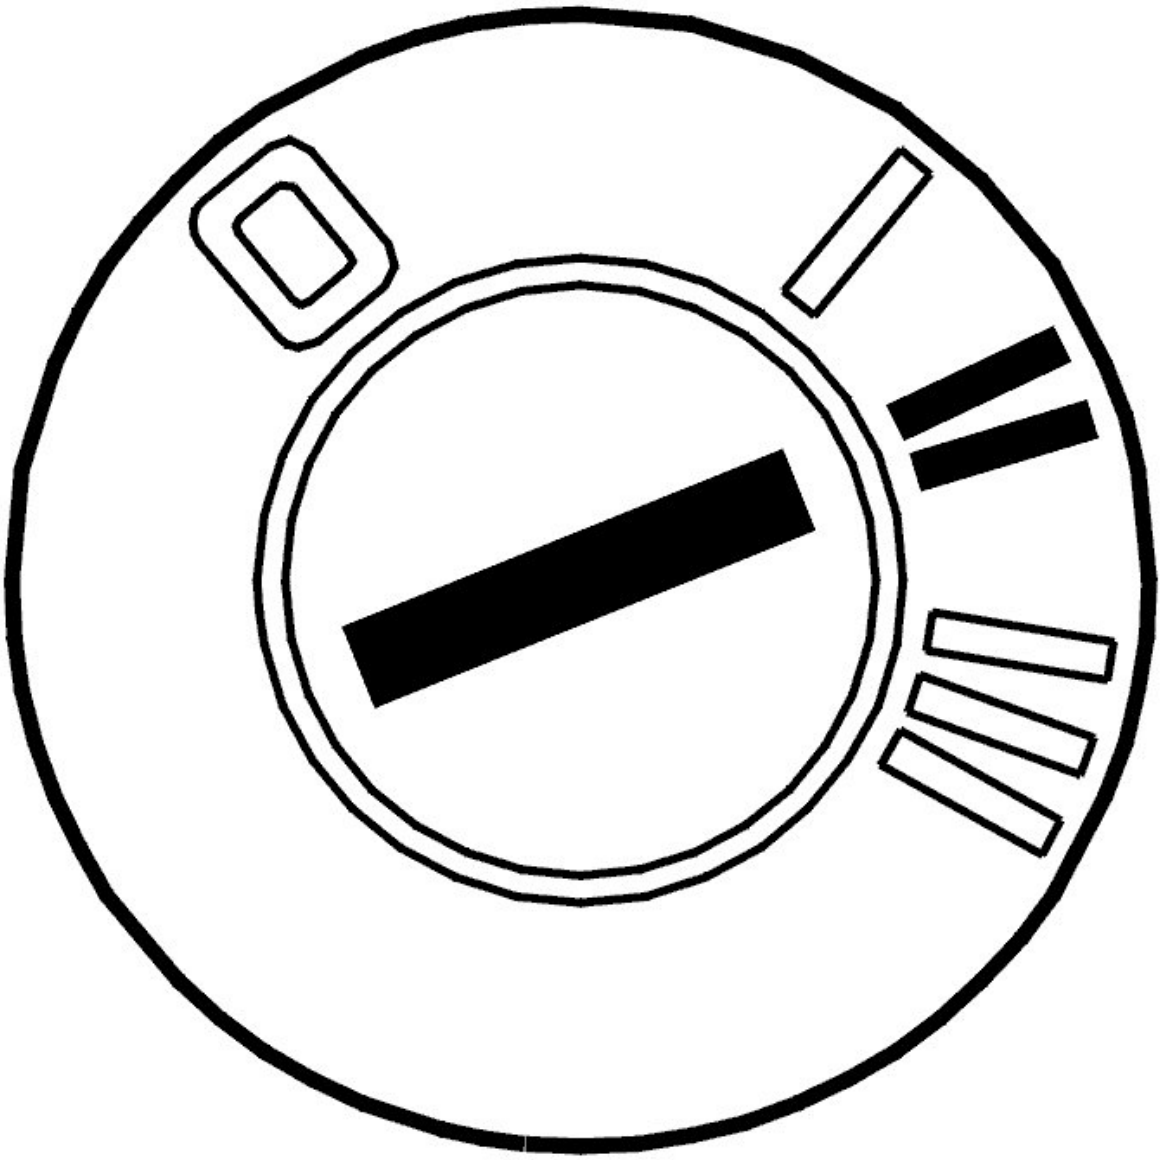
Possible source
- Short-circuit to supply voltage in signal cable MX+.

Fault symptom[s]
- Power door mirror control does not function.

Signal Too High

Signal too high

Checking for permanent or intermittent faults



- Ignition on.

Press the switch for the power door mirrors to check the function of the power door mirrors.

Can the power door mirrors be maneuvered?

Yes - Intermittent fault

No - Checking for a short-circuit

Checking for a short-circuit

Check the cable between the driver/passenger door control module (DDM/PDM) and the power door mirror (as follows). Check for a short-circuit to supply voltage.
Remedy as necessary.
Try a new power door mirror if the cable is OK.

If the car is equipped with a 10-pin connector

DDM-0023 Door mirror motor MX+

Control module terminal #26A and power door mirror terminal #9.

DDM-0026 Door mirror motor MY+

Control module terminal #28A and power door mirror terminal #10.

DDM-0028 Door mirror motor MF+

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

Control module terminal #29A and power door mirror terminal #8.

If the car is equipped with a 16-pin connector

DDM-0023 Door mirror motor MX+

Control module terminal #26A and power door mirror terminal #15.

DDM-0026 Door mirror motor MY+

Control module terminal #28A and power door mirror terminal #16.

DDM-0028 Door mirror motor MF+

Control module terminal #29A and power door mirror terminal #14.

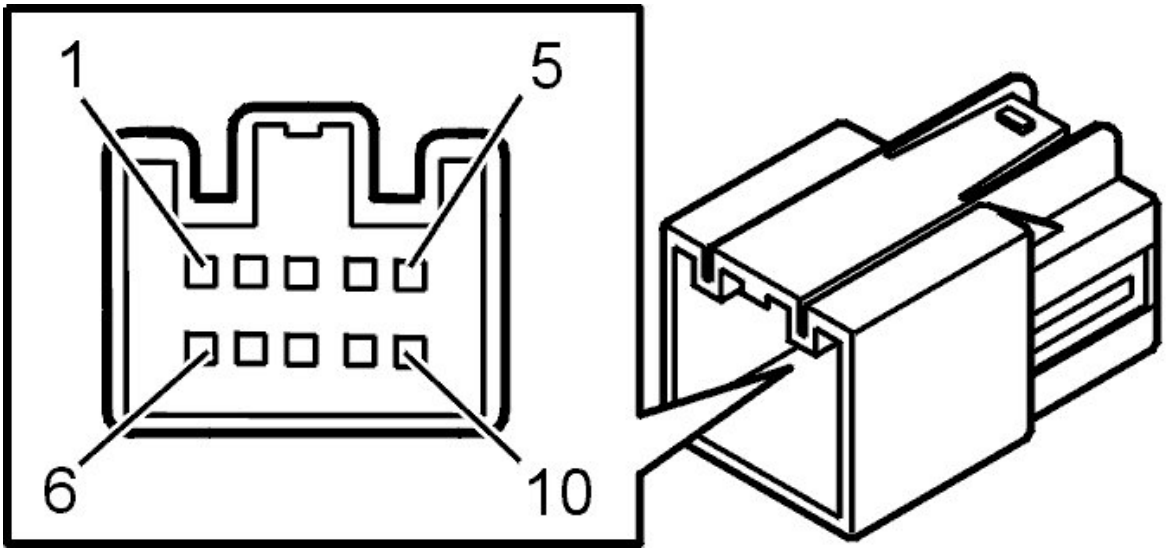
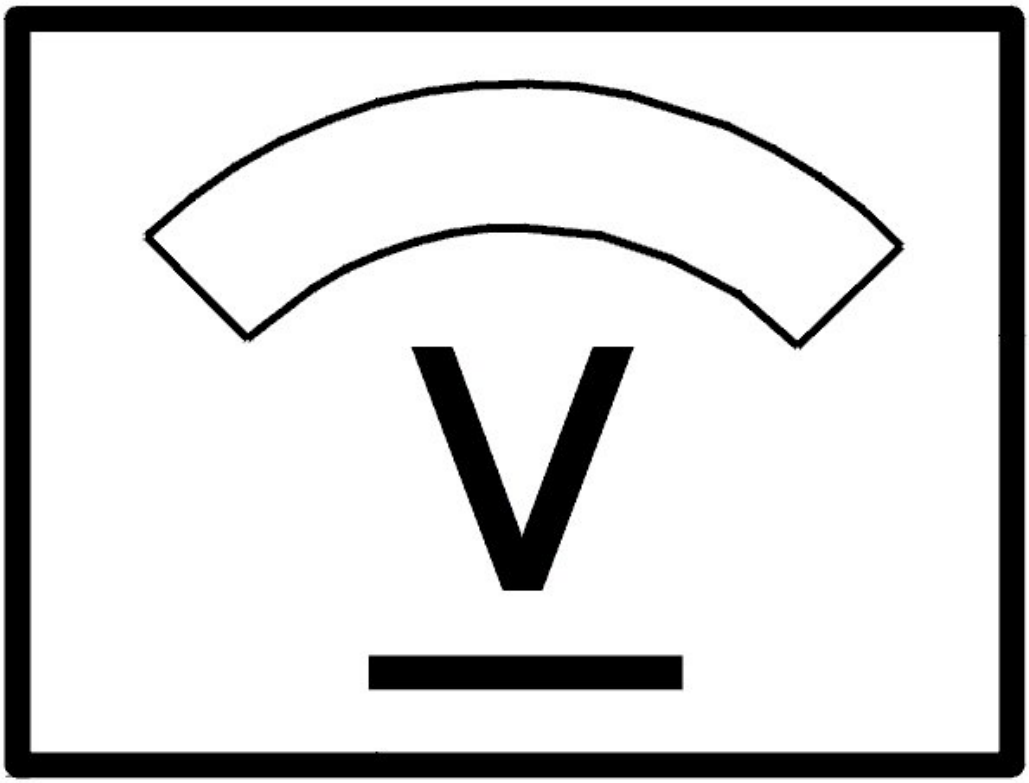
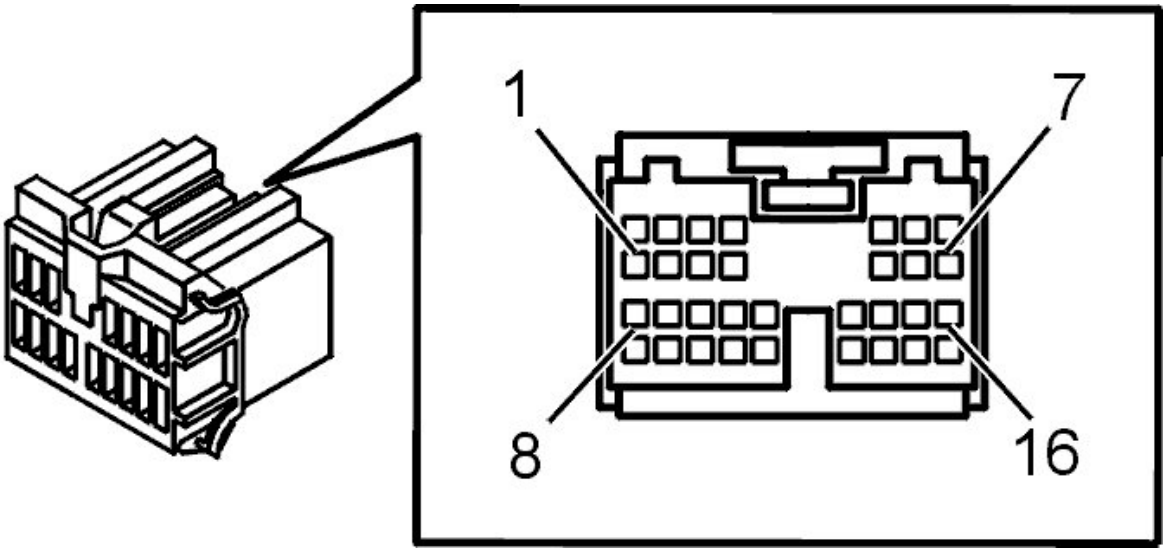
- For further information about signals and other values, see Signal specification See: Body and Frame/Body Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters
- To access the driver/passenger door module (DDM/PDM), see Driver's door module / passenger door module (DDM/PDM), replacing See: Body Control Module/Service and Repair/Driver's Door Module / Passenger Door Module (DDM/PDM), Replacing
- To access the power door mirror, see Door mirror, replacing See: Body and Frame/Mirrors/Service and Repair
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals.







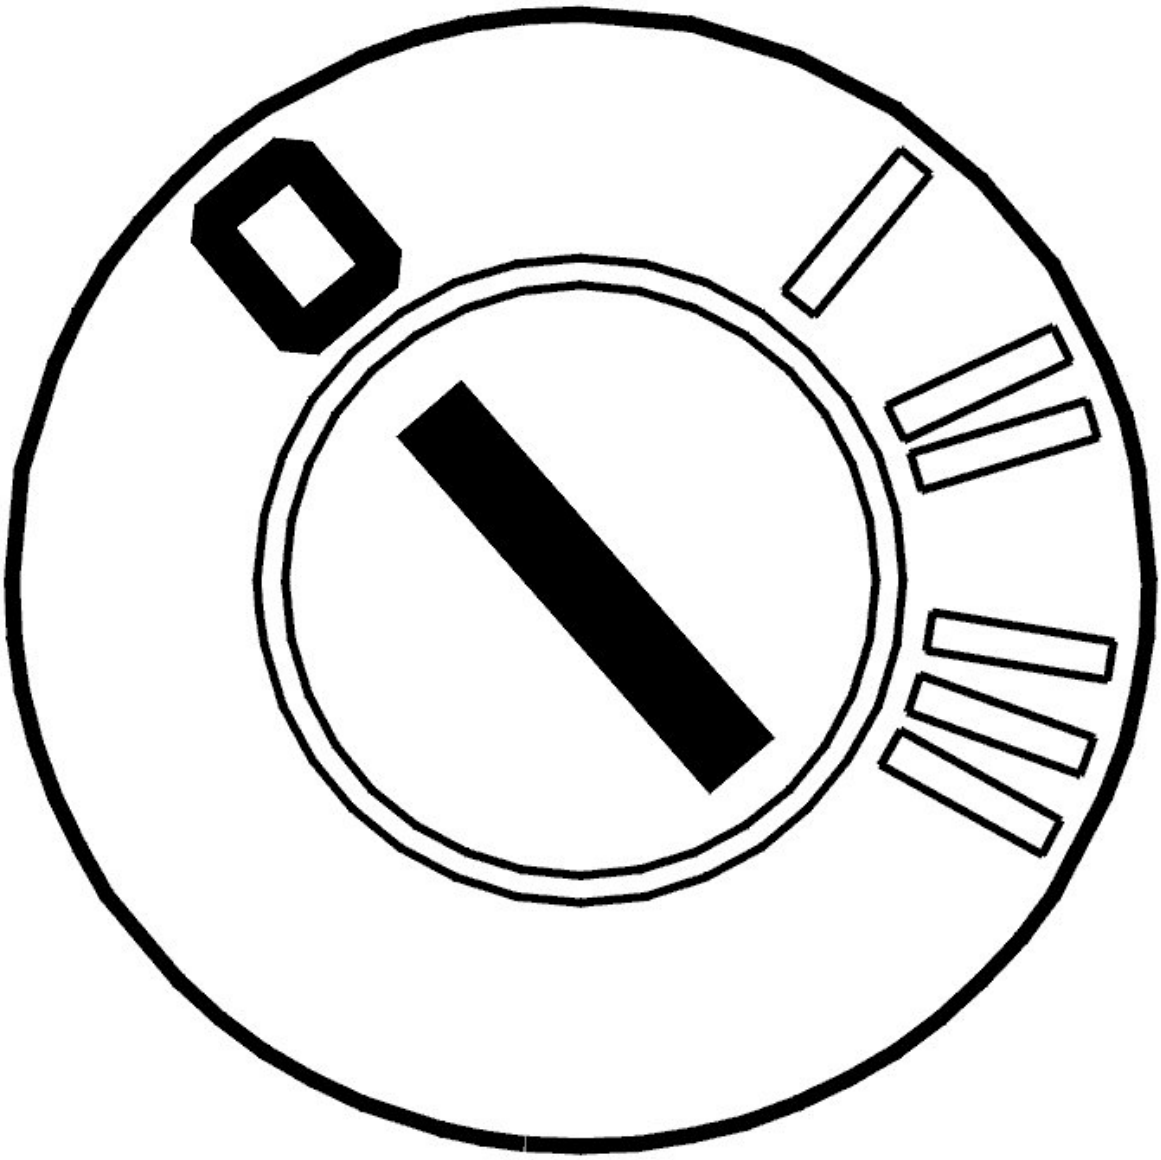
Continue - Verification

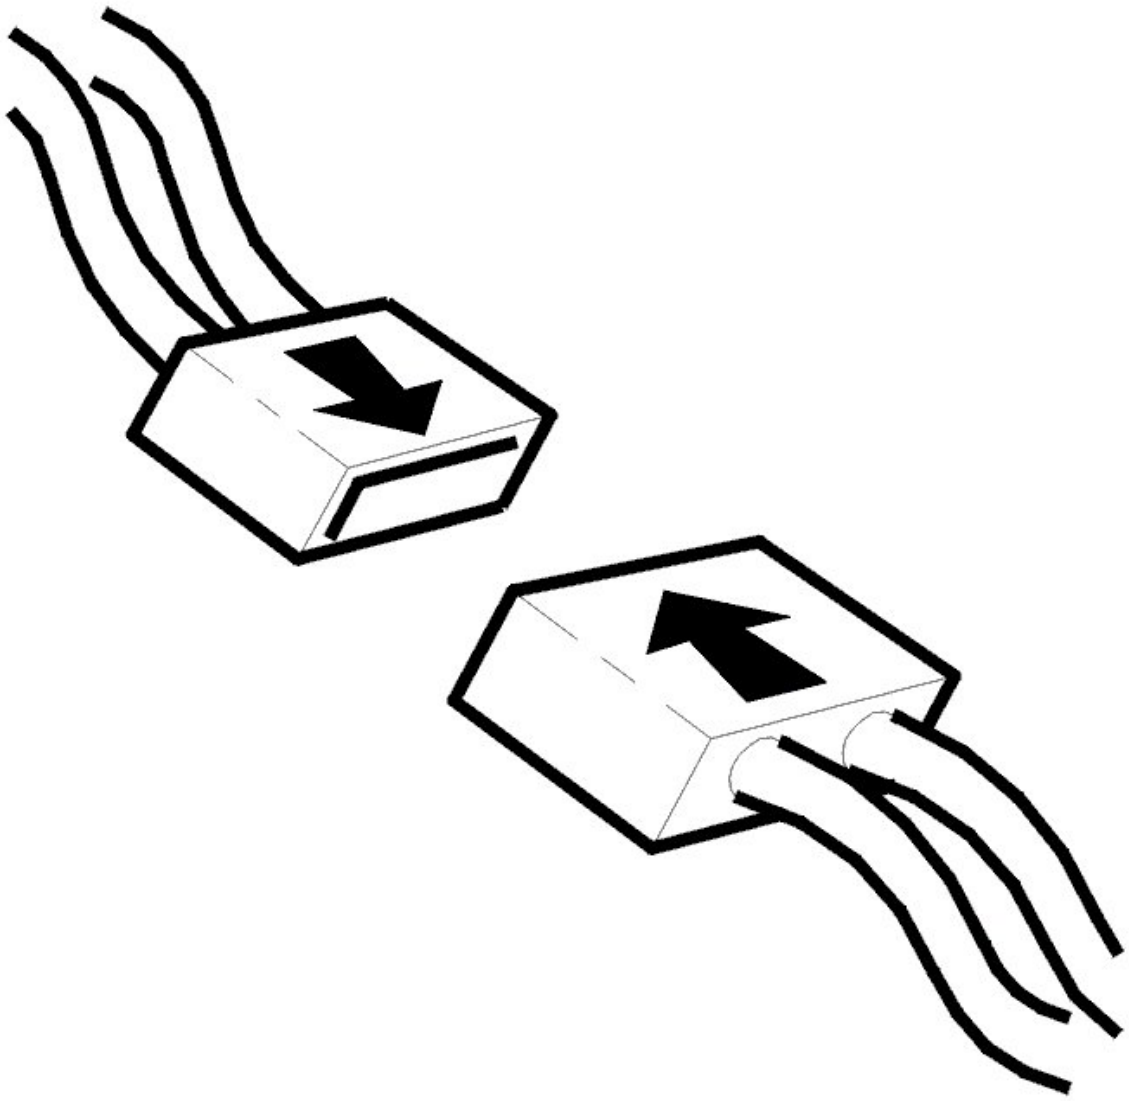
Verification

Verification

Verification

Hint: After carrying out the repair, check that the fault has been remedied.





- Ignition off
- Reconnect the components, connectors etc.

Operate the door mirror to each limit position using the control. The mirror must move in the corresponding directions.

Is the mirror working?

Yes - VERIFIED

No - VERIFICATION FAILED

VERIFIED - Fault Found

VERIFICATION FAILED - Fault-tracing information

Intermittent fault

Check the driver/passenger door control module (DDM/PDM) and power door mirror connectors. Check for contact resistance, oxidation and loose connections.
Check the cable between the door control module and the power door mirror (as follows). Check for an intermittent short-circuit to supply voltage. Check for an intermittent open-circuit.

If the car is equipped with a 10-pin connector

DDM-0023 Door mirror motor MX+

Control module terminal #26A and power door mirror terminal #9.

DDM-0026 Door mirror motor MY+

Control module terminal #28A and power door mirror terminal #10.

DDM-0028 Door mirror motor MF+

Control module terminal #29A and power door mirror terminal #8.

If the car is equipped with a 16-pin connector

DDM-0023 Door mirror motor MX+

Control module terminal #26A and power door mirror terminal #15.

DDM-0026 Door mirror motor MY+

Control module terminal #28A and power door mirror terminal #16.

DDM-0028 Door mirror motor MF+

Control module terminal #29A and power door mirror terminal #14.

Other information:

- When the function is not activated the voltage between the control module and ground must be **0 V**

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition

Diagnostic trouble code (DTC) DDM/PDM-0025 is stored if the control module registers that the signal cable for one of the power door mirror motors or defroster is interrupted at the same time that the relevant function is activated.

Substitute value
- None.

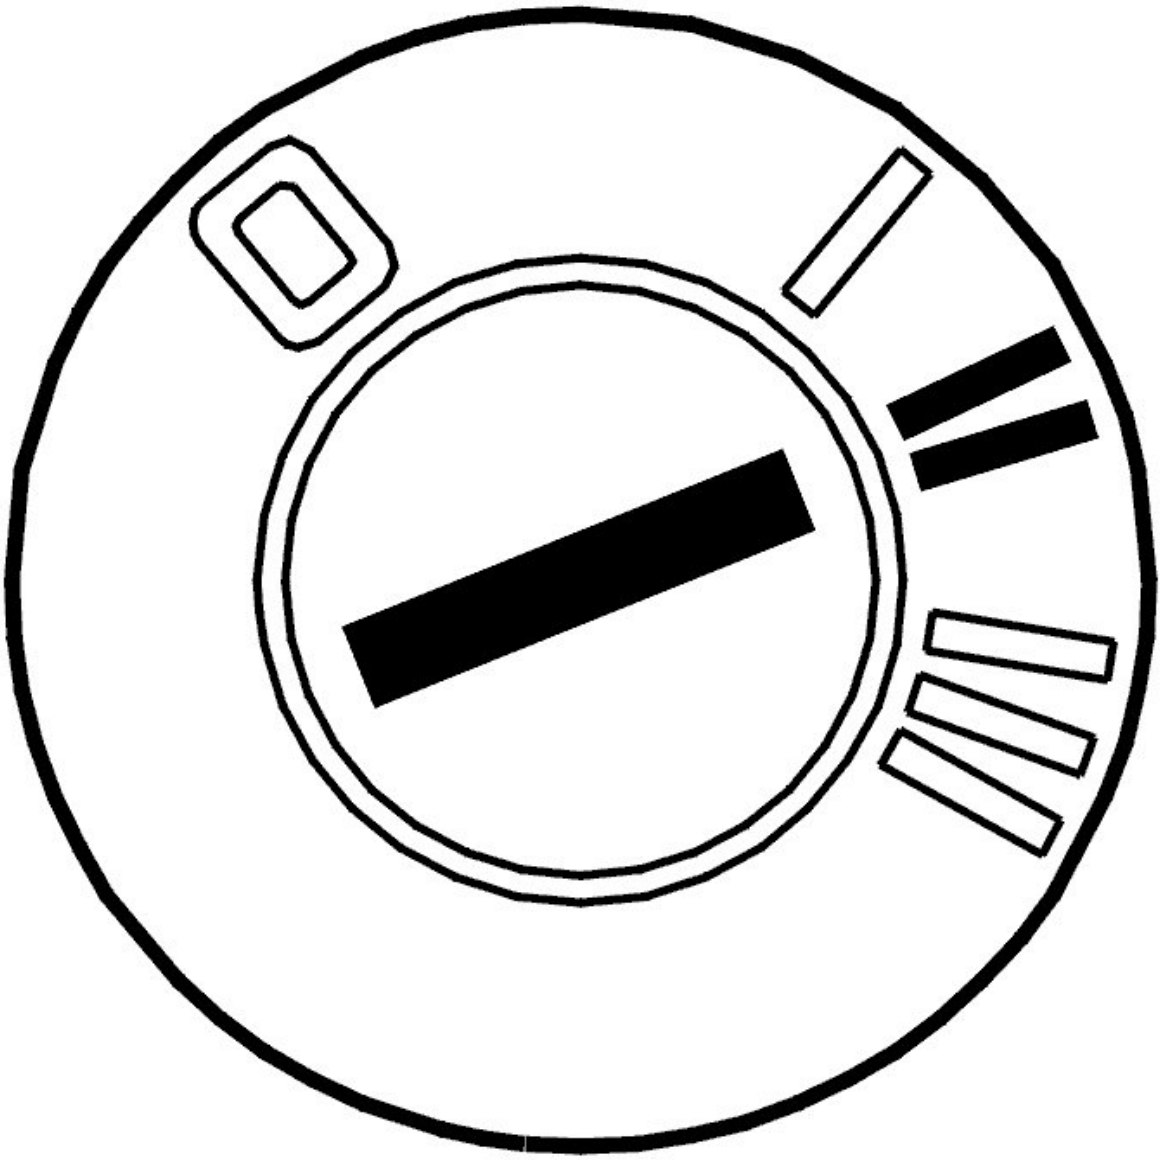
Possible source
- Open-circuit in the signal cable to the door mirror heating or motors (including the motor for electric folding door mirrors)
- Blown fuse 11C/35 or 11C/36.
- Damaged defroster in external mirror.

Fault symptom[s]
- Power door mirror control does not function
- Misting on the windows and/or door mirrors.

Signal Missing

Signal missing

Checking for permanent or intermittent faults



- Ignition on.

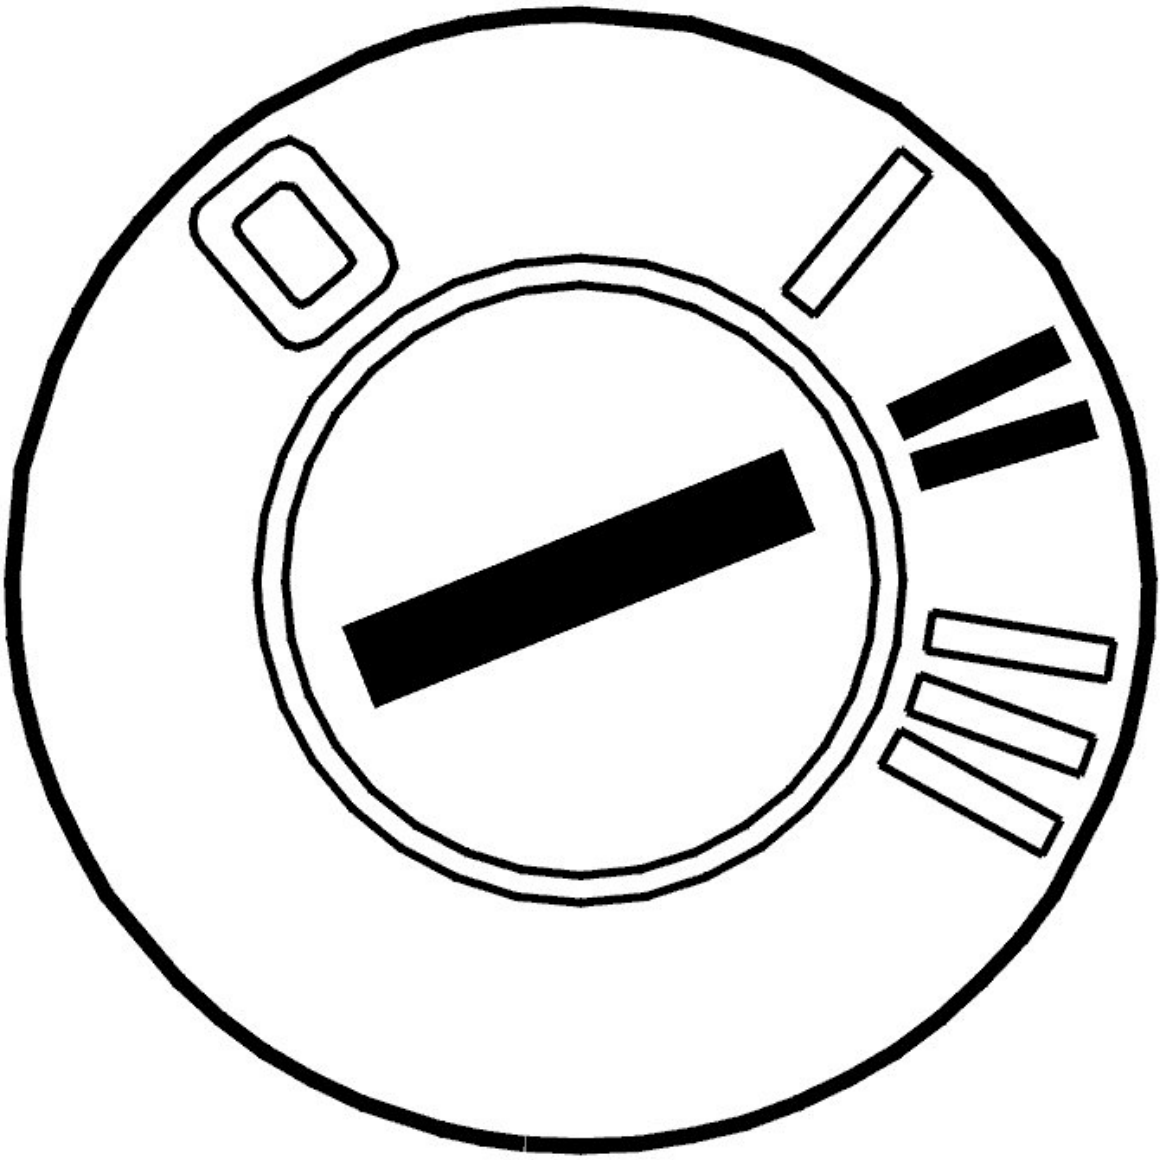
Press the switch for the power door mirrors to check the function of the power door mirrors in all directions.

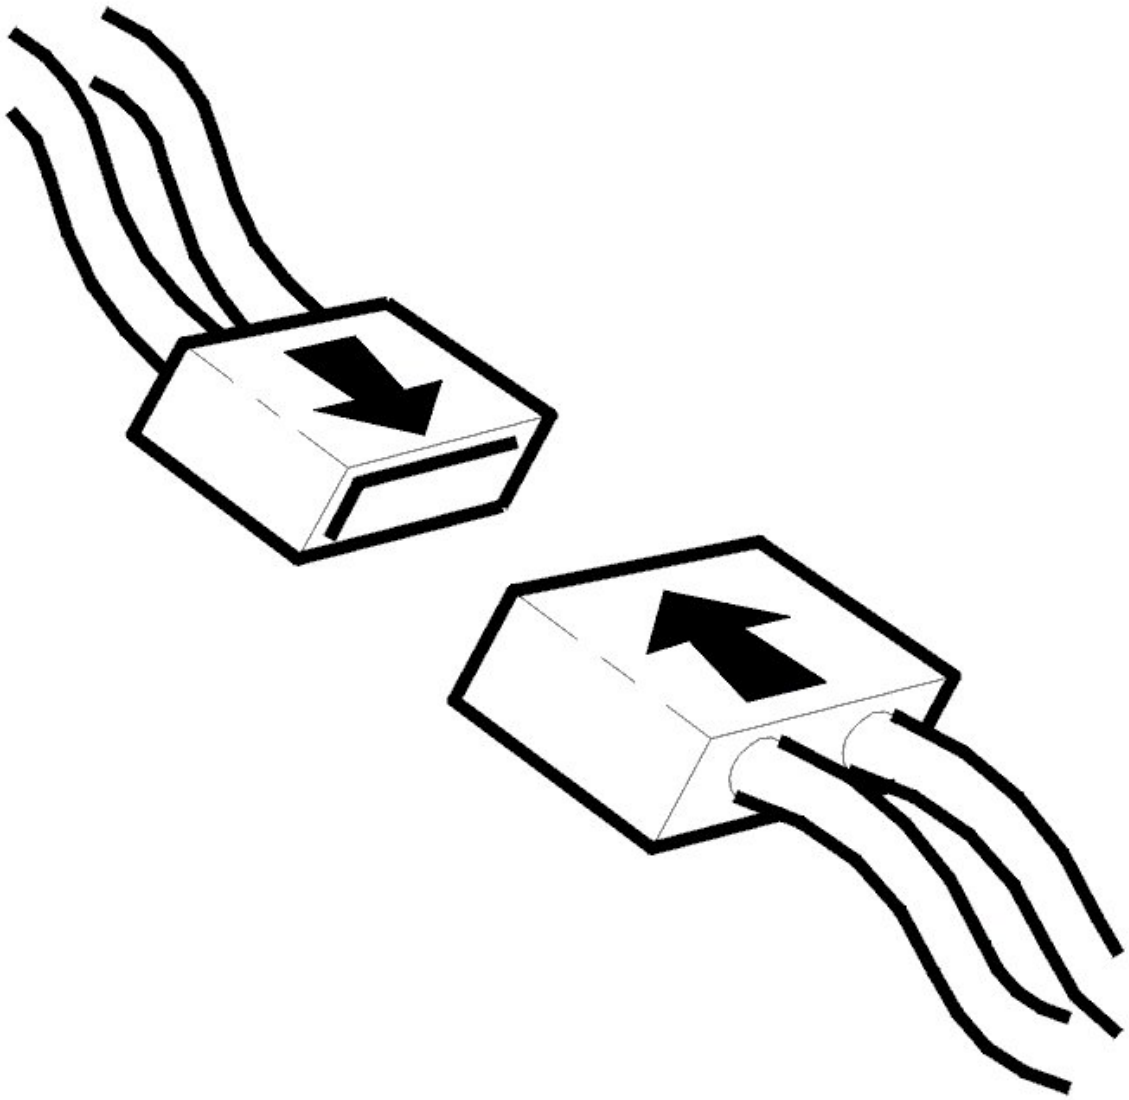
Can the power door mirrors be maneuvered?

Yes - Intermittent fault

No - Checking the connectors

Checking the connectors





- Ignition off
- Check that fuse 11C/35 or 11C/36 in the integrated relay / fusebox in the passenger compartment is intact
- Check the power door mirror connector for contact resistance and oxidation. Remedy.

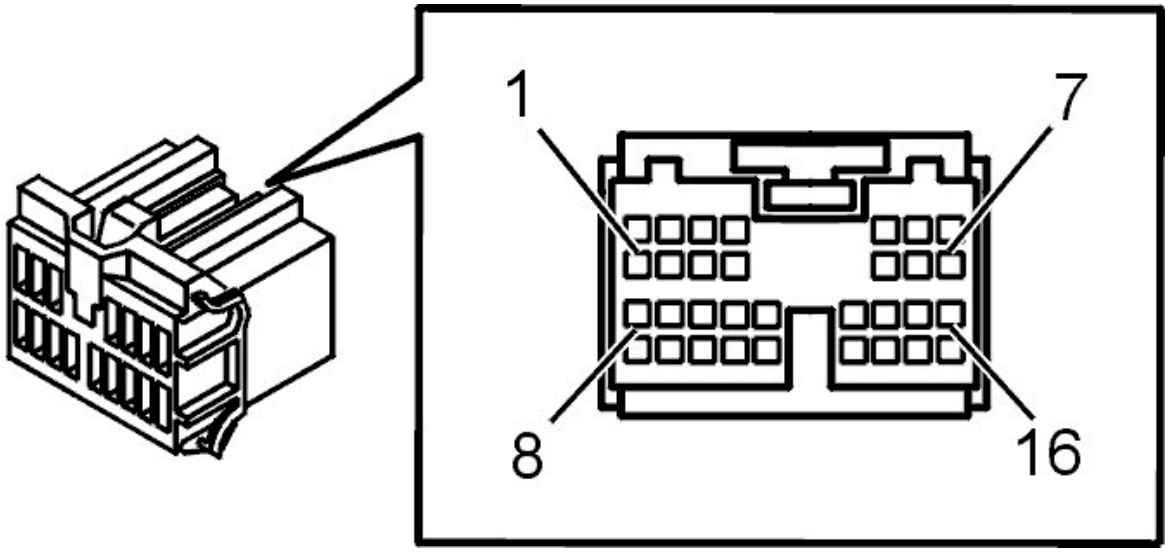
In particular, check for any damage

- Reinstall the components, reconnect the connectors etc.
- Ignition on.

Press the switch for the power door mirrors to check the function of the power door mirrors in all directions.
If no fault is found, try replacing the mirror glass.
Remedy as necessary.

Other information:

- To access the connector for the power door mirror, see Door mirror, replacing See: Body and Frame/Mirrors/Service and Repair
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals.



Can the power door mirrors be maneuvered?

Yes - Verification

No - Checking for a short-circuit

Checking for a short-circuit

Check the cable between the door control module and the power door mirror (as follows). Check for an open-circuit.
Control module terminal #26A and power door mirror terminal #15.
Control module terminal #27A and power door mirror terminal #7.
Control module terminal #28A and power door mirror terminal #16.
Control module terminal #29A and power door mirror terminal #14.

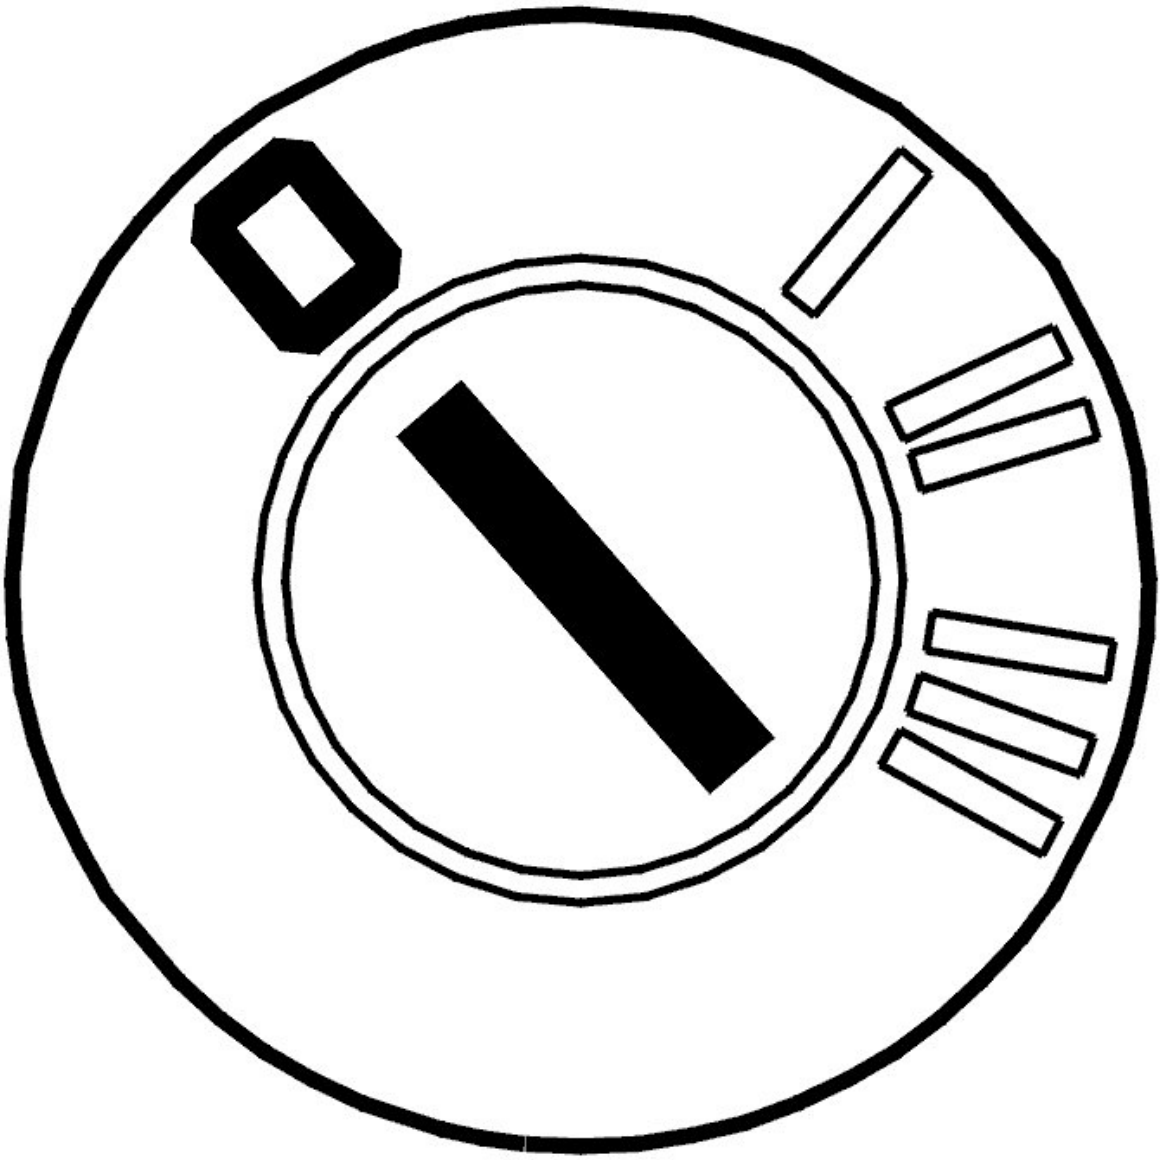
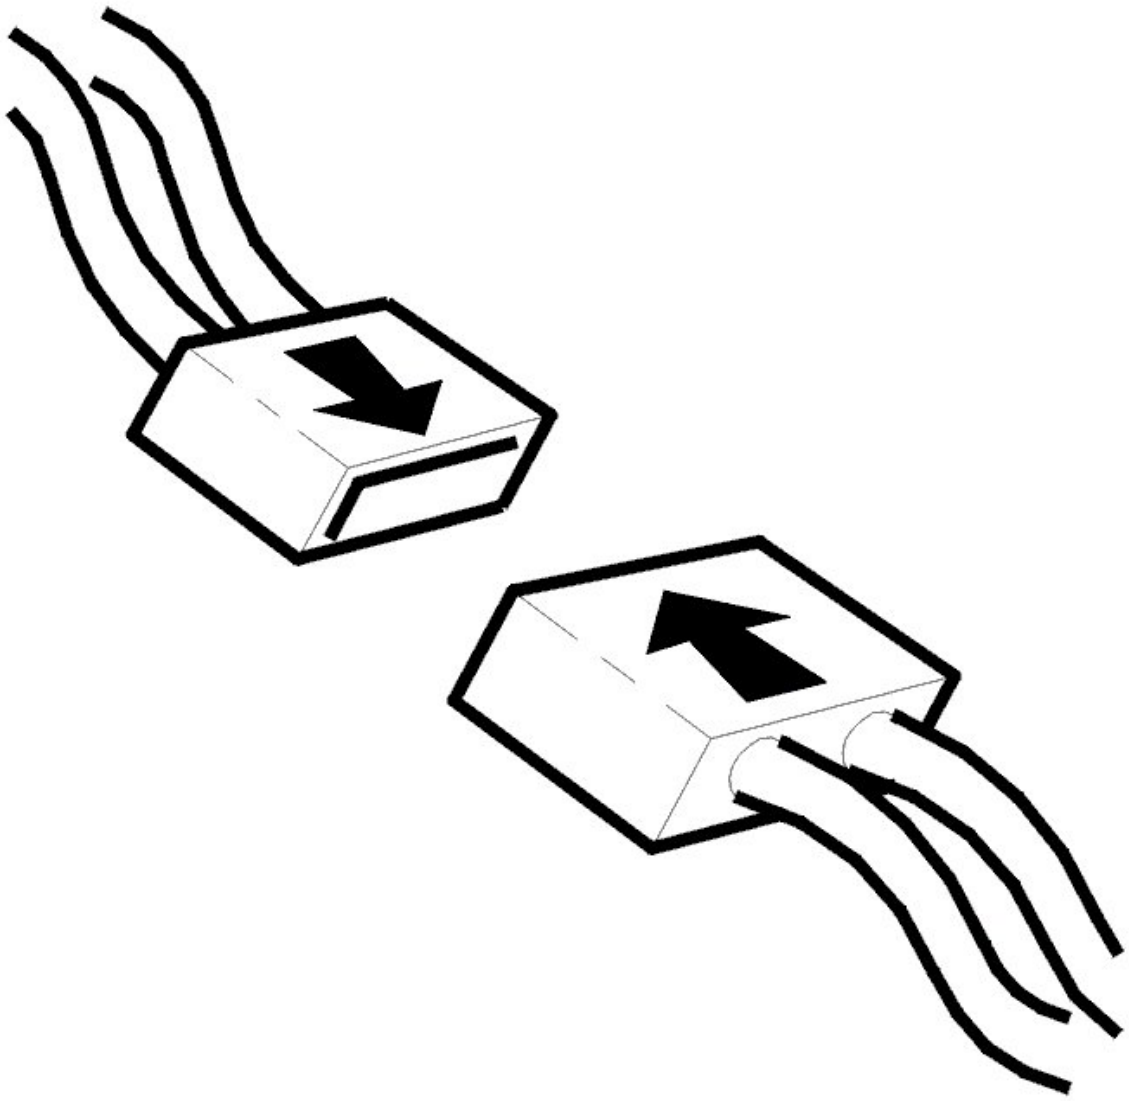
Hint: After carrying out the repair, check that the fault has been remedied.





- Ignition off
- Reconnect the components, connectors etc.

Operate the door mirror to each limit position using the control. The mirror must move in the corresponding directions.

Is the mirror working?

Yes - VERIFIED

No - VERIFICATION FAILED

VERIFIED - Fault Found

VERIFICATION FAILED - Fault-tracing information

Intermittent fault

Check the driver/passenger door control module (DDM/PDM) and power door mirror connectors. Check for contact resistance, oxidation and loose connections.
Check the cable between the door control module and the power door mirror (as follows). Check for an intermittent short-circuit to supply voltage. Check for an intermittent open-circuit.

If the car is equipped with a 10-pin connector

DDM-0023 Door mirror motor MX+

Control module terminal #26A and power door mirror terminal #9.

DDM-0026 Door mirror motor MY+

Control module terminal #28A and power door mirror terminal #10.

DDM-0028 Door mirror motor MF+

Control module terminal #29A and power door mirror terminal #8.

If the car is equipped with a 16-pin connector

DDM-0023 Door mirror motor MX+

Control module terminal #26A and power door mirror terminal #15.

DDM-0026 Door mirror motor MY+

Control module terminal #28A and power door mirror terminal #16.

DDM-0028 Door mirror motor MF+

Control module terminal #29A and power door mirror terminal #14.

Other information:

- When the function is not activated the voltage between the control module and ground must be **0 V**

Diagnostic trouble code information

Condition

If control unit registers that signal wire for lowering of external rear-view mirror is short circuited to ground when only one of the external rear-view mirror motors is activated, diagnostic trouble code DDM/PDM-0029 is displayed.

Substitute value
- Nothing.

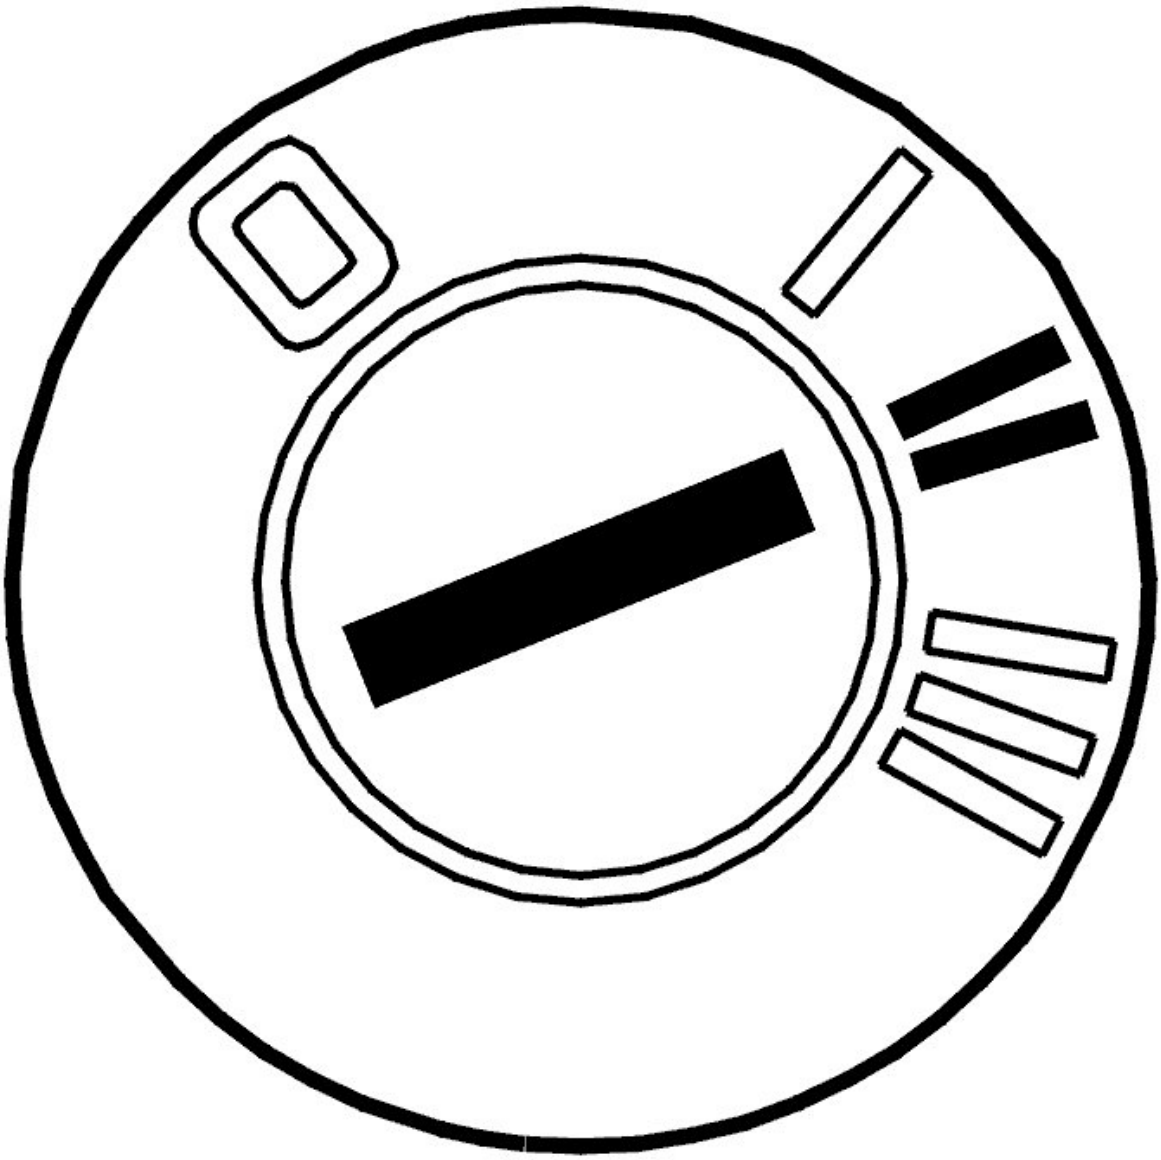
Possible source
- Signal wire MF+ short circuited to ground.

Fault symptom[s]
- External rear-view mirror operation does not work.

Signal Too Low

Signal too low

Checking for permanent or intermittent faults



- Ignition on.

Press the switch for the power door mirrors to check the function of the power door mirrors.

Can the power door mirrors be maneuvered?

Yes - Intermittent fault

No - Checking for a short-circuit

Checking for a short-circuit

Check the cable between the door control module and the power door mirror (as follows). Check for a short-circuit to ground. Remedy as necessary.
Try a new power door mirror if the cable is OK.

If the car is equipped with a 10-pin connector

DDM-0024 Door mirror motor MX+

Control module terminal #26A and power door mirror terminal #9.

DDM-0027 Door mirror motor MY+

Control module terminal #28A and power door mirror terminal #10.

The diagnostic trouble code (DTC) is stored if the signal from the oil pressure sensor corresponds to a pressure lower than 0 MPa or higher than 4 MPa.
The diagnostic trouble code (DTC) can be diagnosed when the ignition is switched on.

Substitute value
- Four wheel drive is disengaged.

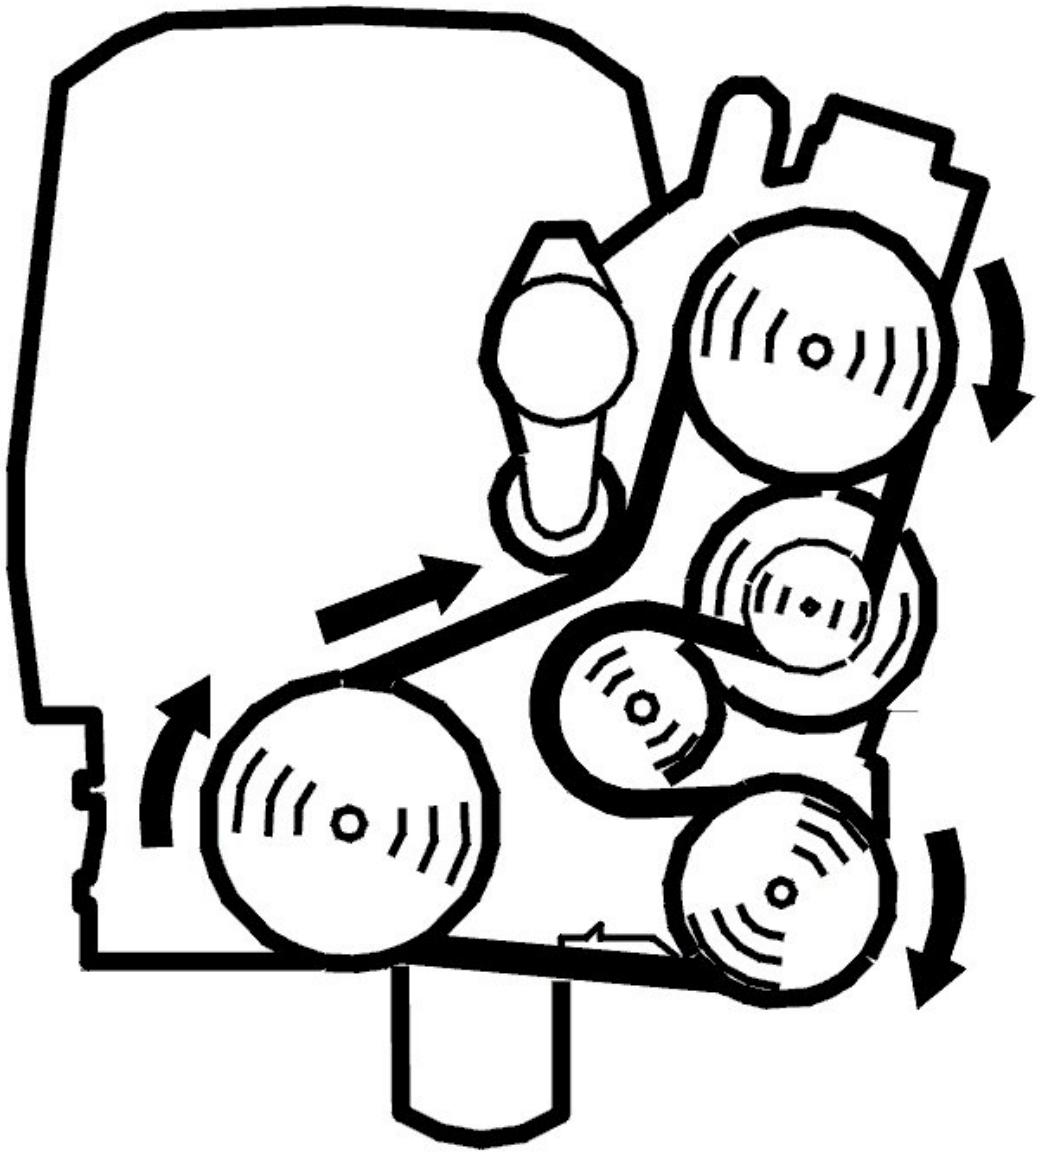
Possible source
- Damaged oil pressure sensor
- Damaged control module.

Fault symptom[s]
- Four wheel drive is not functioning.

Faulty Signal

Faulty signal

Checking the function



Caution! Carry out the test with the vehicle raised so that all four wheels can rotate freely with the mounting at the ends of the control arms to prevent damage to the drive shafts.

Warning! Ensure that the vehicle is safely raised. Check that no objects are caught in the tire treads.

Note! If the vehicle is equipped with TRACS (traction control system) or Traction Control (DSTC (Dynamic stability and traction control), STC (Stability and traction control)) the function must be deactivated. This is carried out by removing the fuse for the brake system pump motor in the engine compartment relay and fusebox. Note that diagnostic trouble codes (DTCs) will be stored in the brake control module (BCM). These must be erased before returning the vehicle to the customer.

- Engine idling
- Read off the oil pressure.

Check that the function of the oil pressure sensor is OK. Run the engine with the vehicle on the lift to increase the clutch oil pressure. Read off the pressure during the test drive. Check that the pressure has been updated.

Hint: The oil pressure sensor has a measurement range of 0 to 4 Mpa.

Check the connector between the differential electronic module (DEM) and the oil pressure sensor. Check for contact resistance and oxidation. Also check the clutch for leakage.
Remedy as necessary.

Other information:

- For further information about the fuses and relays, see the Wiring Diagram

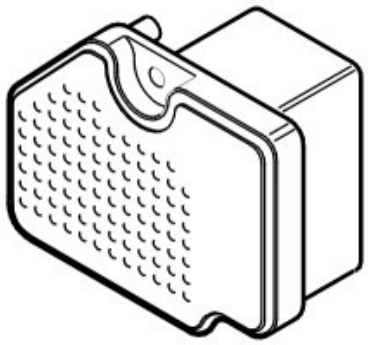
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information DEM-0003

Condition



The differential electronic module (DEM) checks its voltage supply by comparing the voltage between the differential electronic module (DEM) and the central electronic module (CEM).
Diagnostic trouble code (DTC) is stored if the control module registers a difference in the power supply between the central electronic module (CEM) and the differential electronic module (DEM) which is greater than 2.5 V.
The diagnostic trouble code (DTC) can be diagnosed when the ignition has been on for 10 seconds.

Substitute value
- Four wheel drive is disengaged.

Possible source

Signal too high:
- Short-circuit to supply voltage in signal cable.

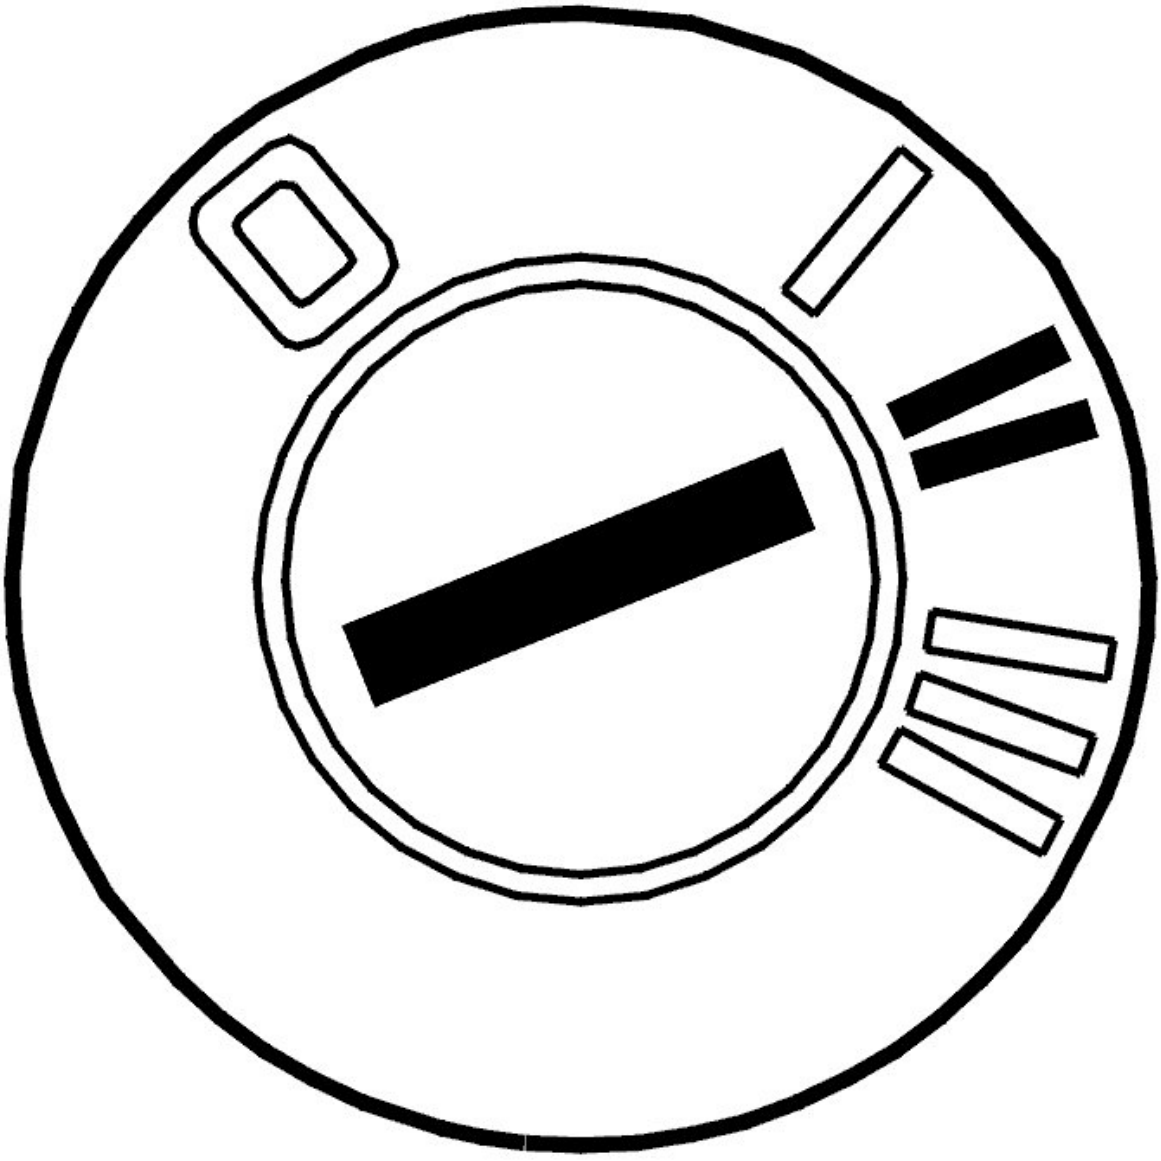
Signal too low:
- Short-circuit to ground in the signal cable
- Open-circuit in the power supply.

Fault symptom[s]
- Four wheel drive is not functioning.

Faulty Voltage

Faulty voltage

Checking the status



- Ignition on.

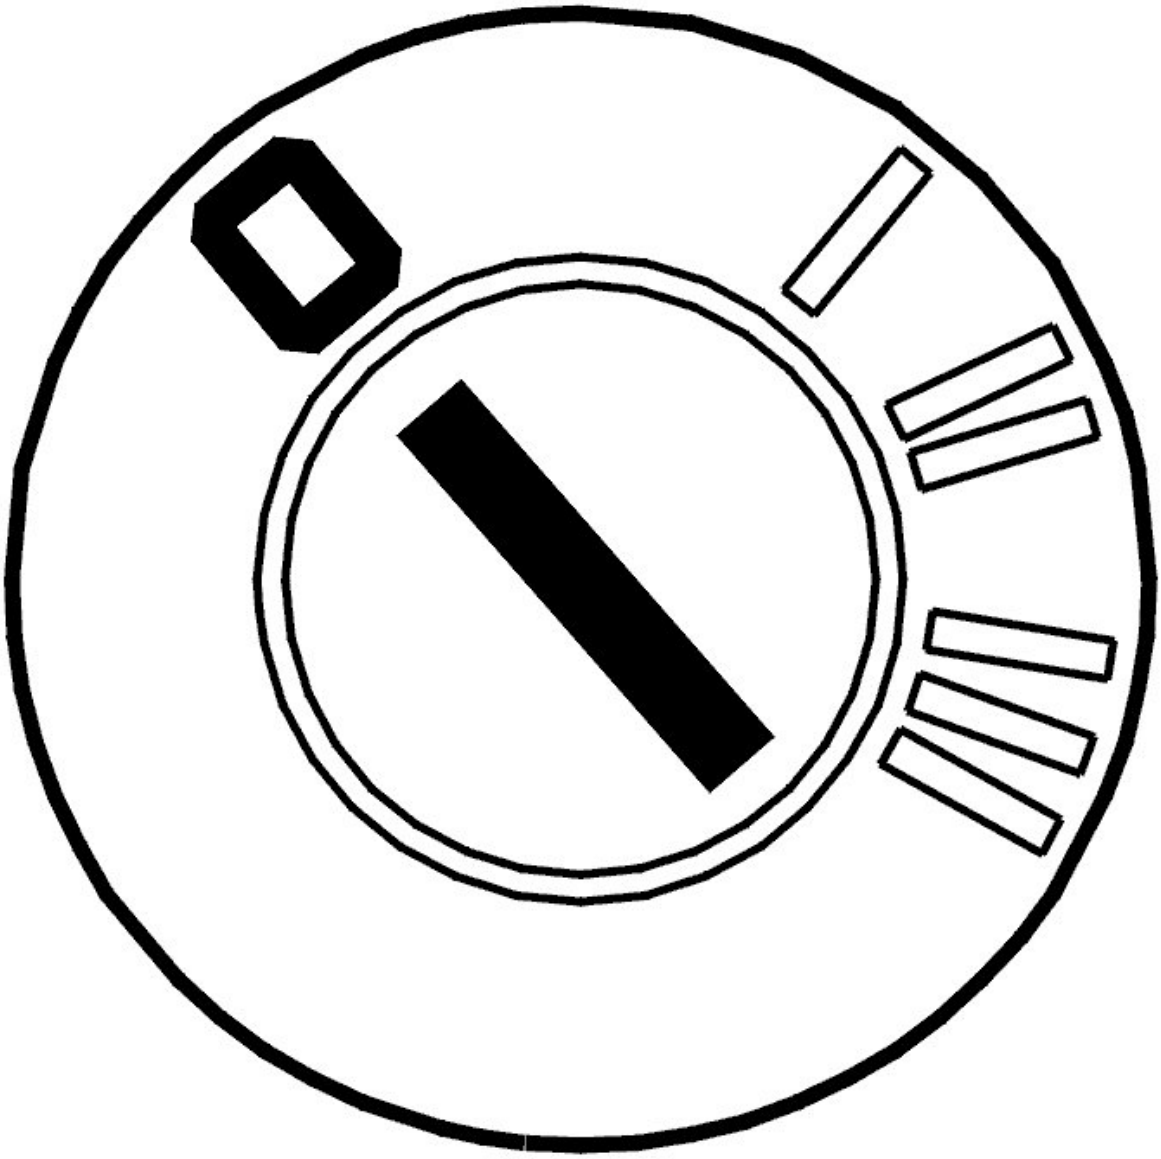
Read off the voltage for the differential electronic module (DEM) and the central electronic module (CEM).
The voltage must be able to be compared with the power supply to the central electronic module (CEM) +/-2.5 V.

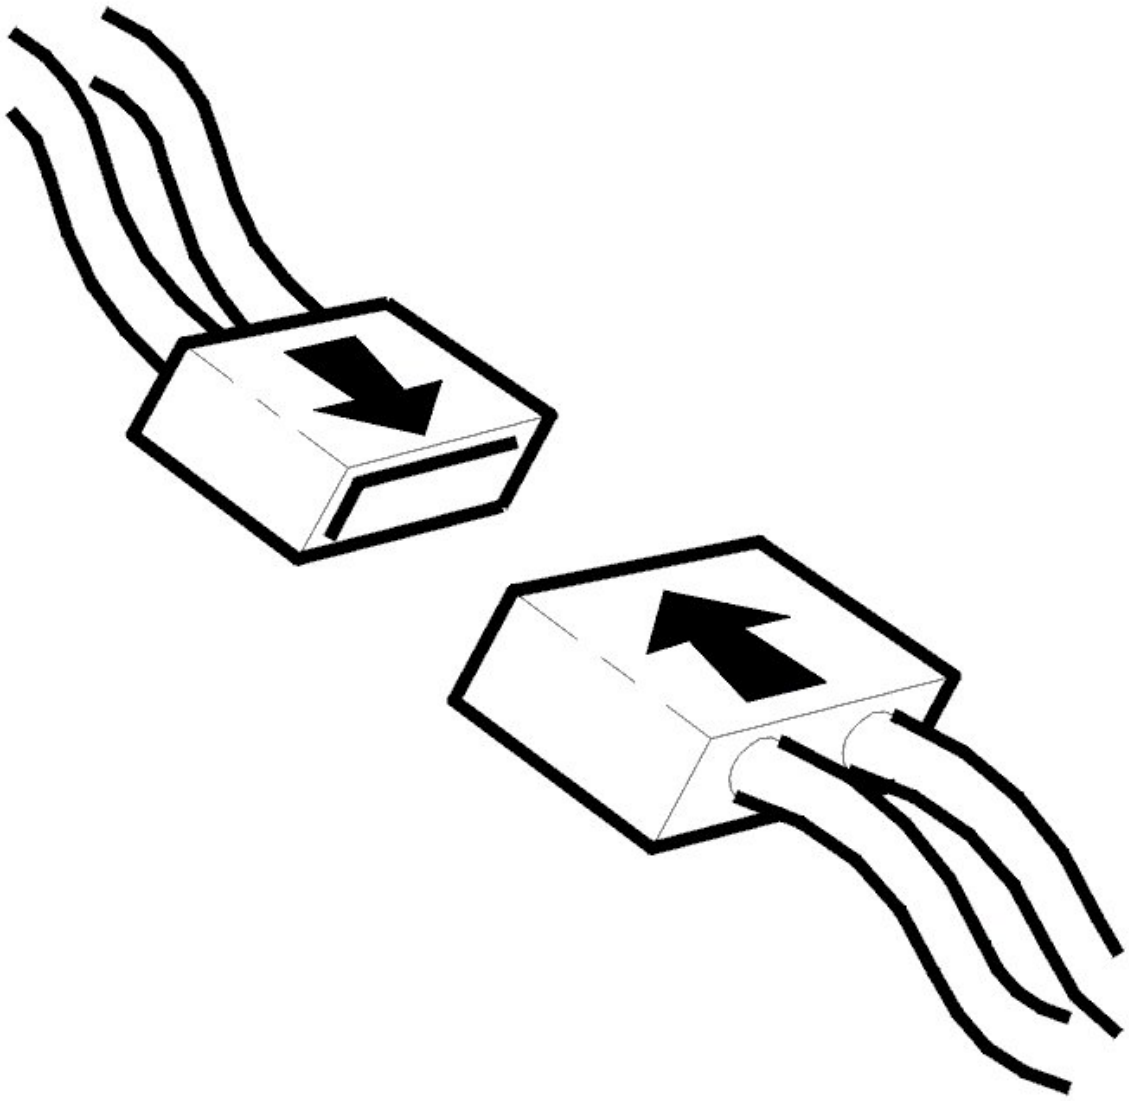
Hint: Compare to the battery voltage.

The fault is permanent if the power supply to the differential electronic module (DEM) deviates by more than 2.5 V from the central electronic module (CEM).
If the voltage is correct, this is an indication that the fault was present previously but is not active at the moment, i.e. an intermittent fault.

Continue - Checking the connectors and cables

Checking the connectors and cables





- Ignition off
- Check the connectors between the differential electronic module (DEM) and the Active on Demand Coupling- control module. Check for contact resistance and oxidation
- Check the cable between the differential electronic module (DEM) and the Active on Demand Coupling control module. Check for damage.

Hint: Read off the voltage to check the function.

Remedy as necessary.

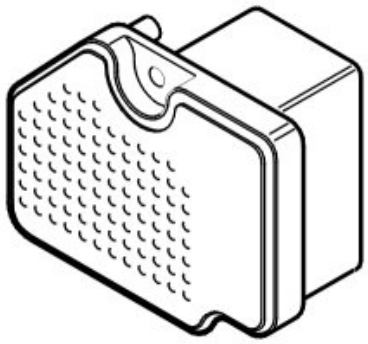
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information DEM-0005

Condition



The differential electronic module (DEM) checks if the signal from the control valve is within the permitted range by comparing the signal with a predefined parameter.
The diagnostic trouble code (DTC) is stored if the control module registers a incorrect signal, i.e. a current value outside the predefined parameters.
The diagnostic trouble code (DTC) can be diagnosed with the engine running and the engine speed (RPM) greater than 500 rpm.

Substitute value
- Four wheel drive is disengaged.

Possible source
- Damaged control module.

Fault symptom[s]
- Four wheel drive is not functioning.

Internal Fault

Internal fault

Information

The differential electronic module (DEM) has registered an internal fault.
If the fault is intermittent, it has been registered previously but is no longer present. Intermittent faults can be caused by interference at start up of the differential electronic module (DEM) or may be a different type of fault which occurs on different occasions. The fault is evaluated depending on how it occurs. Replace the differential electronic module (DEM) if the fault recurs.

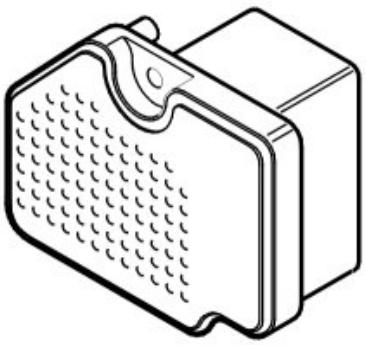
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information DEM-0006

Condition



The differential electronic module (DEM) checks if the signal from the feed pump is within the permitted range by comparing the signal with predefined parameters.

The diagnostic trouble code (DTC) is stored if the control module registers a incorrect signal, i.e. a current value outside the predefined parameters.
The diagnostic trouble code (DTC) can be diagnosed with the engine running and the engine speed (RPM) greater than 500 rpm.

Substitute value
- Four wheel drive is disengaged.

Possible source
- Damaged feed pump
- Damaged cable harness to the feed pump

Signal too high
- Short-circuit to ground.

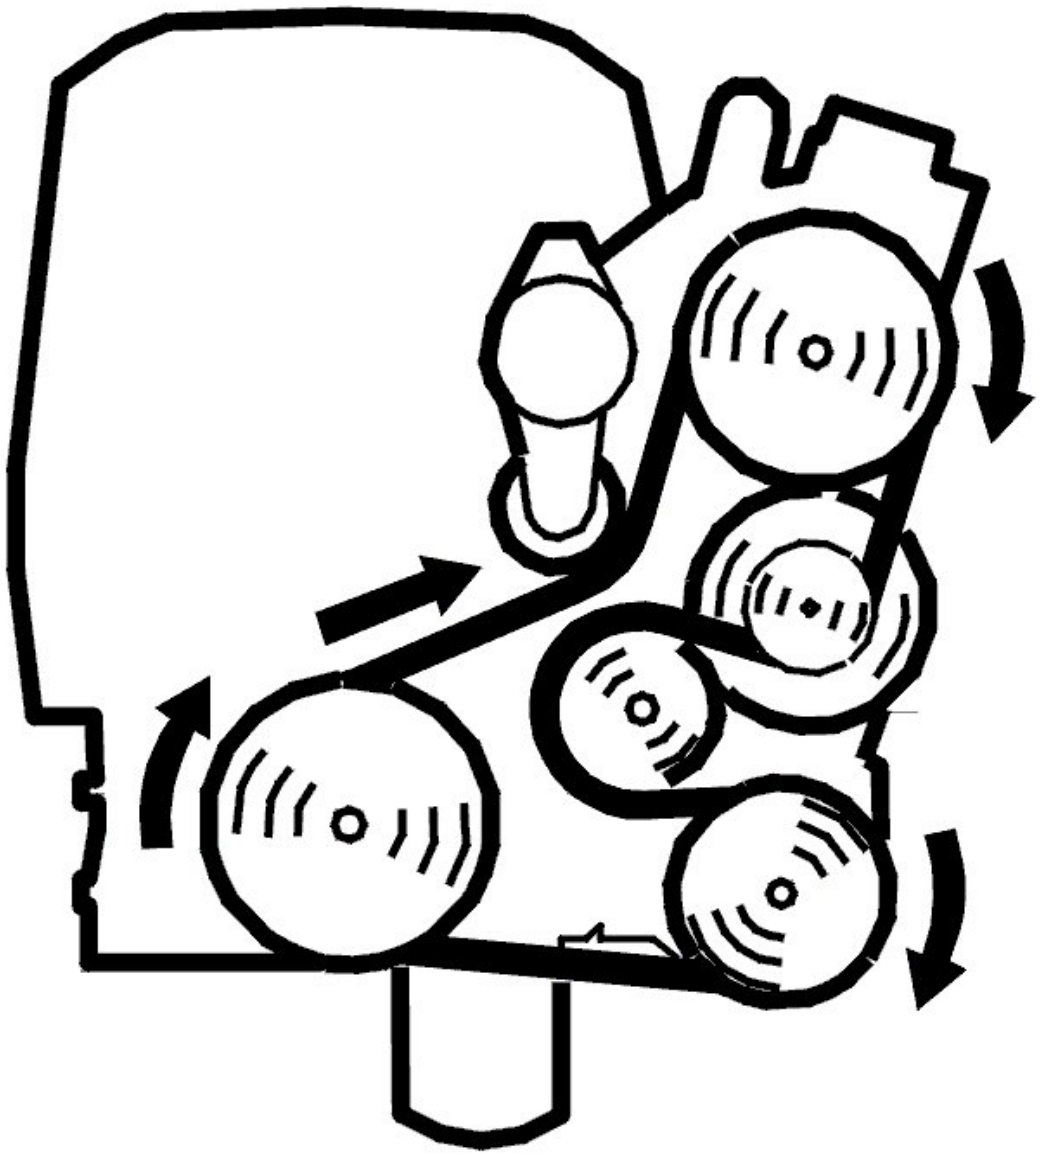
Signal too low
- Open-circuit in the power supply.

Fault symptom[s]
- Four wheel drive is not functioning.

Faulty Signal

Faulty signal

Checking the status

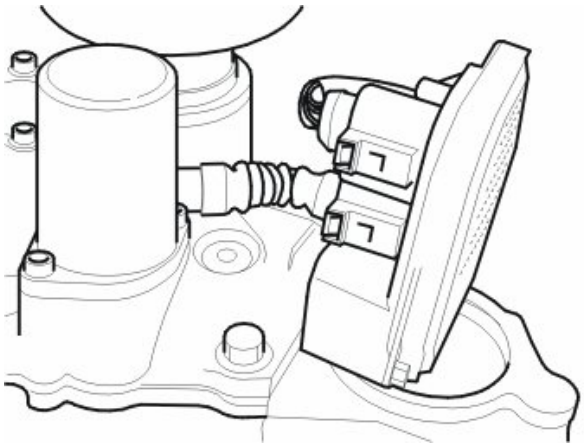


- Engine idling.

Check if the pump motor in the unit for four wheel drive (Active on Demand Coupling) starts and runs normally.

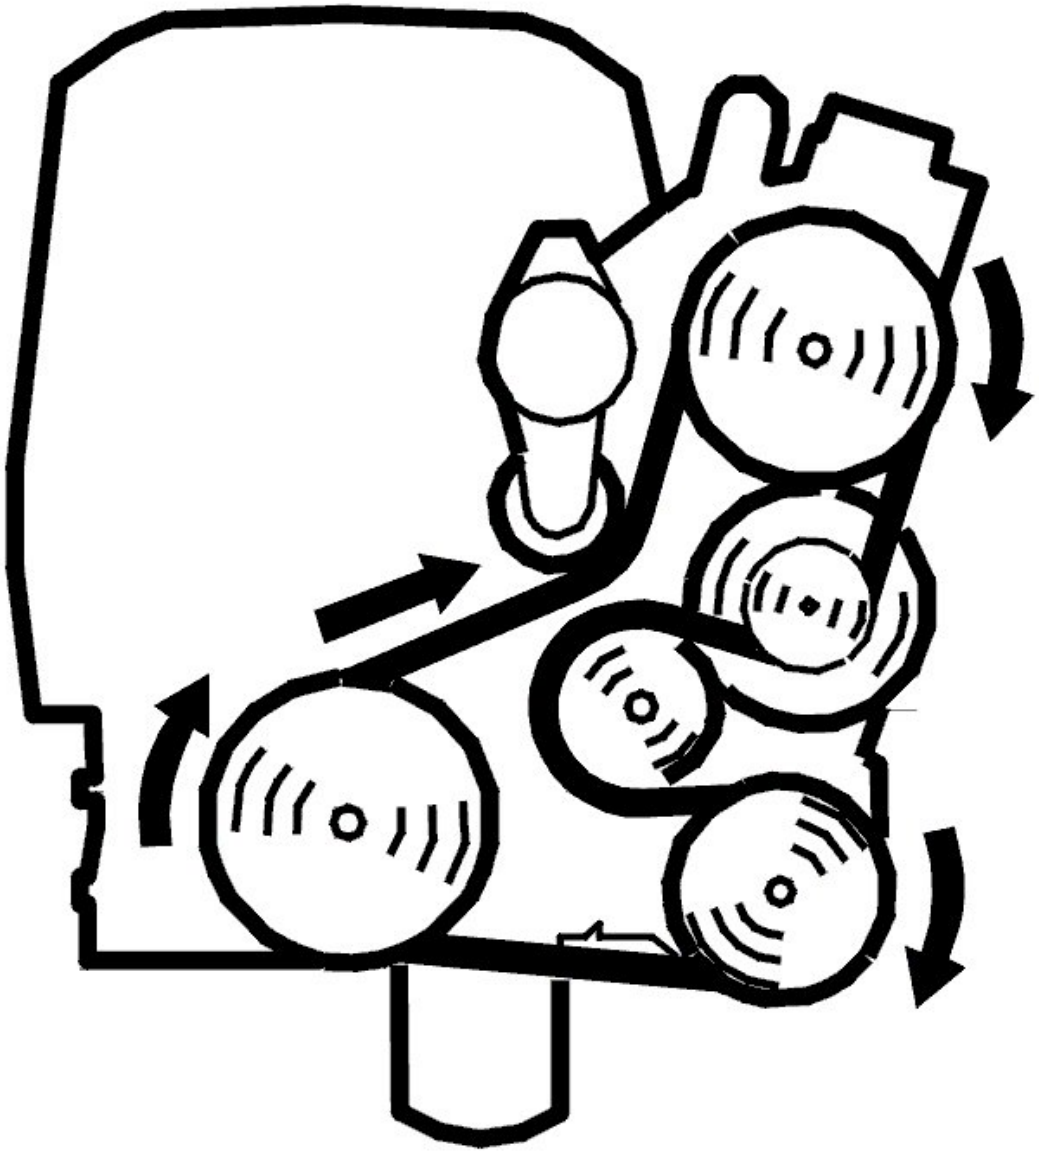
Hint: The motor must hum and vibrate slightly. Listen using a stethoscope or a screwdriver pressed to your ear.

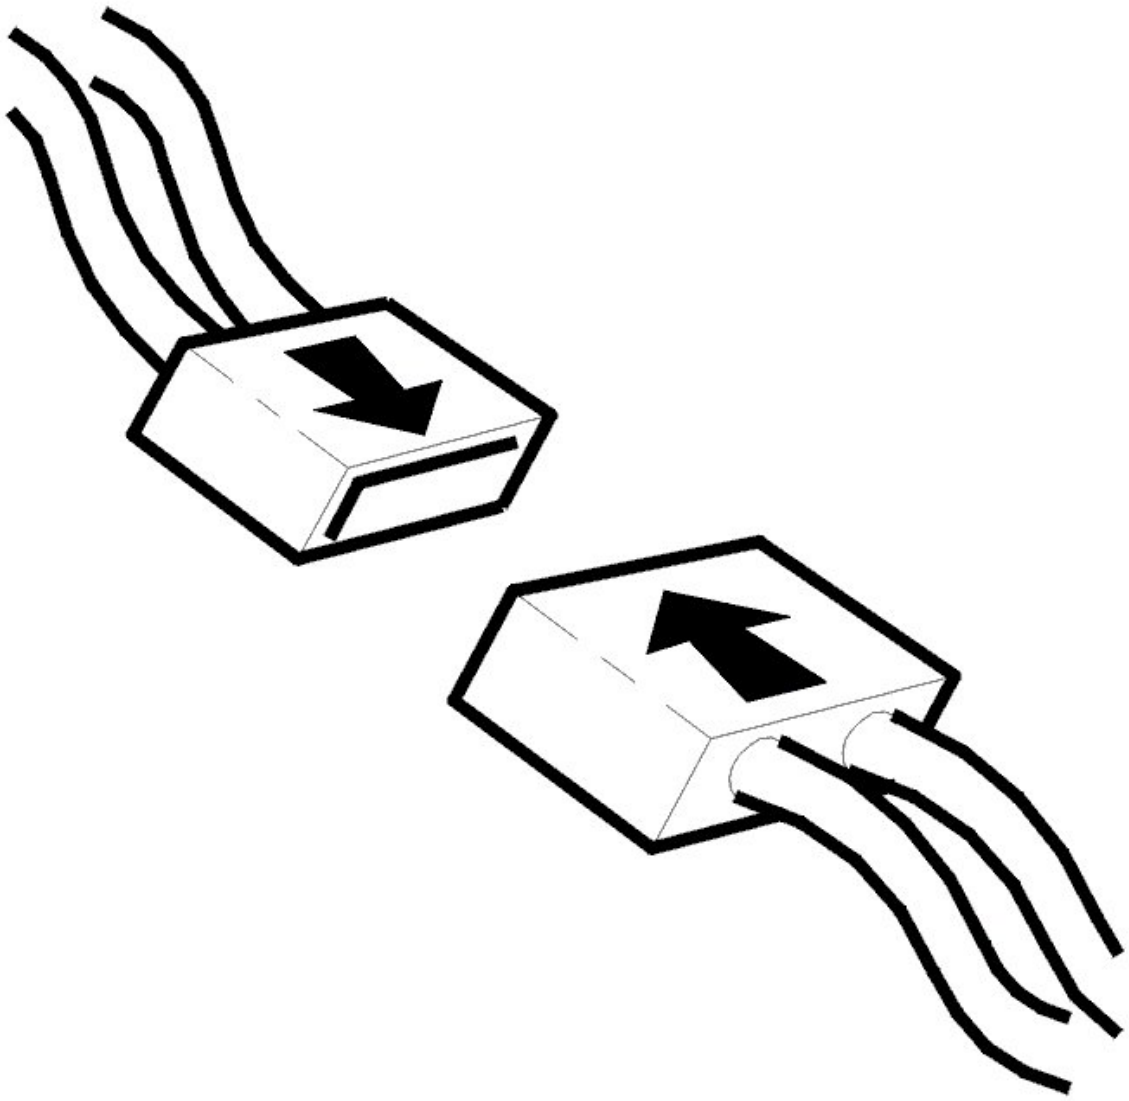
If the pump motor starts, this is an indication that the fault was present previously but that it is not active at the moment, i.e. the fault is intermittent.



Continue - Checking the connectors and cables

Checking the connectors and cables





- Ignition off
- Check the connector between the differential electronic module (DEM) and the feed pump. Check for contact resistance and oxidation
- Check the cable between the differential electronic module (DEM) and the feed pump. Check for damage
- Engine idling.

Check the voltage by taking readings using a voltmeter on the control module connector for the pump motor. Take readings between terminals #1 and #2.

Note! The voltage is a pulse width modulated signal which varies greatly and can only be read off for a short time. The purpose of the reading is only to provide an indication of whether there is an open-circuit or not.

Remedy as necessary.

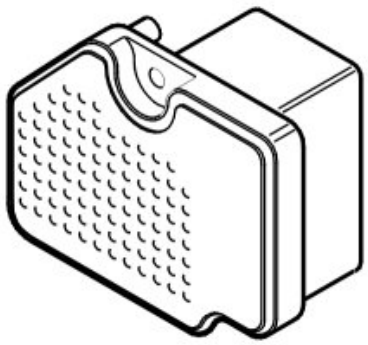
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information DEM-0007

Condition



The Differential electronic module (DEM) checks the oil pressure in the Haldex clutch using an oil pressure sensor.
When the engine speed exceeds 500 rpm, an initial pressure builds up in the clutch via an electric feed pump.
The diagnostic trouble code (DTC) is stored if the control module detects that:

- Initial pressure not reached within 2-4 minutes.

The control module's test for the diagnostic trouble code (DTC) starts in the event of:

- Engine speed (RPM) higher than 500 rpm.

Substitute value

- Four wheel drive is disengaged.

Possible source

- Damaged pressure sensor.
- Damaged feed pump.
- Too low oil volume in clutch.
- Internal leak in the clutch.

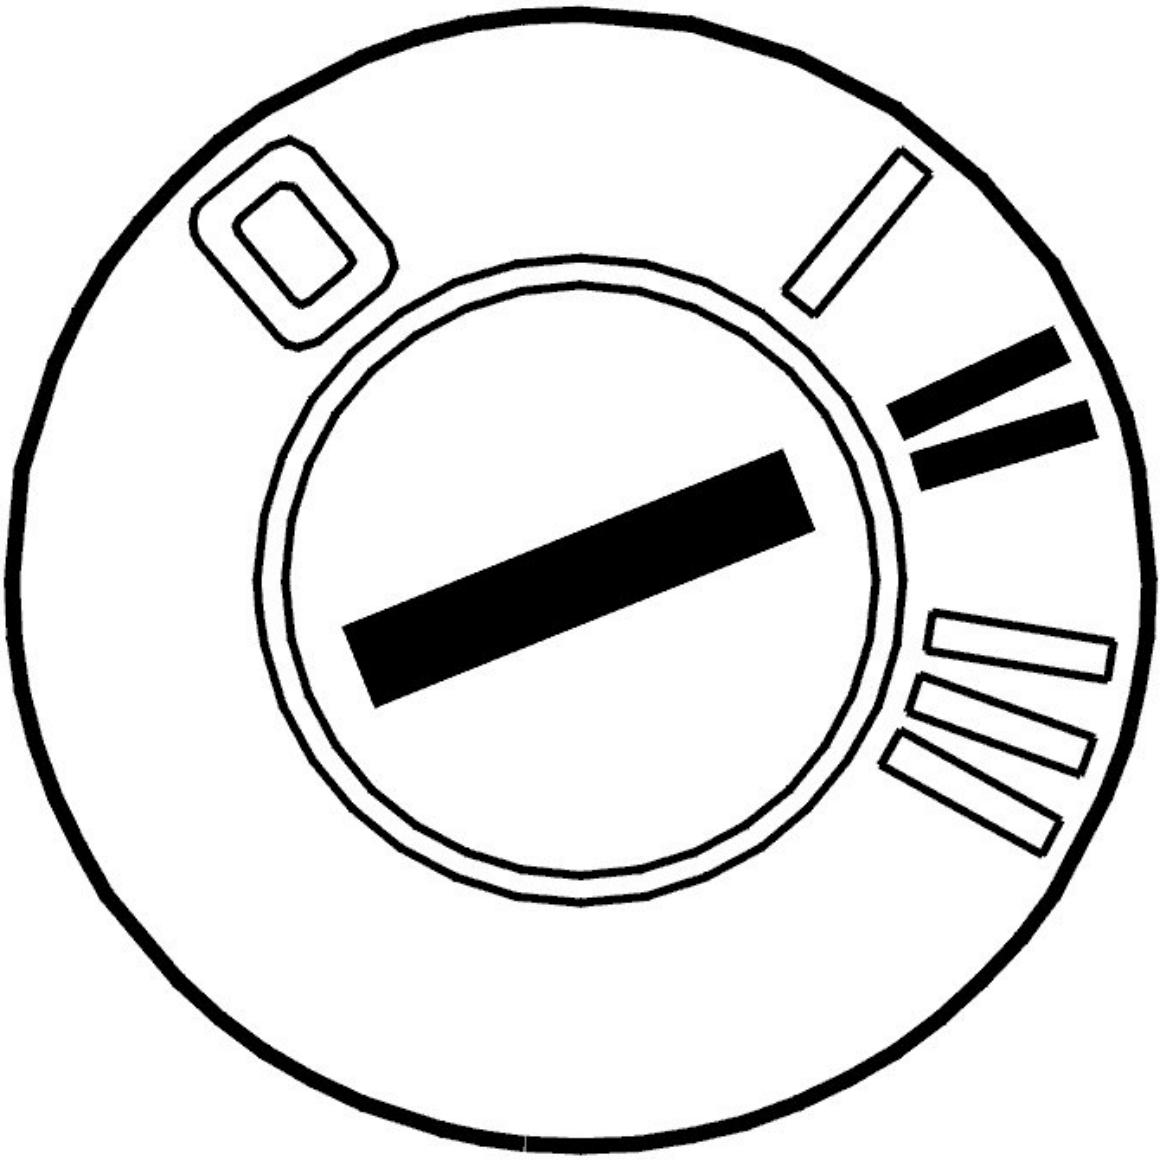
Fault symptom[s]

- Four wheel drive is not functioning.

Incorrect Value

Incorrect value

Checking the oil pressure



- Ignition on.

Read off the oil pressure in the Differential Electronic Module (DEM). The pressure must rise when the engine speed exceeds 500 rpm. Use **VIDA Vehicle communication**.
First read off the oil pressure with the ignition on and then with the engine running. At read out, the oil pressure must rise when the engine rpm exceeds 500 rpm, the pressure must rise immediately after the engine's rpm increases.
If the pressure does not rise, this means that a fault has occurred.

Does the pressure increase?

Yes - Information

No - Checking the component and wiring

Checking the function

- Ignition off.
- Check the connector between the Differential Electronic Module (DEM) and the feed pump with respect to contact resistance and oxidation.
- Check the lead between the Differential Electronic Module (DEM) and the feed pump for damage.

Reinstall the connectors, components etc.

- Ignition on.

Activate the feed pump and check that it starts and runs normally. Listen using a stethoscope or a screwdriver pressed to your ear.

Note! The feed pump may sound like it's running but in certain cases it only oscillates.

Remedy as necessary.

Select continue when the defect has been remedied.

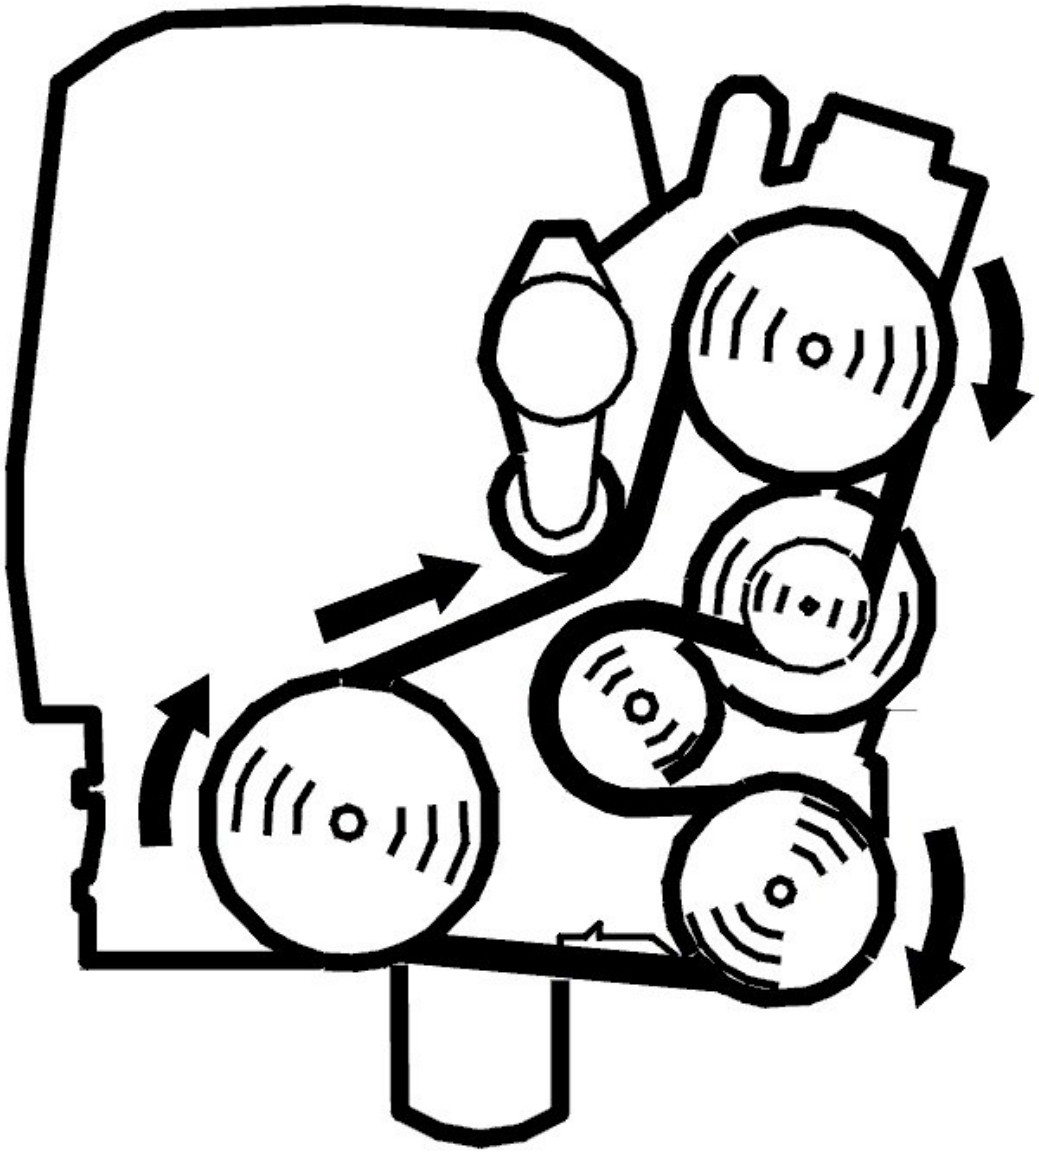
Continue - Information

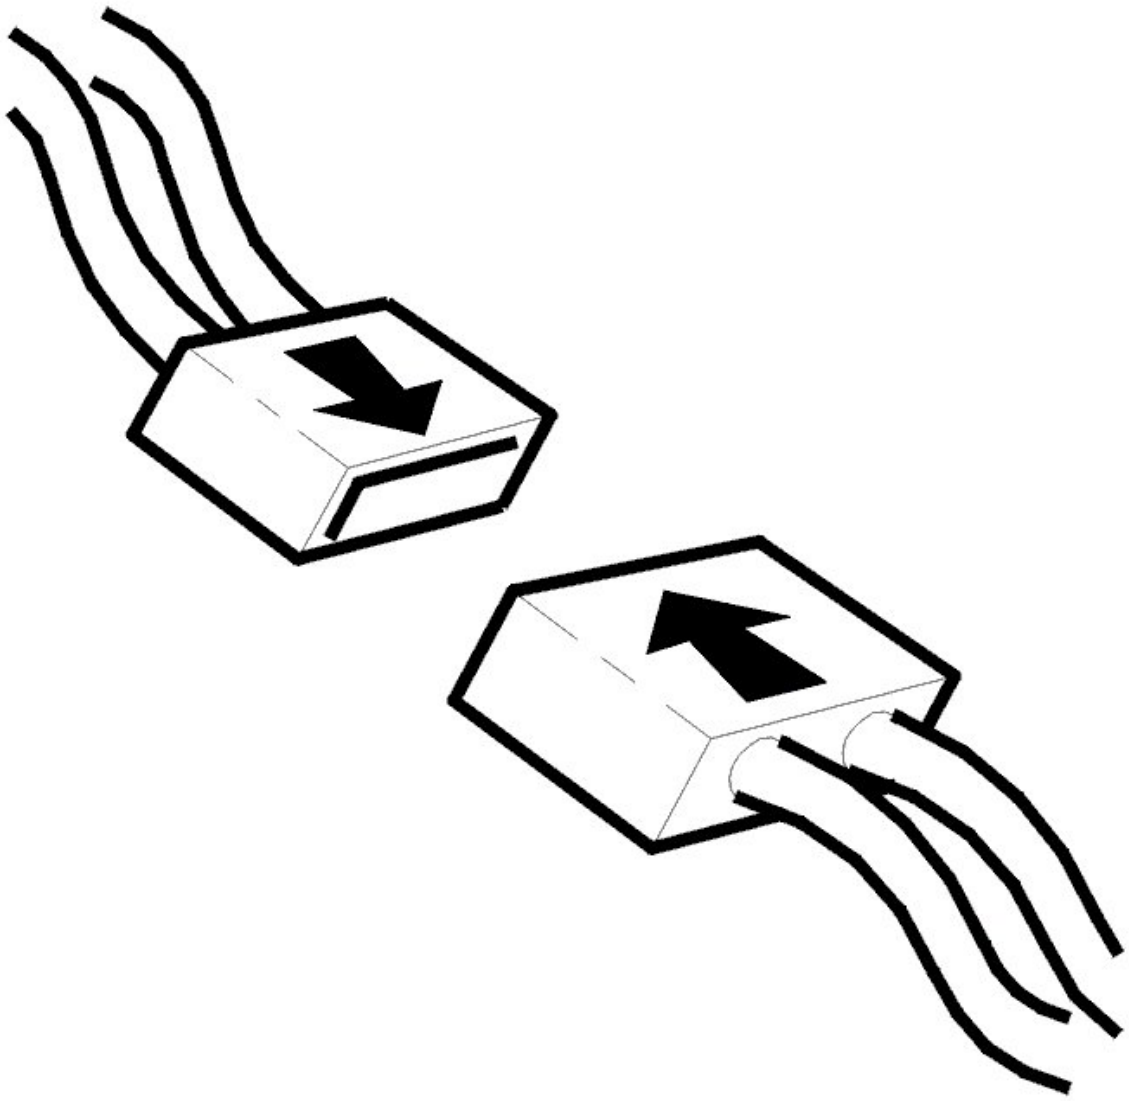
Verification

Verification

Verification

Hint: After carrying out the repair, check that the fault has been remedied.





Caution! Carry out the test with the vehicle raised so that all four wheels can rotate freely with the mounting at the ends of the control arms to prevent damage to the drive shafts.

Warning! Ensure that the vehicle is safely raised. Check that no objects are caught in the tire treads.

Note! If the vehicle is equipped with TRACS (traction control system) or Traction Control (DSTC (Dynamic stability and traction control), STC (Stability and traction control)) the function must be deactivated. This is carried out by removing the fuse for the brake system pump motor in the engine compartment relay and fusebox. Note that diagnostic trouble codes (DTCs) will be stored in the brake control module (BCM). These must be erased before returning the vehicle to the customer.

- Ignition off
- Reinstall the connectors, components etc.
- Engine idling
- Read off the oil pressure.

Check that the function of the oil pressure sensor is OK. Run the engine with the vehicle on the lift to increase the clutch oil pressure. Read off the pressure during the test drive. Check that the pressure has been updated.

Hint: The oil pressure sensor has a measurement range of 0 to 4 Mpa.

Is the function OK?

Diagnostic Trouble Code (DTC) Information

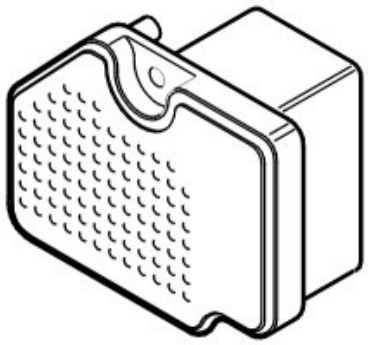
Diagnostic trouble code (DTC) information DEM-000B

Condition



Differential Electronic Module (DEM) calculates an expected oil pressure increase in the AOC-unit (the mechanical clutch) during driving. The control module checks how reasonable the oil pressure change is by comparing the calculated value with the signal from the oil pressure sensor. If the signal deviates too much from the expected value the control module interprets this as a malfunction, and the diagnostic trouble code is generated.
The diagnostic trouble code (DTC) can be diagnosed when driving.

Substitute value
- Four wheel drive is disengaged.

Possible source
- Damaged temperature sensor.
- Damaged AOC unit (mechanic clutch).
- Oil leakage.
- Damaged Differential Electronic Module (DEM).

Fault symptom[s]
- Four wheel drive is not functioning.

Incorrect Value

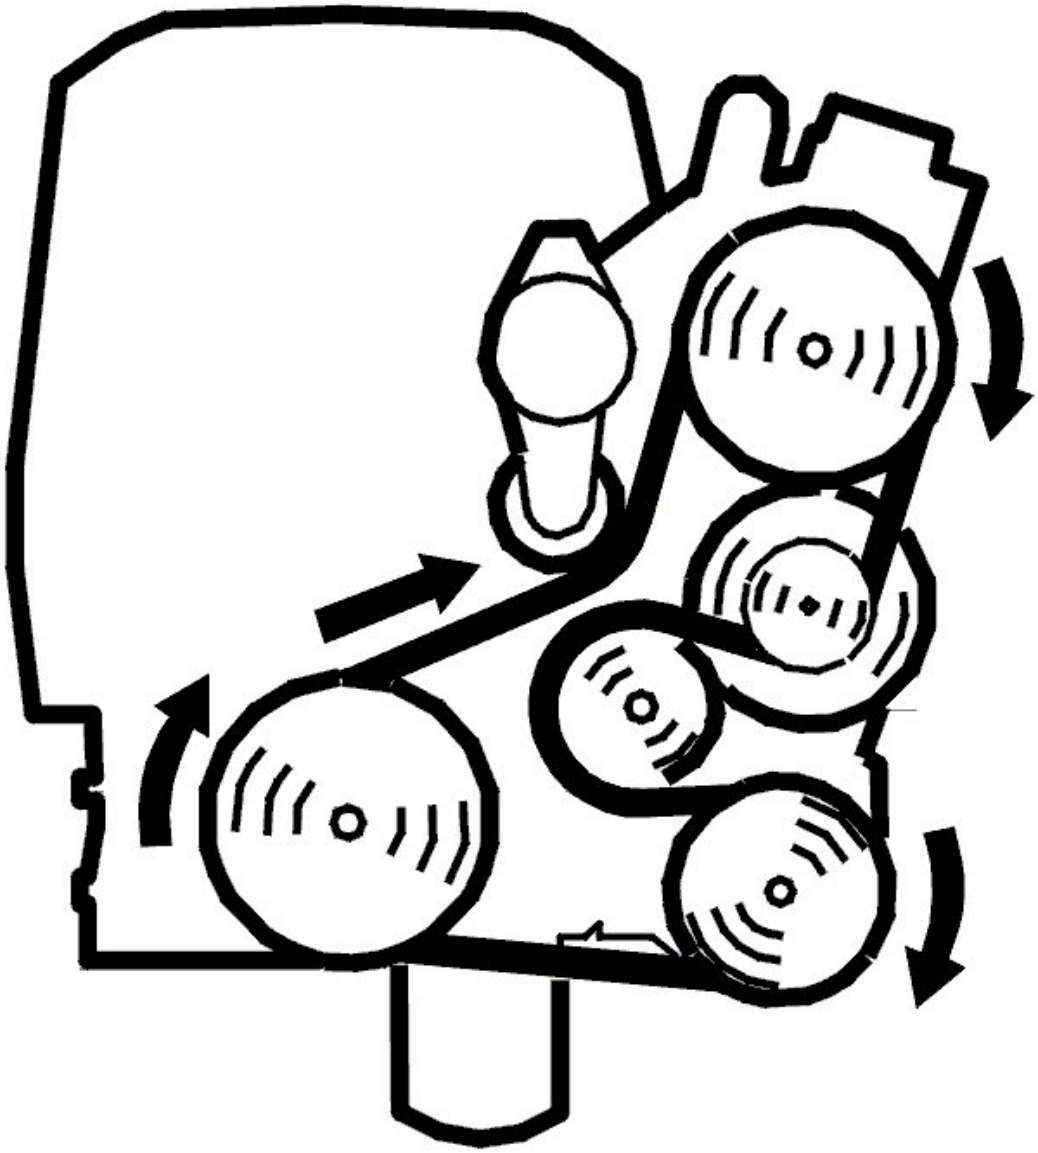
Incorrect value

Information

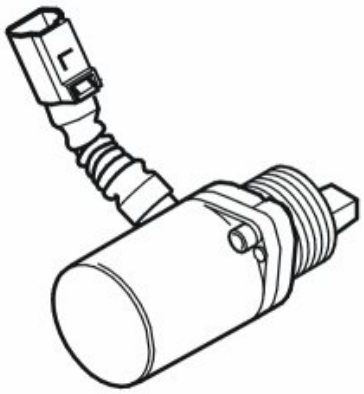
Note! The diagnostic trouble code can also be generated due to damaged AOC-unit (clutch).Check the AOC-unit for visible damages. Listen for noise.Check the oil level in the coupling (Active on Demand Coupling).

Continue - Checking components

Checking components



- Engine idling.



Check the function of the oil pump.
Listen using a stethoscope or a screwdriver pressed to your ear. The oil pump motor shall hum and vibrate slightly.

Note! The pump motor may sound like it's running but in certain cases it only oscillates.

Is the feed pump working?

Yes - Information

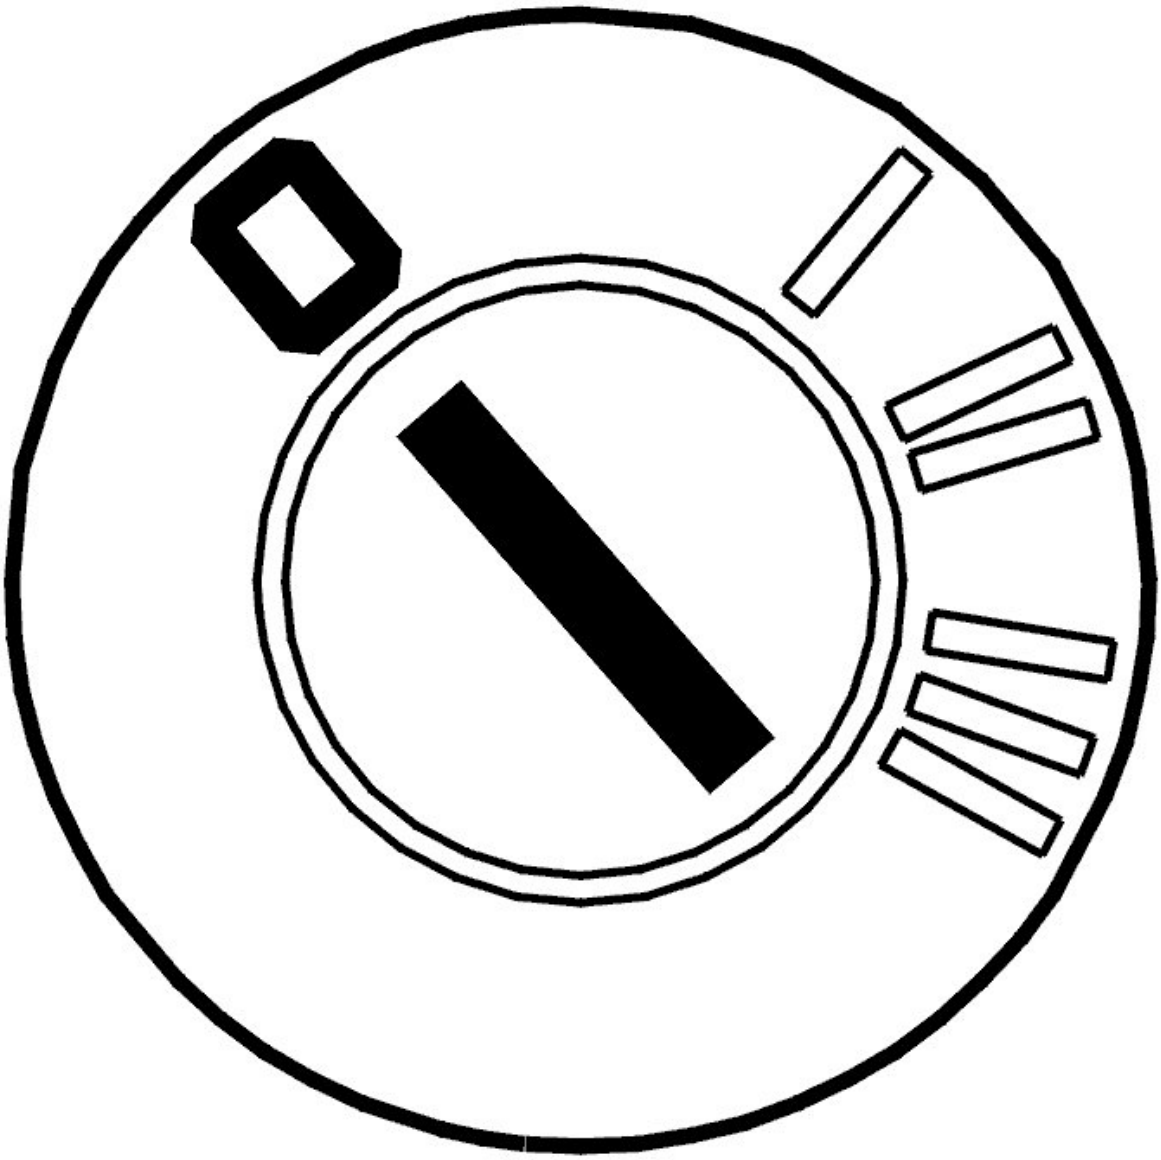
No - Checking the connectors and cables

Information

Note! The brake control module (BCM) can cause interference in the differential electronic module (DEM). For example, incorrect information from one of the wheel speed sensors causes the information from the Brake control module (BCM) to store a diagnostic trouble code (DTC). Therefore, troubleshoot the Brake Control Module (BCM) for incorrect signals from the wheel speed sensors.

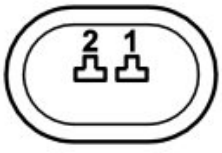
Continue - Checking the function

Checking the connectors and cables

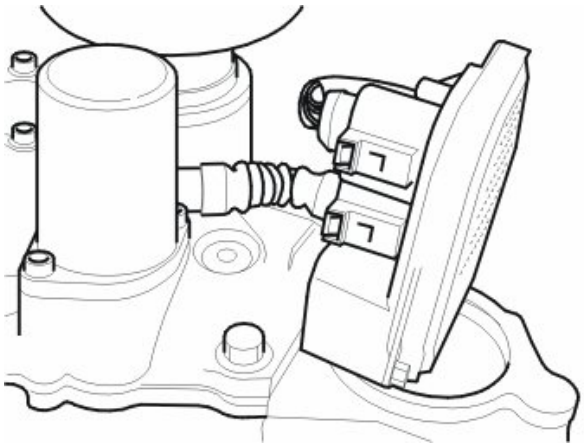


- Ignition off.

Check the connector between the Differential Electronic Module (DEM) and the feed pump with respect to contact resistance and oxidation.
Check the lead between the Differential Electronic Module (DEM) and the feed pump for damage.
Reinstall the connectors, components etc.



- Engine idling.



Check the function of the oil pump.
Listen using a stethoscope or a screwdriver pressed to your ear. The oil pump motor shall hum and vibrate slightly.

Note! The pump motor may sound like it's running but in certain cases it only oscillates.

Remedy as necessary.

Diagnostic Trouble Code (DTC) Information

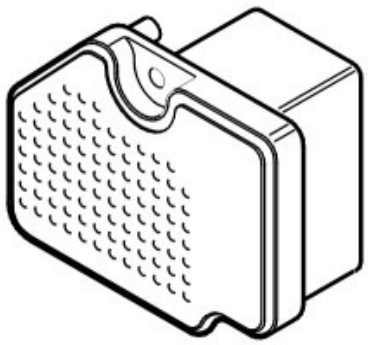
Diagnostic trouble code (DTC) information DEM-E000

Condition



The control modules transmit and receive information via a standardized serial communication method - CAN (Control Area Network). The diagnostic trouble code (DTC) is stored if the control module registers serious interference (CAN communication blocked).

Note! In the event of system communication problems, it is not possible to communicate with the control module. Therefore it will only be possible to read off the diagnostic trouble code (DTC) if the fault is intermittent.

Substitute value
- The control module shuts itself off ("bus-off").

Hint: Control module will remain shut off until the power supply is broken (15, 30, X). When the power supply is connected the control module will make a new attempt to communicate.

Possible source
- Short-circuit between the control area network (CAN) wiring
- Open-circuit in the control area network (CAN) wiring
- Internal fault in the control module
- Internal fault in another control module in the same part of the control area network (CAN).

Fault symptom[s]
- Four wheel drive is not functioning
- Message in the display
- The anti-spin warning lamp is lit
- General warning lamp lit.

Signal Missing

Signal missing

General information

Note! Figures shown are only examples.

Hint: For general information about CAN-troubleshooting, see:

- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

General about CAN-related diagnostic trouble codes.
CEM-DF01 - DF17can only be stored in Central electronic module (CEM). These diagnostic trouble codes are stored when an electric fault is detected in CAN-lines. Start with these diagnostic trouble codes first.
CEM-1AXX only stored in Central electronic module (CEM). One diagnostic trouble code for every control module on the CAN-net. These diagnostic trouble codes indicate that Central electronic module (CEM) does not receive any reply from other control modules.
XXX-E000 (HS-CAN)/E001 (LS-CAN) can be stored in all CAN-connected control modules. These diagnostic trouble codes indicate that the control module has detected interference on the CAN-net.
XXX-E003 can be stored in all CAN-connected control modules except in Central electronic module (CEM). The control modules on the CAN-net listen for a message (identity number) that is sent out at regular intervals from Central electronic module (CEM). This diagnostic trouble code indicates that the control module has not received any identity number, or that the expected number is not correct. Interference on the CAN-net can also store this diagnostic trouble code.

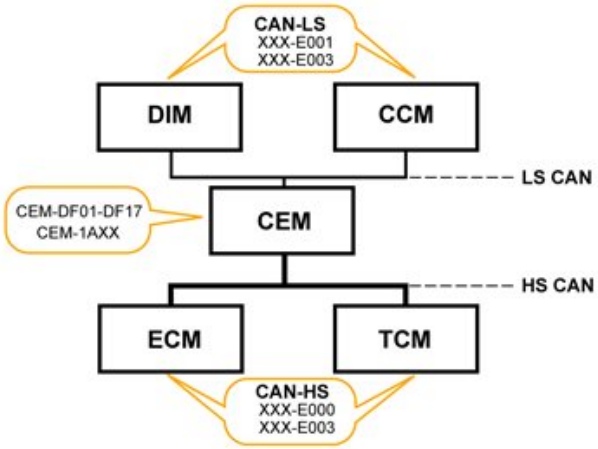
Note! In case of CAN-related faults, it is likely that a combination of above diagnostic trouble codes occur.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

If a communication diagnostic trouble code can be read from the control module, the malfunction is probably intermittent.
Intermittent fault in the voltage supply and ground to a control module on the CAN network results in the Central electronic module (CEM) storing a diagnostic trouble code (DTC) for an open-circuit in communication with the control module where the voltage supply does not work. There will probably not be a diagnostic trouble code (DTC) in the control module where the open-circuit in the voltage supply occurred as the control module cannot store a diagnostic trouble code (DTC) when it is not supplied with power.

Note! Central electronic module (CEM) should not be replaced in case of CAN-fault, unless troubleshooting reveals that Central electronic module (CEM) has an internal fault.

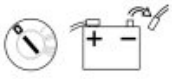
Caution! During this fault-tracing use the wiring diagram to provide support when taking readings.



Select "Continue".

Continue - Checking resistance in CAN-net

Checking resistance in CAN-net



- Ignition off
- Disconnect the battery negative lead
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #6 and #14. The resistance should be approx. 55 - 65 ohms.
- If resistance is approx. 120 ohms, this indicates open circuit in the circuit so that only one terminating resistor (120 ohms) has been measured.
- If resistance is above 1 kohms this indicates open circuit/high contact resistance somewhere in the circuit.
- If resistance is below 55 ohms this indicates short-circuiting/contact resistance between the CAN-lines somewhere in the circuit.

Hint: For HS-CAN (High Speed) the terminating resistors are located in Brake control module (BCM) and in Engine control module (ECM).

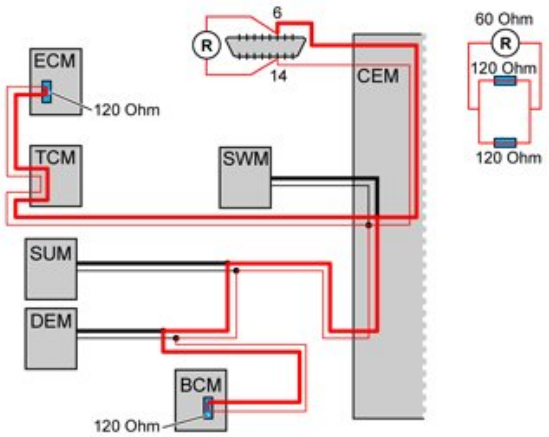
Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

Note! Resistance measurement measures only main lines in the CAN-net (in circuit where both terminating resistors are found), not branches to certain control modules. See wiring diagram for vehicle model in question.Open circuit on branching without a terminating resistor cannot be detected with this measurement. However, short-circuiting on a branch can be detected. To measure resistance in the CAN-net to control modules located in a branching of their own, the measurement shall be done against the CAN-net at that control module. The values shall be as above.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy wiring as necessary.

Other information
- Battery, disconnecting See: Starting and Charging/Battery/Service and Repair/Procedures/Battery, Disconnecting
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

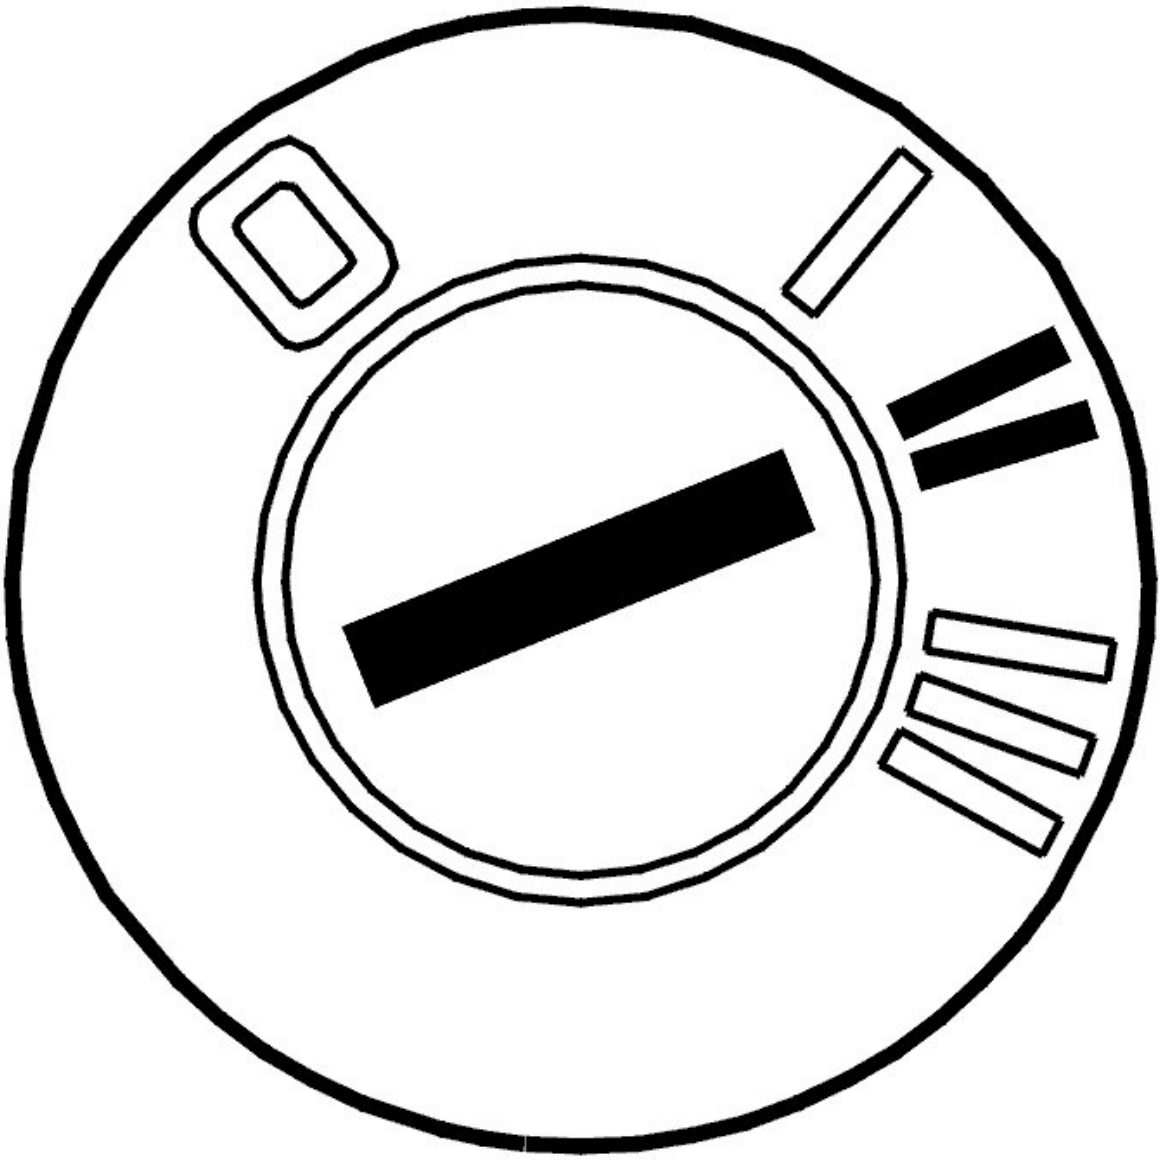


Was a fault detected?

Yes - Verification

No - Checking short-circuiting to ground/voltage in CAN-net

Checking the traffic load on the CAN cables



- Connect the battery
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Faults in the CAN network may be due to a control module sending faulty messages that disrupt normal communication. When messages are sent incorrectly, this results in a considerable increase in the amount of traffic on the CAN network. Check the load by measuring the average voltage value on the CAN cables in relation to ground.
For further information, see the wiring diagram.
Measure voltage between the following connections on the OBDII-box/diagnostics socket.
- #6 and #4 (ground). The voltage should be approx: 2,8 - 3,2 V.
- #14 and #4 (ground). The voltage should be approx: 1,8 - 2,2 V.
- #6 and #14. The voltage shall be between approx. 0.55-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Hint: DiCE Error Frame Finder can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools: **951 3010** (memory card) as well as associated TJ 20402.

- Ignition on.
- Connect DiCE Error Frame Finder to the diagnostics socket.
- Note the blue LED-indicator. The indicator flashes to show detection of fault messages.

Note! Certain interference may occur without any real fault!

Cable fault

- Shake the cables lightly and pull lightly on the connections during the check to locate any fault. Note the blue LED-indicator.

"Chatting" control modules

- "Chatting" control modules may be difficult to find and troubleshooting may take time. Let the vehicle stand with DiCE connected for an extended time period. Afterwards, activate functions to provoke a malfunction. It may take up to several hours before the fault messages are sent. When the indicator starts to flash, remove the fuse for one control module at a time until the indicator stops flashing. When the indicator stops flashing, restore the fuse for the relevant control module and check that the indicator starts to flash again. Then it is likely that the problem is identified.

Remedy wiring as necessary.

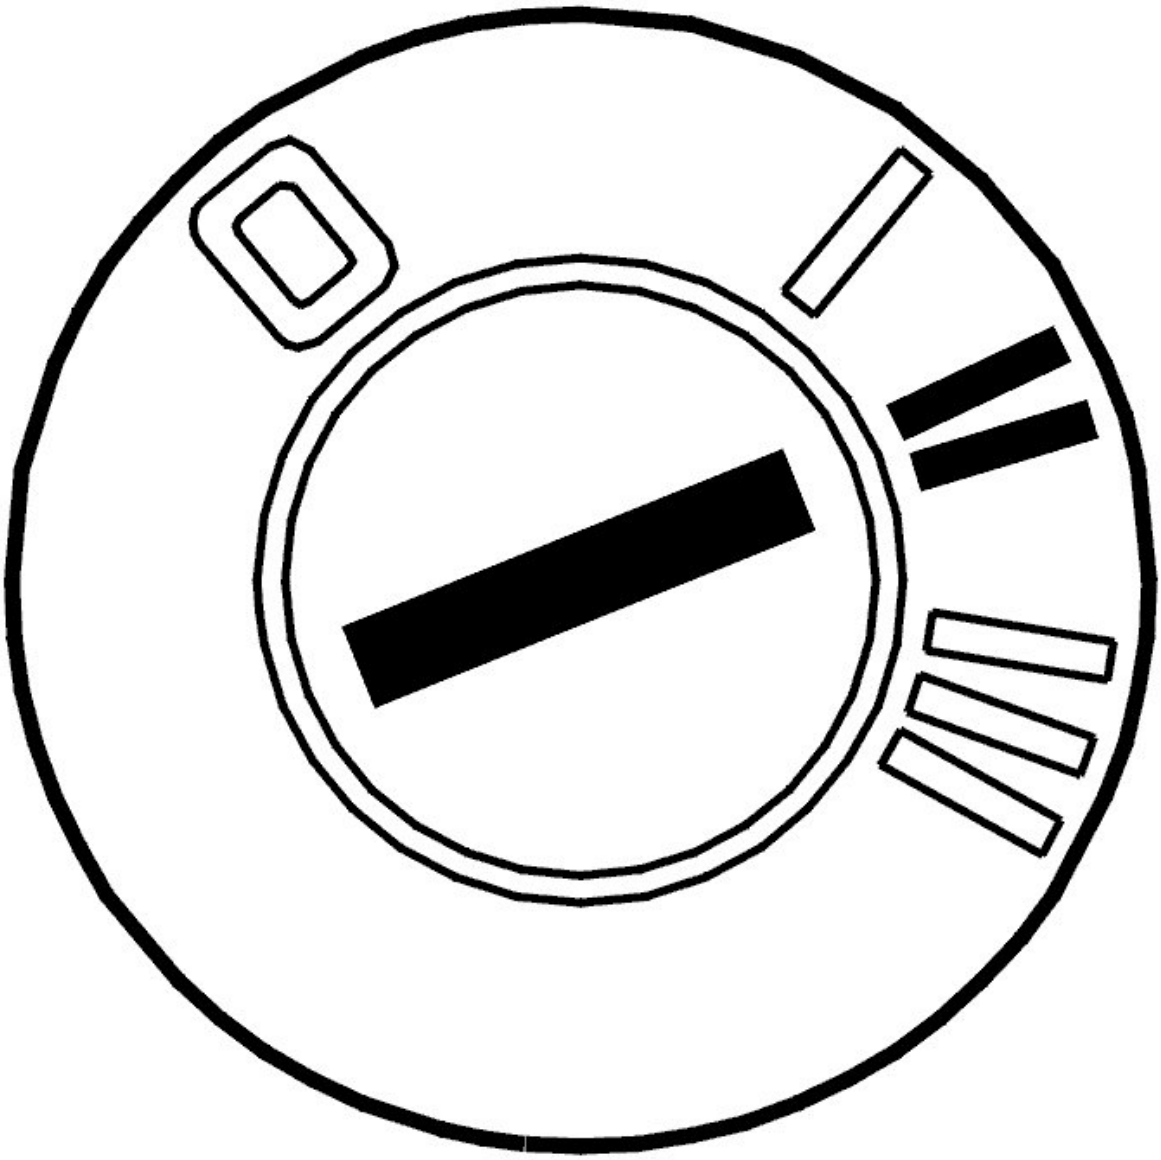
Was a fault detected?

Yes - Identifying a control module in the CAN network

No - respectively

Identifying a control module in the CAN network



Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:

- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Hint: DiCE Error Frame Finder can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools: **951 3010** (memory card) as well as associated TJ 20402.

If the load on the CAN network is too high, this may be due to a control module sending faulty messages on the CAN network (known as a disruptive control module). The fault may also be due to an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The faults can occur without a diagnostic trouble code (DTC) being stored by the control modules. The voltage can be measured between the CAN cables in order to check the load on the CAN network.

Note! It is not necessarily the control module(s) that stored the diagnostic trouble code (DTC) that is communicating faultily. Faulty messages can come from any control module in the same section of the CAN network. However, faulty communication in one network cannot affect the communication on the other network. In other words, faulty communication on the LS-CAN cannot disrupt communication on the HS-CAN and vice versa.

- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Check communication/load on CAN-net by measuring voltage between CAN-L and CAN-H. Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #6 and #14. The average value of the voltage must be approximately 0.6-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

In order to identify which control module has faulty communication, cut the power supply to one control module at a time. Check the voltage in the

CAN cables again. The easiest way to cut the power supply is to remove the fuse(s) for the relevant control module. Repeat until the voltage between the CAN wiring drops to the normal level.

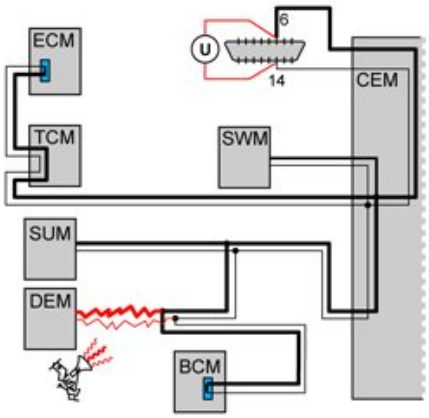
Note! When connecting and disconnecting individual control modules, other diagnostic trouble codes (DTCs) may be stored in certain control modules.

Hint: When the suspected defective control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the malfunction appears and disappears. Switch off the ignition between each check.

Note! Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.

A control module that is communicating incorrectly must be replaced. See Repairing and installing/Removing, replacing and installing.

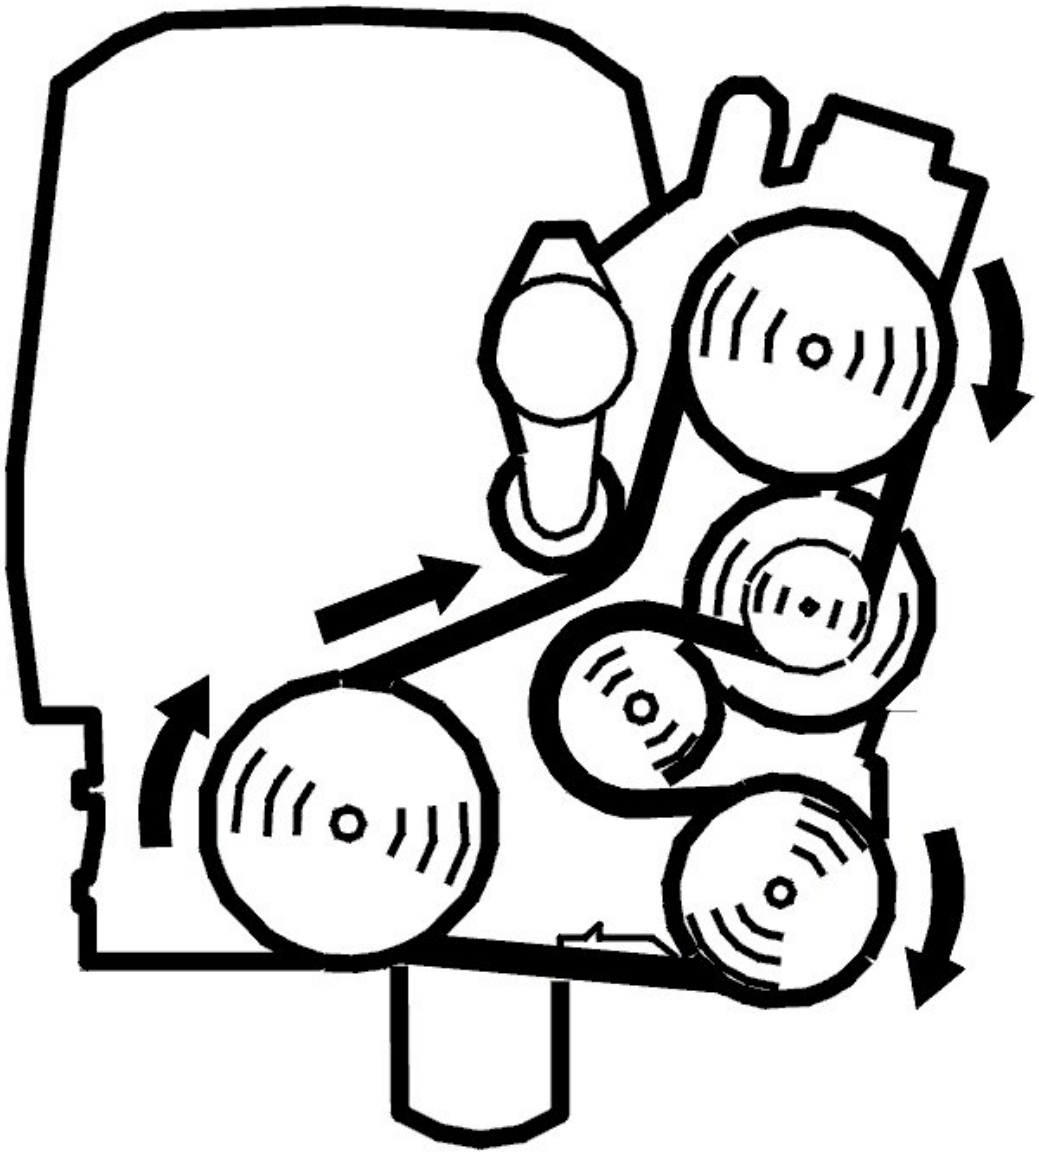
Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

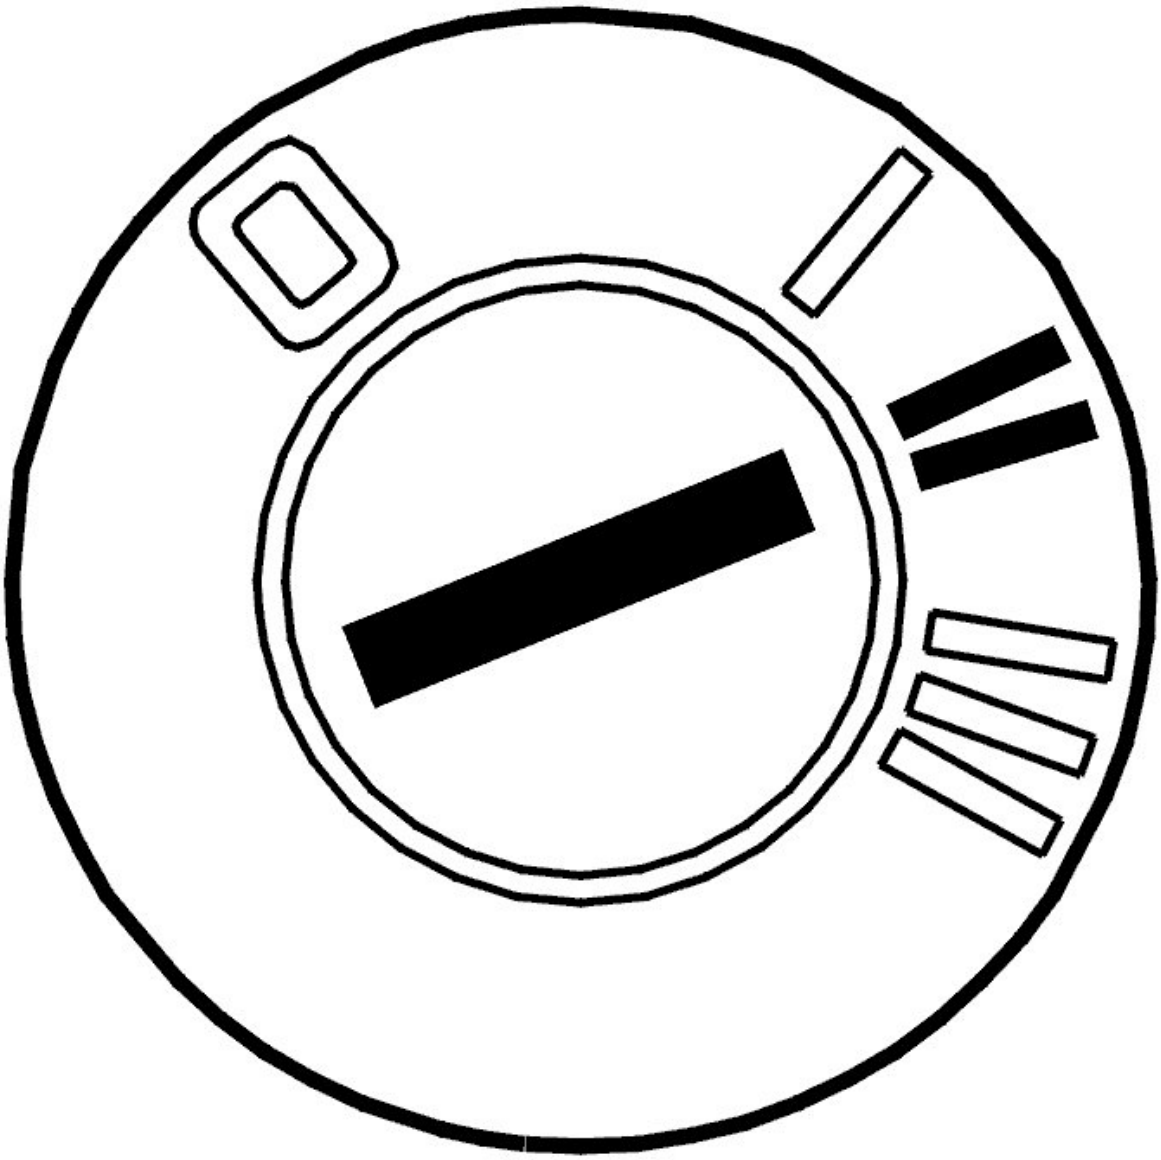


Continue - Verification

Verification

Hint: After rectifying a fault, a verification should be carried out.





- Reinstall the connectors, components etc.
- Ignition on.

Note! For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

- Erase diagnostic trouble codes (DTCs) in all control modules.
- Ignition off.
- Ignition on.
- Start the vehicle. Allow the vehicle to run for 10 minutes.
- Read out the diagnostic trouble codes in the vehicle via the DIAGNOSTICS tab.

Does the diagnostic trouble code (DTC) for faulty communication return?

Yes - Fault-tracing information

No - Fault Found

Fault-tracing information

Information

Fault-tracing information

The fault should have been detected and remedied. As this is not the case fault-tracing has failed.
Exit fault-tracing for this diagnostic trouble code (DTC) or make another attempt.

Do you want to exit fault-tracing?

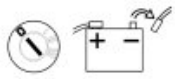
Yes - **FAULT-TRACING FAILED**

No - **Attempt New Test**

FAULT-TRACING FAILED - **FAULT-TRACING FAILED**

Attempt New Test - General information

Checking short-circuiting to ground/voltage in CAN-net



- Ignition off.
- Disconnect the battery negative lead.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Checking for a short-circuit to ground

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #6 and #4 (ground). Measurement is shown in the figure. The resistance should be above 1 kohms.
- #14 and #4 (ground). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and ground.

Checking for a short-circuit to voltage

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #6 and #16 (voltage). Measurement is shown in the figure. The resistance should be above 1 kohms.
- #14 and #16 (voltage). The resistance should be above 1 kohms.

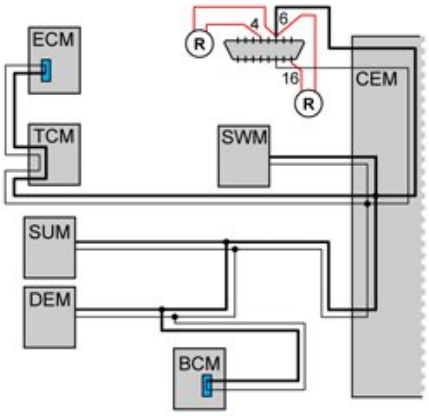
If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and voltage cable.
Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

Hint: Part the CAN-net at suitable points to decide where a short-circuit may be found.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy wiring as necessary.

Other information
- Battery, disconnecting See: Starting and Charging/Battery/Service and Repair/Procedures/Battery, Disconnecting
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

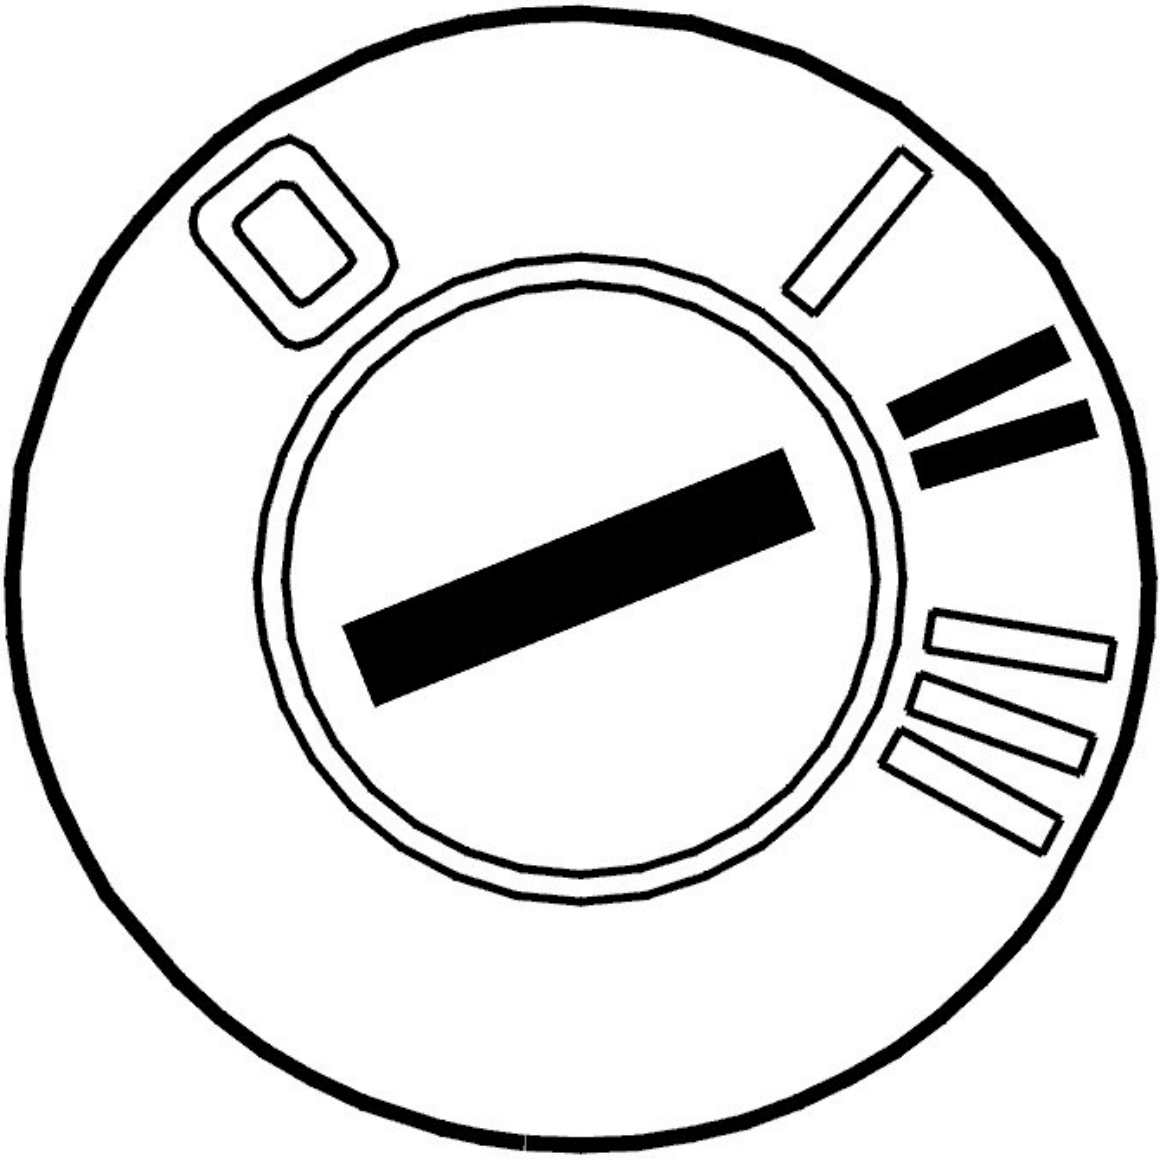


Was a fault detected?

Yes - Verification

No - Checking the traffic load on the CAN cables

Checking voltage-drop in cable for CAN-H and CAN-L, respectively



- Connect the battery.
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

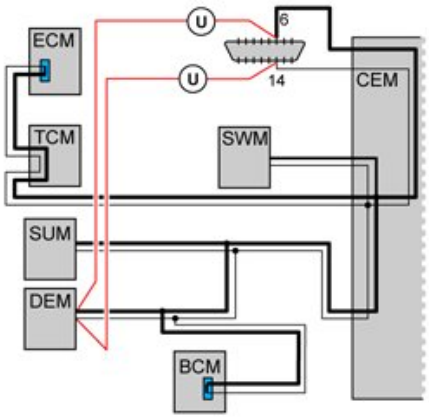
In principle, the voltage measured in each cable in the CAN-net shall be the same at each control module in the network. This means that the voltage-drop in the cable for CAN-H and CAN-L, respectively, between the control modules should be very low. If there is a voltage-difference in the CAN-lines between the diagnostics socket/Central electronic module (CEM) and a control module due to, e.g., contact resistance in a connector or branching, communication may be lost/interfered with.
Check if there is voltage-drop in the cable for CAN-H and CAN-L between the diagnostics socket/Central electronic module (CEM) and the control module where there is problem with communication.
Carry out the following:
Measure voltage between the following connections on the OBDII-box/diagnostics socket.
- #6 and corresponding connection on relevant control module for CAN-H. The voltage shall be lower than 50 mV.
- #14 and corresponding connection on relevant control module for CAN-L. The voltage shall be lower than 50 mV.

If voltage is too high, this indicates too high contact resistance in cable, connector, or branching. Check the circuit between the diagnostics socket and control module in question for contact resistance and oxidation.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy wiring as necessary.

Other information
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

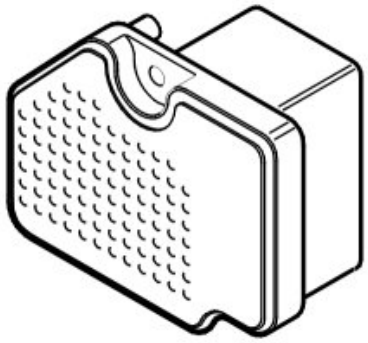


Continue - Verification

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information DEM-E003

Condition



The control module compares its configuration ID with the signal configuration transmitted on the control area network (CAN) by the central electronic module (CEM). If the configuration IDs do not correspond the fault code is stored. The diagnostic trouble code (DTC) is also stored if the communication between the control module and the central electronic module (CEM) is interrupted.

Note! In the event of an open-circuit in both the control area network (CAN) cables, it is not possible to communicate with the control module. Therefore it will only be possible to read off the diagnostic trouble code (DTC) if this type of fault is intermittent. When the diagnostic trouble code (DTC) is stored, the control module responds to the diagnostic command, however normal control area network (CAN) communication does not work. ("Expulsion-mode").

Substitute value
- None.

Possible source
- Incorrect CAN configuration ID. (The node is not intended for this vehicle, for example, a used control module with different software/hardware)
- Open-circuit in the control area network (CAN) wiring between the control module and the central electrical module (CEM).

Fault symptom[s]
- Four wheel drive is not functioning
- Message in the display
- The anti-spin warning lamp is lit
- General warning lamp lit.

Signal Missing

Signal missing

General information

Note! Figures shown are only examples.

Hint: For general information about CAN-troubleshooting, see:
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

General about CAN-related diagnostic trouble codes.
CEM-DF01 - DF17can only be stored in Central electronic module (CEM). These diagnostic trouble codes are stored when an electric fault is detected in CAN-lines. Start with these diagnostic trouble codes first.
CEM-1AXX only stored in Central electronic module (CEM). One diagnostic trouble code for every control module on the CAN-net. These diagnostic trouble codes indicate that Central electronic module (CEM) does not receive any reply from other control modules.
XXX-E000 (HS-CAN)/E001 (LS-CAN) can be stored in all CAN-connected control modules. These diagnostic trouble codes indicate that the control module has detected interference on the CAN-net.
XXX-E003 can be stored in all CAN-connected control modules except in Central electronic module (CEM). The control modules on the CAN-net listen for a message (identity number) that is sent out at regular intervals from Central electronic module (CEM). This diagnostic trouble code indicates that the control module has not received any identity number, or that the expected number is not correct. Interference on the CAN-net can also store this diagnostic trouble code.

Note! In case of CAN-related faults, it is likely that a combination of above diagnostic trouble codes occur.

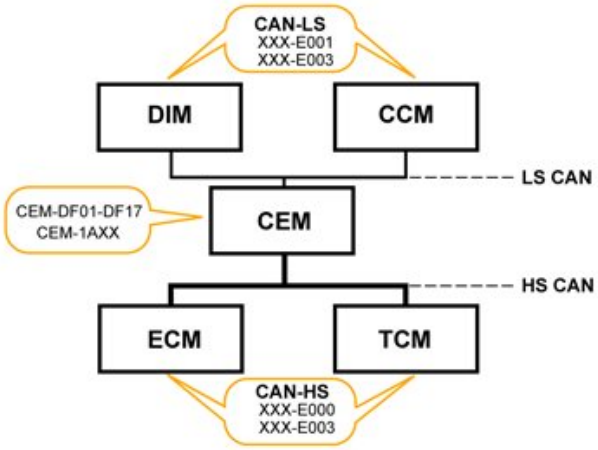
Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

If a communication diagnostic trouble code can be read from the control module, the malfunction is probably intermittent.

Intermittent fault in the voltage supply and ground to a control module on the CAN network results in the Central electronic module (CEM) storing a diagnostic trouble code (DTC) for an open-circuit in communication with the control module where the voltage supply does not work. There will probably not be a diagnostic trouble code (DTC) in the control module where the open-circuit in the voltage supply occurred as the control module cannot store a diagnostic trouble code (DTC) when it is not supplied with power.

Note! Central electronic module (CEM) should not be replaced in case of CAN-fault, unless troubleshooting reveals that Central electronic module (CEM) has an internal fault.

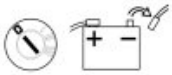
Caution! During this fault-tracing use the wiring diagram to provide support when taking readings.



Select "Continue".

Continue - Checking resistance in CAN-net

Checking resistance in CAN-net



- Ignition off
- Disconnect the battery negative lead
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #6 and #14. The resistance should be approx. 55 - 65 ohms.
- If resistance is approx. 120 ohms, this indicates open circuit in the circuit so that only one terminating resistor (120 ohms) has been measured.
- If resistance is above 1 kohms this indicates open circuit/high contact resistance somewhere in the circuit.
- If resistance is below 55 ohms this indicates short-circuiting/contact resistance between the CAN-lines somewhere in the circuit.

Hint: For HS-CAN (High Speed) the terminating resistors are located in Brake control module (BCM) and in Engine control module (ECM).

Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

Note! Resistance measurement measures only main lines in the CAN-net (in circuit where both terminating resistors are found), not branches to certain control modules. See wiring diagram for vehicle model in question.Open circuit on branching without a terminating resistor cannot be detected with this measurement. However, short-circuiting on a branch can be detected. To measure resistance in the CAN-net to control modules located in a branching of their own, the measurement shall be done against the CAN-net at that control module. The values shall be as above.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they

work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy wiring as necessary.

Other information

- Battery, disconnecting See: Starting and Charging/Battery/Service and Repair/Procedures/Battery, Disconnecting

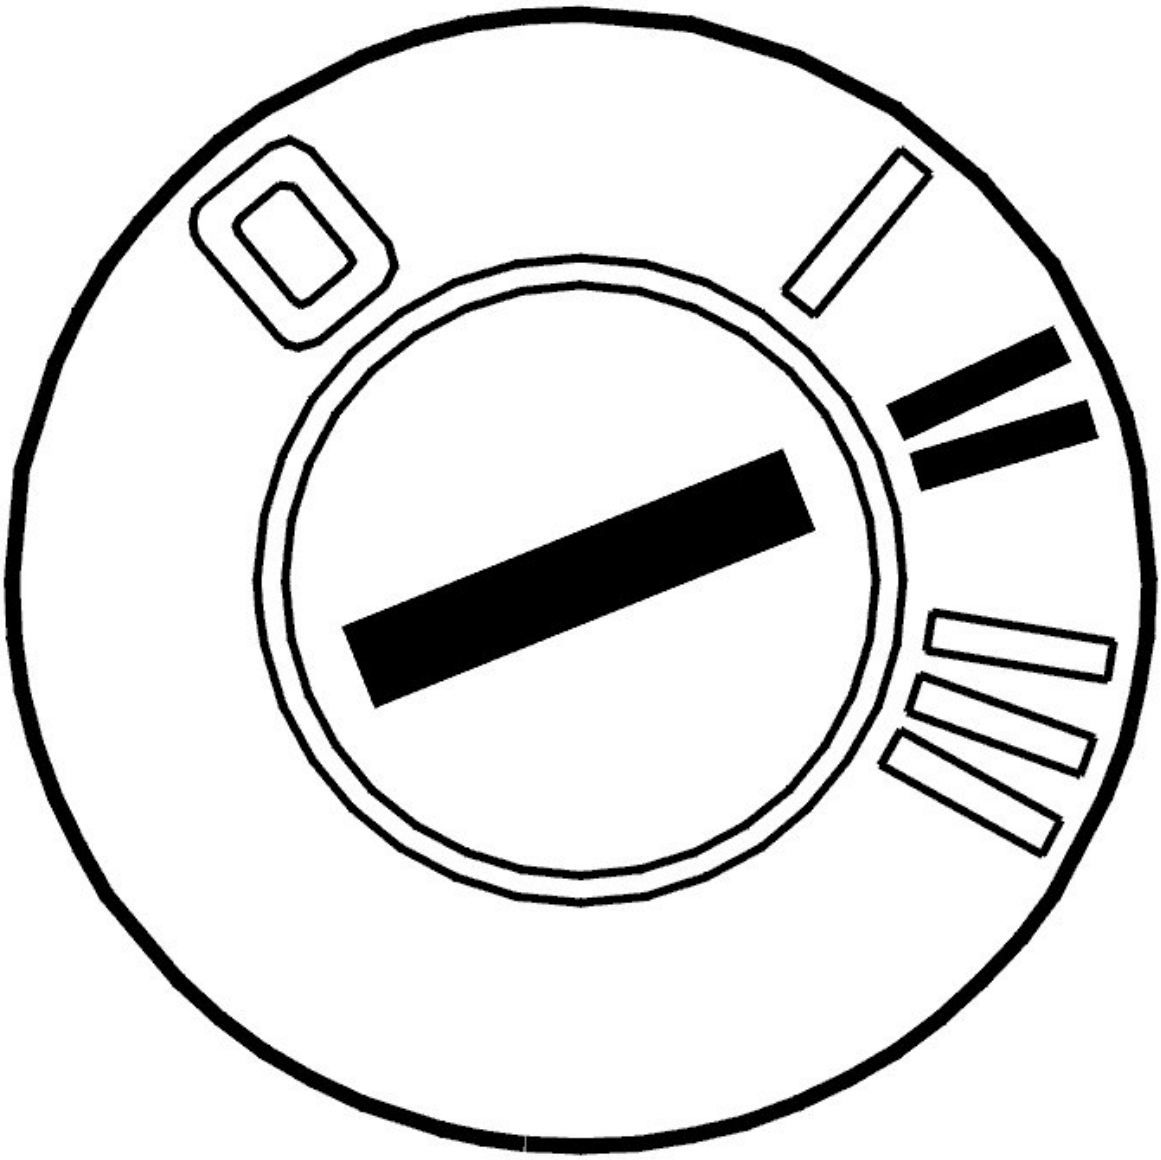
Was a fault detected?

Yes - Verification

No - Checking short-circuiting to ground/voltage in CAN-net

Checking the traffic load on the CAN cables



- Connect the battery
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Faults in the CAN network may be due to a control module sending faulty messages that disrupt normal communication. When messages are sent incorrectly, this results in a considerable increase in the amount of traffic on the CAN network. Check the load by measuring the average voltage value on the CAN cables in relation to ground.
For further information, see the wiring diagram.
Measure voltage between the following connections on the OBDII-box/diagnostics socket.
- #6 and #4 (ground). The voltage should be approx: 2,8 - 3,2 V.
- #14 and #4 (ground). The voltage should be approx: 1,8 - 2,2 V.
- #6 and #14. The voltage shall be between approx. 0.55-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Hint: DiCE Error Frame Finder can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools: **951 3010** (memory card) as well as associated TJ 20402.

- Ignition on.
- Connect DiCE Error Frame Finder to the diagnostics socket.
- Note the blue LED-indicator. The indicator flashes to show detection of fault messages.

Note! Certain interference may occur without any real fault!

Cable fault

- Shake the cables lightly and pull lightly on the connections during the check to locate any fault. Note the blue LED-indicator.

"Chatting" control modules

- "Chatting" control modules may be difficult to find and troubleshooting may take time. Let the vehicle stand with DiCE connected for an extended time period. Afterwards, activate functions to provoke a malfunction. It may take up to several hours before the fault messages are sent. When the indicator starts to flash, remove the fuse for one control module at a time until the indicator stops flashing. When the indicator stops flashing, restore the fuse for the relevant control module and check that the indicator starts to flash again. Then it is likely that the problem is identified.

Remedy wiring as necessary.

Hint: DiCE Error Frame Finder can be used as fault detection tool if fault is suspected on the CAN-net that cannot be detected with normal troubleshooting. Interference, intermittent faults, faulty messages on the CAN-net (chattering control modules) etc., are examples of such faults. The tool registers fault messages used on the CAN-net. Fault messages may be caused by short intermittent malfunctions on the CAN-net or by a control module sending fault messages. See tools: **951 3010** (memory card) as well as associated TJ 20402.

If the load on the CAN network is too high, this may be due to a control module sending faulty messages on the CAN network (known as a disruptive control module). The fault may also be due to an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The faults can occur without a diagnostic trouble code (DTC) being stored by the control modules. The voltage can be measured between the CAN cables in order to check the load on the CAN network.

Note! It is not necessarily the control module(s) that stored the diagnostic trouble code (DTC) that is communicating faultily. Faulty messages can come from any control module in the same section of the CAN network. However, faulty communication in one network cannot affect the communication on the other network. In other words, faulty communication on the LS-CAN cannot disrupt communication on the HS-CAN and vice versa.

- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Check communication/load on CAN-net by measuring voltage between CAN-L and CAN-H. Measure voltage between the following connections on the OBDII-box/diagnostics socket.

- #6 and #14. The average value of the voltage must be approximately 0.6-1.4 V. The voltage shall normally be between 0.55 - 0.90 V. A higher voltage may indicate increased traffic on the CAN-net. In case of fault in communication/too high traffic on the CAN-net, the voltage is considerably higher than the above stated values.

In order to identify which control module has faulty communication, cut the power supply to one control module at a time. Check the voltage in the

CAN cables again. The easiest way to cut the power supply is to remove the fuse(s) for the relevant control module. Repeat until the voltage between the CAN wiring drops to the normal level.

Note! When connecting and disconnecting individual control modules, other diagnostic trouble codes (DTCs) may be stored in certain control modules.

Hint: When the suspected defective control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the malfunction appears and disappears. Switch off the ignition between each check.

Note! Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.

A control module that is communicating incorrectly must be replaced. See Repairing and installing/Removing, replacing and installing.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

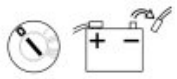
Checking short-circuiting to ground/voltage in CAN-net



- Ignition off.
- Disconnect the battery negative lead.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

Checking for a short-circuit to ground

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #6 and #4 (ground). Measurement is shown in the figure. The resistance should be above 1 kohms.
- #14 and #4 (ground). The resistance should be above 1 kohms.

If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and ground.

Checking for a short-circuit to voltage

Measure resistance between the following connections on the OBDII-box/diagnostics socket.
- #6 and #16 (voltage). Measurement is shown in the figure. The resistance should be above 1 kohms.
- #14 and #16 (voltage). The resistance should be above 1 kohms.

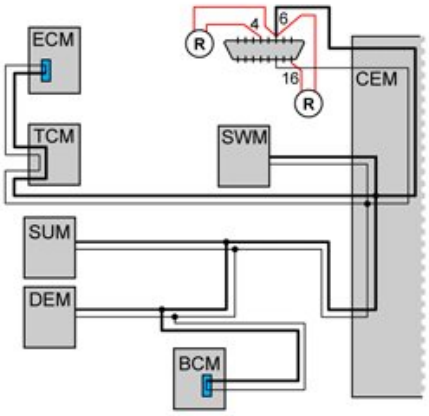
If resistance is below 1 kohms this indicates short-circuiting between the CAN-line and voltage cable.
Twist the cable harness and wiggle connectors where they can be accessed along the cable harness during every measurement, and note if the resistance changes to detect intermittent short-circuits or open circuit.

Hint: Part the CAN-net at suitable points to decide where a short-circuit may be found.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy wiring as necessary.

Other information
- Battery, disconnecting See: Starting and Charging/Battery/Service and Repair/Procedures/Battery, Disconnecting
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

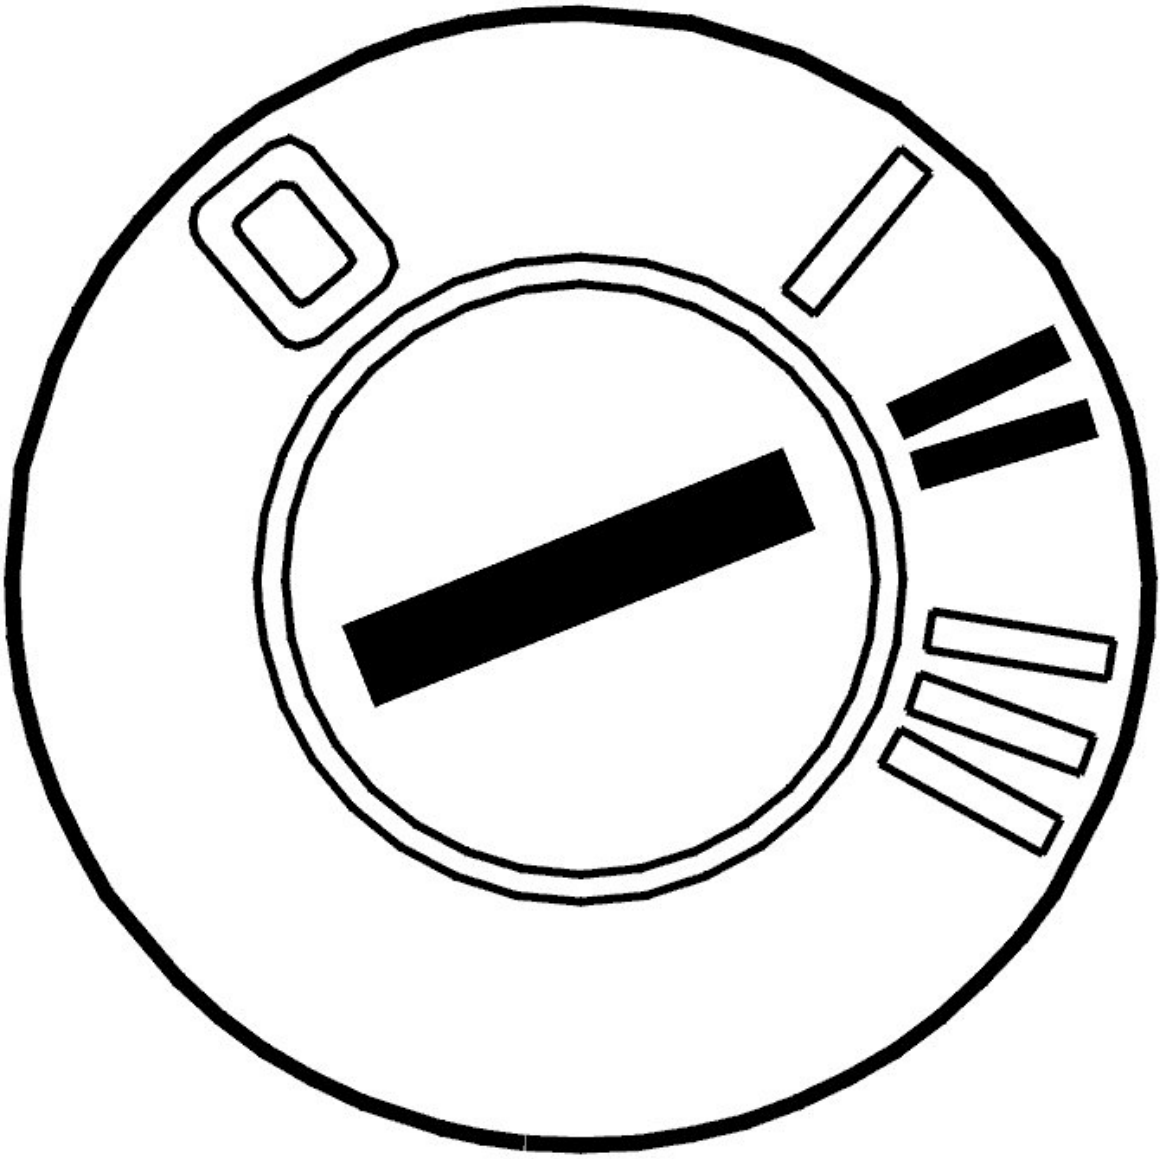


Was a fault detected?

Yes - Verification

No - Checking the traffic load on the CAN cables

Checking voltage-drop in cable for CAN-H and CAN-L, respectively



- Connect the battery.
- Ignition on.
- Connect OBDII-Box **(951 3015)** to the diagnostics socket.

Hint: Use the wiring diagram to provide support when taking readings.

For general information about CAN-troubleshooting, see:
- INFORMATION/PRODUCTSPECIFICATIONS/Design and function/37/CAN-net.
- General information about fault-tracing in the CAN network See: Information Bus/Description and Operation/General Information About Fault-tracing In the CAN Network

In principle, the voltage measured in each cable in the CAN-net shall be the same at each control module in the network. This means that the voltage-drop in the cable for CAN-H and CAN-L, respectively, between the control modules should be very low. If there is a voltage-difference in the CAN-lines between the diagnostics socket/Central electronic module (CEM) and a control module due to, e.g., contact resistance in a connector or branching, communication may be lost/interfered with.
Check if there is voltage-drop in the cable for CAN-H and CAN-L between the diagnostics socket/Central electronic module (CEM) and the control module where there is problem with communication.
Carry out the following:
Measure voltage between the following connections on the OBDII-box/diagnostics socket.
- #6 and corresponding connection on relevant control module for CAN-H. The voltage shall be lower than 50 mV.
- #14 and corresponding connection on relevant control module for CAN-L. The voltage shall be lower than 50 mV.

If voltage is too high, this indicates too high contact resistance in cable, connector, or branching. Check the circuit between the diagnostics socket and control module in question for contact resistance and oxidation.

Note! After fault with control modules that interfere with communication, other control modules may remain in Limp-Home (that is, they work with reduced functionality) even when the ignition has been turned off and on a few times. For certain faults in the CAN-net where control modules have stopped communicating, it may help to disconnect/reconnect the battery to "restart" the control module/CAN-net.

Remedy wiring as necessary.

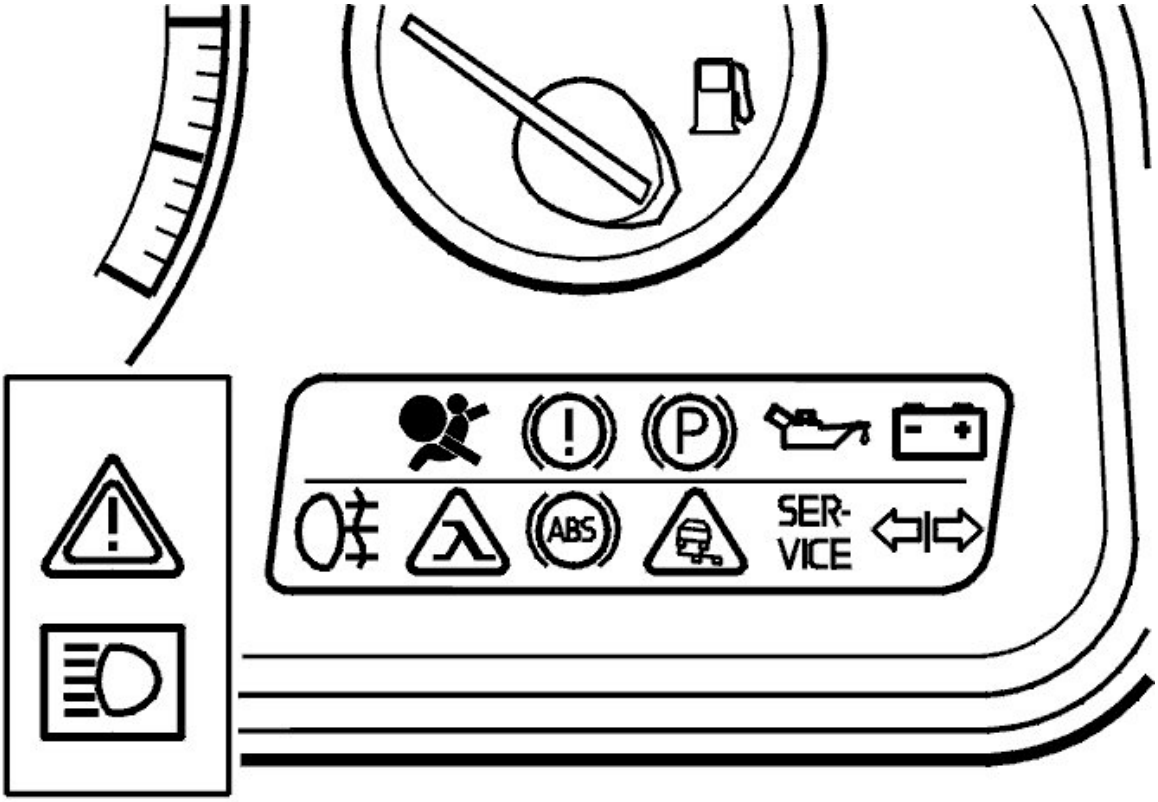
Diagnostic trouble code (DTC) information DIM-0003

Condition



Note! The illustrations in this service information are used for different model years and / or models. Some variation may occur. However, the essential information in the illustrations is always correct.

The diagnostic trouble code (DTC) is stored if the driver information module (DIM) detects an internal open-circuit in the circuit for the SRS warning lamp.

Substitute value
- None.

Possible source
- Software fault in the control module.

Fault symptom[s]
- The SRS warning lamp does not light
- General red warning lamp lit.

Faulty Circuit

Faulty circuit

Checking the diagnostic trouble codes (DTCs)

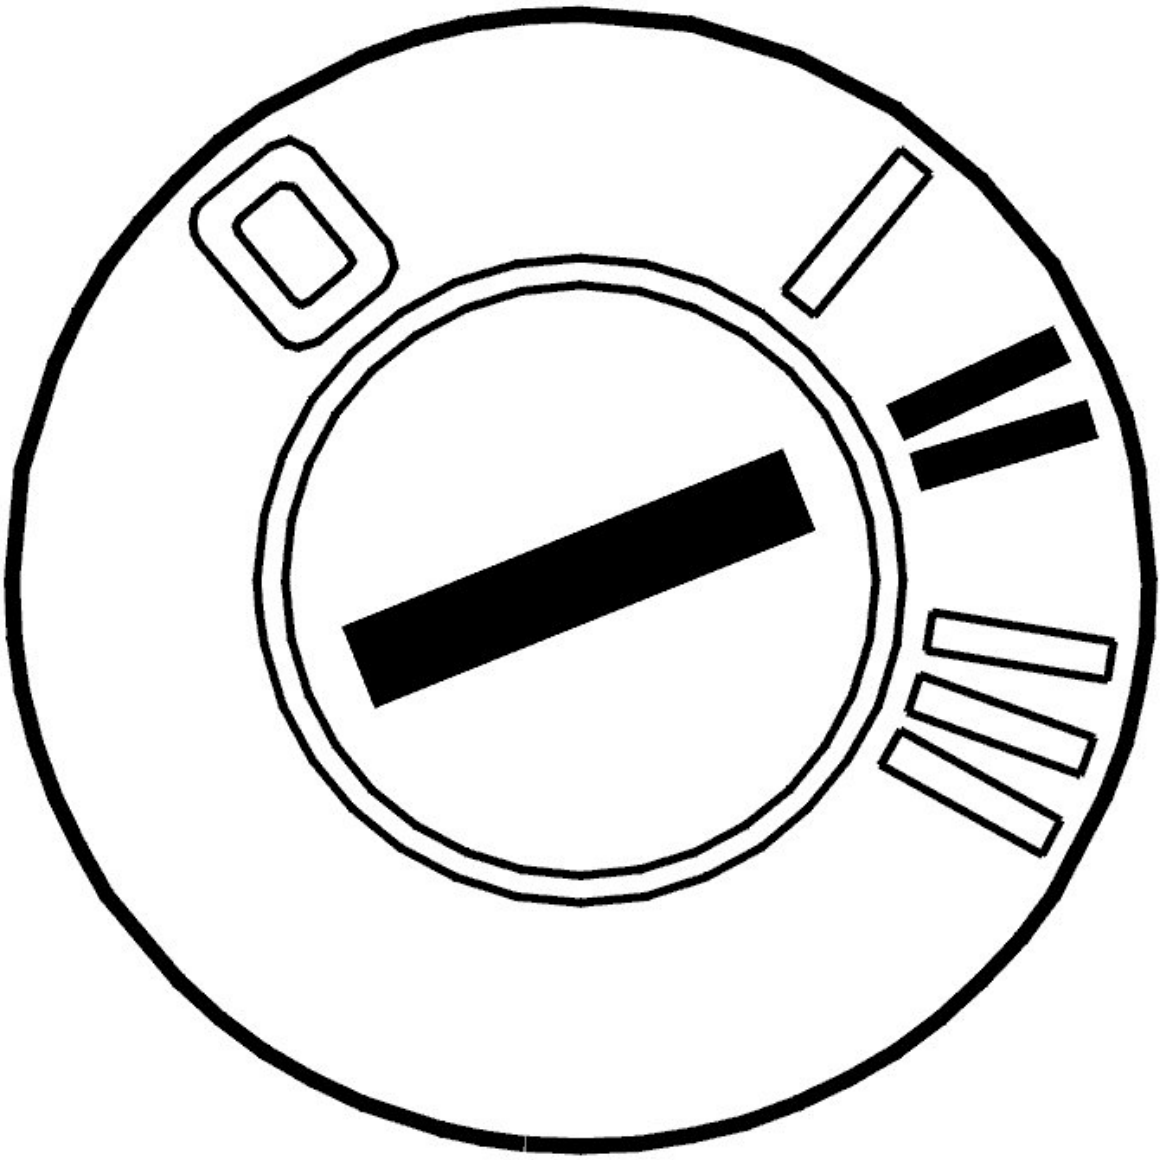
Check and remedy any diagnostic trouble codes (DTCs) in the central electronic module (CEM) before fault-tracing this diagnostic trouble code (DTC).

Were diagnostic trouble codes (DTCs) stored in the central electronic module (CEM)?

Yes - DONE

No - Checking the function of the lamp

Checking the function of the lamp



- Ignition on.

Check whether the lamp lights when the ignition is on.

Does the lamp function?

Yes - DONE

No - Replacing the driver information module (DIM)

Replacing the driver information module (DIM)

Replace the driver information module (DIM). See Driver information module (DIM), replacing See: Instrument Panel, Gauges and Warning Indicators/Instrument Cluster / Carrier/Service and Repair/Driver Information Module (DIM), Replacing.

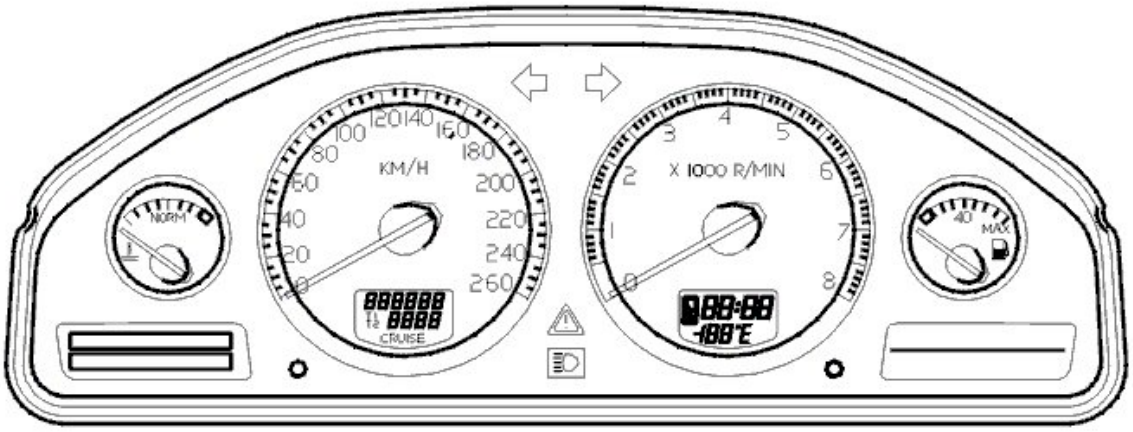
DONE - DONE

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information DIM-000C

Condition



The diagnostic trouble code (DTC) is stored if the control module detects a damaged memory element.

Substitute value
- None.

Possible source
- Damaged memory in the instrument.

Fault symptom[s]
- The combined instrument panel is not functioning.

Internal Fault

Internal fault

Damaged memory element

The diagnostic trouble code (DTC) is stored if the control module has detected a damaged memory element in the driver information module (DIM). This can affect the control module, although not necessarily. Replace the driver information module (DIM) if the customer complains.

Do you want to replace the driver information module (DIM)?

Yes - Replacing the combined instrument panel

No - No Fault Found

Replacing the combined instrument panel

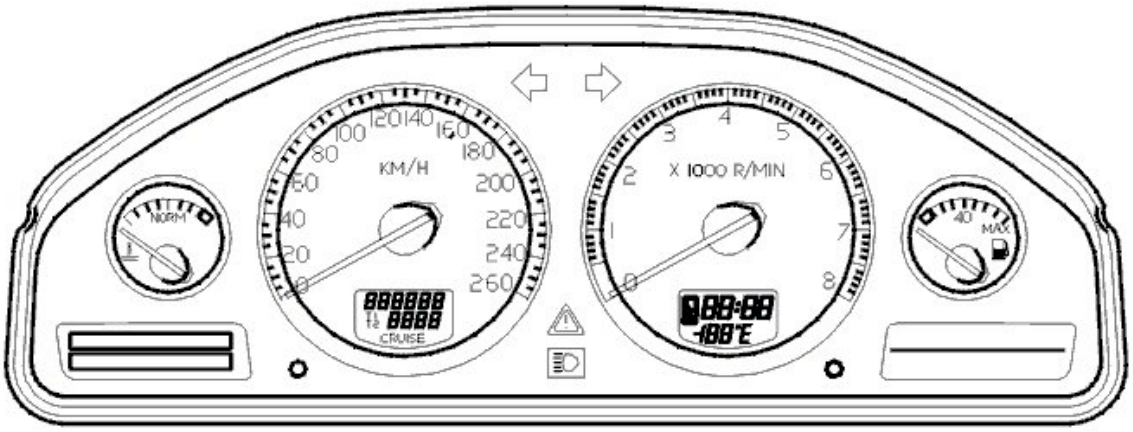
Replace the combined instrument panel. See Driver information module (DIM), replacing See: Instrument Panel, Gauges and Warning Indicators/Instrument Cluster / Carrier/Service and Repair/Driver Information Module (DIM), Replacing.

Continue - Fault Found

DIM-E001

Diagnostic trouble code (DTC) information DIM-E001

Condition



The control modules transmit and receive information via a standardized serial communication method - CAN (Control Area Network). The diagnostic trouble code (DTC) is stored if the control module registers serious interference on the low speed network (CAN communication blocked).

Note! In the event of system communication problems, it is not possible to communicate with the control module. Therefore it will only be possible to read off the diagnostic trouble code (DTC) if the fault is intermittent.

Substitute value
- The control module shuts itself off ("bus-off").

Hint: The driver information module (DIM) will remain shut off until the power supply is broken (15, 30, X). When the power supply is connected the control module will make a new attempt to communicate.

Possible source
- Short-circuit between the control area network (CAN) wiring
- Open-circuit in the control area network (CAN) wiring
- Internal fault in the control module
- Internal fault in another control module in the same part of the control area network (CAN).

Fault symptom[s]
- The ABS warning lamp is lit
- The SPIN warning lamp is lit
- The general red warning lamp is lit
- No vehicle speed display (because there is no signal to the combined instrument panel)
- No gauges working.

DIM-E003

Diagnostic trouble code (DTC) information DIM-E003

Condition

The driver information module (DIM) compares its configuration ID with the signal configuration transmitted on the control area network (CAN) by the central electronic module (CEM). If the configuration IDs do not correspond the fault code is stored. The diagnostic trouble code (DTC) is also stored if the communication between the control module and the central electronic module (CEM) is interrupted.

Note! In the event of an open-circuit in both the control area network (CAN) cables, it is not possible to communicate with the control

module. Therefore it will only be possible to read off the diagnostic trouble code (DTC) if this type of fault is intermittent. When the diagnostic trouble code (DTC) is stored, the control module responds to the diagnostic commands. However, normal control area network (CAN) communication does not work ("Expulsion mode").

Substitute value
- None.

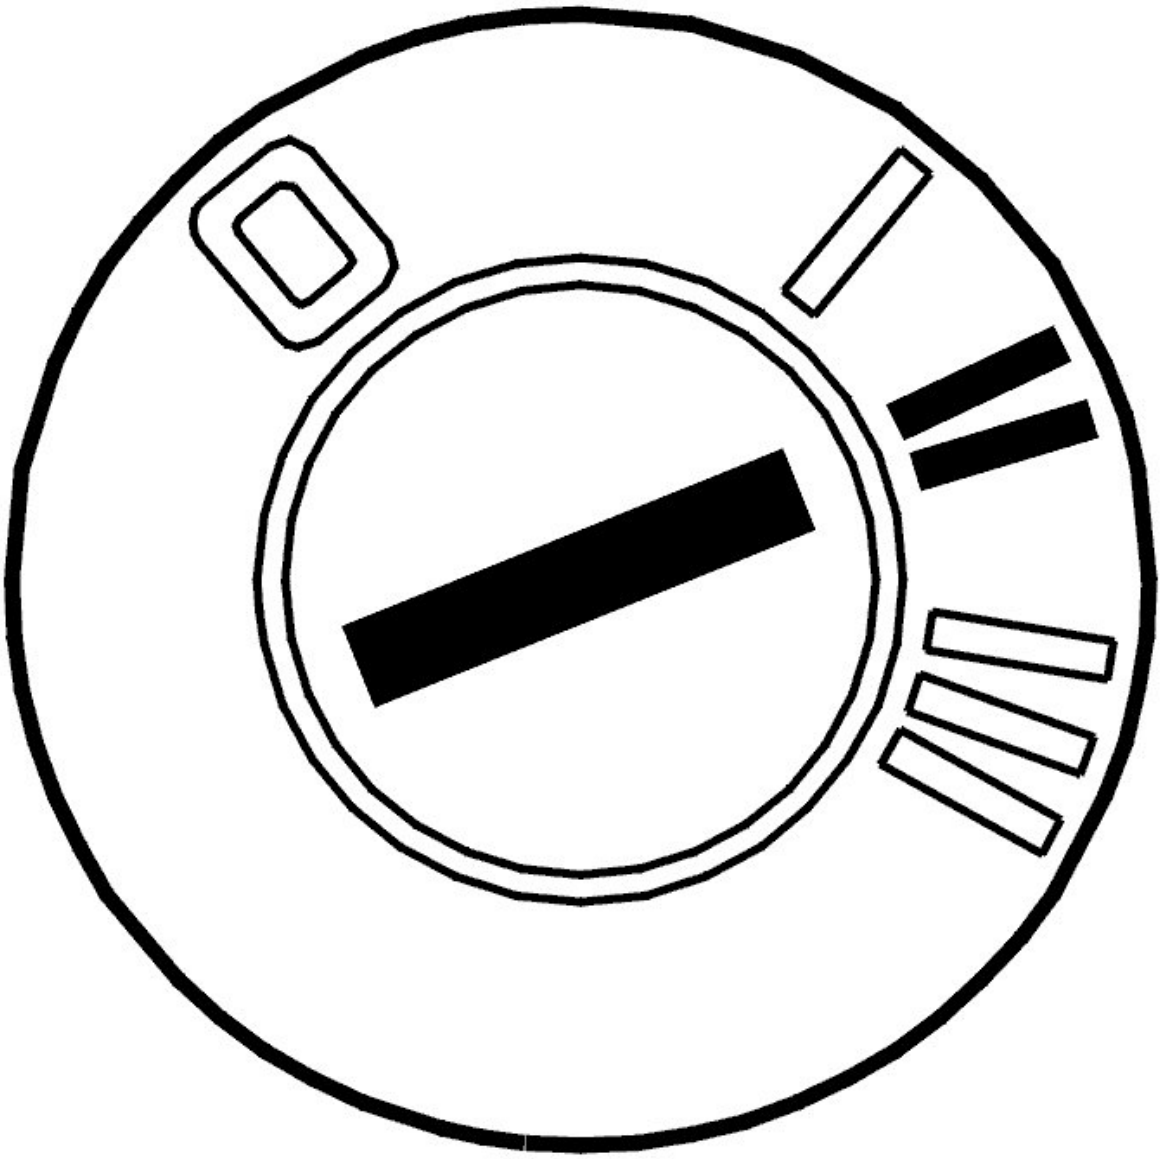
Possible source
- Incorrect control area network (CAN) configuration ID (the control module is not intended for this car, for example it is a used control module with different software/hardware)
- Open-circuit in the control area network (CAN) wiring between the control module and the central electrical module (CEM).

Fault symptom[s]
- The driver information module (DIM) panel does not function if there is no CAN communication.

DIM-XXXX

Unknown diagnostic trouble code (DTC) for the current control module version

Reading off diagnostic trouble codes (DTCs)



- Ignition on.

Read off the diagnostic trouble code (DTC) that is stored in the car.
Make a note of the code. Report the code to VIDA customer support.

Diagnostic Trouble Code (DTC) Information

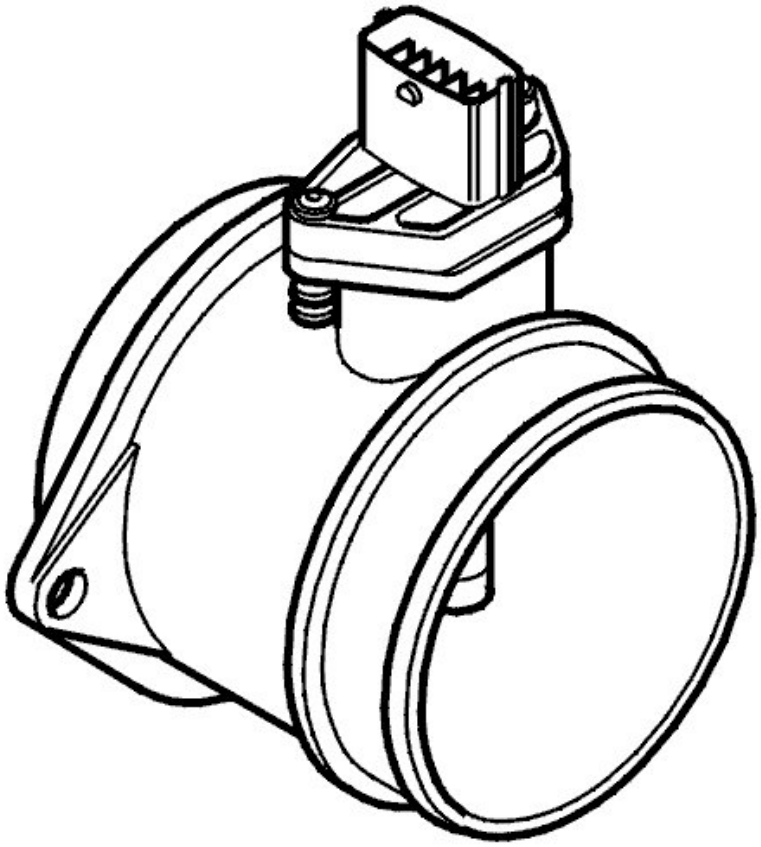
Diagnostic trouble code (DTC) information ECM-120C

Condition



The engine control module (ECM) calculates the expected mass air flow. The calculation is based on a number of different parameters. The calculated value for mass air flow is divided (/) by the measured value from the mass air flow (MAF) sensor (= correction value, mass air flow). The diagnostic trouble code (DTC) is stored if the correction value deviates from 1 (higher than 1) i.e. the calculated air mass is higher than the measured air mass.
The diagnostic trouble code (DTC) can be diagnosed when the engine is running.

Substitute value
- None.

Possible source
- Air leakage in the intake system
- Contaminated throttle body (TB).
- Blocked intake system
- Damaged mass air flow (MAF) sensor.

Fault symptom[s]
- Malfunction indicator lamp (MIL) lit.
- Uneven idle

Flow Too Low or Too High

Flow too low or too high

Checking the intake system

Check the mass air flow (MAF) sensor connector. Check for contact resistance and oxidation.
Check the intake system for leakage. In particular, check the hoses and hose connectors between the mass air flow (MAF) sensor and the throttle unit. Check for leakage and damage.
Check the inside of the throttle body (TB). Check for contamination. When the throttle body (TB) is contaminated, the air flow to the engine is impaired and diagnostic trouble code (DTCs) or fault symptoms can occur.
Clean the throttle body (TB) if needed.
If no fault is found, try a new mass air flow(MAF) sensor.
Remedy as necessary.

Diagnostic Trouble Code (DTC) Information

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

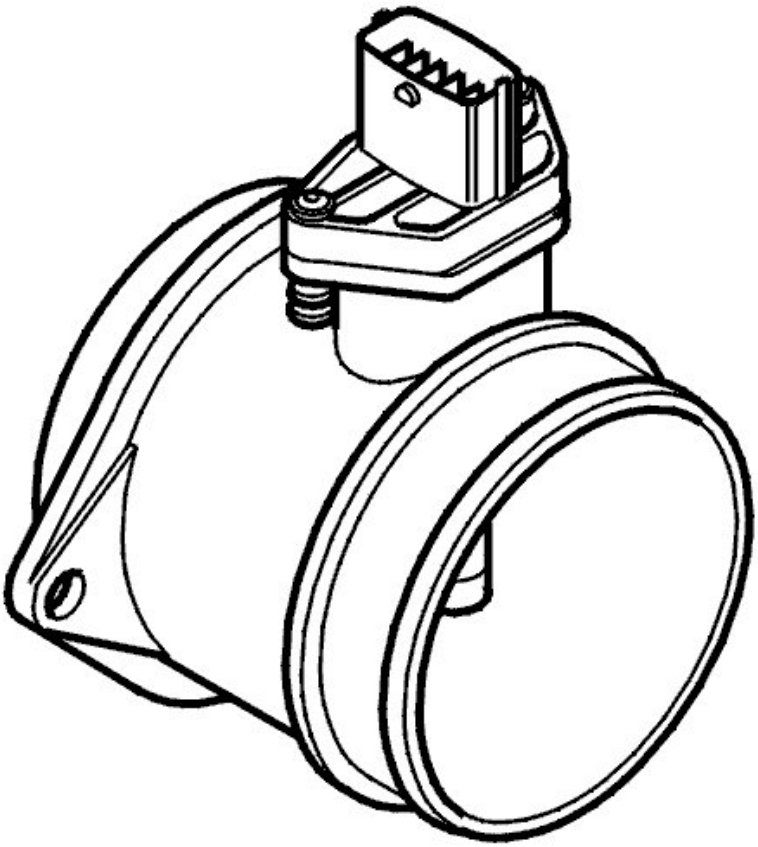
Diagnostic trouble code (DTC) information ECM-121D

Condition



The engine control module (ECM) calculates the expected mass air flow. The calculation is based on a number of different parameters. The calculated value for mass air flow is then compared with the measured value from the mass air flow (MAF) sensor.
The diagnostic trouble code (DTC) is stored if the engine control module (ECM) detects that the value for the measured air mass is lower than the calculated value for air mass.
The diagnostic trouble code (DTC) can be diagnosed when the engine is running.

Substitute value
- Calculated boost pressure
- Calculated air mass
- Rear heated oxygen sensor (HO2S) control shut off
- Misfire diagnostic shut off.

Possible source
- Air leakage in the intake system
- Contact resistance in the mass air flow (MAF) sensor connectors
- Short-circuit to ground in the signal cable
- Open-circuit in the signal cable
- Open-circuit in the power supply
- Damaged mass air flow (MAF) sensor.

Fault symptom[s]
- Malfunction indicator lamp (MIL) lit
- Poor performance.

Signal Too Low

Signal too low

Checking components and wiring

Check the mass air flow (MAF) sensor connector. Check for contact resistance and oxidation.
Check for air leakage in the intake system and for damage to hoses etc.
Check the power supply cable between system relay terminal #5 and mass air flow (MAF) sensor terminal #2. Check for an open-circuit.
Check the signal cable between engine control module (ECM) terminal #A22 (#A22) and mass air flow (MAF) sensor terminal #5. Check for an

open-circuit. Check for a short-circuit to ground.
Check the power supply cable between engine control module (ECM) terminal #A39 (#A39) and mass air flow (MAF) sensor terminal #4. Check for an open-circuit.

Hint: With the ignition on and the mass air flow (MAF) sensor connector connected the voltage at mass air flow (MAF) sensor terminal #2 must be approximately U bat.

Remedy as necessary.

Diagnostic Trouble Code (DTC) Information

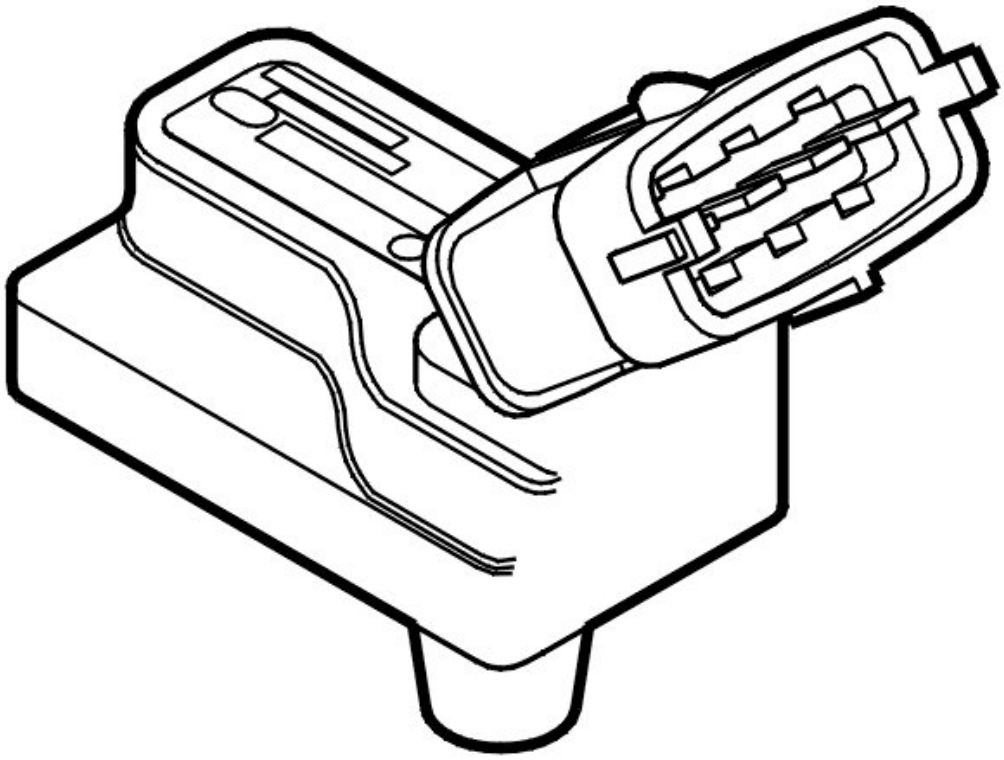
Diagnostic trouble code (DTC) information ECM-131C

Condition



The engine control module (ECM) checks the signal for the intake air temperature.
The diagnostic trouble code (DTC) is stored if the engine control module (ECM) detects that the signal for the intake air temperature corresponds to a temperature that is higher than a certain value.
The diagnostic trouble code (DTC) can be diagnosed when the engine is running.

Substitute value
- Predefined value for intake air temperature
- Three-way catalytic converter (TWC) preheating and idle air trim diagnostics are disabled.

Possible source
- Short-circuit to ground in the signal cable

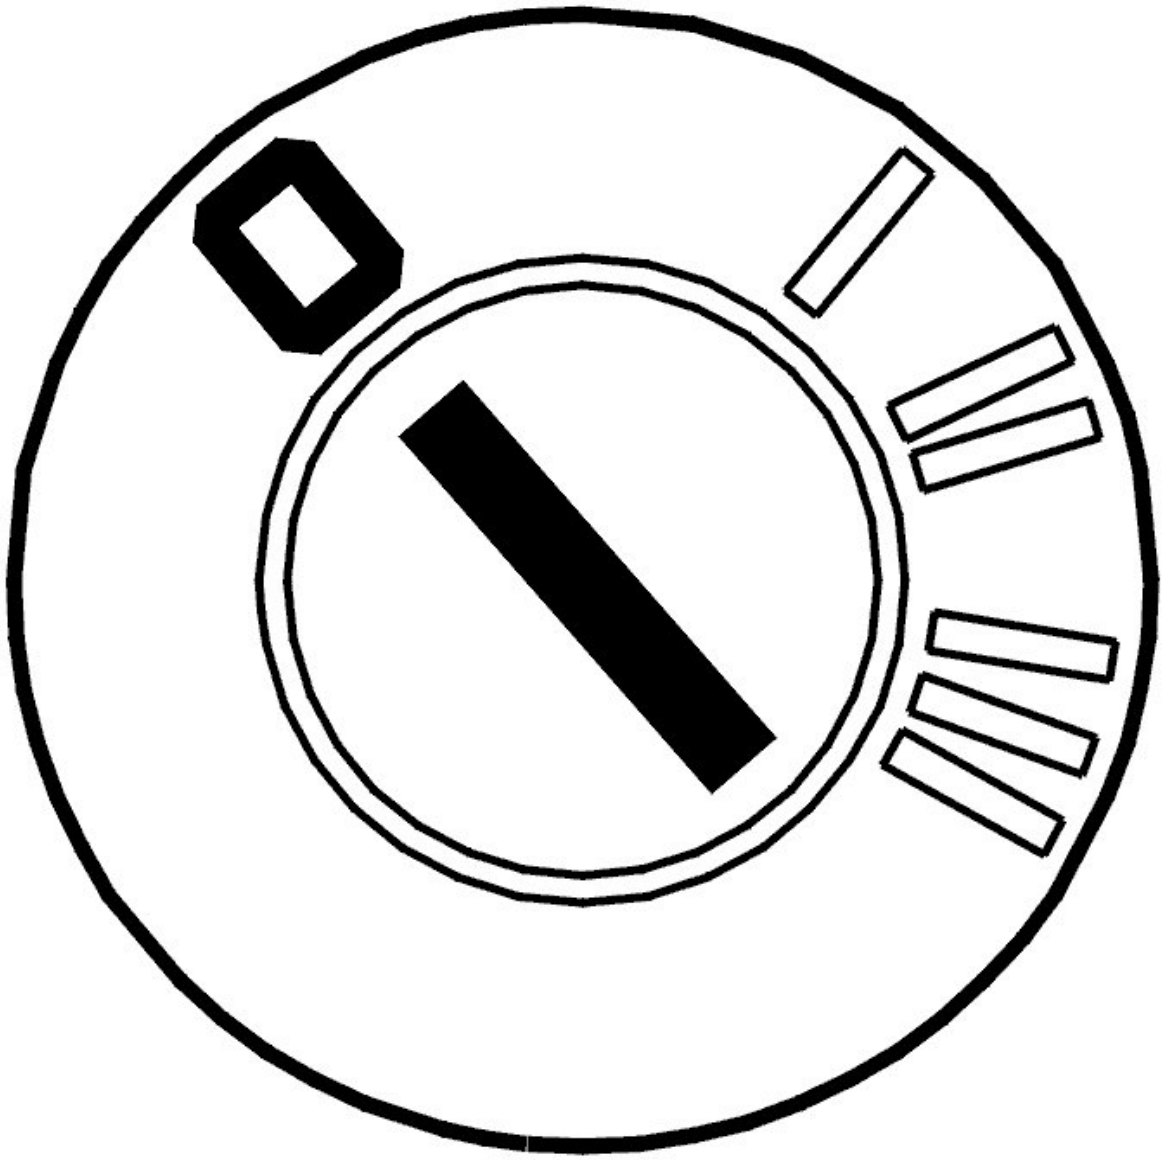
- Damaged intake air temperature (IAT) sensor.

Fault symptom[s]
- Malfunction indicator lamp (MIL) lit
- Poor performance.

Signal Too High

Signal too high

Checking the wiring and component



- Ignition off.

Check the intake air temperature (IAT) sensor resistance between terminals #1 and #2 on the boost pressure sensor.

Note! The intake air temperature (IAT) sensor is integrated in the boost pressure sensor.

Check the signal cable between engine control module (ECM) terminal #A5 (#A5) and boost pressure sensor terminal #2 for short circuit to ground.

Hint: With the ignition on and the boost pressure sensor connector unplugged, the voltage between terminal #2 and the grounding terminal should be 5 V, measured at the connector. Read off air temperature by clicking on the VCT2000 symbol.

If no errors are found and the fault is permanent, replace the intake air temperature (IAT) sensor.
Remedy as necessary.

Possible source
- Contact resistance in the terminals
- Open-circuit in the signal cable
- Short-circuit to supply voltage in the signal cable

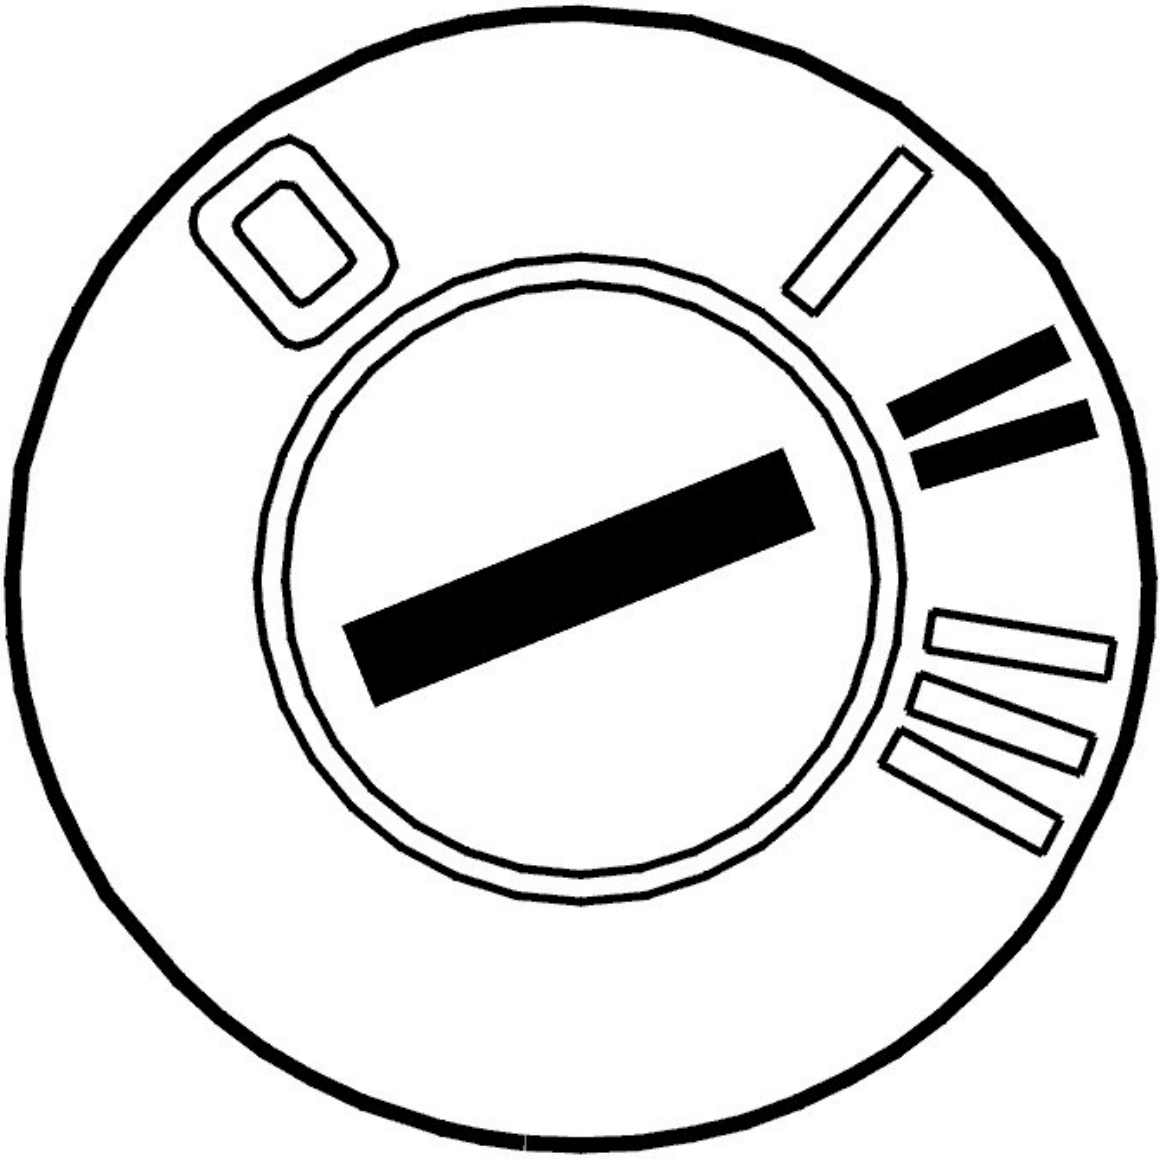
- Damaged intake air temperature (IAT) sensor.

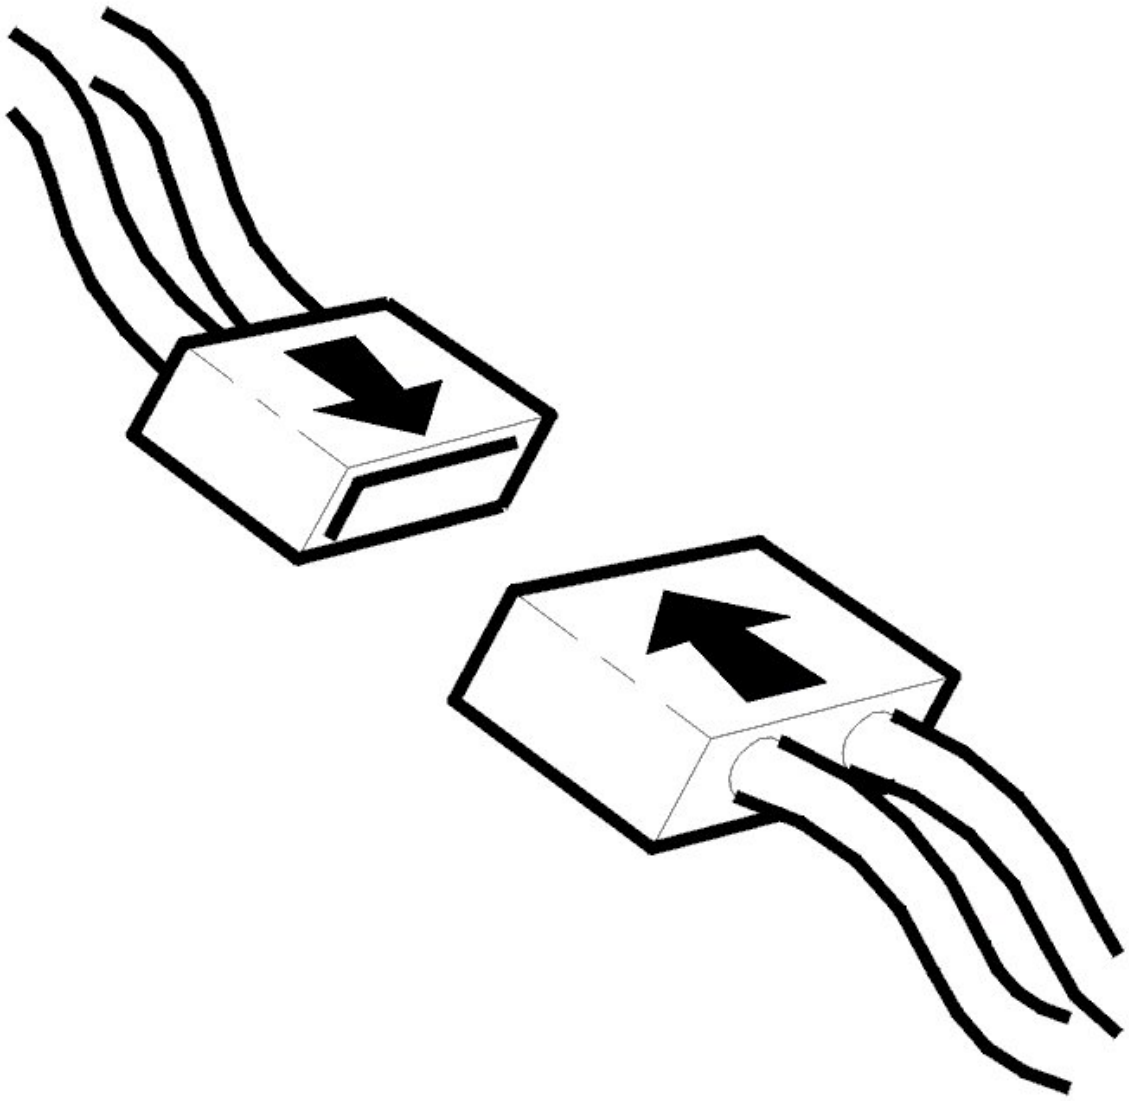
Fault symptom[s]
- Malfunction indicator lamp (MIL) lit
- Poor performance.

Signal Too Low

Signal too low

Checking the connector





- Ignition off
- Check the boost pressure sensor connector. Check for contact resistance and oxidation.

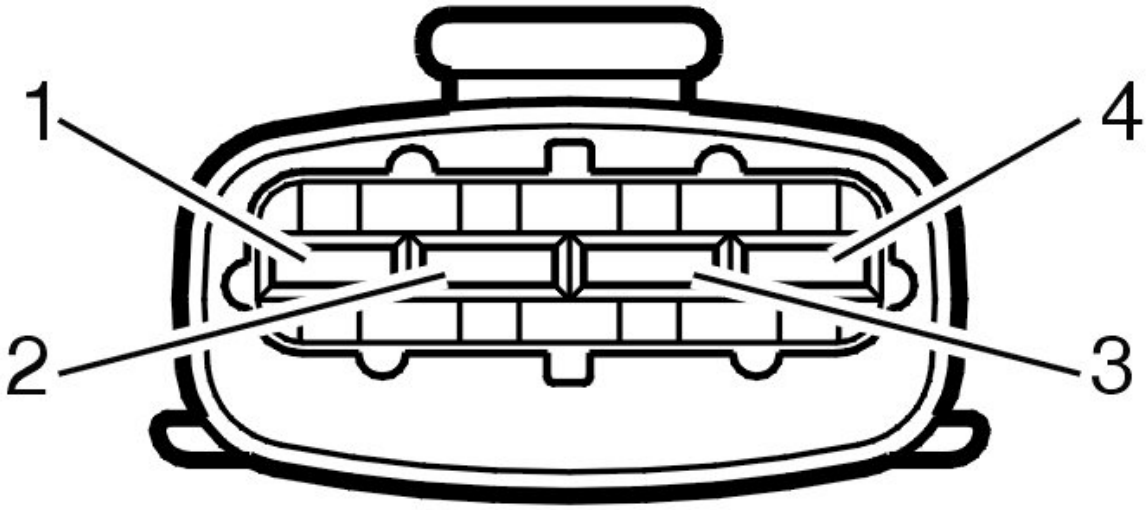
Note! The intake air temperature (IAT) sensor is integrated in the boost pressure sensor

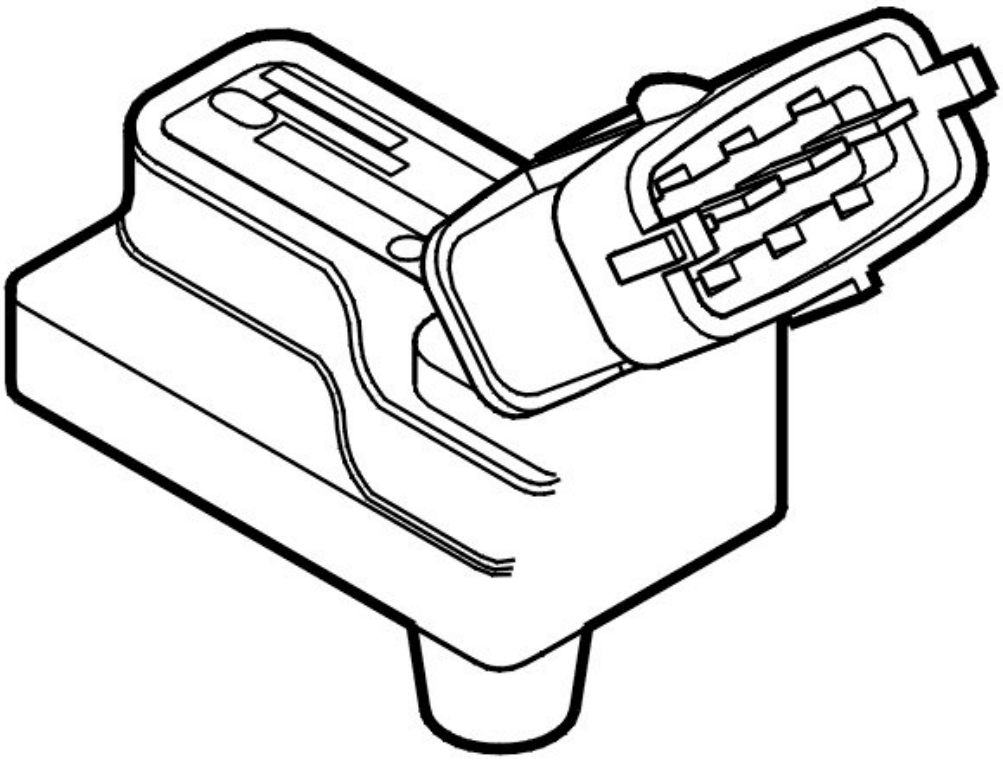
- Reinstall the components, reconnect the connectors etc.
- Ignition on
- Read off the intake air temperature (IAT).

Check that the intake air temperature (IAT) is within its permitted range. If the intake air temperature (IAT) is now within its permitted range, the fault was caused by loose connections in the connector.

Other information:

- To access or replace the intake air temperature (IAT) sensor, see Temperature and pressure sensor, replacing See: Coolant Temperature Sensor/Switch (For Computer)/Service and Repair.



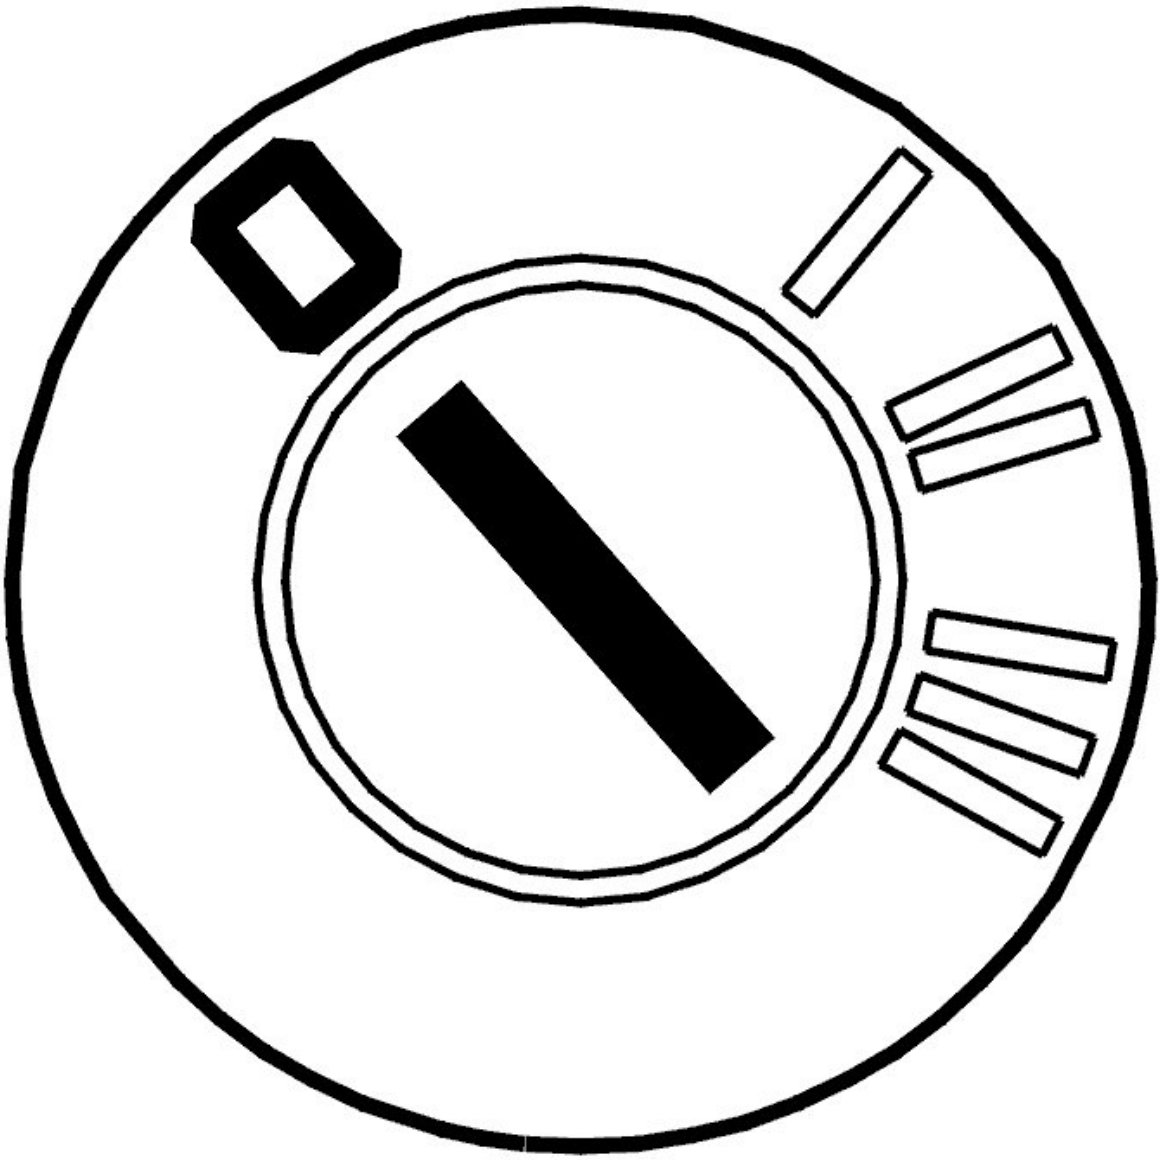


Is the temperature within its permitted range?

Yes - Fault Found

No - Checking the wiring and component

Checking the wiring and component



- Ignition off.

Check the intake air temperature (IAT) sensor resistance between terminals #1 and #2 on the boost pressure sensor.

Note! The intake air temperature (IAT) sensor may be defective if there gas been a short-circuit to supply voltage in the signal cable. Check this before replacing the sensor.

Check the signal cable between control module terminal #A5 (#A5) and boost pressure sensor terminal #2. Check for a short-circuit to supply voltage. Check for an open-circuit.

Hint: With the ignition on and the boost pressure sensor connector disconnected, the voltage between terminal #2 and ground must be approximately 5 V.

Check the ground lead between control module terminal #A60 (#A60) and boost pressure sensor terminal #1. Check for an open-circuit.
If no errors are found and the fault is permanent, replace the intake air temperature (IAT) sensor.
Remedy as necessary.

Diagnostic Trouble Code (DTC) Information

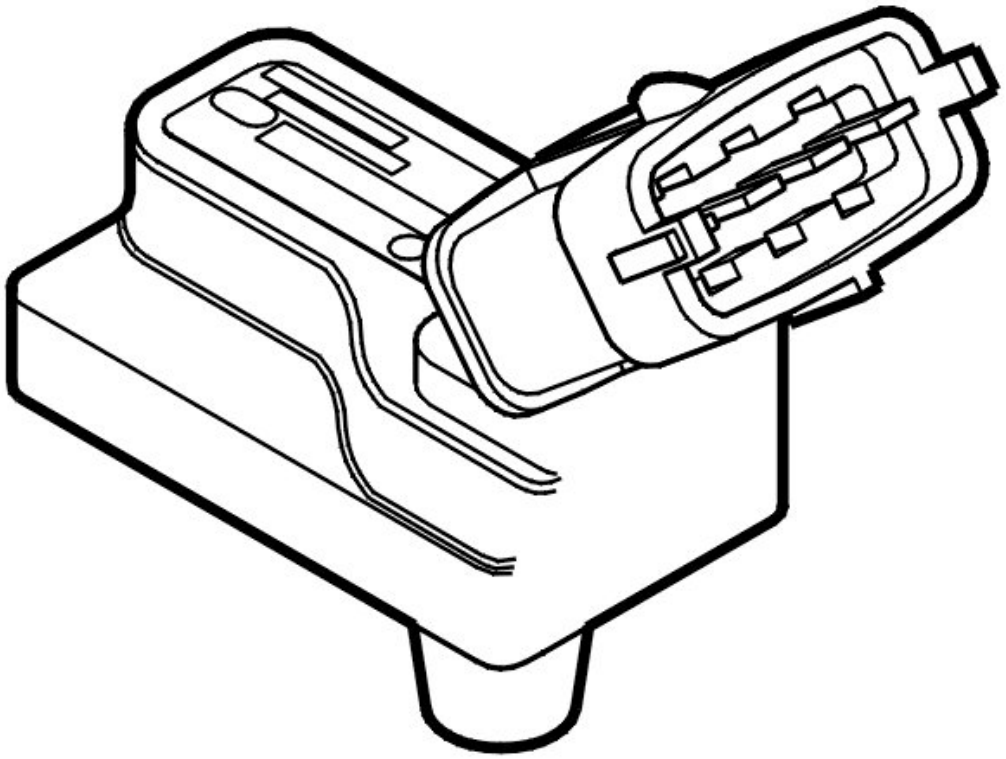
Diagnostic trouble code (DTC) information ECM-132D

Condition



The engine control module (ECM) checks the signal for the intake air temperature.
The diagnostic trouble code (DTC) is stored if the engine control module (ECM) detects that the difference between the signals from the intake air temperature (IAT) sensor and the engine coolant temperature (ECT) sensor is more than 50 °C after the engine has been off for a certain amount of time.
The diagnostic trouble code (DTC) can be diagnosed when the engine is running.

Substitute value
- Predefined value for intake air temperature
- Three-way catalytic converter (TWC) preheating and idle air trim diagnostics are disabled.

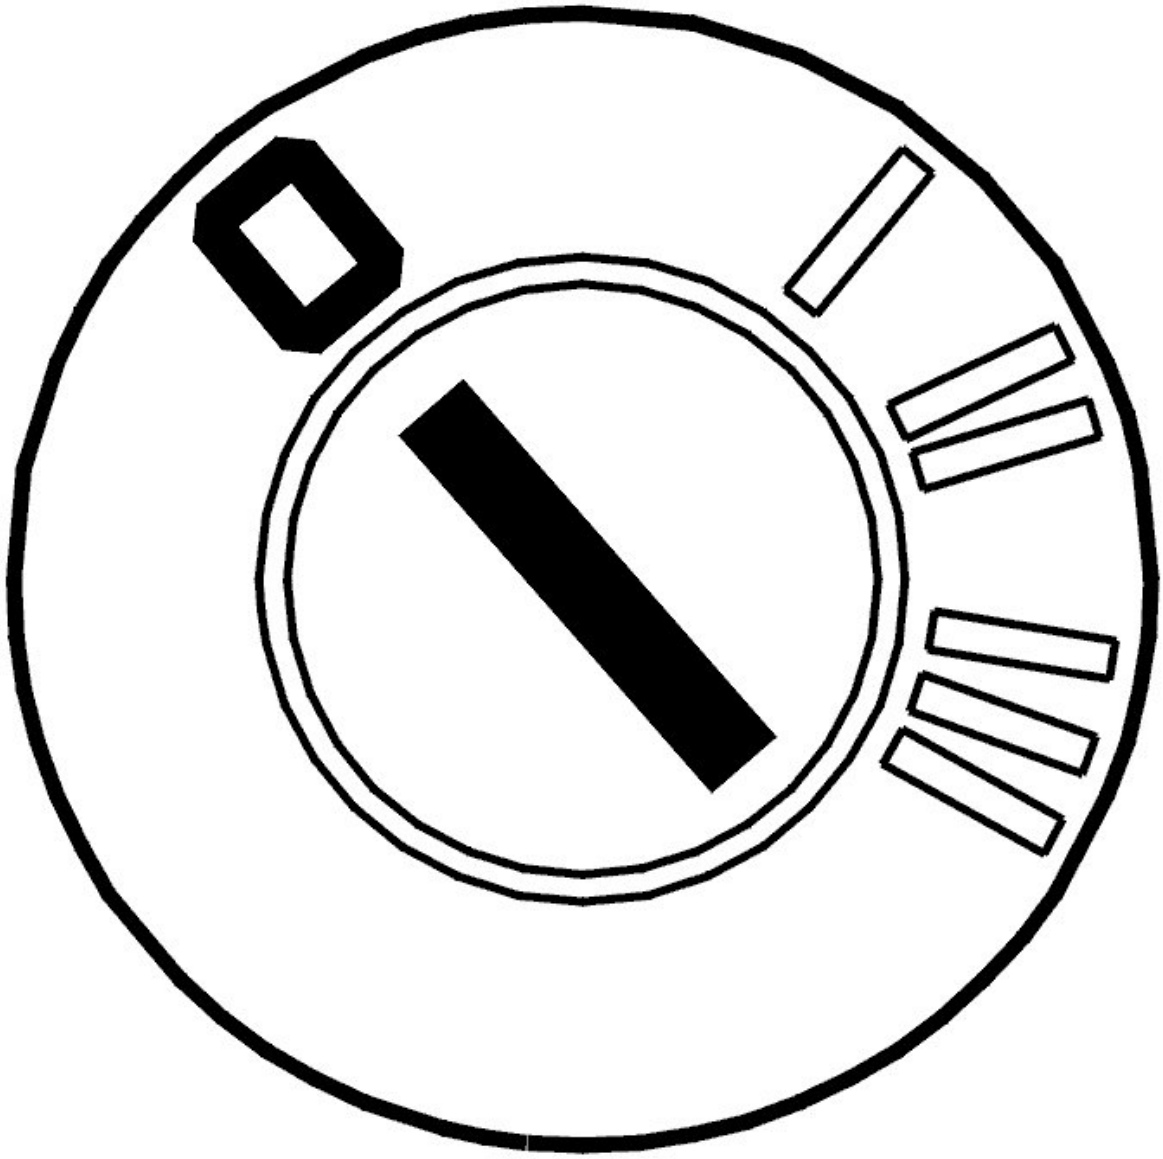
Possible source
- Contact resistance or oxidation in the intake air temperature (IAT) sensor terminals
- Damaged intake air temperature (IAT) sensor.

Fault symptom[s]
- Malfunction indicator lamp (MIL) lit
- Poor performance.

Signal Too High/Signal Too Low

Signal too high / Signal too low

Checking components and connectors

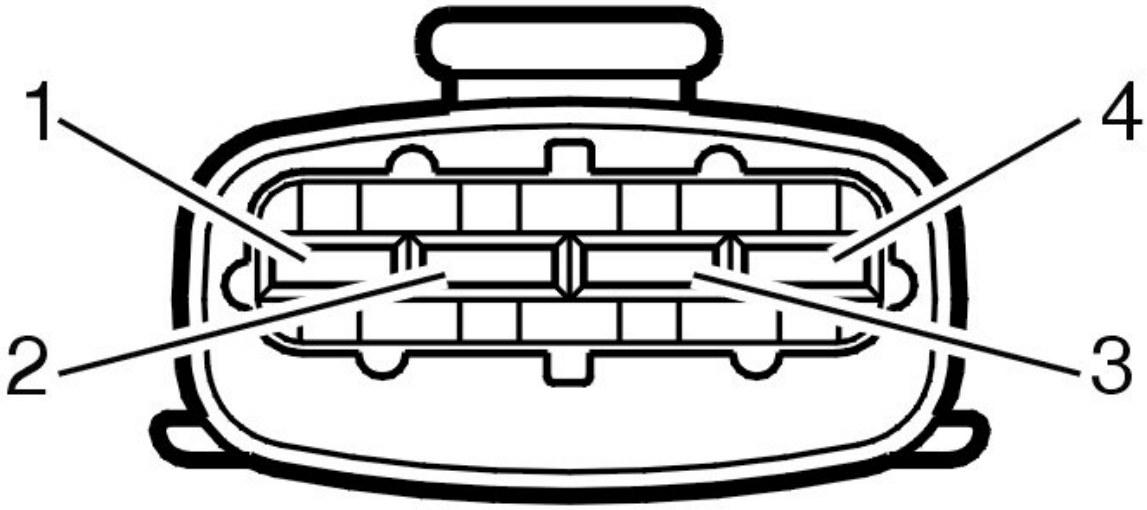


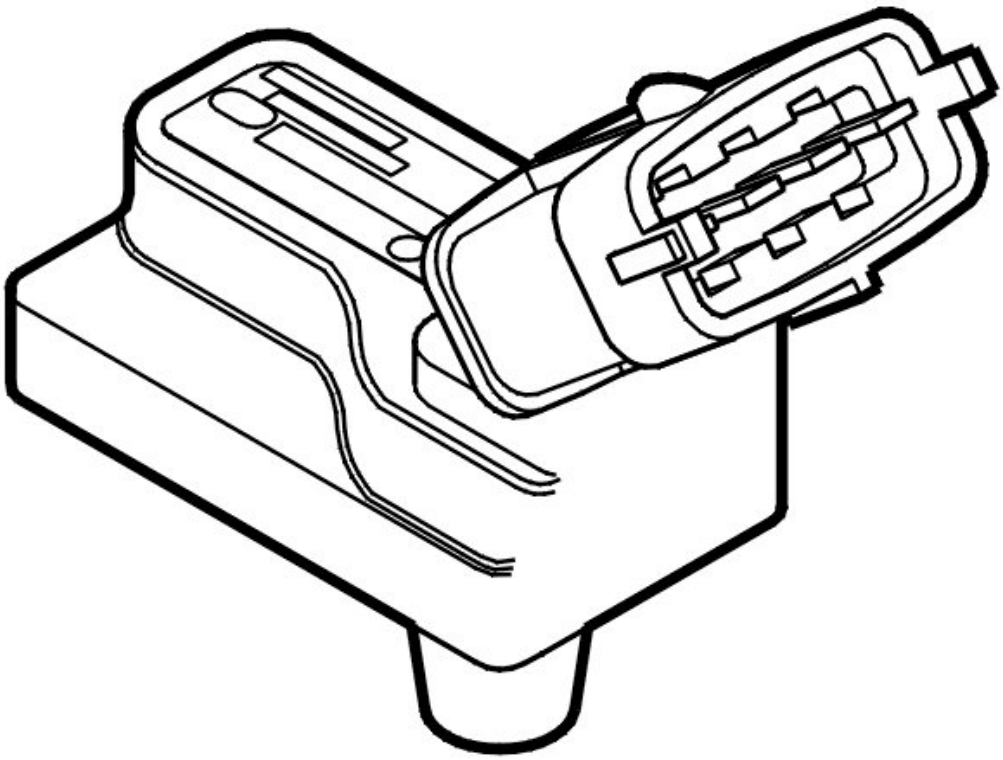
- Ignition off
- Check the boost pressure sensor connector and terminal. Check for contact resistance and oxidation.

Note! The intake air temperature (IAT) sensor is integrated in the boost pressure sensor.

If no errors are found and the fault is permanent, replace the intake air temperature (IAT) sensor.
Remedy as necessary.

Other information:
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals
- For resistance values: Component specifications See: Engine Control Module/Specifications
- Temperature and pressure sensor, replacing See: Coolant Temperature Sensor/Switch (For Computer)/Service and Repair





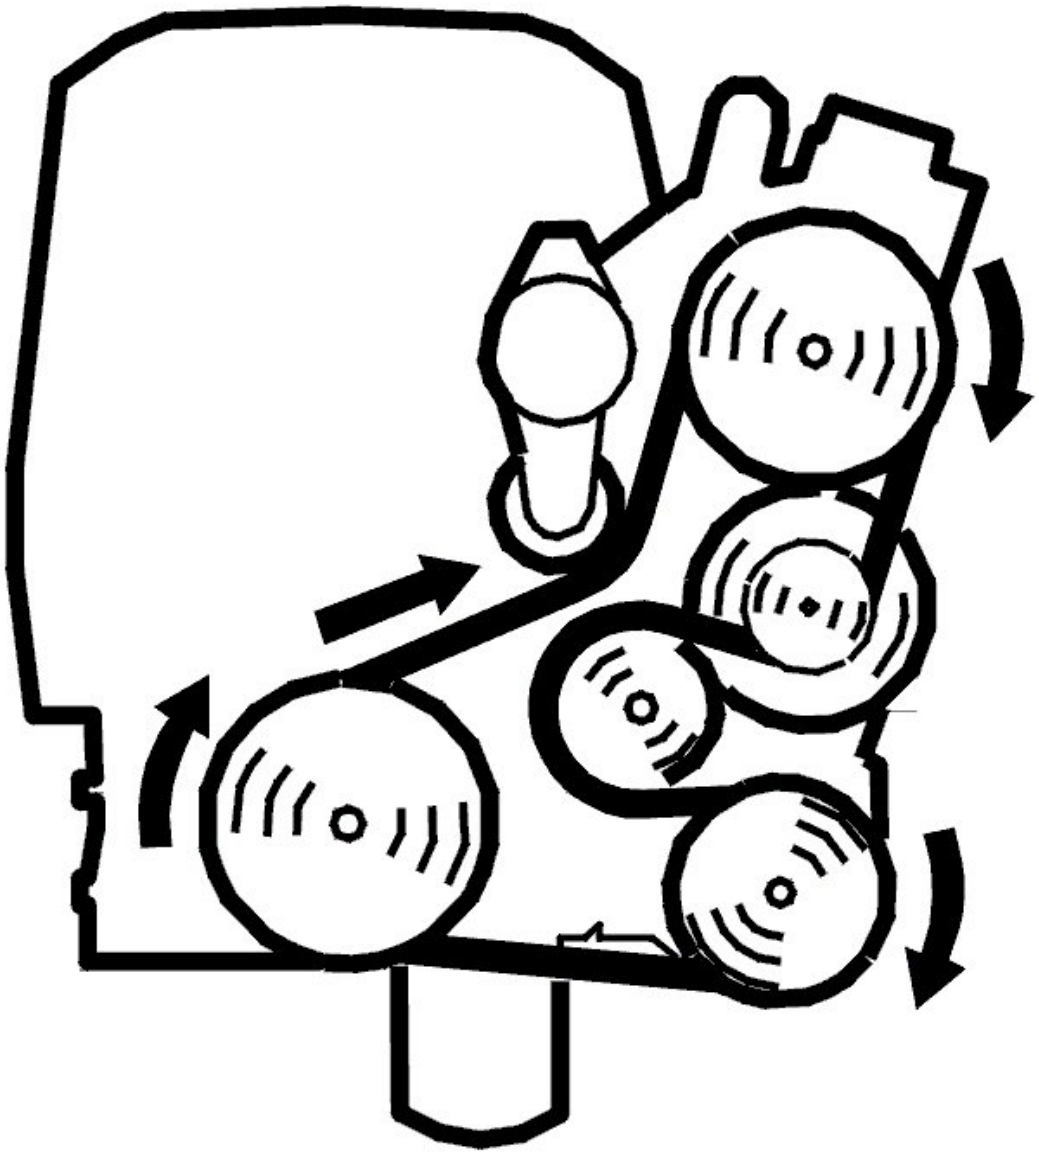
Continue - Verification

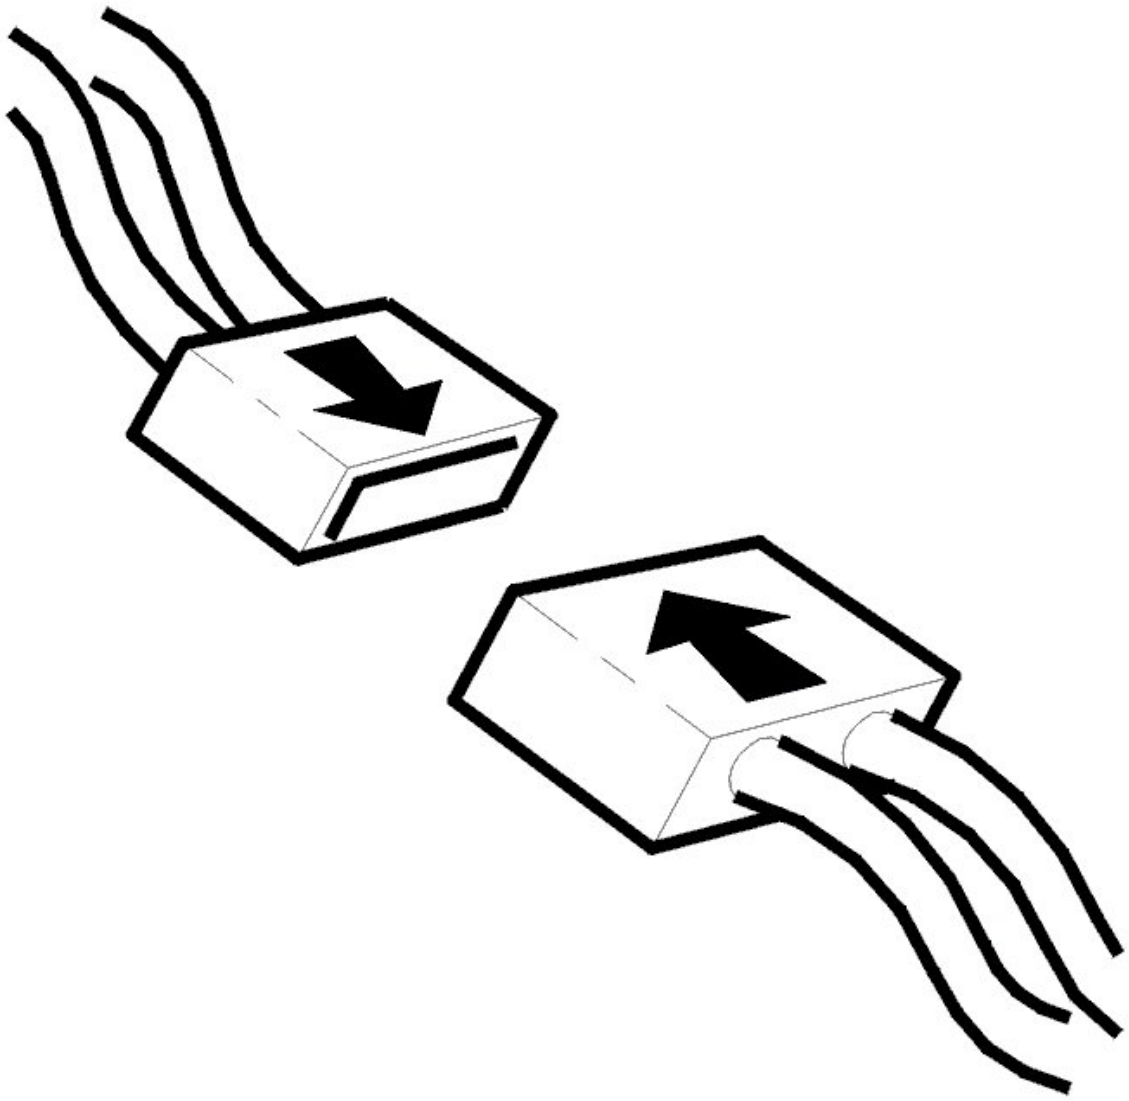
Verification

Verification

Verification

Hint: After carrying out the repair, check that the fault has been remedied.





- Ignition off
- Reconnect the connectors, reinstall components etc.
- Start the engine. Allow the engine to idle for 5 minutes
- Read off diagnostic trouble codes (DTCs).

The fault has been remedied if status of the diagnostic trouble code (DTC) is intermittent.

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information ECM-140C

Condition

The diagnostic trouble code (DTC) is stored if there is a short-circuit to ground in the outside temperature sensor.
The diagnostic trouble code (DTC) can be diagnosed when the ignition is switched on.

Substitute value
- The value is taken from the intake air temperature (IAT) sensor.

Possible source
- Contact resistance in the terminals
- Short-circuit to ground in the signal cable
- Damaged outside temperature sensor.

Fault symptom[s]
- Malfunction indicator lamp (MIL) lit.

Signal Too High

Signal too high

Checking components and wiring

Check the resistance of the outside temperature sensor.
Check the signal cable between control module terminal #B29 (#B39) and outside temperature sensor terminal #2. Check for a short-circuit to ground.

Hint: With the ignition on and the outside temperature sensor connector disconnected, the voltage between #2 and the ground terminal must be approximately 5V.

Remedy as necessary.

Other information:
- To connect the breakout box / access the control module, see Connecting the breakout box, B5244T5, B5254T2 See: Pinout Values and Diagnostic Parameters/Connecting the Breakout Box
- To access and replace the outside temperature sensor, see Outside temperature sensor door mirror, replacing See: Instrument Panel, Gauges and Warning Indicators/Outside Temperature Display/Outside Temperature Display Sensor/Service and Repair/Outside Temperature Sensor Door Mirror, Replacing

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information ECM-140D

Condition

The diagnostic trouble code (DTC) is stored if there is a short-circuit to supply voltage in the outside temperature sensor.
The diagnostic trouble code (DTC) can be diagnosed when the ignition is switched on.

Substitute value
- The value is taken from the intake air temperature (IAT) sensor.

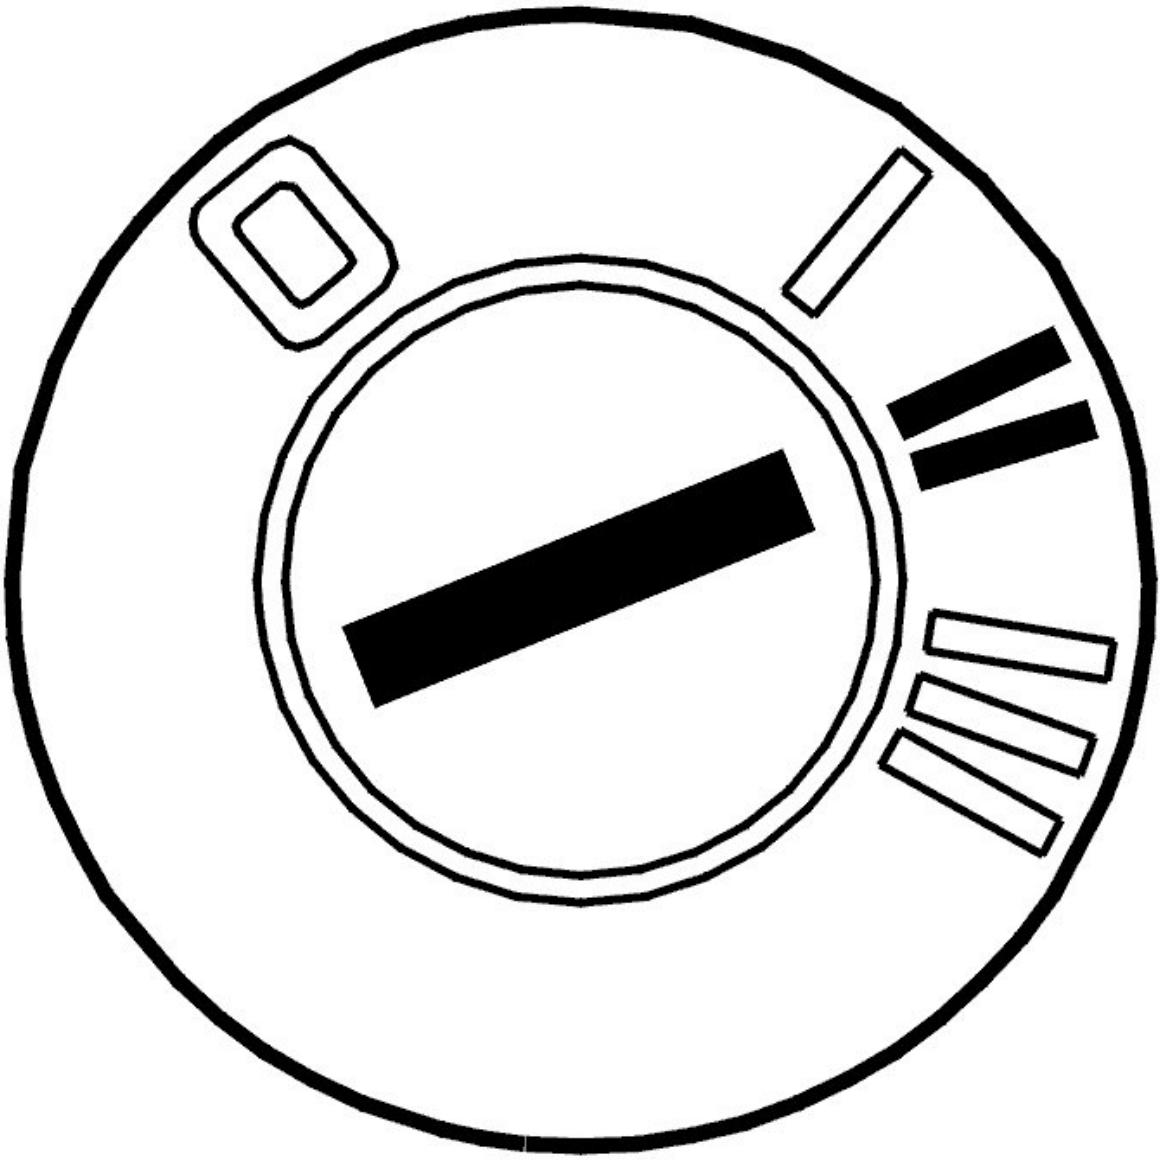
Possible source
- Contact resistance in the terminals
- Short-circuit to supply voltage in the signal cable
- Open-circuit in the signal cable
- Damaged outside temperature sensor.

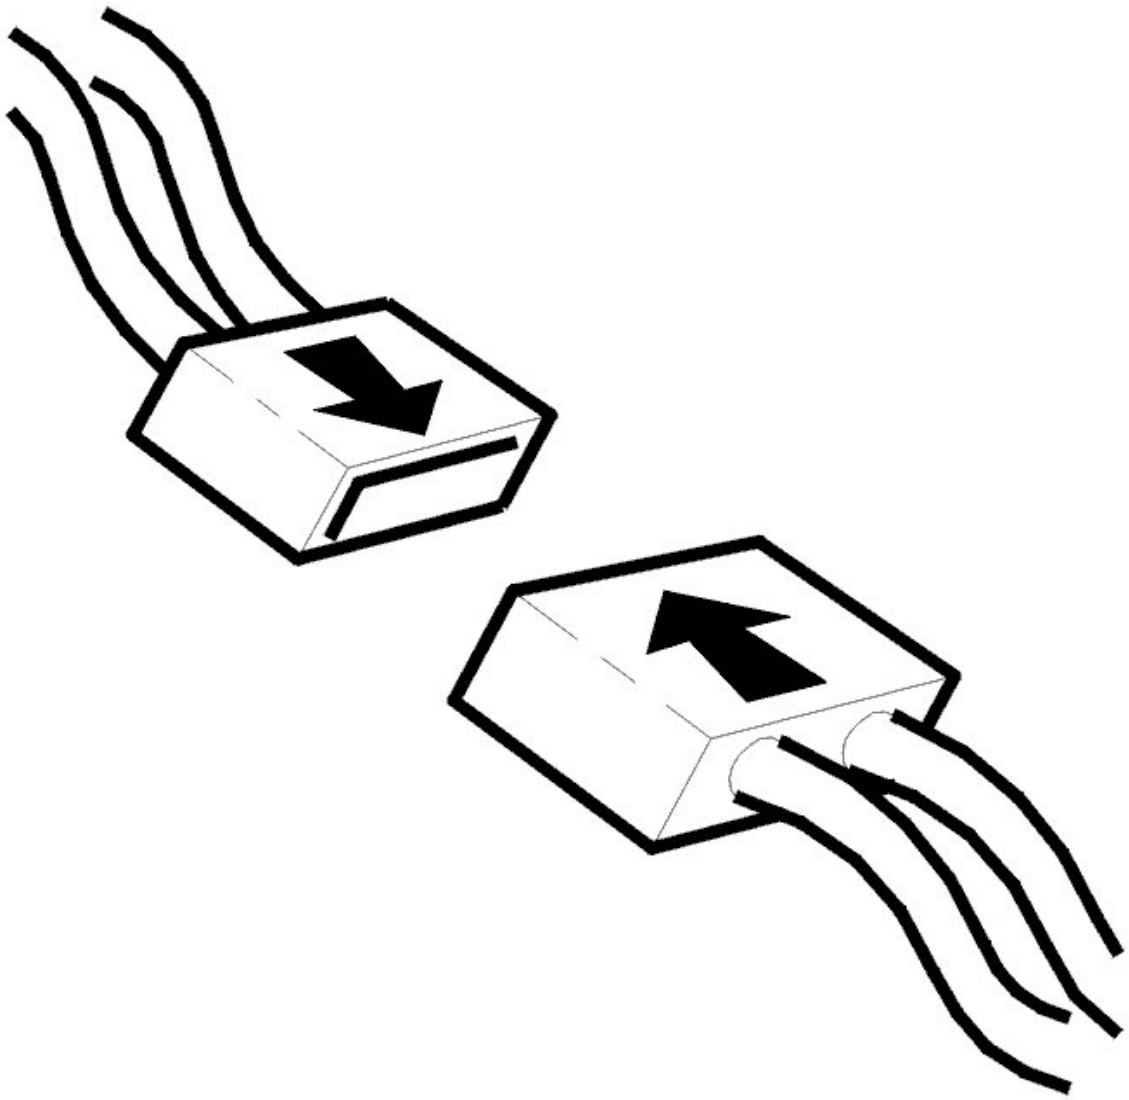
Fault symptom[s]
- Malfunction indicator lamp (MIL) lit.

Signal Too Low

Signal too low

Checking the connector



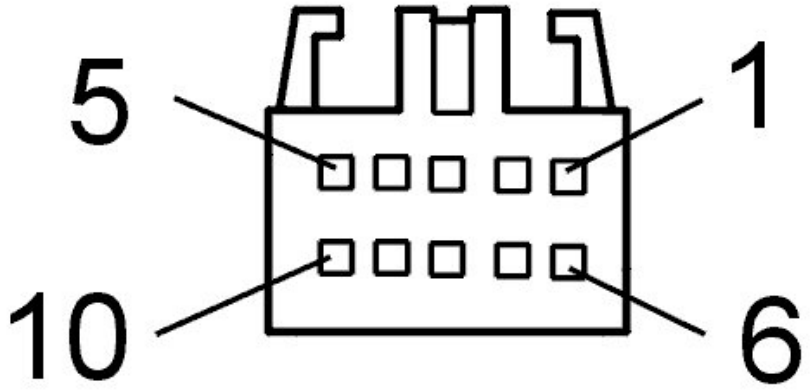


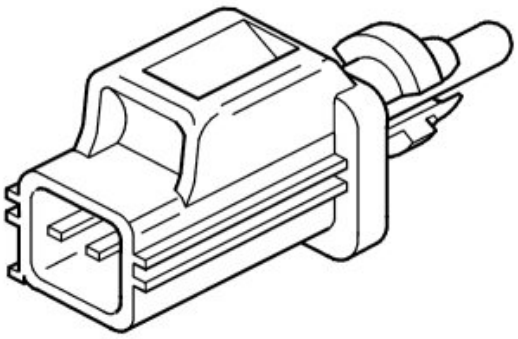
- Ignition off
- Check the wiring and connectors. Check for contact resistance and oxidation
- Reinstall the components, reconnect the connectors etc.
- Ignition on
- Read off the outside temperature.

If the temperature is now within its permitted range, the fault was caused by loose connections in the connector.

Other information

- To access and replace the outside temperature sensor, see Outside temperature sensor door mirror, replacing See: Instrument Panel, Gauges and Warning Indicators/Outside Temperature Display/Outside Temperature Display Sensor/Service and Repair/Outside Temperature Sensor Door Mirror, Replacing.





Is the temperature within its permitted range?

Yes - Fault Found

No - Checking components and wiring

Checking components and wiring

Check the resistance of the outside temperature sensor.

Note! The outside temperature sensor may be defective if there was a short-circuit to supply voltage in the signal cable. Check this before replacing the sensor.

Check the signal cable between control module terminal #B29 (#B39) and outside temperature sensor terminal #2. Check for a short-circuit to supply voltage. Check for an open-circuit.

Hint: With the ignition on and the outside temperature sensor connector disconnected, the voltage between #2 and ground must be approximately 5 V.

Check the ground lead between control module terminal #B4 (#B14) and outside temperature sensor terminal #3. Check for an open-circuit. Remedy as necessary.

Diagnostic Trouble Code (DTC) Information

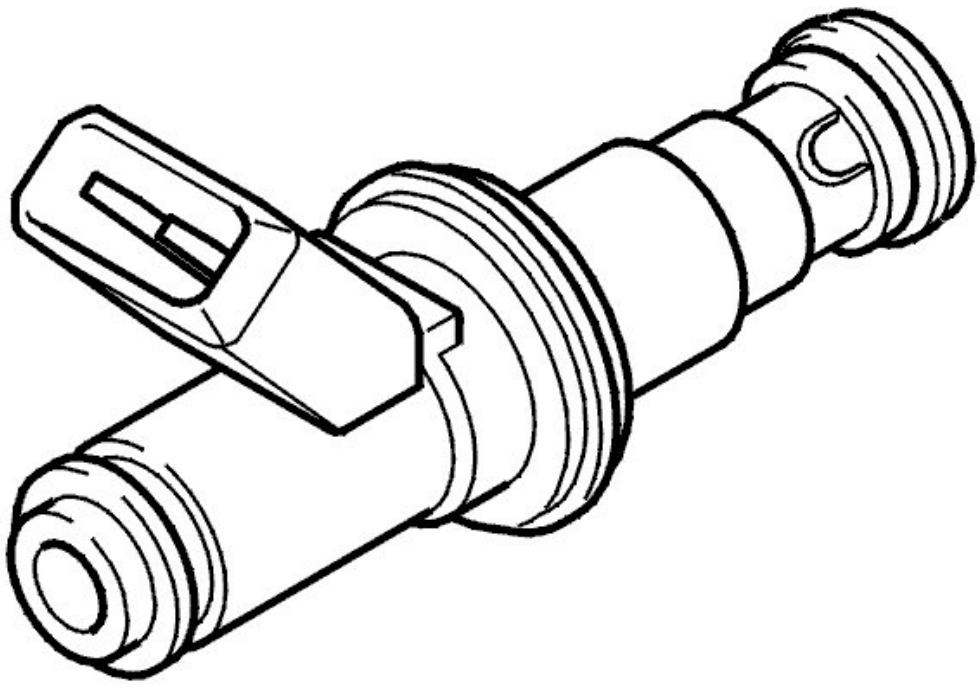
Diagnostic trouble code (DTC) information

Condition



The engine control module (ECM) checks the circuit for the injectors.
The diagnostic trouble code (DTC) is stored if the engine control module (ECM) detects that the signal for one of the injector circuits is missing.
The diagnostic trouble code (DTC) indicates which injector is being referred to.

- ECM-200B: injector 1
- ECM-201B: injector 2
- ECM-202B: injector 3
- ECM-203B: injector 4
- ECM-204B: injector 5.

The diagnostic trouble code (DTC) can be diagnosed when the engine is running.

Substitute value

- None.

Possible source
- Contact resistance in the terminals
- Open-circuit in the signal cable
- Open-circuit in the power supply to the injector
- Damaged injector.

Fault symptom[s]
- Malfunction indicator lamp (MIL) lit
- The engine is not firing on all cylinders.

Signal Missing

Signal missing

Checking components and wiring

Check the cable that relates to the diagnostic trouble code (DTC). Check for an open-circuit.
Check between:
- Engine control module (ECM) terminal #A16 (#A16) and injector terminal #2 (ECM-200B, injector 1)
- Engine control module (ECM) terminal #A34 (#A34) and injector terminal #2 (ECM-201B, injector 2)
- Engine control module (ECM) terminal #A15 (#A15) and injector terminal #2 (ECM-202B, injector 3)
- Engine control module (ECM) terminal #A33 (#A33) and injector terminal #2 (ECM-203B, injector 4)
- Engine control module (ECM) terminal #A14 (#A14) and injector terminal #2 (ECM-204B, injector 5).

Remedy as necessary.

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information ECM-210C

Condition

The engine control module (ECM) receives information from the heated oxygen sensor (HO2S) (bank 1) about the fuel / air mixture when idling and at both the upper and lower part-load range. If the fuel / air mixture deviates from lambda=1, the short-term fuel trim will compensate for this by adjusting the injection time so that lambda=1 is achieved. When the short-term fuel trim makes an adjustment, the integrator median must be adjusted by the long-term trim. The diagnostic trouble code (DTC) is stored when the long-term trim must be adjusted to almost maximum in the upper part load area.

Substitute value
- None.

Possible source
- Intake air leakage
- Air leakage in the exhaust system
- Low fuel pressure
- Damaged heated oxygen sensor (HO2S) (bank 1).

Fault symptom[s]
- None.

Signal Too High

Signal too high

Checking the fuel injection system

Check the intake system for air leakage.

Hint: Air leakage in the intake system can occur through the evaporative emission system (EVAP) valve, the secondary air solenoid valve or the power brake booster.

Check the fuel pressure.
Test drive the car for approximately 10 minutes.
Check the mass air flow (MAF) sensor. Read off its correction factor. The value must be between 0.8 and 1.2.

Note! There must not be any air leakage when this test is carried out.

Remedy as necessary.

Other information
- Check for air leaks in the intake system See: Fuel Delivery and Air Induction/Testing and Inspection/Air Leaks in the Intake System, Checking

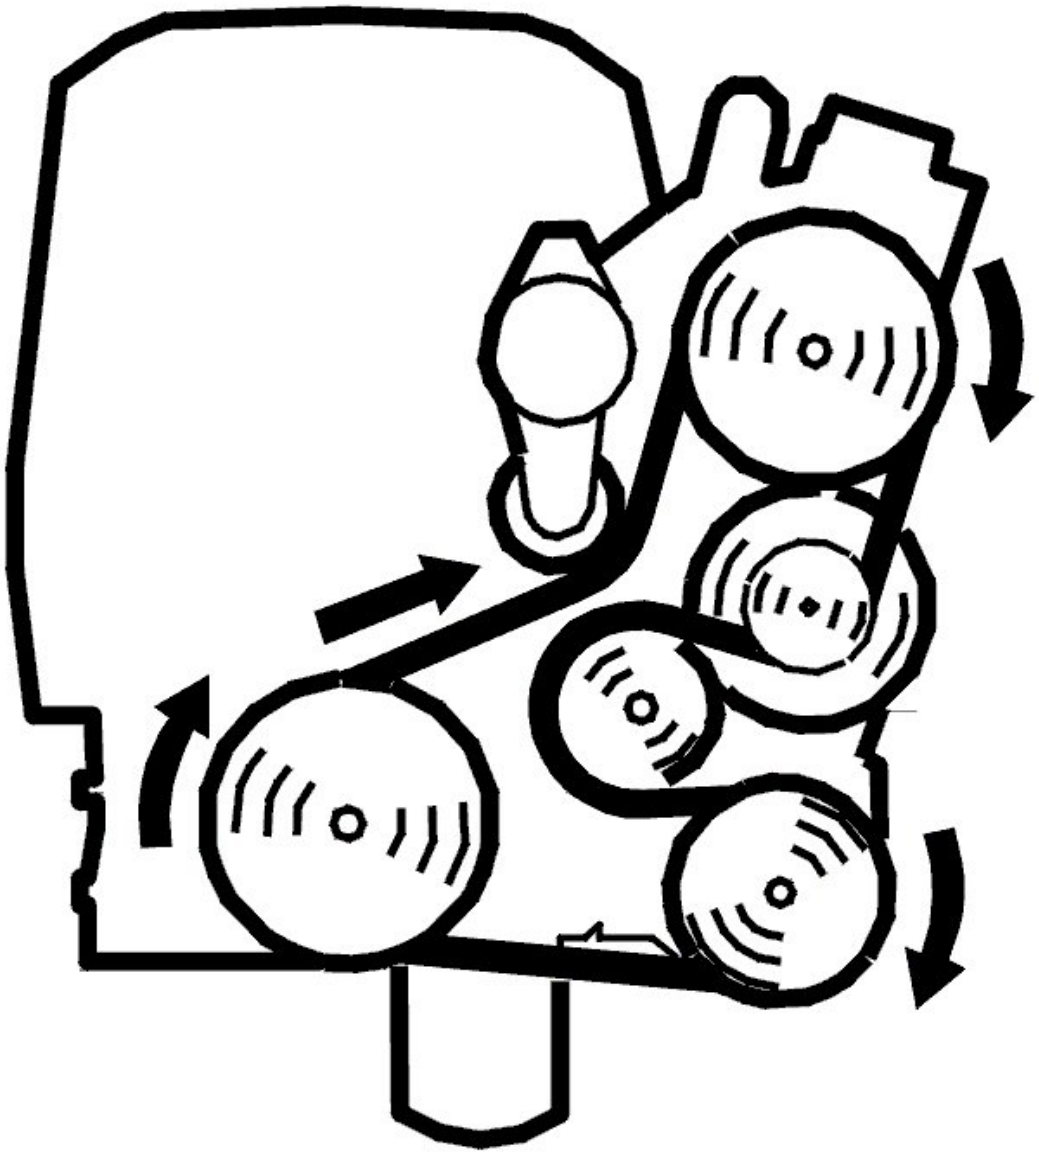
Continue - Verification

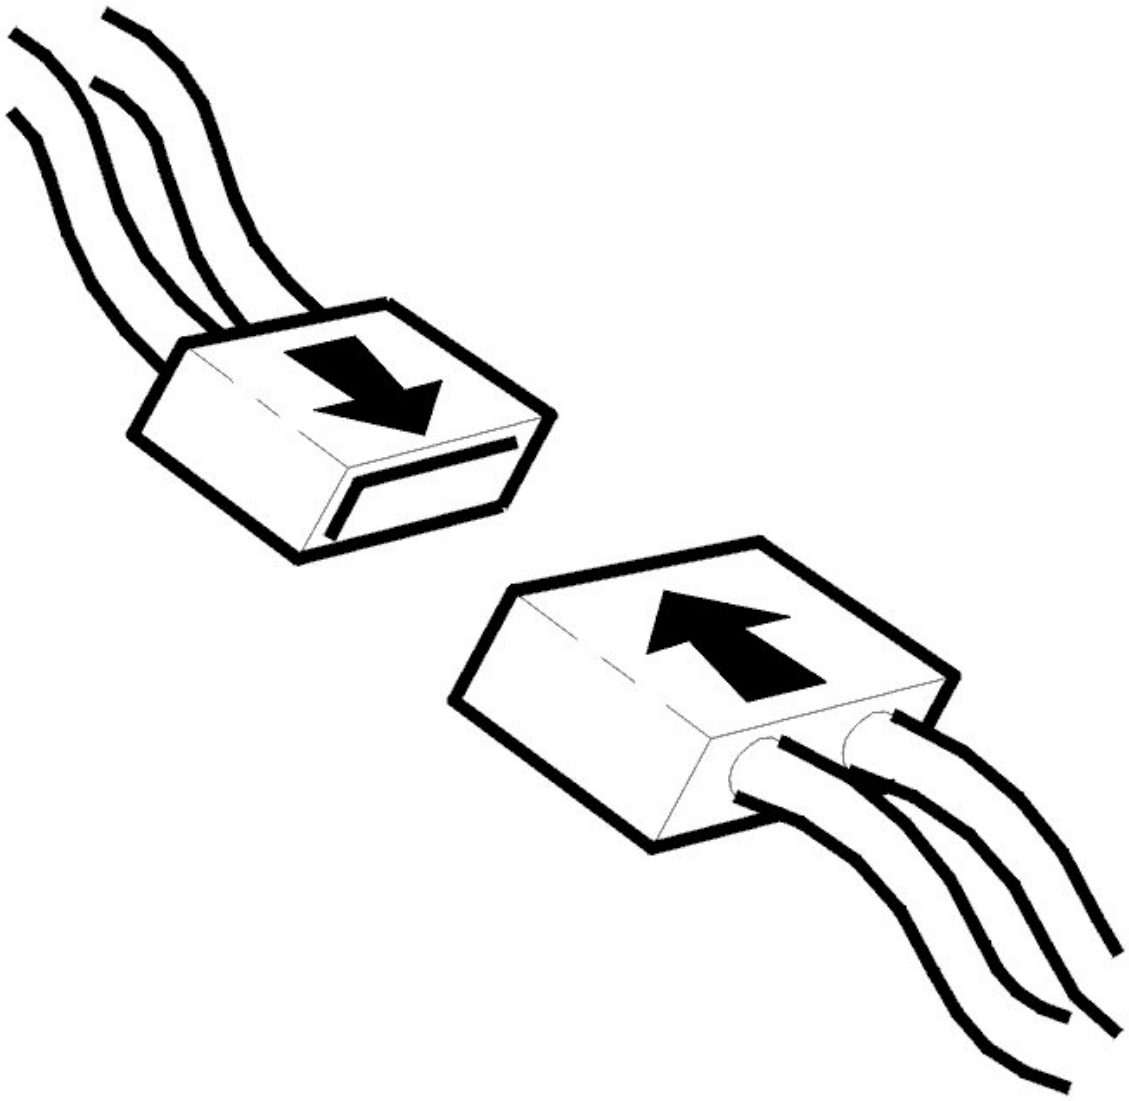
Verification

Verification

Verification

Hint: After carrying out the repair, check that the fault has been remedied.





- Ignition off
- Reconnect the connectors, reinstall components etc.
- Test drive the vehicle on the road. Run a TRIP schedule so that the engine control module (ECM) compares the diagnostics. To run a TRIP schedule, see: Verifying repairs See: Monitors, Trips, Drive Cycles and Readiness Codes/Verifying Repairs
- Connect VCT2000 to the data link connector (DLC) without switching off the engine.

Note! If the engine is switched off, the stored fault status will be erased and the test drive will have to be repeated.

Read off the diagnostic status and fault status for the diagnostic trouble code (DTC) by selecting the relevant diagnostic trouble code (DTC) from the list.
Check the fault status for the diagnostic trouble code (DTC) when the diagnostic is "Complete". If the function is correct, the fault status must be "No fault found" when the diagnostic is complete.

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information ECM-210D

Condition

The engine control module (ECM) receives information from the heated oxygen sensor (HO2S) (bank 1) about the fuel / air mixture when idling and at both the upper and lower part-load range. If the fuel / air mixture deviates from lambda=1, the short-term fuel trim will compensate for this by adjusting the injection time so that lambda=1 is achieved. When the short-term fuel trim makes an adjustment, the integrator median must be adjusted by the long-term trim. The diagnostic trouble code (DTC) is stored when the long-term trim must be adjusted to almost maximum in the upper part load area.

Substitute value
- None.

Possible source
- Intake air leakage
- High fuel pressure
- Leaking injectors
- Damaged mass air flow (MAF) sensor
- Contaminated engine oil
- Oil level too high
- Damaged heated oxygen sensor (HO2S) (bank 1).

Fault symptom[s]
- None.

Signal Too Low

Signal too low

Checking the fuel injection system

Check the intake system for air leakage.

Hint: Air leakage in the intake system can occur through the evaporative emission system (EVAP) valve, the secondary air solenoid valve or the power brake booster.

Check the exhaust system for leakage.
Check the fuel pressure and residual pressure.
Check that the oil level is within the minimum and maximum markings.

Check the viscosity of the engine oil by reading off the short-term fuel trim with the engine running. Plug the crankcase ventilation and read off the short-term fuel trim again. The value must be more or less unchanged.
Remedy as necessary.

Other information:

- Check for air leaks in the intake system See: Fuel Delivery and Air Induction/Testing and Inspection/Air Leaks in the Intake System, Checking
- Checking for air leakage in the exhaust system See: Diagnostic Trouble Code Tests and Associated Procedures/Related Tests, Information and Procedures/Air Leakage Exhaust System, Check

Was a fault detected?

Yes - Verification

No - Checking the mass air flow (MAF) sensor

Checking the mass air flow (MAF) sensor

Test drive the car for approximately 10 minutes.
Read off the correction factor of the mass air flow (MAF) sensor. The value must be between 0.8 and 1.2.

Note! There must not be any air leakage when this test is carried out.

Remedy as necessary.

Description of Diagnostic Trouble Code (DTC) Status

Description of diagnostic trouble code (DTC) status

The purpose of "Reading off the diagnostic trouble code (DTC) status" is to determine whether the diagnostic trouble code (DTC) is permanent or intermittent. Because of the different criteria for diagnostics, the text message "Diagnostic function not ready" may appear when reading off. Below is an explanation of the different statuses which may occur.

Diagnostic function not ready

To run a diagnostic, all conditions must be met for the test of the relevant component or sub-system. For certain components/sub-systems, switching on the ignition is sufficient to run the diagnostic. Other require more specific conditions, such as engine speed and temperature etc. This means for example, that diagnostics requiring an engine speed above 3000 rpm will never run on a stationary car when the engine is only idling. In such cases, where the diagnostic has not run in the present operating cycle, the test message "Diagnostic function not ready" will be displayed.

Permanent

If a diagnostic trouble code (DTC) with a permanent status is stored, the control module has registered a fault and the fault is still present.

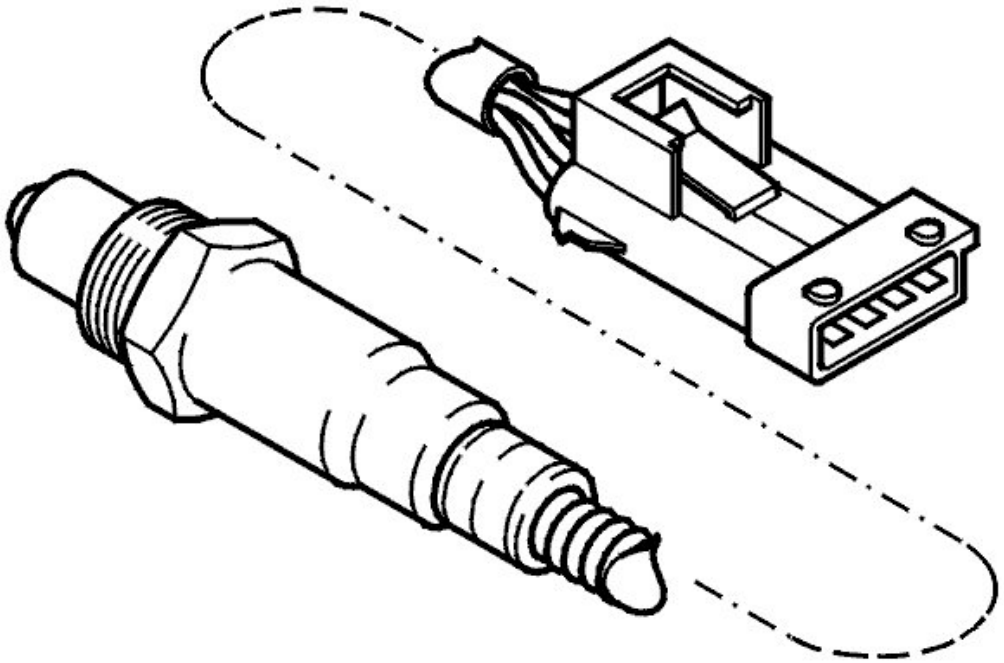
Intermittent

If a diagnostic trouble code (DTC) with an intermittent status is stored, the control module has registered a fault and the fault is not present at the moment.
An intermittent electrical fault can be caused by faults in the wiring, components or connectors.
Intermittent functional faults could be caused by mechanical defects in the components.

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information ECM-2200

Condition



The diagnostic trouble code (DTC) is stored if the engine control module (ECM) registers that the resistance of the rear heated oxygen sensor (HO2S) in the pre-heating circuit is too high for a certain amount of time.

Substitute value
- None.

Possible source
- Contact resistance or oxidation in the terminals
- Damaged rear heated oxygen sensor (HO2S).

Fault symptom[s]
- Malfunction indicator lamp (MIL) lit.

Faulty Signal

Faulty signal

Checking the connector

Check power cable terminal #1 in the rear heated oxygen sensor (HO2S) connector. Check for contact resistance. Check for oxidation.
Check ground lead terminal #2 in the rear heated oxygen sensor (HO2S) connector. Check for contact resistance. Check for oxidation.
Try a new heated oxygen sensor (HO2S) if the above fault-tracing does not remedy the fault.
Remedy as necessary.

Other information
- Heated oxygen sensor (HO2S), replacing See: Oxygen Sensor/Service and Repair/Heated Oxygen Sensor (HO2S), Replacing

Diagnostic Trouble Code (DTC) Information

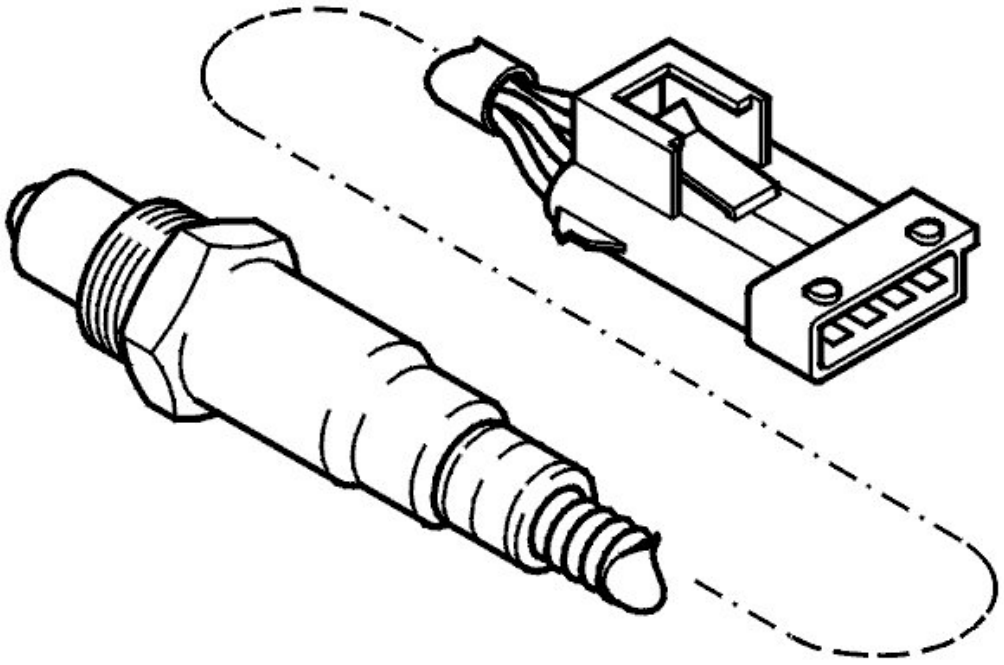
Diagnostic trouble code (DTC) information ECM-221C

Condition



The engine control module (ECM) monitors the operation of the rear heated oxygen sensor (HO2S) by checking its signal. The engine control module (ECM) checks that the probe has registered a rich fuel/air mixture. If this is not the case, the engine control module (ECM) changes the fuel/air mixture. The diagnostic trouble code (DTC) is stored if the rear probe has still not registered a rich fuel / air mixture.

Substitute value

- None.

Possible source
- Leakage in the exhaust system
- Damaged rear heated oxygen sensor (HO2S).

Fault symptom[s]
- Malfunction indicator lamp (MIL) lit.

Signal Too High/Signal Too Low/Signal Missing

Diagnostic Trouble Code (DTC) Information

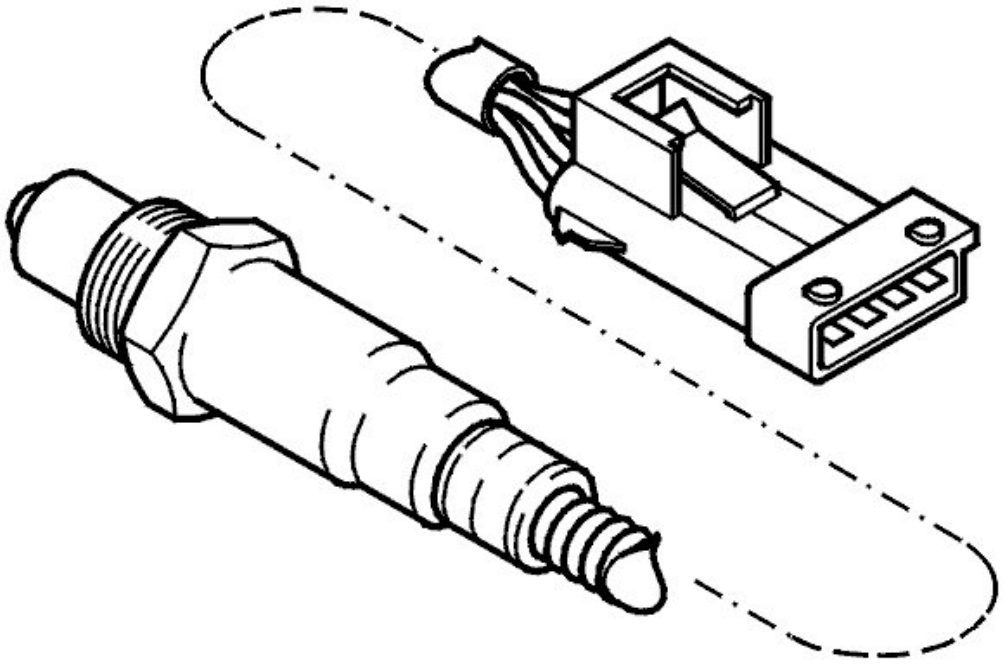
Diagnostic trouble code (DTC) information ECM-2220

Condition



The engine control module (ECM) monitors the operation of the rear heated oxygen sensor (HO2S) by checking its signal. The diagnostic trouble code (DTC) is stored if the engine control module (ECM) registers that the signal deviates from its permitted operational range or if the voltage for the heated oxygen sensor (HO2S) preheating disrupts the heated oxygen sensor (HO2S) signal.

Substitute value

- Rear heated oxygen sensor (HO2S) control is disabled
- Three-way catalytic converter (TWC) diagnostics are disabled.

Possible source
- Short-circuit in the signal cable for the pre-heating circuit
- Short-circuit in the ground lead for the preheating circuit
- Damaged rear heated oxygen sensor (HO2S).

Fault symptom[s]
- Malfunction indicator lamp (MIL) lit.

Faulty Signal

Faulty signal

Checking the components and wiring

Check the following cables for a short-circuit to each other.
- Engine control module (ECM) terminal #A61 (#B1) and heated oxygen sensor (HO2S) terminal #4
- Engine control module (ECM) terminal #A6 (#A6) and heated oxygen sensor (HO2S) terminal #2
- Heated oxygen sensor (HO2S) terminal #1 and the system relay.

Check the following cables for a short-circuit to each other.
- Engine control module (ECM) terminal #A62 (#B2) and heated oxygen sensor (HO2S) terminal #3
- Engine control module (ECM) terminal #A6 (#A6) and heated oxygen sensor (HO2S) terminal #2
- Heated oxygen sensor (HO2S) terminal #1 and the system relay.

Try a new heated oxygen sensor (HO2S) if the above fault-tracing does not remedy the fault.
Remedy as necessary.

Diagnostic Trouble Code (DTC) Information

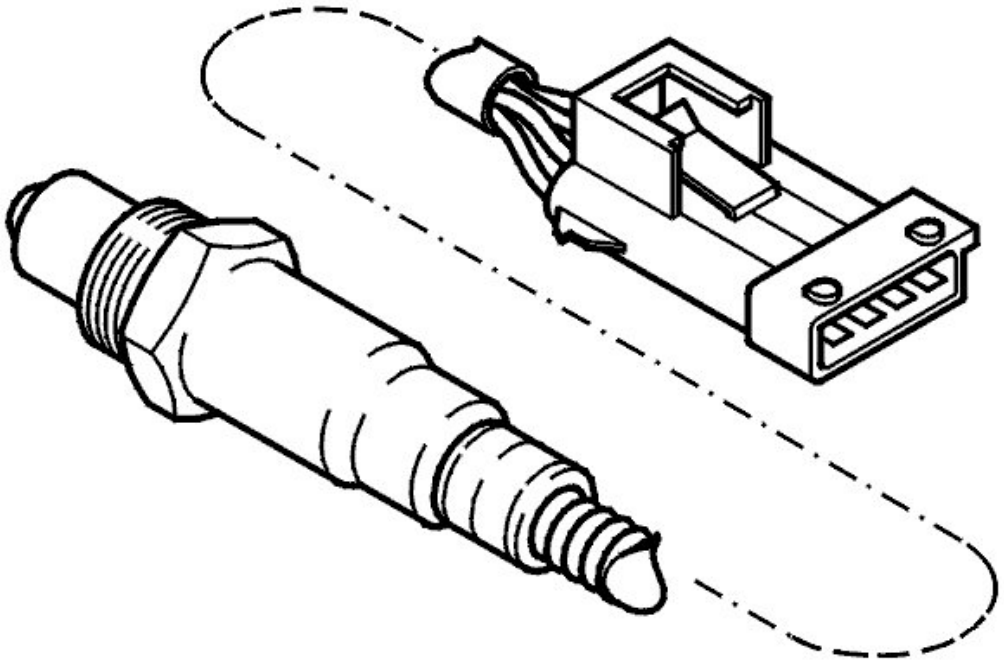
Diagnostic trouble code (DTC) information ECM-223B

Condition



The engine control module (ECM) controls the preheating of the rear heated oxygen sensor (HO2S) by pulsing the current to the positive temperature coefficient (PTC) element in the heated oxygen sensor (HO2S). Pulse lengths are dependent on the temperature of the heated oxygen sensor (H02S).
The diagnostic trouble code (DTC) is stored if the engine control module (ECM) registers that the signal is lower than a certain value when preheating is deactivated.

Substitute value
- The fuel trim is shut off.

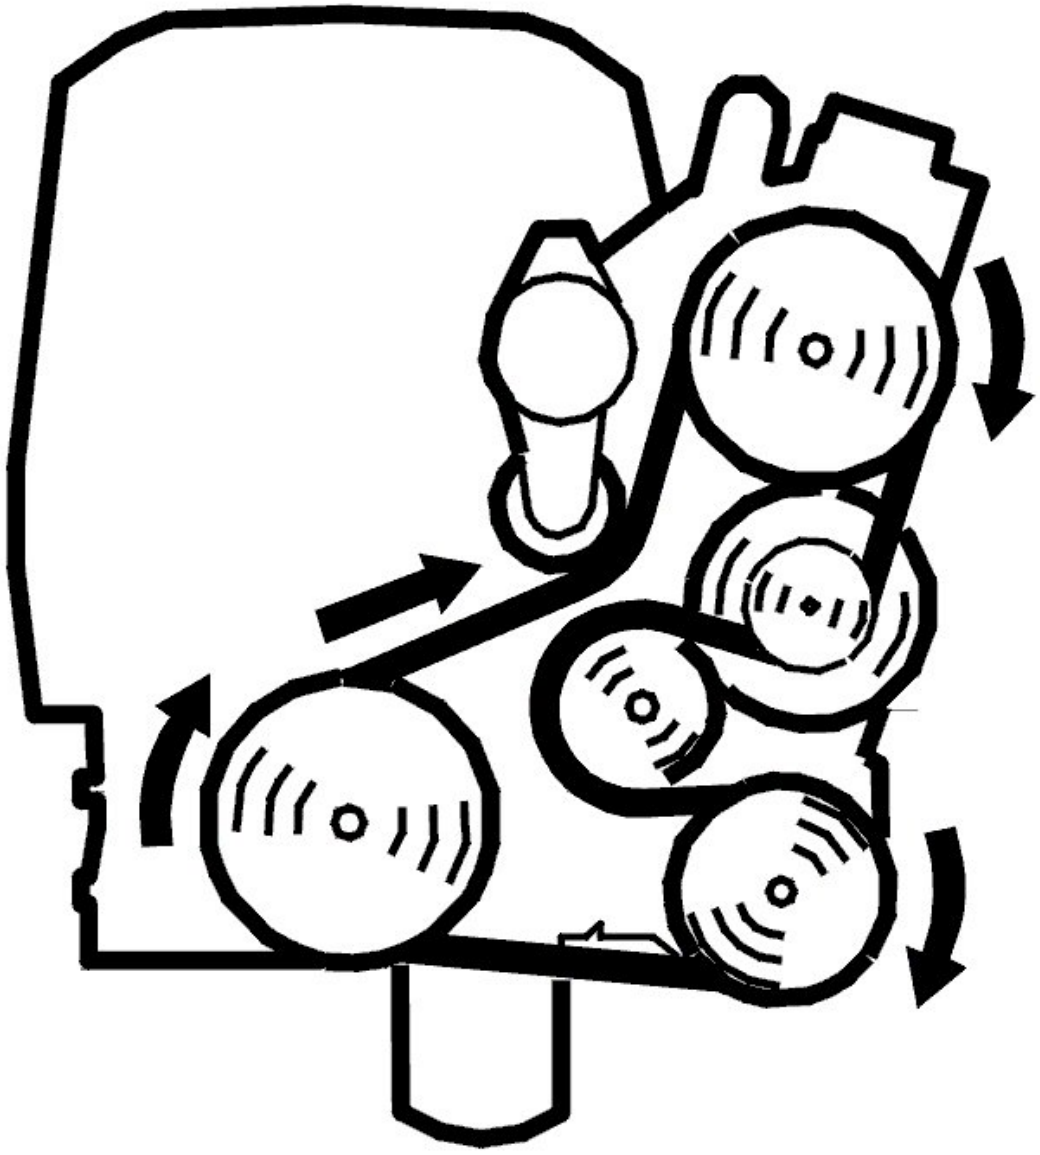
Possible source
- Contact resistance and oxidation in the terminals
- Open-circuit in the power supply from the system relay
- Damaged heated oxygen sensor (HO2S).

Fault symptom[s]
- Malfunction indicator lamp (MIL) lit.

Signal Missing

Signal missing

Checking the status

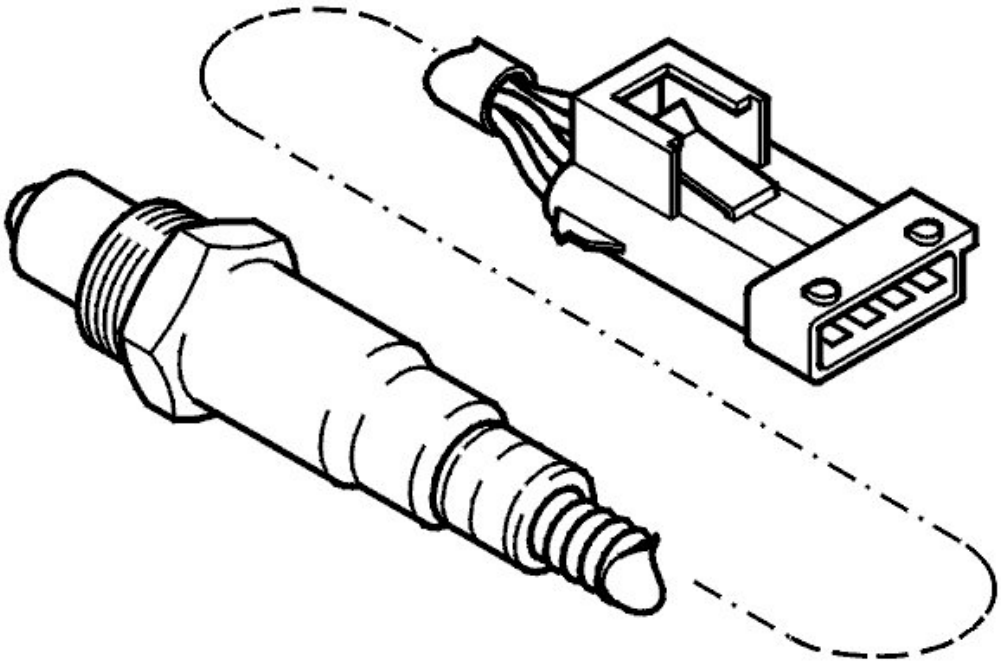


- Start the engine.

Read off the diagnostic status and fault status for the diagnostic trouble code (DTC) by selecting the relevant diagnostic trouble code (DTC) from the list.
Increase the engine speed to 2500 rpm until the diagnostic is "Complete".
Check whether the fault is permanent or intermittent. Read off the diagnostic trouble code (DTC) fault status when the diagnostic status is "Completed".

Hint: In some cases several functions of the component will be diagnosed. The affects the amount of time taken to run the diagnostic.

The fault is permanent if the fault status is "Fault found". If the fault status is "No fault found" the fault is intermittent and not presently active.



Continue - Checking the components and wiring

Checking the components and wiring

Verification

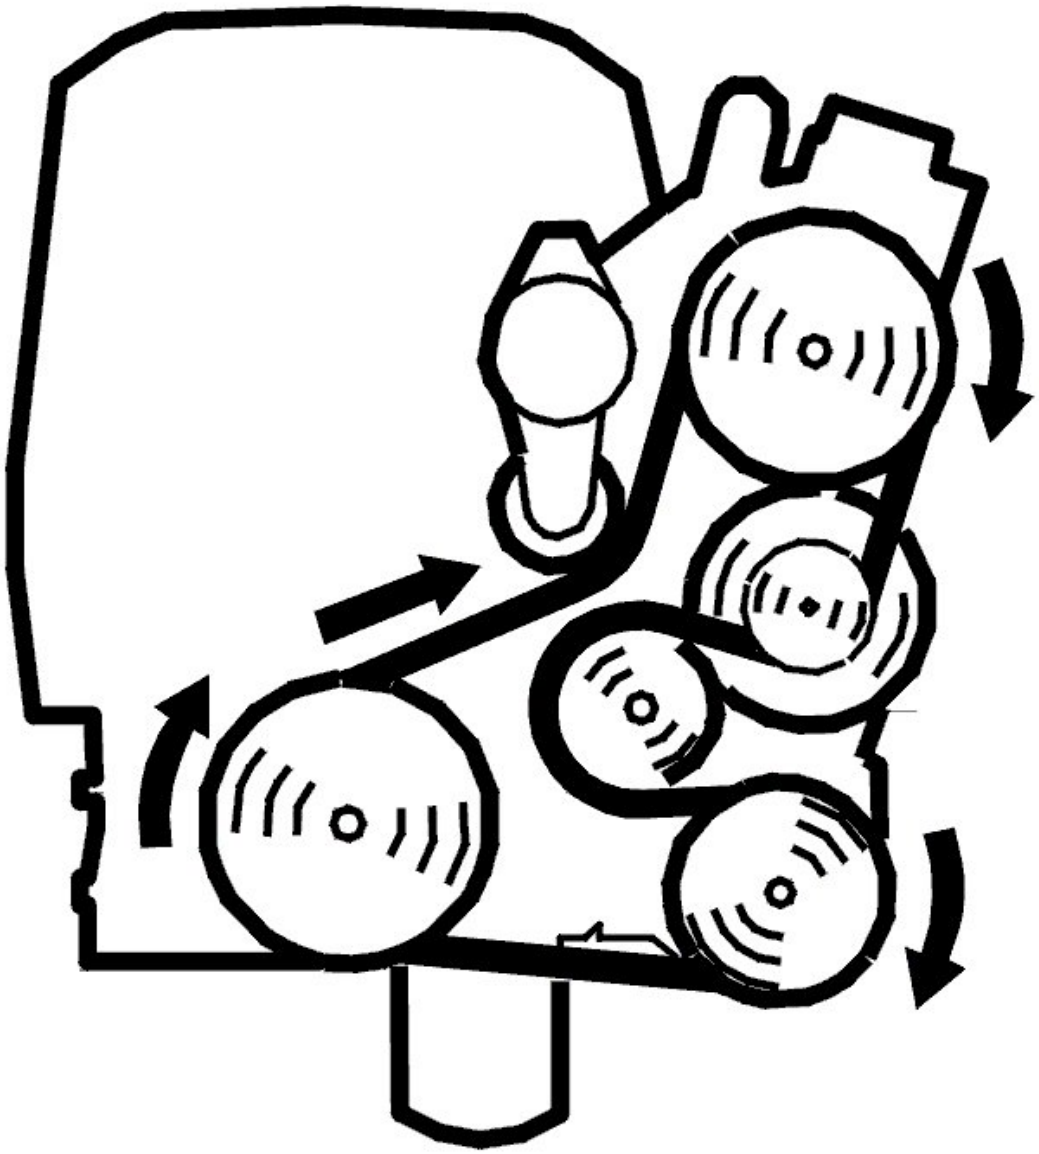
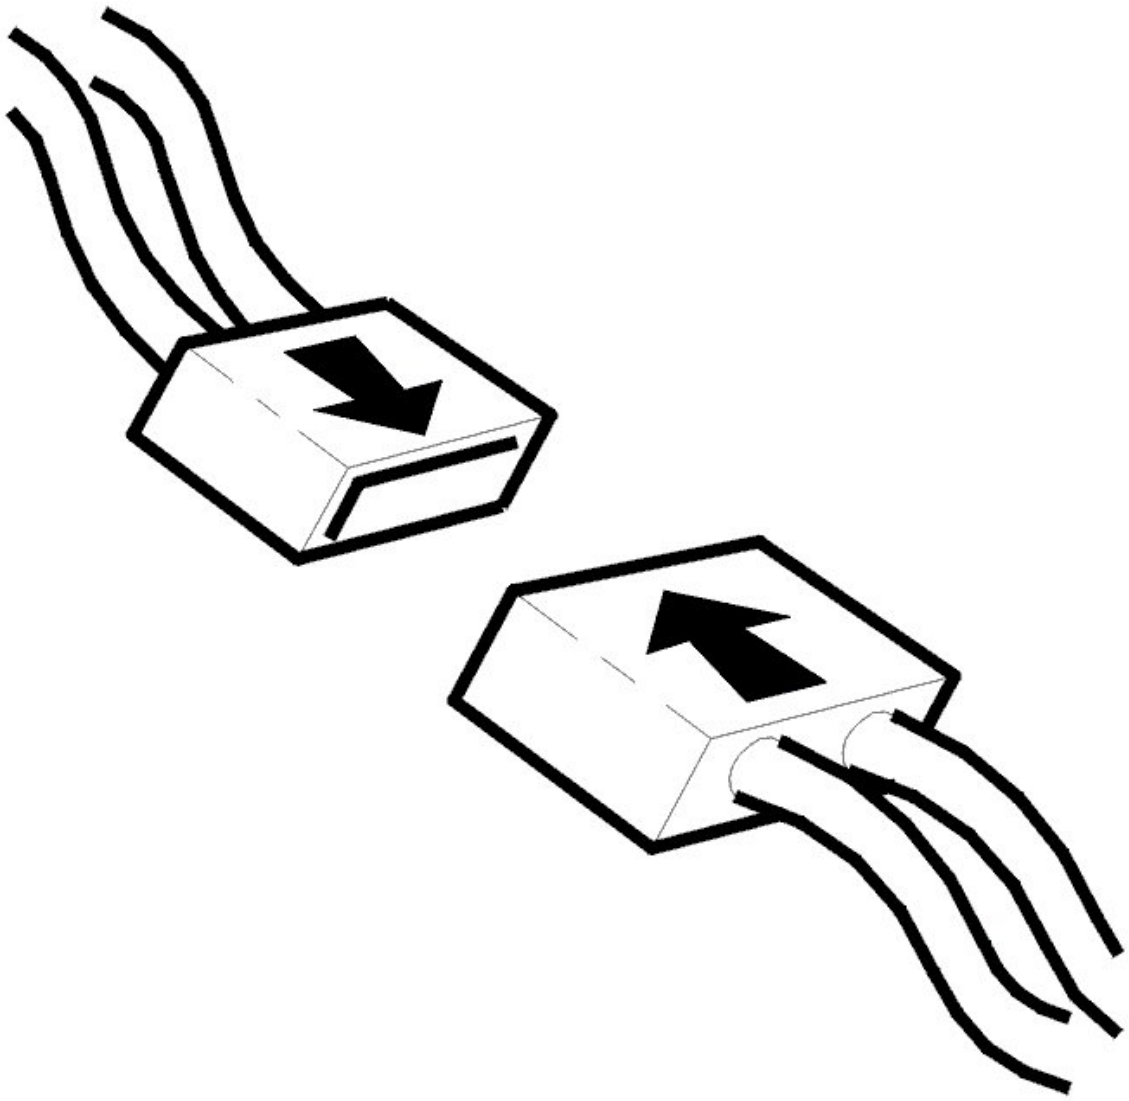
Hint: After carrying out the repair, check that the fault has been remedied.





- Ignition off
- Reconnect the connectors, reinstall components etc.
- Start the engine.

Read off the diagnostic status and fault status for the diagnostic trouble code (DTC) by selecting the relevant diagnostic trouble code (DTC) from the list.
Increase the engine speed to 2500 rpm until the diagnostic is "Complete".
Check the fault status for the diagnostic trouble code (DTC) when the diagnostic is "Complete". If the function is correct, the fault status must be "No fault found" when the diagnostic is complete.

Is the function OK?

Yes - VERIFIED

No - VERIFICATION FAILED

VERIFICATION FAILED - Fault-tracing information

VERIFIED - Fault Found

Information

Fault-tracing information

The fault should have been detected and remedied. As this is not the case fault-tracing has failed.
Exit fault-tracing for this diagnostic trouble code (DTC) or make another attempt.

Do you want to exit fault-tracing?

Yes - FAULT-TRACING FAILED

No - Attempt New Test

FAULT-TRACING FAILED - FAULT-TRACING FAILED

Attempt New Test - Checking the components and wiring

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information ECM-2240

Condition

The diagnostic trouble code (DTC) is stored if the engine control module (ECM) detects that the rear heated oxygen sensors (HO2S) (banks 1 and 2) have been switched.
The diagnostic trouble code (DTC) is diagnosed when the engine has been idling for 10 minutes.

Substitute value
- The heated oxygen sensor (HO2S) control is disabled
- Three-way catalytic converter (TWC) diagnostics are disabled.

Possible source
- The rear heated oxygen sensors (HO2S) have been installed in the wrong bank
- Both the rear heated oxygen sensors (HO2S) are damaged.

Fault symptom[s]
- Malfunction indicator lamp (MIL) lit.

Faulty Signal

Faulty signal

Checking the components and wiring

Visually check that the rear heated oxygen sensors (HO2S) have not been mounted in the wrong bank on banks 1 and 2.
Read off the voltage of the probe on the rear heated oxygen sensor (HO2S) for bank 1.
Read off the voltage of the probe on the rear heated oxygen sensor (HO2S) for bank 2.

Hint: If the voltage is constantly close to 0 V on one bank and 1 V on the other bank, or vice-versa, the rear heated oxygen sensors (HO2S) have been switched.

Try new heated oxygen sensors (HO2S) if the above fault-tracing does not remedy the fault.
Remedy as necessary.

Diagnostic Trouble Code (DTC) Information

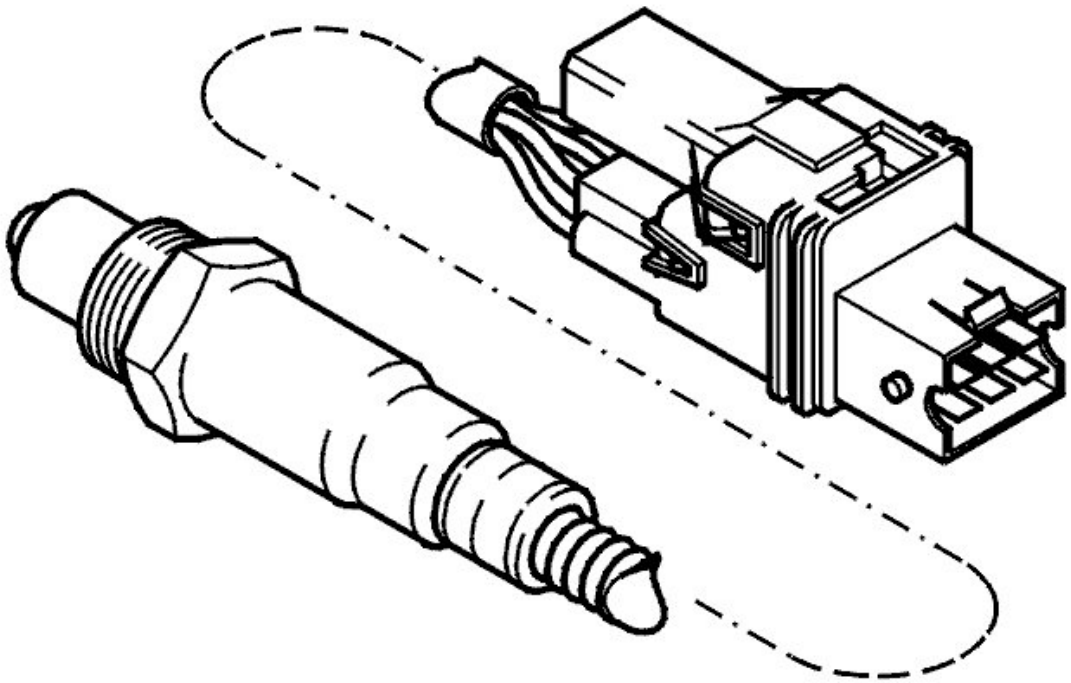
Diagnostic trouble code (DTC) information ECM-2450

Condition



The diagnostic trouble code (DTC) is stored if the engine control module (ECM) registers an internal fault in the control for the heated oxygen sensors (HO2S).
The diagnostic trouble code (DTC) can be diagnosed when the ignition is switched on.

Substitute value

- None.

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

Possible source
- Damaged engine control module (ECM).

Fault symptom[s]
- Malfunction indicator lamp (MIL) lit.

Internal Fault

Internal fault

Replacing the component

The engine control module (ECM) has registered an internal fault.
If the fault is intermittent, it has been registered previously but is no longer present. Intermittent faults can be caused by interference at start up of the engine control module (ECM) or may be a different type of fault which occurs on different occasions. The fault is evaluated depending on how it occurs. Replace the engine control module (ECM) if the fault recurs.
Replace the engine control module (ECM) in the event of a permanent fault.
Engine control module (ECM), replacing See: Engine Control Module/Service and Repair
Remedy as necessary.

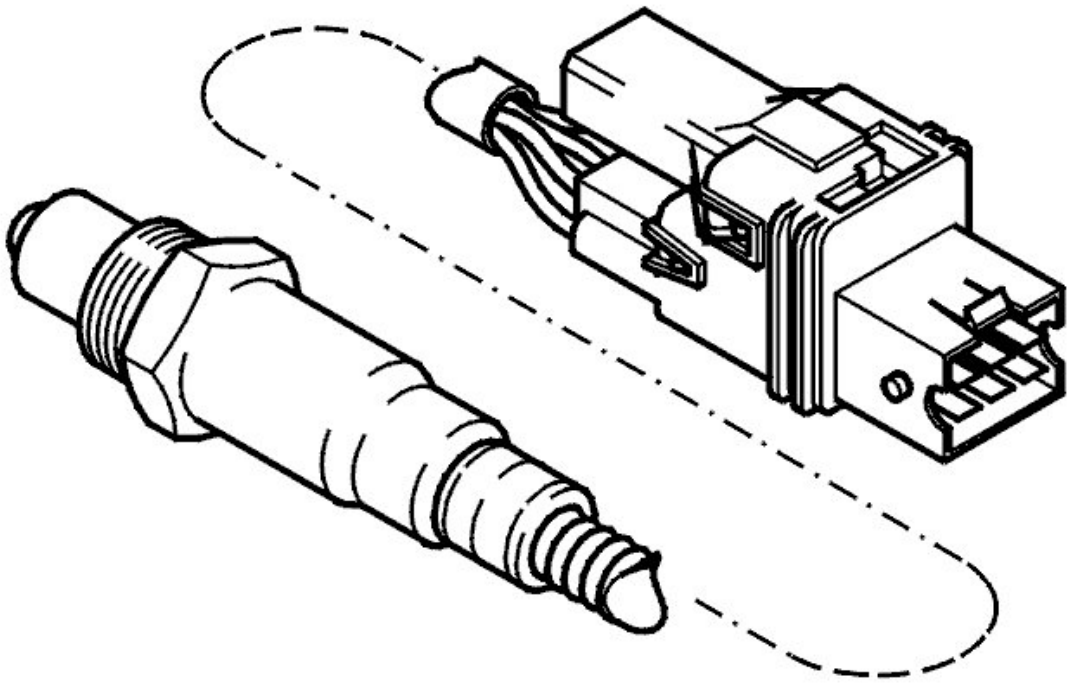
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information ECM-245B

Condition



The diagnostic trouble code (DTC) is stored if the engine control module (ECM) registers an internal fault in the control for the heated oxygen sensors (HO2S).
The diagnostic trouble code (DTC) can be diagnosed when the ignition is switched on.

Substitute value
- None.

Possible source
- Damaged engine control module (ECM).

Fault symptom[s]
- Malfunction indicator lamp (MIL) lit.

Internal Fault

Internal fault

Replacing the component

The engine control module (ECM) has registered an internal fault.
If the fault is intermittent, it has been registered previously but is no longer present. Intermittent faults can be caused by interference at start up of the engine control module (ECM) or may be a different type of fault which occurs on different occasions. The fault is evaluated depending on how it occurs. Replace the engine control module (ECM) if the fault recurs.
Replace the engine control module (ECM) in the event of a permanent fault.

Engine control module (ECM), replacing See: Engine Control Module/Service and Repair
Remedy as necessary.

Diagnostic Trouble Code (DTC) Information

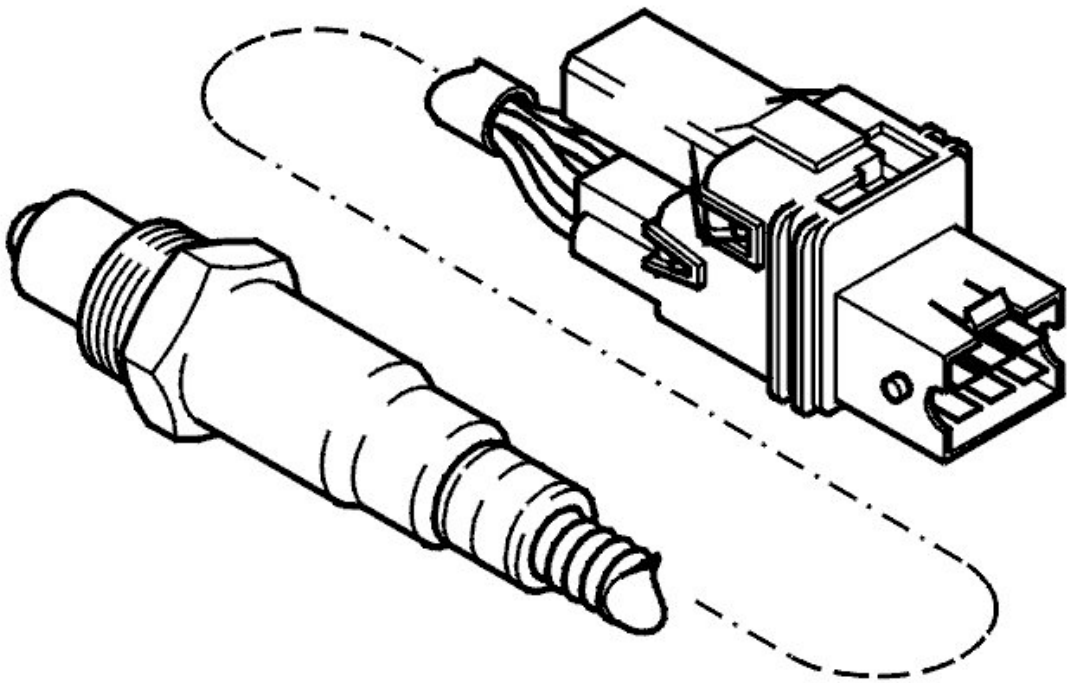
Diagnostic trouble code (DTC) information ECM-246B

Condition



The diagnostic trouble code (DTC) is stored if the engine control module (ECM) registers that the calibration current has ceased and the front heated oxygen sensor (HO2S) signal (bank 1) is implausibly high at fuel shut-off.

Substitute value
- None.

Possible source
- Contact resistance and oxidation in the terminals
- Open-circuit in the cable for calibration current
- Damaged front heated oxygen sensor (HO2S).

Fault symptom[s]
- Malfunction indicator lamp (MIL) lit.

Signal Missing

Signal missing

Checking the components and wiring

Caution! Do not apply rust solvent spray or grease to the heated oxygen sensor (HO2S) connector.

Check the heated oxygen sensor (HO2S) connector. Check for contact resistance and oxidation.
Check the cable between engine control module (ECM) terminal #A28 (#A28) and heated oxygen sensor (HO2S) terminal #2. Check for an open-circuit.

Note! If possible, measure from the rear of the affected connectors in order to minimize any damage and future loose connections.

Try a new heated oxygen sensor (HO2S) if the above fault-tracing does not remedy the fault.
Remedy as necessary.

Diagnostic trouble code (DTC) information ECM-24A0

Condition

The diagnostic trouble code (DTC) is stored if the engine control module (ECM) detects that the front heated oxygen sensors (HO2S) (bank 1 and bank 2) have been switched. This means they are installed in the incorrect bank of cylinders.
The diagnostic trouble codes (DTCs) are diagnosed when the engine has been idling for 10 minutes

Substitute value
- The heated oxygen sensor (HO2S) control is disabled
- Three-way catalytic converter (TWC) diagnostics are disabled.

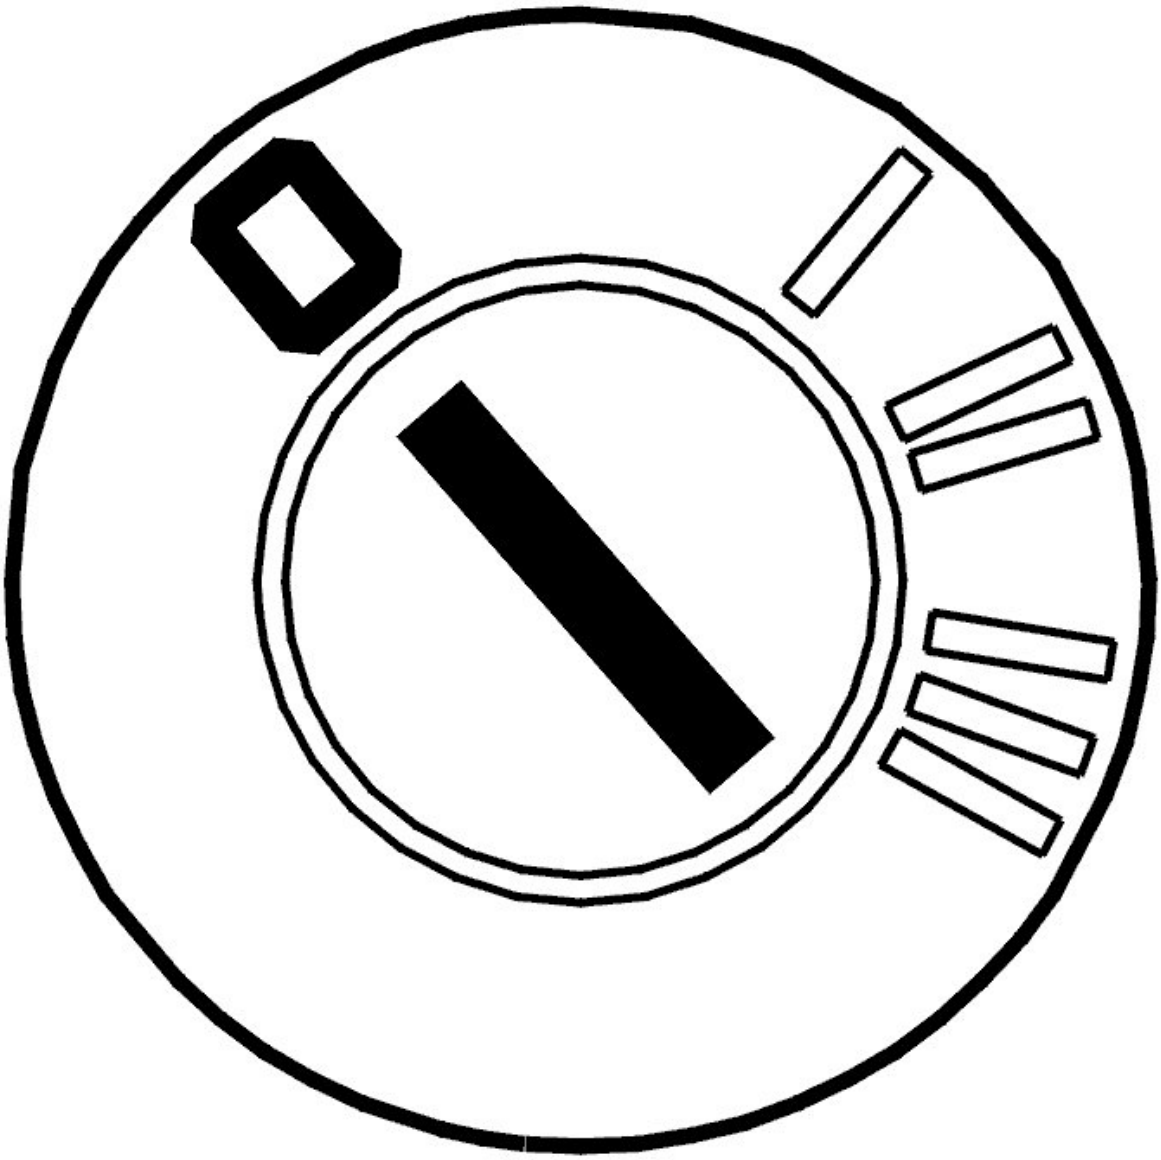
Possible source
- The front heated oxygen sensors (HO2S) are mounted in the incorrect cylinder banks
- Leakage in the fuel injection system
- Both the front heated oxygen sensors (HO2S) are damaged.

Fault symptom[s]
- Malfunction indicator lamp (MIL) lit.

Faulty Signal

Faulty signal

Checking the component



- Ignition off
- Check that the front heated oxygen sensors (HO2S) bank 1 and bank 2 have not been switched (mounted in the incorrect bank of cylinders)
- Remedy as necessary.

Other information:
- To access or replace the front heated oxygen sensors (HO2S), see Heated oxygen sensor (HO2S), replacing See: Oxygen Sensor/Service and Repair/Heated Oxygen Sensor (HO2S), Replacing.

Have the heated oxygen sensors (HO2S) been switched?

Yes - Verification

No - Checking the fuel injection system for leakage

Checking the fuel injection system for leakage
- Check the fuel injection system for leakage
- Remedy as necessary.

If no faults are found during the checks and the fault recurs as permanent, replace both heated oxygen sensors (HO2S).

Other information:
- To access or replace the front heated oxygen sensors (HO2S), see Heated oxygen sensor (HO2S), replacing See: Oxygen Sensor/Service and Repair/Heated Oxygen Sensor (HO2S), Replacing.

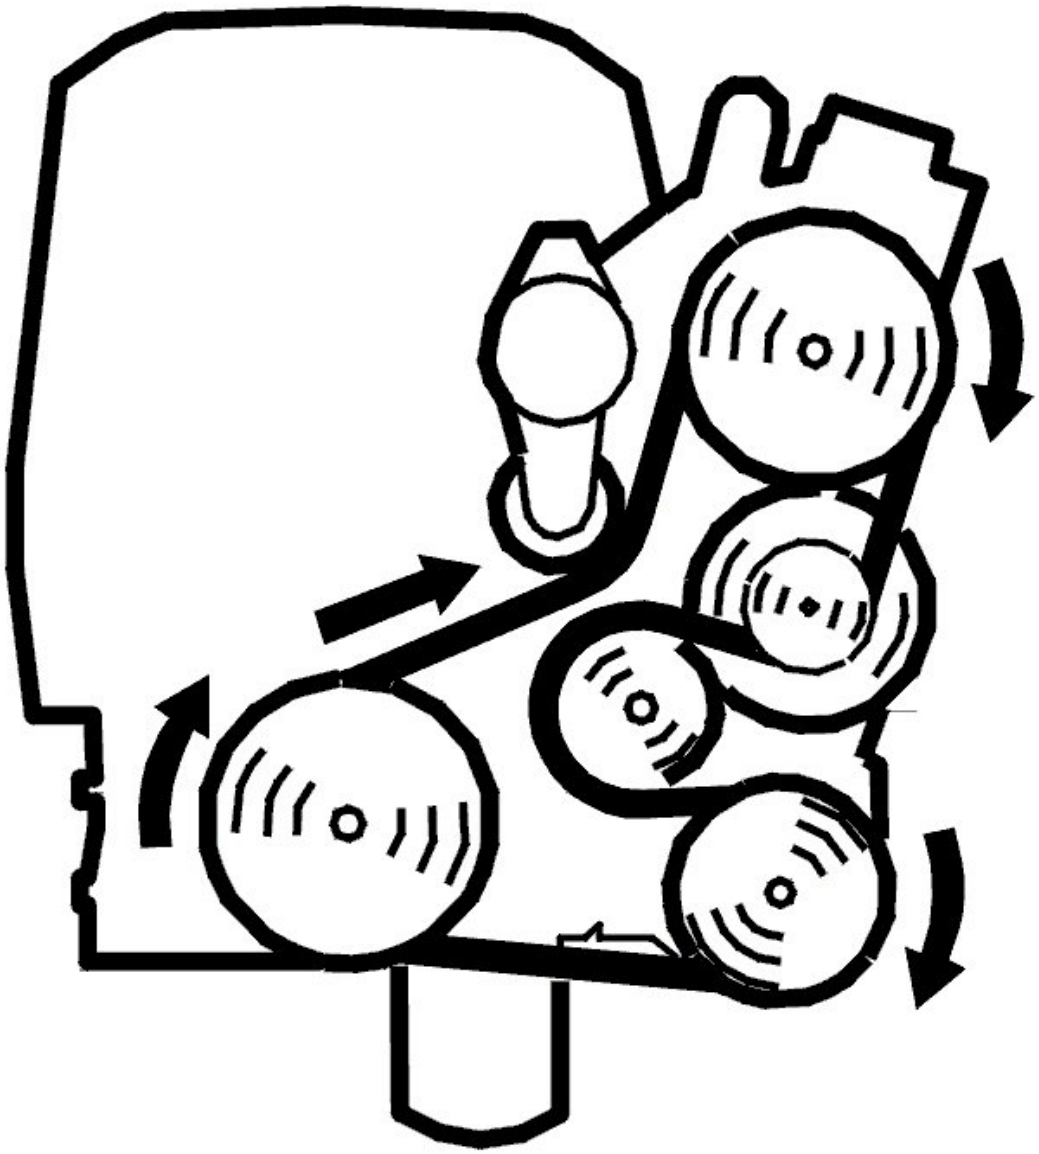
Continue - Verification

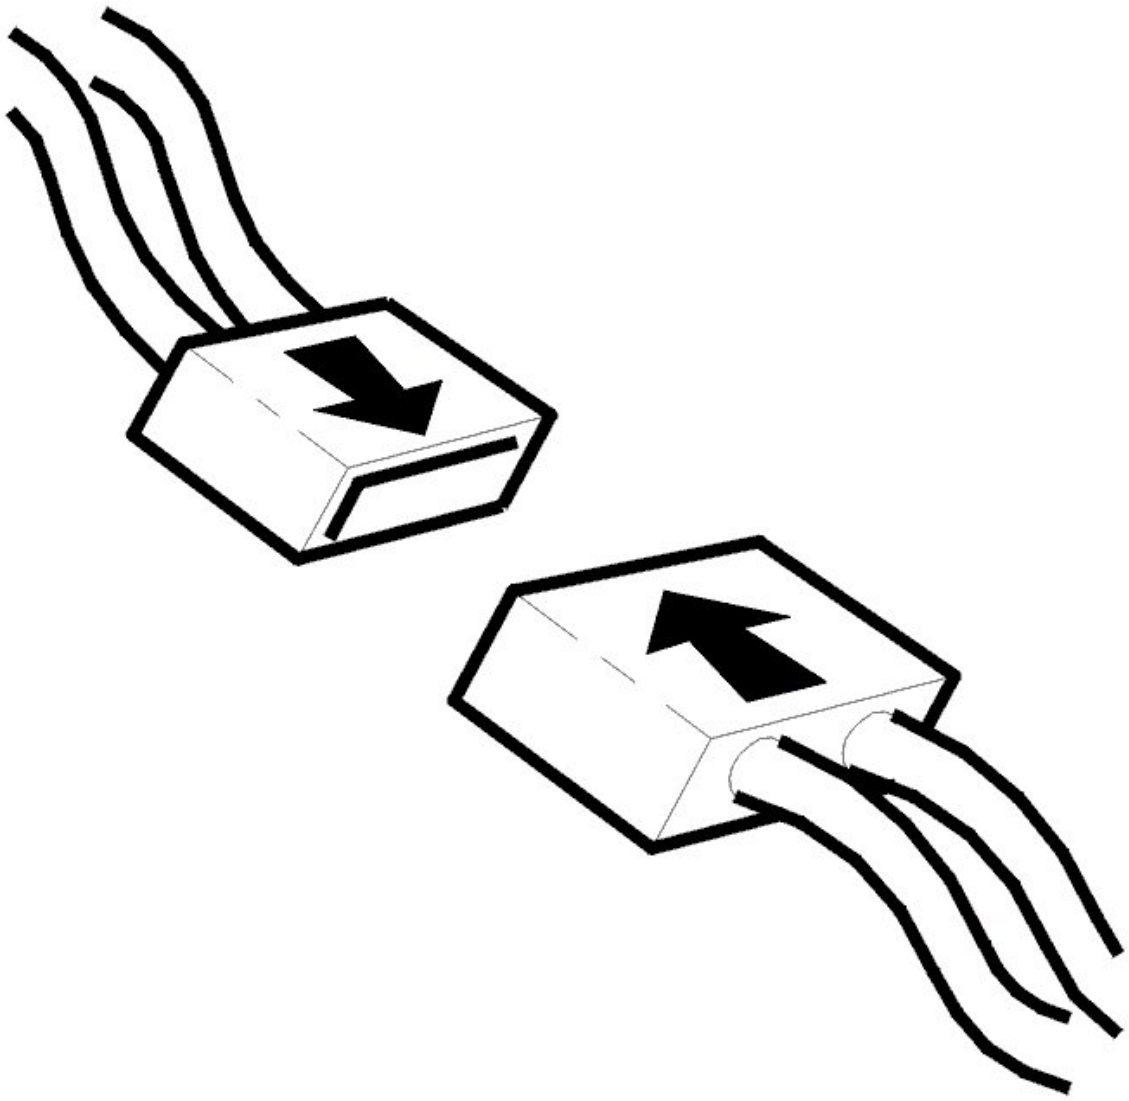
Verification

Verification

Verification

Hint: After carrying out the repair, check that the fault has been remedied.





- Ignition off
- Reconnect the connectors, reinstall components etc.
- Start the engine. Allow the engine to idle for 10 minutes
- Read off diagnostic trouble codes (DTCs).

The fault has been remedied if status of the diagnostic trouble code (DTC) is intermittent.

Is the status of the diagnostic trouble code (DTC) intermittent?

Yes - VERIFIED

No - VERIFICATION FAILED

VERIFICATION FAILED - Fault-tracing information

VERIFIED - Fault Found

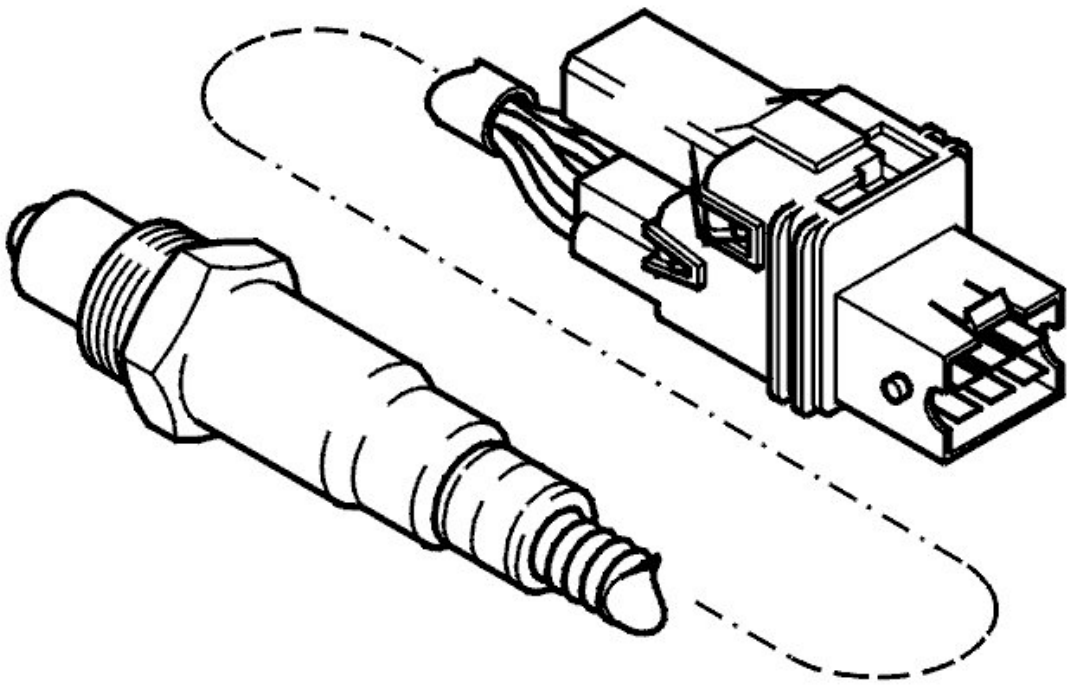
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information ECM-24BB

Condition



The engine control module (ECM) monitors the function of the front heated oxygen sensor (HO2S) (bank 1) by checking its signal. The engine control module (ECM) compares the adaptation values of the front and rear heated oxygen sensor (HO2S). The diagnostic trouble code (DTC) is stored when the values deviate by more than 3%.

Note! The fault may be in the front or rear heated oxygen sensor (HO2S) circuit.

Substitute value
- Long-term fuel trim is switched off
- Three-way catalytic converter (TWC) diagnostics are disabled.

Possible source
- Leakage in the exhaust system
- Heated oxygen sensor (HO2S) indicates an incorrectly rich fuel/air mixture

- Contact resistance or oxidation in the terminals
- Damaged heated oxygen sensor (HO2S).

Fault symptom[s]
- Malfunction indicator lamp (MIL) lit.

Signal Missing

Signal missing

Checking components

Check the connectors for the heated oxygen sensors (HO2S). Check for contact resistance. Check for oxidation.
Check the exhaust system for air leakage.

Hint: If the above fault-tracing does not remedy the fault, try replacing the heated oxygen sensors (HO2S), as the diagnostic trouble code (DTC) can also be stored by a damaged front/rear heated oxygen sensor (HO2S).

Remedy as necessary.

Other information
- Checking for air leakage in the exhaust system See: Diagnostic Trouble Code Tests and Associated Procedures/Related Tests, Information and Procedures/Air Leakage Exhaust System, Check
- Heated oxygen sensor (HO2S), replacing See: Oxygen Sensor/Service and Repair/Heated Oxygen Sensor (HO2S), Replacing
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

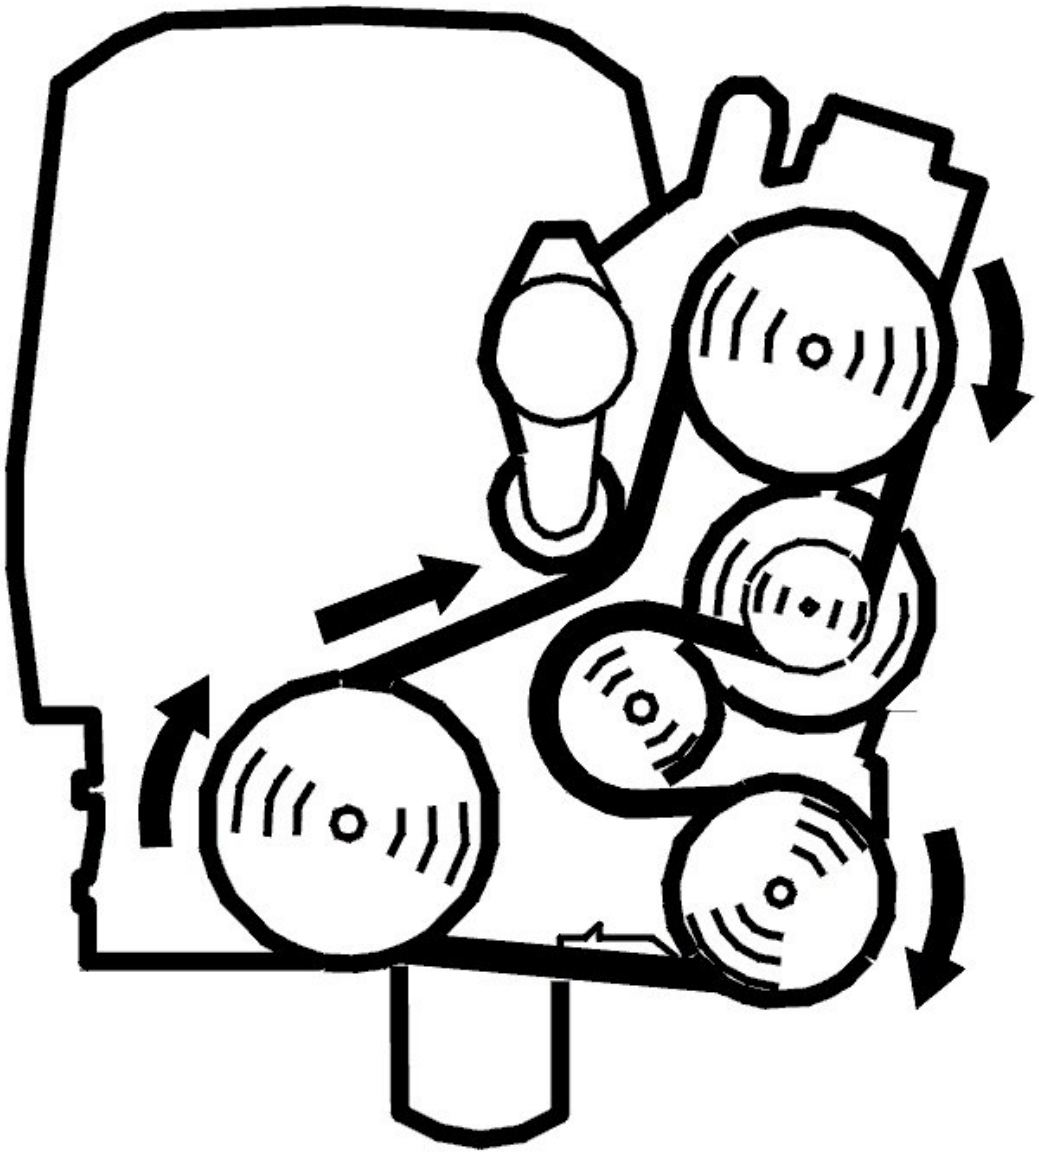
Continue - Verification

Verification

Verification

Verification

Hint: After carrying out the repair, check that the fault has been remedied.



- Ignition off
- Reconnect the connectors, reinstall components etc.
- Test drive the car at an even speed (engine speed (RPM) above 2000 rpm) for at least 10 minutes
- Release the accelerator pedal (AP) quickly at least three times to simulate fuel shut-off
- Connect VCT2000 to the data link connector (DLC) without switching off the engine.

Note! If the engine is switched off, the stored fault status will be erased and the test drive will have to be repeated.

Read out the deviation between the front and rear heated oxygen sensor (HO2S).
Check that the value is between -0.03 and +0.03.

Diagnostic Trouble Code (DTC) Information

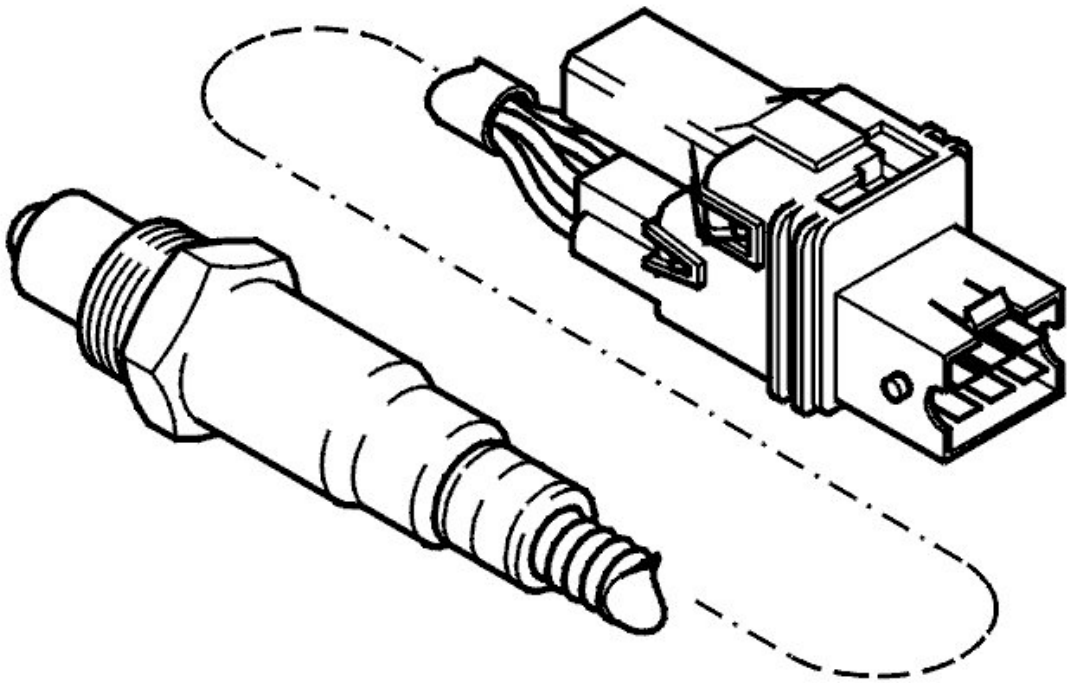
Diagnostic trouble code (DTC) information ECM-24B0

Condition



The engine control module (ECM) monitors the function of the front heated oxygen sensor (HO2S) (bank 1) by checking its signal. The diagnostic trouble code (DTC) is stored if the engine control module (ECM) registers that the signal from the heated oxygen sensor (HO2S) indicates an incorrect lean or rich fuel/air mixture compared to that anticipated by the engine control module (ECM).

Note! The fault may be in the front or rear heated oxygen sensor (HO2S) circuit.

Substitute value

- Long-term fuel trim is switched off
- Three-way catalytic converter (TWC) diagnostics are disabled.

Possible source
- Leakage in the exhaust system
- Short-circuit to supply voltage or ground in signal cable (-)
- Short-circuit to supply voltage or ground in the pump supply cable
- Short-circuit to supply voltage or ground in calibration supply cable
- Open-circuit in signal cable (+)
- Damaged heated oxygen sensor (HO2S).

Fault symptom[s]
- Malfunction indicator lamp (MIL) lit.

Faulty Signal

Faulty signal

Checking components

Check the exhaust system for air leakage.
Check the cable for a short-circuit to supply voltage or ground.
Check between:
- The cable between engine control module (ECM) terminal #A42 (#A42) and heated oxygen sensor (HO2S) terminal #5
- The cable for pump current between engine control module (ECM) terminal #A24 (#A24) and heated oxygen sensor (HO2S) terminal #6
- The cable for calibration current between engine control module (ECM) terminal #A28 (#A28) and heated oxygen sensor (HO2S) terminal #2.

Check the cable between engine control module (ECM) terminal #A41 (#A41) and heated oxygen sensor (HO2S) terminal #1. Check for an open-circuit.

Hint: If the above fault-tracing does not remedy the fault, try replacing the heated oxygen sensors (HO2S), as the diagnostic trouble code (DTC) can also be stored by a damaged front/rear heated oxygen sensor (HO2S).

Remedy as necessary.

Diagnostic Trouble Code (DTC) Information

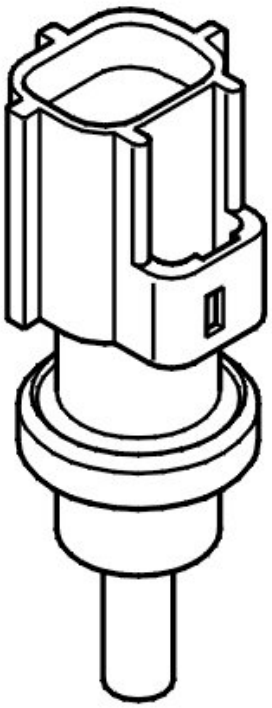
Diagnostic trouble code (DTC) information

Condition



The engine control module (ECM) checks the signal for engine coolant temperature (ECT).
After the engine is started, the engine control module (ECM) calculates the theoretical engine coolant temperature (ECT) based on factors such as time since start, engine speed (RPM) and load. The diagnostic trouble code (DTC) is stored if the signal from the engine coolant temperature (ECT) sensor is static and does not correspond to the calculated temperature.
The diagnostic trouble code (DTC) is stored together with another diagnostic trouble code (DTC) for the engine coolant temperature (ECT) sensor.

The diagnostic trouble code (DTC) can be diagnosed when the engine is running.

Substitute value
- None.

Possible source
- Contact resistance or oxidation in the connectors
- Damaged temperature sensor.

Fault symptom[s]
- Malfunction indicator lamp (MIL) lit
- The engine is difficult to start.

Fault-Tracing

Fault-tracing

Checking the component

Warning! Engine cooling fan (FC) can also operate if the ignition is switched off when this diagnostic trouble code (DTC) is stored.

Hint: To avoid injury, disconnect the power supply to the engine cooling fan (FC) during fault-tracing.

- Check the connector on the engine coolant temperature (ECT) sensor. Check for contact resistance and oxidation.

This diagnostic trouble code (DTC) is stored if the engine coolant temperature (ECT) sensor freezes. This may happen if the coolant level is low or there is too little glycol in the coolant. Check the engine coolant level and its freezing point.

Hint: The diagnostic trouble code (DTC) can be caused by a thermostat that doesn't open.

Replace the engine coolant temperature (ECT) sensor if the above does not remedy the fault.
Remedy as necessary.

Diagnostic Trouble Code (DTC) Information

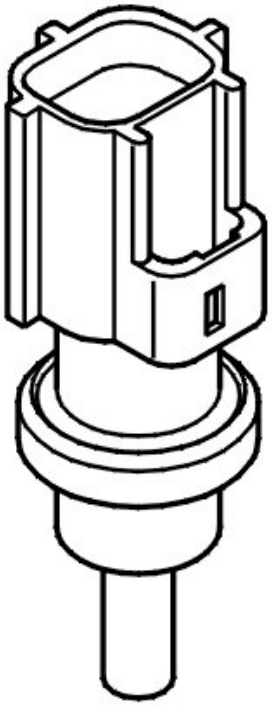
Diagnostic trouble code (DTC) information ECM-273C

Condition



The engine control module (ECM) checks the signal for engine coolant temperature (ECT).
A diagnostic trouble code (DTC) is stored if the engine control module (ECM) receives a signal from the engine coolant temperature (ECT) sensor corresponding to a temperature that is higher than a certain value.
The diagnostic trouble code (DTC) can be diagnosed when the ignition is switched on.

Substitute value
- Initial boost pressure
- The engine coolant temperature (ECT) is calculated based on a model. Three-way catalytic converter (TWC) heating and fuel trim at start (starting trim), idle diagnostic and misfire diagnostic are disabled
- The engine cooling fan (FC) runs at a predefined speed.

Possible source
- Short-circuit to ground in the signal cable

- Damaged temperature sensor.

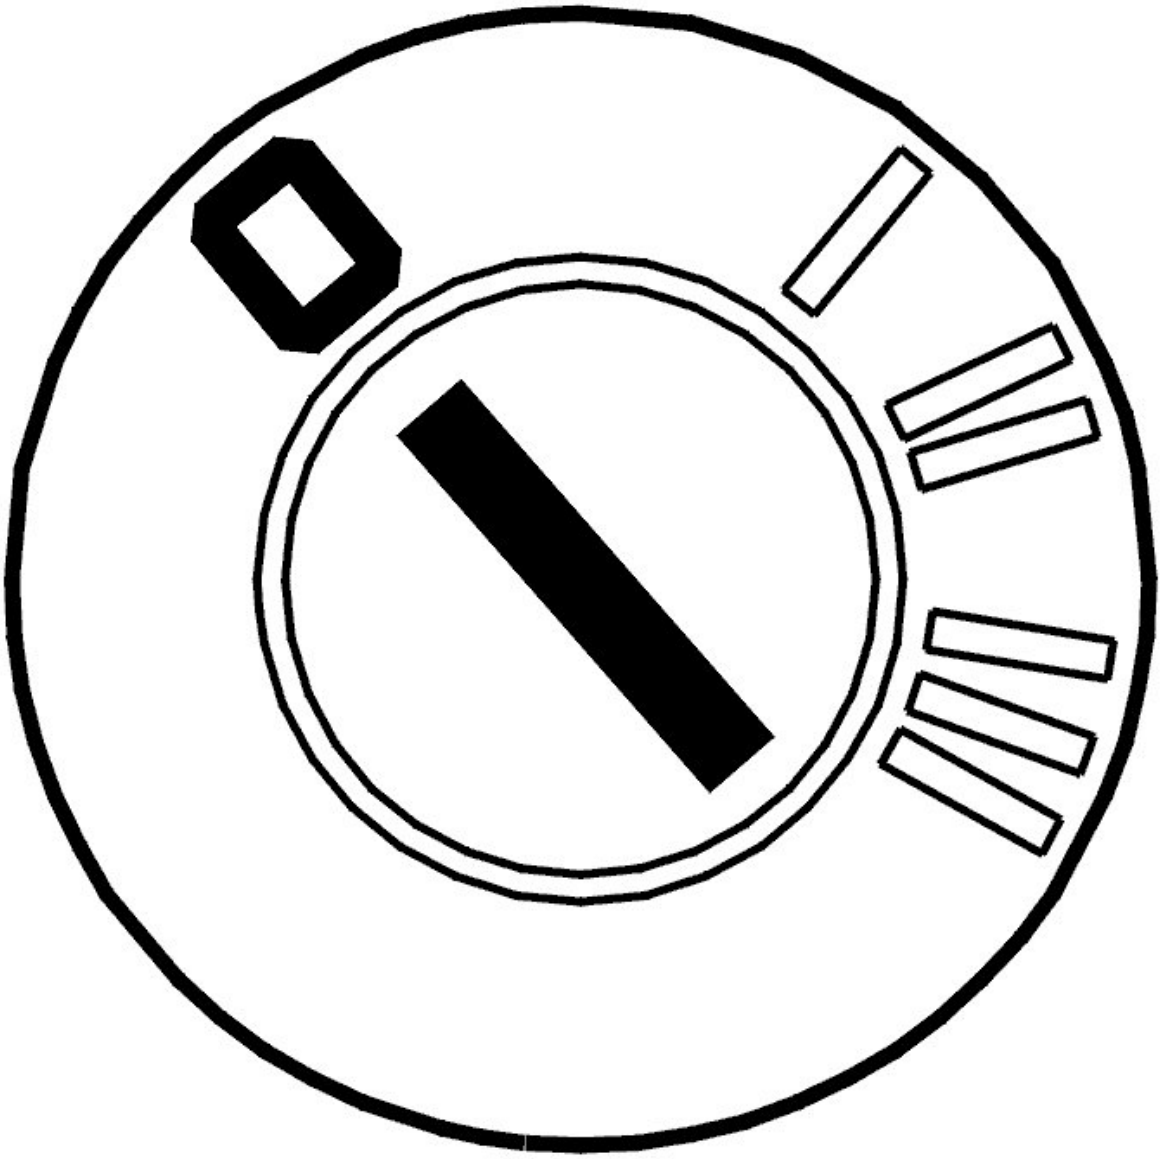
Fault symptom[s]
- Malfunction indicator lamp (MIL) lit
- The engine is difficult to start.

Signal Too High

Signal too high

Checking the wiring and component

Warning! Before fault-tracing can begin, the engine cooling fan (FC) connector must be disconnected to prevent the engine cooling fan (FC) engaging. A diagnostic trouble code (DTC) for engine cooling fan (FC) low-speed may be stored. After fault-tracing the connector must be reconnected.



- Ignition off.

Check the resistance of the engine coolant temperature (ECT) sensor. Take readings between terminals #1 and #2 on the component.
Check the signal cable between engine control module (ECM) terminal #A4 (#A4) and engine coolant temperature (ECT) sensor terminal #1.
Check for a short-circuit to ground.
If no faults are found and the fault is permanent, replace the engine coolant temperature (ECT) sensor.
Remedy as necessary.

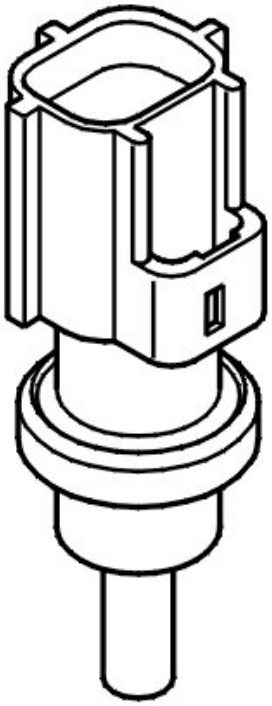
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information ECM-273D

Condition



The engine control module (ECM) checks the signal for engine coolant temperature (ECT).
A diagnostic trouble code (DTC) is stored if the engine control module (ECM) receives a signal from the engine coolant temperature (ECT) sensor corresponding to a temperature that is lower than a certain value.
The diagnostic trouble code (DTC) can be diagnosed when the ignition is switched on.

Substitute value
- Initial boost pressure
- The engine coolant temperature (ECT) is calculated based on a model. Three-way catalytic converter (TWC) heating and fuel trim at start (starting trim), idle diagnostic and misfire diagnostic are disabled
- The engine cooling fan (FC) runs at a predefined speed.

Possible source
- Contact resistance and oxidation in the terminals

- Open-circuit in the signal cable
- Open-circuit in the signal ground cable
- Short-circuit to supply voltage in the signal cable
- Damaged temperature sensor.

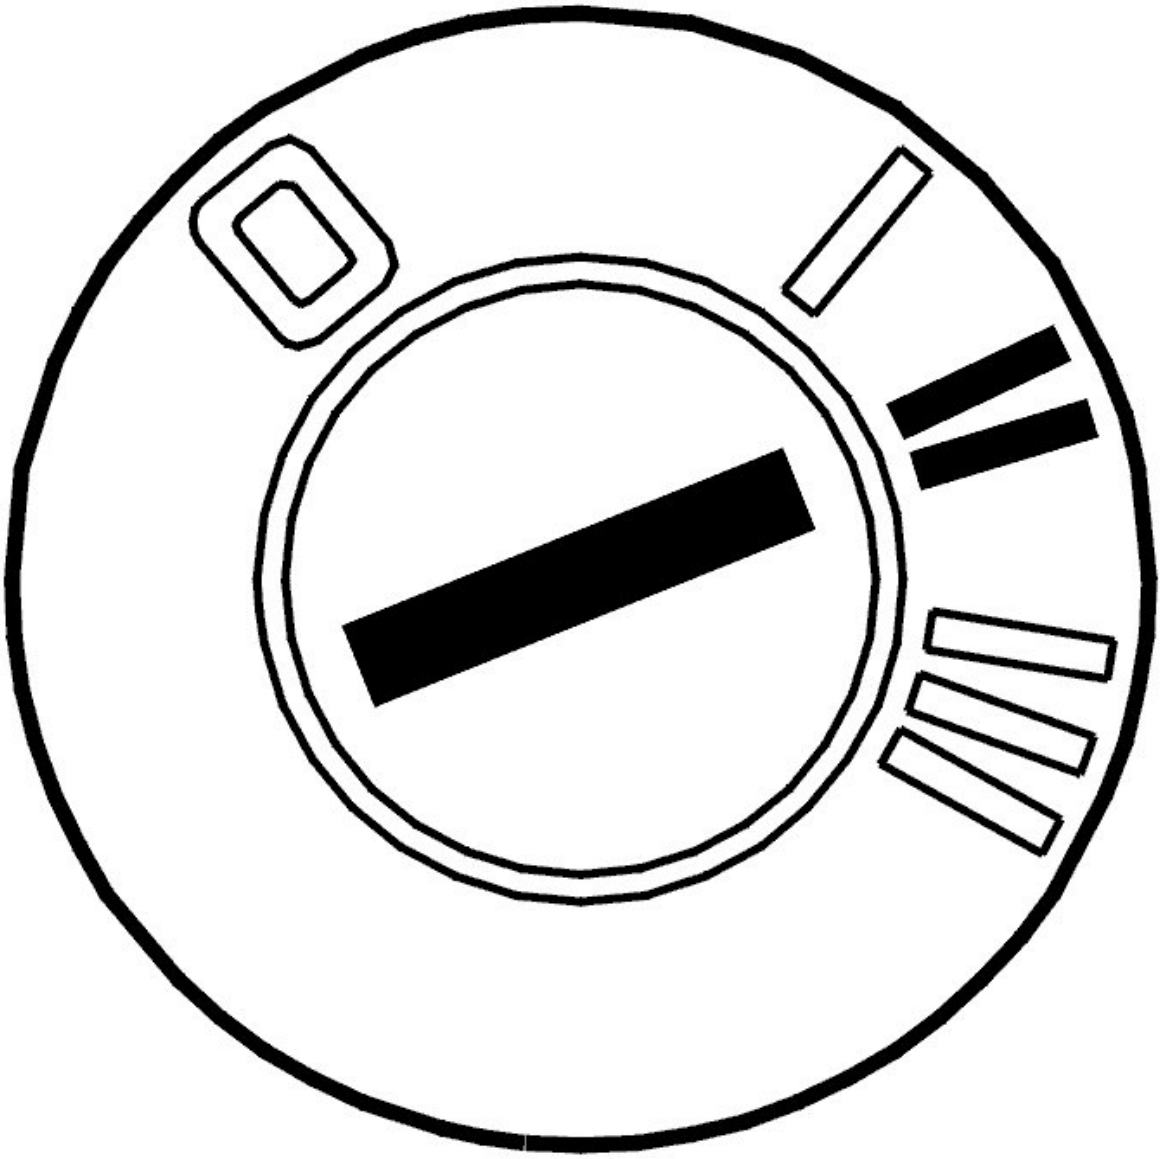
Fault symptom[s]
- Malfunction indicator lamp (MIL) lit
- The engine is difficult to start.

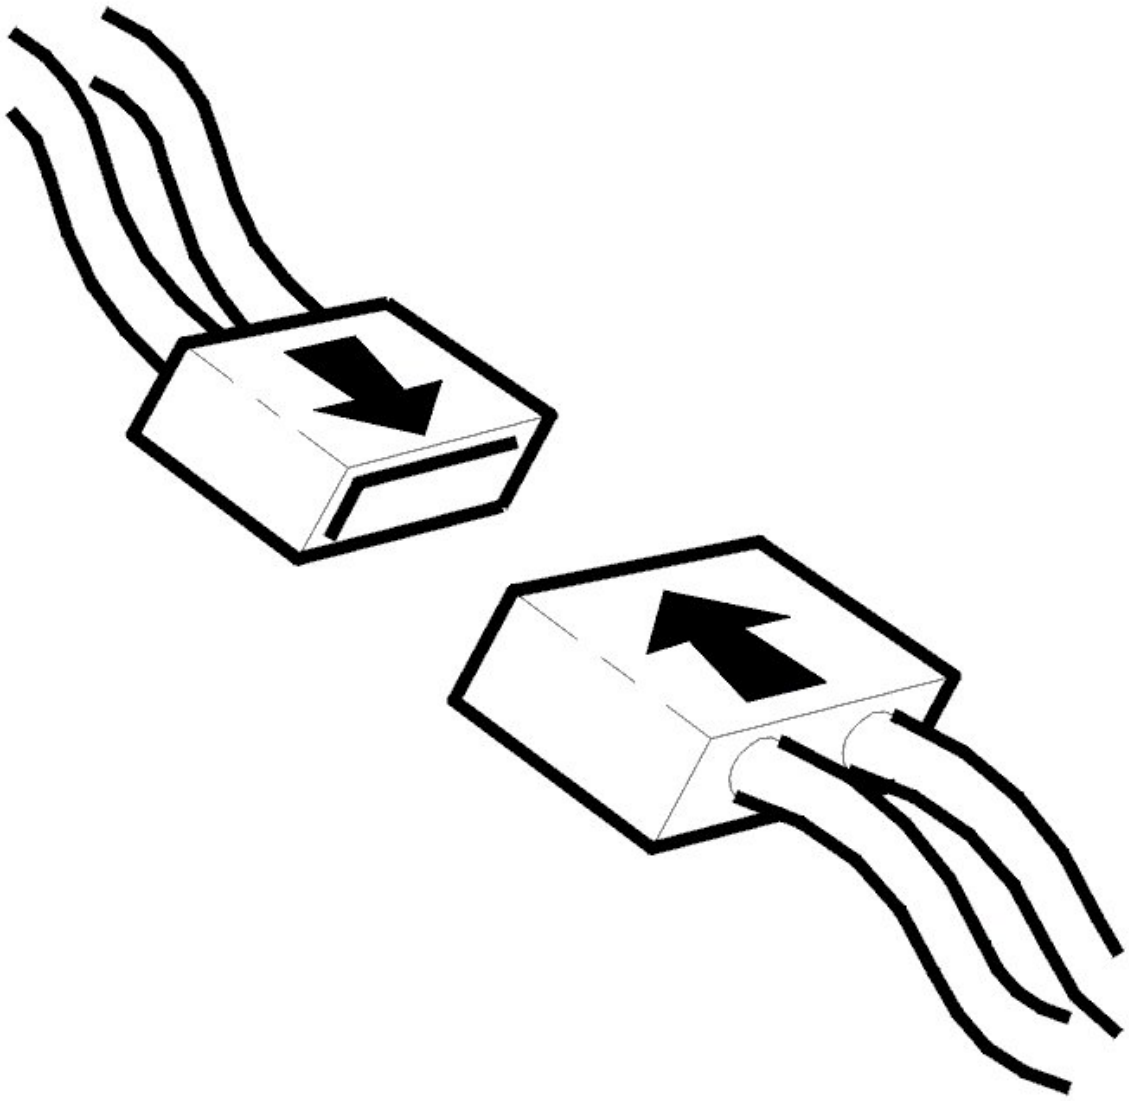
Signal Too Low

Signal too low

Checking the connector

Warning! Before fault-tracing can begin, the engine cooling fan (FC) connector must be disconnected to prevent the engine cooling fan (FC) engaging. A diagnostic trouble code (DTC) for the engine cooling fan (FC) control module may be stored. After fault-tracing the connector must be reconnected.





- Ignition off
- Check the connector on the engine coolant temperature (ECT) sensor. Check for contact resistance and oxidation
- Reinstall the components, reconnect the connectors etc.
- Ignition on
- Read off the engine coolant temperature (ECT) sensor.

If the temperature is now within its permitted range, the fault was caused by poor contact in the connector.

Other information

- Temperature sensor engine coolant, replacing See: Coolant Temperature Sensor/Switch (For Computer)/Service and Repair

- Contact resistance or oxidation in the connectors
- Damaged temperature sensor.

Fault symptom[s]
- Malfunction indicator lamp (MIL) lit
- The engine is difficult to start.

Faulty Signal/Fault-Tracing

Fault-tracing

Checking the component

Warning! Engine cooling fan (FC) can also operate if the ignition is switched off when this diagnostic trouble code (DTC) is stored.

Hint: To avoid injury, disconnect the power supply to the engine cooling fan (FC) during fault-tracing.

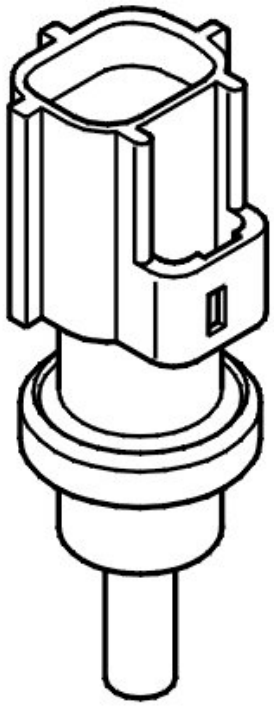
- Check the connector on the engine coolant temperature (ECT) sensor. Check for contact resistance and oxidation.

This diagnostic trouble code (DTC) is stored if the engine coolant temperature (ECT) sensor freezes. This may happen if the coolant level is low or there is too little glycol in the coolant. Check the engine coolant level and its freezing point.

Hint: The diagnostic trouble code (DTC) can be caused by a thermostat that doesn't open.

Replace the engine coolant temperature (ECT) sensor if the above does not remedy the fault.
Remedy as necessary.

Other information
- Temperature sensor engine coolant, replacing See: Coolant Temperature Sensor/Switch (For Computer)/Service and Repair
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals



Continue - Verification

Verification

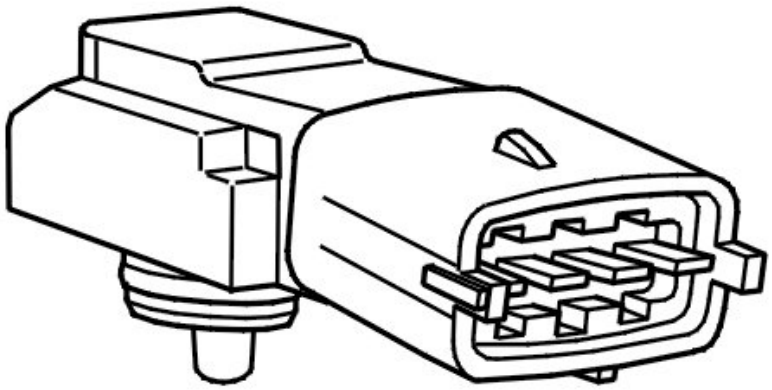
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information ECM-2800

Condition



The engine control module (ECM) checks the signal from the fuel pressure sensor.
The diagnostic trouble code (DTC) is stored if the engine control module (ECM) registers that the signal from the fuel pressure sensor is within the normal signal range of the sensor but that the signal is below a calculated desired value for the fuel pressure.
The diagnostic trouble code (DTC) can be diagnosed when the engine is running.

Substitute value
- None.

Possible source
- Short-circuit to ground in the signal cable
- Damaged fuel pressure sensor.

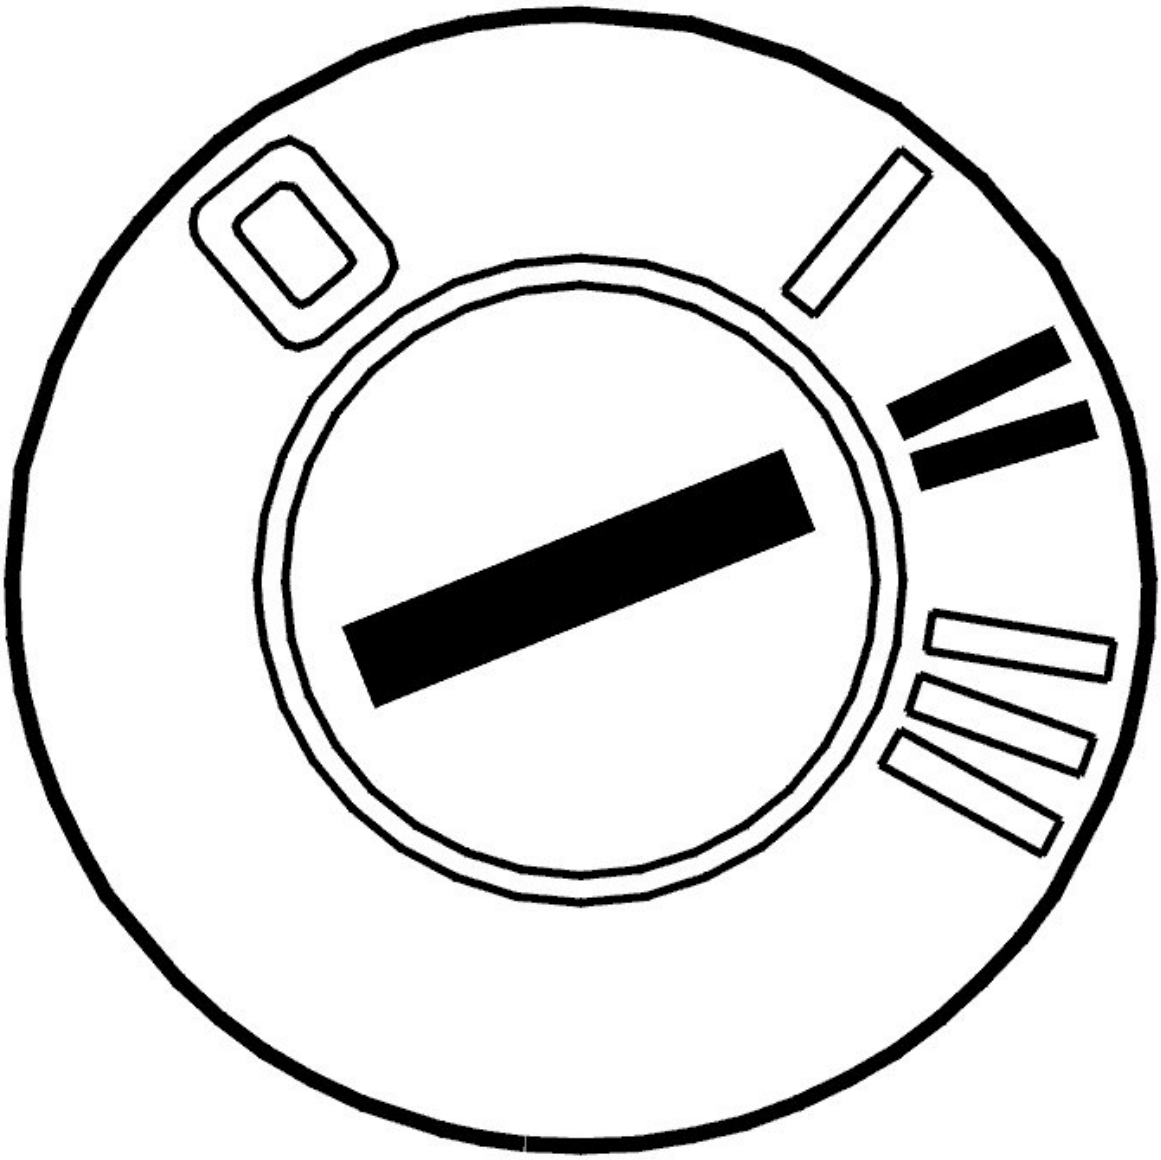
Fault symptom[s]

- Driving/Poor performance/lacks power
- Driving/Engine stalls/Unsure when/at all times

Signal Too Low

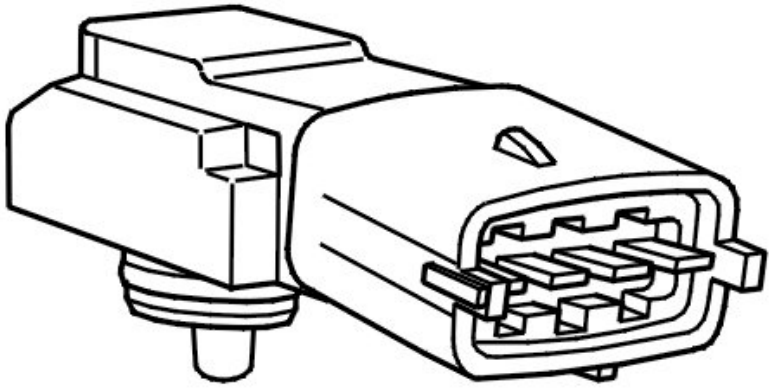
Signal too low

Checking the status



- Ignition on.

Check whether the fault is permanent or intermittent by reading off the signal from the fuel pressure sensor.
With the engine at operating temperature and idling, the signal must be approximately 400 kPa.
The fault is permanent if the signal is incorrect.
The fault is intermittent if the signal is correct.



Continue - Checking components and wiring

Checking components and wiring

Check the signal cable between control module terminal #A2 (#A2) and fuel pressure sensor terminal #4. Check for a short-circuit to ground. Remedy as necessary.
Try a new fuel pressure sensor if no fault is found during the above fault-tracing.

Other information:

Diagnostic Trouble Code (DTC) Information

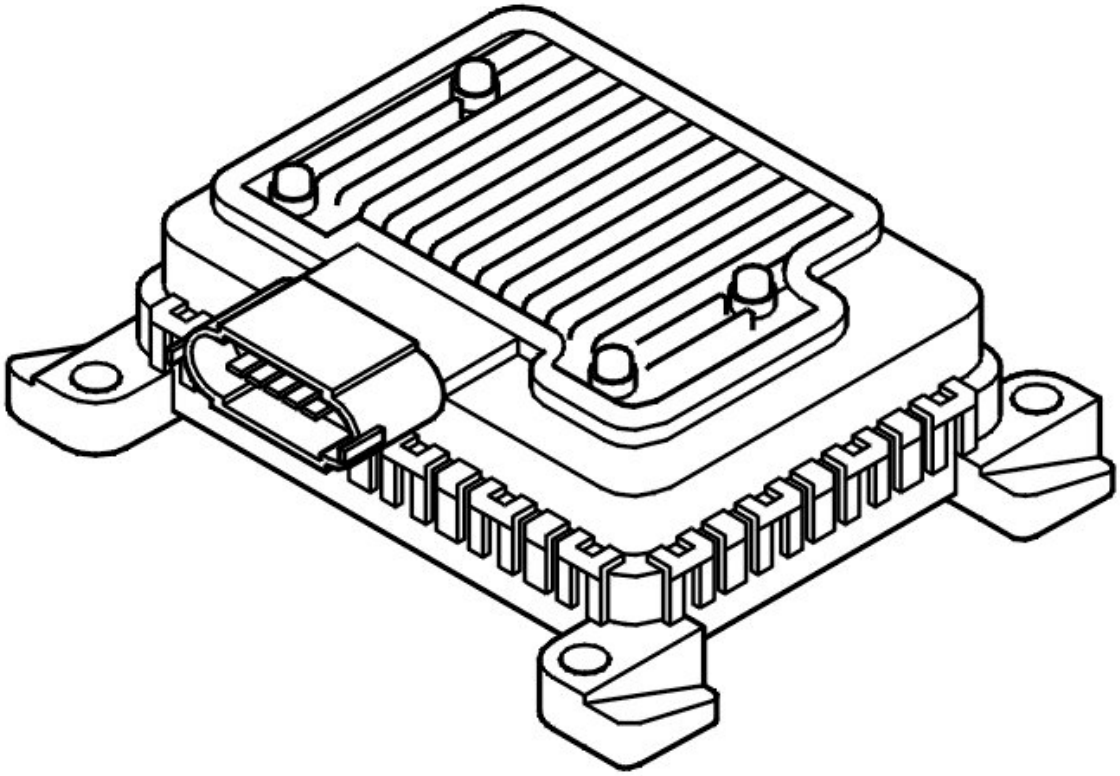
Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

Diagnostic trouble code (DTC) information ECM-2900

Condition



The engine control module (ECM) controls the fuel pressure via the fuel pump (FP) control module using a pulse width modulation (PWM) signal.
The fuel pump (FP) control module then controls the fuel pump (FP) depending on the pressure requested by the engine control module (ECM).
The diagnostic trouble code (DTC) is stored if the control capacity of the engine control module (ECM) for fuel pressure reaches the highest or lowest value and the desired fuel pressure (target value) is not achieved.
The diagnostic trouble code (DTC) can be diagnosed when the engine is running.
For information about fuel pressure regulation, see VIDA Design and Function.

Substitute value
- None.

Possible source
- Leakage in the fuel lines
- Damaged fuel pressure sensor
- Damaged fuel pump
- Damaged fuel pump control module.

Fault symptom[s]
- Malfunction indicator lamp (MIL) lit
- Deterioration in performance
- The engine stops.

Faulty Signal

Faulty signal

Checking the diagnostic trouble codes (DTCs)

Check if there are diagnostic trouble codes stored for fuel pressure sensor or ambient pressure sensor, in that case troubleshoot and fix these first.

Do you want to continue with this procedure?

Yes - Checking the fuel pressure sensor

No - ANOTHER TEST

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

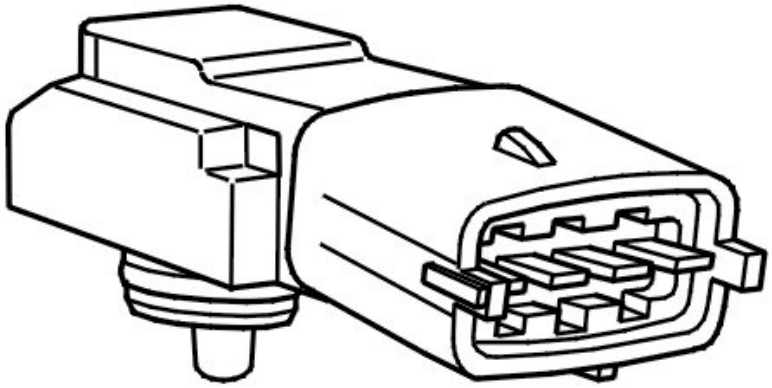
Checking the fuel pressure sensor

Note! If diagnostic trouble codes (DTC) for the fuel pressure sensor or atmospheric pressure sensor are stored, these diagnostic trouble codes (DTC) must be fault-traced and remedied first.

Hint: The method below is used to check whether the diagnostic trouble code (DTC) was caused by a faulty fuel pressure sensor. This can be done by comparing the fuel pressure sensor signal (displayed in VIDA) with the actual fuel pressure (displayed on a manometer connected to the wiring for the fuel injection system). This method assumes that the manometer for measuring fuel pressure is correctly calibrated.

- To connect the manometer, see Fuel pressure gauge See: Fuel Delivery and Air Induction/Fuel Pressure/Testing and Inspection/Fuel Pressure Gauge
- Run the engine to operating temperature. Allow the engine to idle
- air conditioning (A/C) off
- Read off the relative fuel pressure.

The relative fuel pressure is calculated from the fuel pressure sensor and the atmospheric pressure sensor signal (= absolute pressure minus atmospheric pressure).
Check that the value on the manometer and the value displayed in VIDA are the same. If the values are different, the circuit for the fuel pressure sensor is defective.



Are the values equal?

Yes - Checking components

No - Checking components and wiring

Checking components

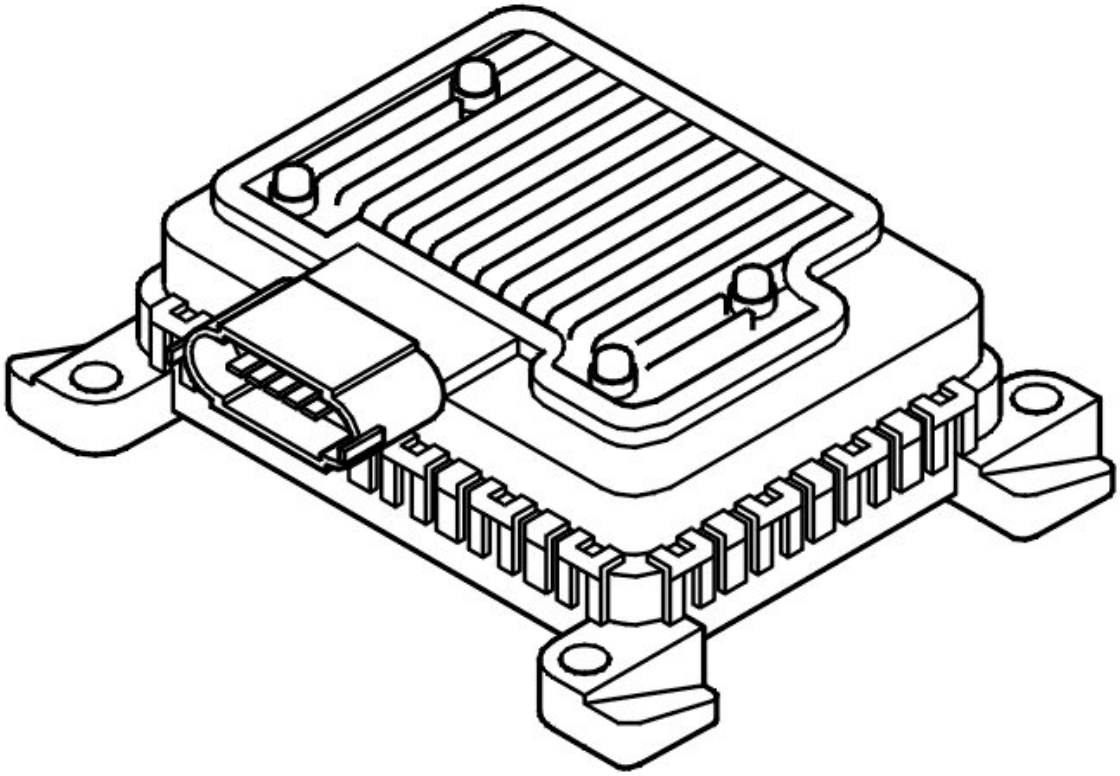
Check that the fuel level in the tank is not too low (almost no fuel).

Check the connectors between the pump control module and the fuel pump (FP). Check for contact resistance and oxidation.
Check the fuel lines and fuel filter for blockage and leaks.
Remedy as necessary.
Try a new fuel pump (FP) if no fault is found during the above fault-tracing.

Hint: The diagnostic trouble code (DTC) can also be caused by a defective pump control module.

Other information:

- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals
- To access or replace the fuel pump (FP), see
- To access or replace the pump control module see Control module fuel pump (FP), replacing, B5244T5, B5254T2 See: Fuel Delivery and Air Induction/Fuel Pump/Fuel Pump Control Unit/Service and Repair.



Continue - Verification

Checking components and wiring

Signal Too High

Signal too high

Checking the diagnostic trouble codes (DTCs)

Check if there are diagnostic trouble codes stored for fuel pressure sensor or ambient pressure sensor, in that case troubleshoot and fix these first.

Do you want to continue with this procedure?

Yes - Checking the fuel pressure sensor

No - **ANOTHER TEST**

Checking the fuel pressure sensor

Note! If diagnostic trouble codes (DTC) for the fuel pressure sensor or atmospheric pressure sensor are stored, these diagnostic trouble codes (DTC) must be fault-traced and remedied first.

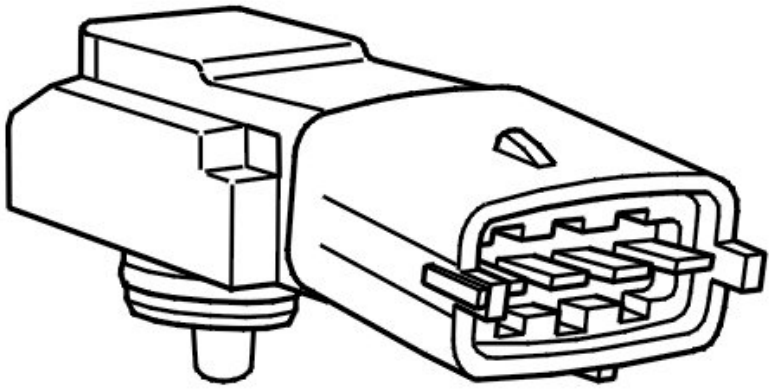
Hint: The method below is used to check whether the diagnostic trouble code (DTC) was caused by a faulty fuel pressure sensor. This can be done by comparing the fuel pressure sensor signal (displayed in VIDA) with the actual fuel pressure (displayed on a manometer connected to the wiring for the fuel injection system).

- Connect the manometer, see Fuel pressure gauge See: Fuel Delivery and Air Induction/Fuel Pressure/Testing and Inspection/Fuel Pressure Gauge.

Note! The pressure in the fuel injection system can reach approximately 650 kPa when this diagnostic trouble code (DTC) is stored. Use an adapted manometer.

- Run the engine to operating temperature. Allow the engine to idle
- air conditioning (A/C) off
- Read off the relative fuel pressure.

The relative fuel pressure is calculated from the fuel pressure sensor and the atmospheric pressure sensor signal (= absolute pressure minus atmospheric pressure).
Check that the value on the manometer and the value displayed in VIDA are roughly the same. If the values are different, the circuit for the fuel pressure sensor is defective.



Are the values equal?

Yes - Checking components

No - Checking components and wiring

Checking components

Check the connectors between the pump control module and the fuel pump (FP). Check for contact resistance and oxidation.

Verification

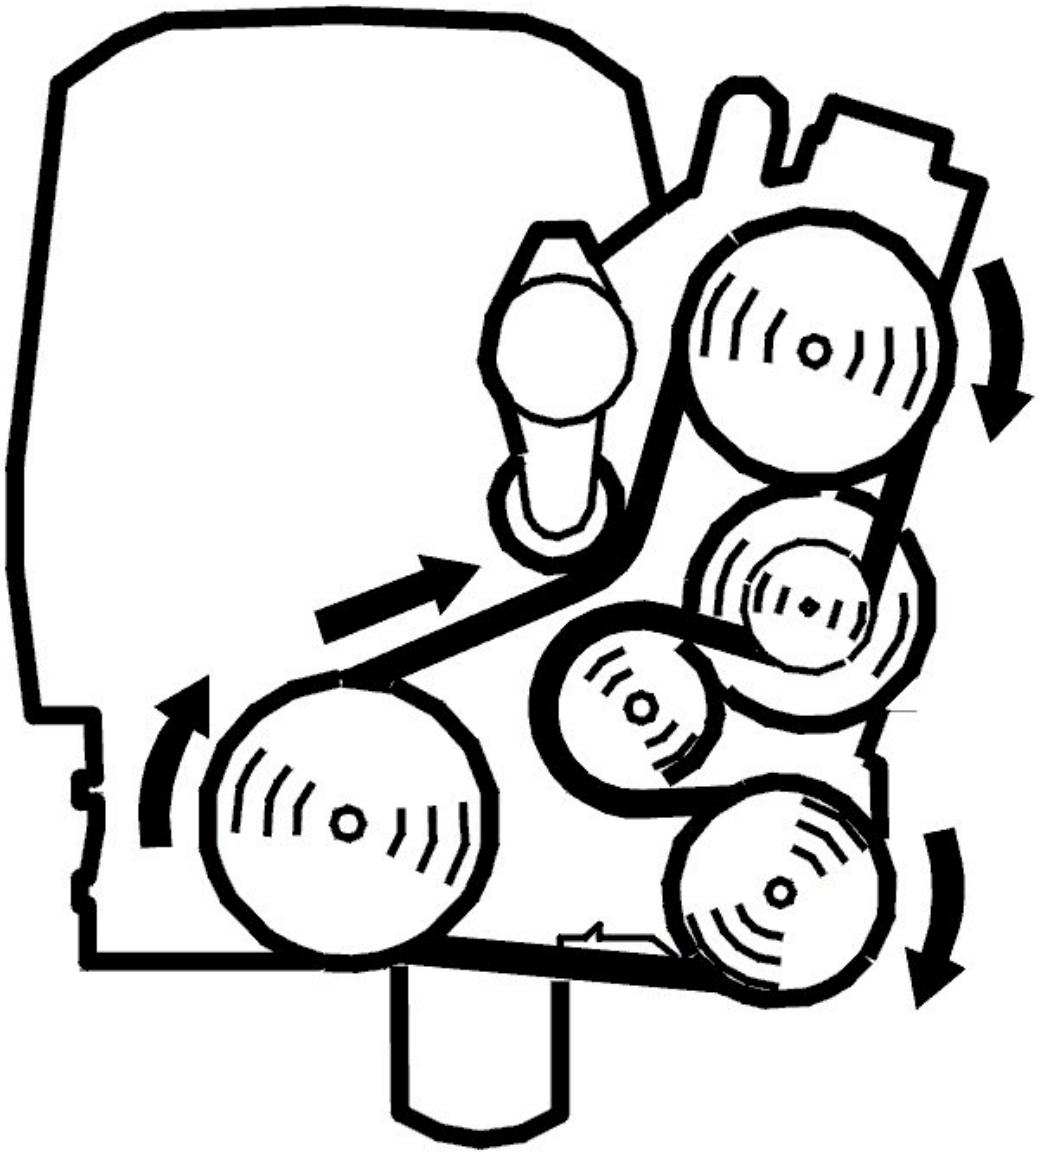
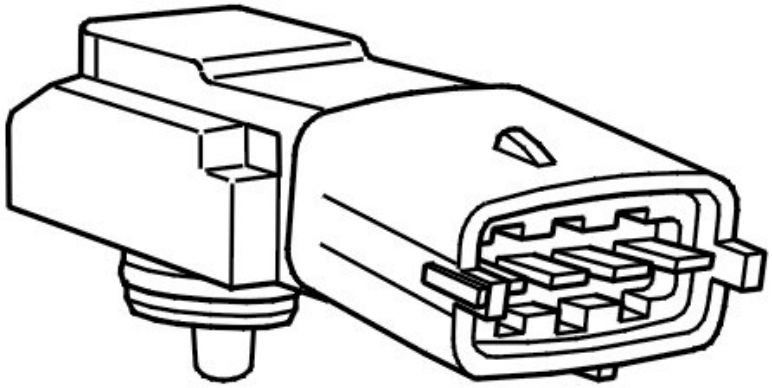
Hint: After carrying out the repair, check that the fault has been remedied.



- Connect the manometer, see Fuel pressure gauge See: Fuel Delivery and Air Induction/Fuel Pressure/Testing and Inspection/Fuel Pressure Gauge
- Run the engine to operating temperature. Allow the engine to idle
- air conditioning (A/C) off
- Read off the relative fuel pressure.

The relative fuel pressure is calculated from the fuel pressure sensor and the atmospheric pressure sensor signal (= absolute pressure minus atmospheric pressure).

Check that the value on the manometer and the value displayed in VIDA are the same. If the values are different, this indicates incorrect function.



Is the function OK?

Yes - VERIFIED

No - VERIFICATION FAILED

VERIFIED - Fault Found

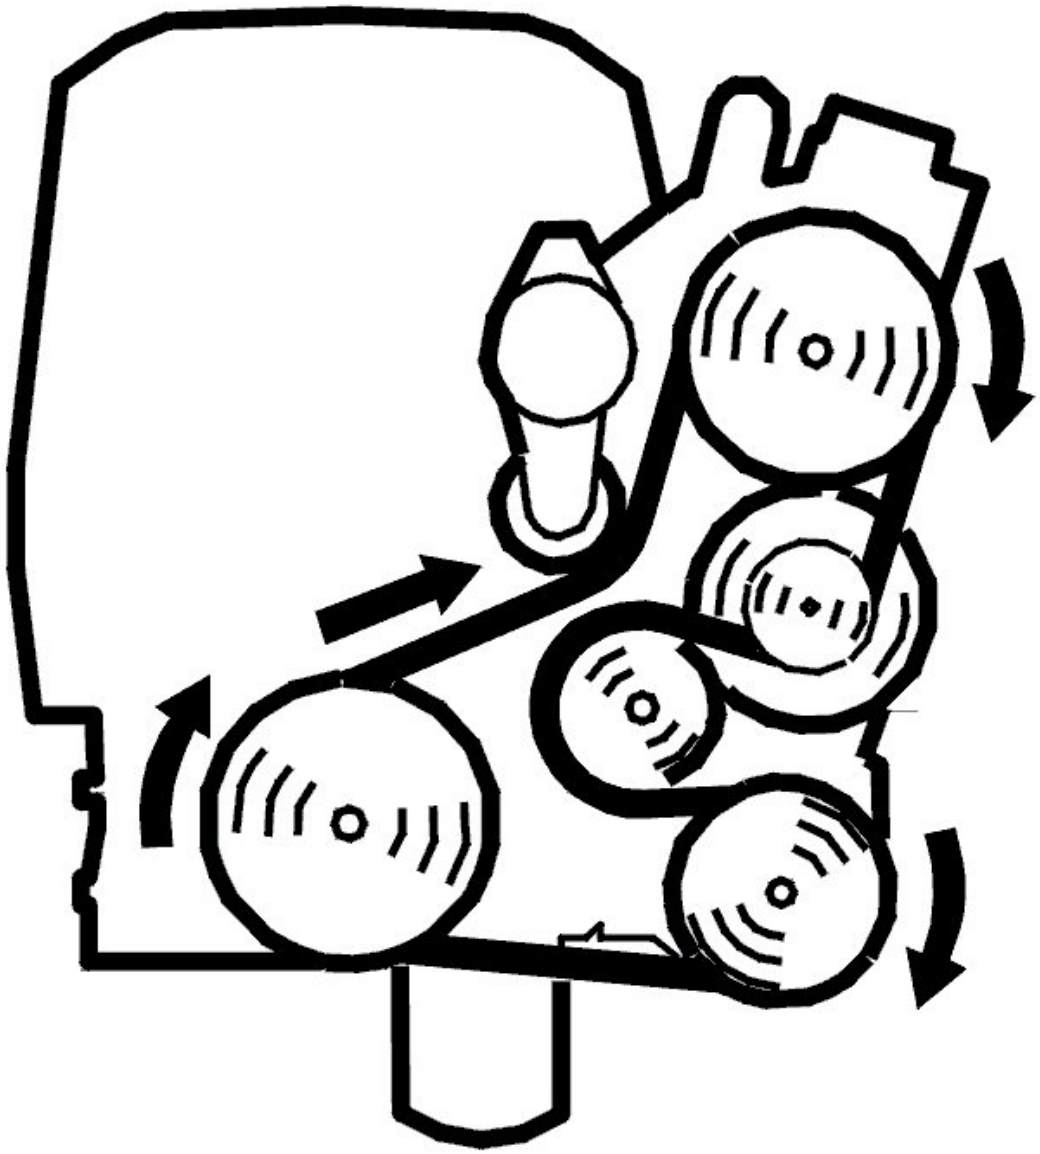
VERIFICATION FAILED - Fault-tracing information

Verification

Verification

Verification

Hint: After carrying out the repair, check that the fault has been remedied.



- Run the engine to operating temperature. Allow the engine to idle
- air conditioning (A/C) off
- Read off the fuel pressure and the fuel pressure desired value
- Start the quick test when the engine is running at idling.

During the course of the quick test, the control module will steer the pressure to different target values in different stages (400, 500, 600 and finally 700 kPa), after which the pressure will be decreased in stages to the same pressure. Each stage lasts for approximately 5 seconds.

Note! Because the by-pass valve in the fuel pump (FP) will be open at approximately 650 kPa, the pressure will not go higher than this.

Hint: The illustration to the left shows an example of normal regulation.

- The upper digital display and the graphic display (red font color) indicate the absolute fuel pressure, calculated from the fuel pressure sensor
- The lower digital display and the graphic display (yellow font color) indicate the control module target value for the absolute fuel pressure
- The lower digital display indicates the relative fuel pressure (white font color), calculated from the fuel pressure sensor and the atmospheric pressure sensor (= absolute pressure minus atmospheric pressure). If a manometer is connected during the test, it should indicate this pressure.

Check that the value for absolute fuel pressure is the same as the target value for absolute fuel pressure. If the values are not the same, this indicates a fault in the pressure regulation. The values may differ during the quick test when the target value is changed. This is due to sluggishness in the fuel regulation and is normal. In some cases, it can take up to 5 seconds before the fuel pressure reaches the target value for the fuel pressure.

Possible source
- Leakage at the fuel lines
- Damaged fuel pressure sensor
- Damaged fuel pump
- Damaged fuel pump control module.

Fault symptom[s]
- Malfunction indicator lamp (MIL) lit
- Deterioration in performance
- The engine stops.

Signal Too Low

Signal too low

Checking the diagnostic trouble codes (DTCs)

Check if there are diagnostic trouble codes stored for fuel pressure sensor or ambient pressure sensor, in that case troubleshoot and fix these first.

Do you want to continue with this procedure?

Yes - Checking the fuel pressure sensor

No - Fault Found

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

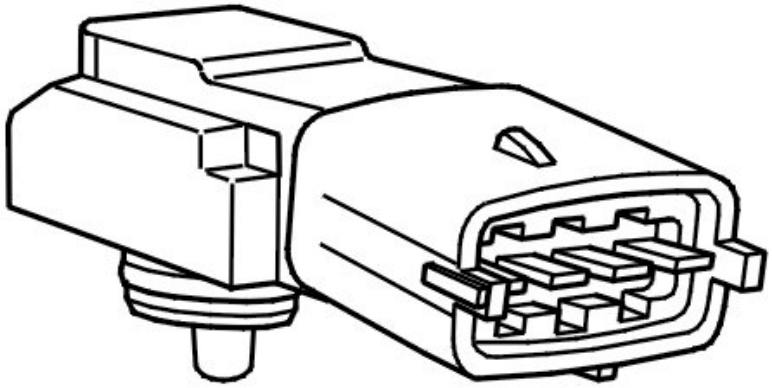
Checking the fuel pressure sensor

Note! If diagnostic trouble codes (DTC) for the fuel pressure sensor or atmospheric pressure sensor are stored, these diagnostic trouble codes (DTC) must be fault-traced and remedied first.

Hint: The method below is used to check whether the diagnostic trouble code (DTC) was caused by a faulty fuel pressure sensor. This can be done by comparing the fuel pressure sensor signal (displayed in VIDA) with the actual fuel pressure (displayed on a manometer connected to the wiring for the fuel injection system). This method assumes that the manometer for measuring fuel pressure is correctly calibrated.

- To connect the manometer, see Fuel pressure gauge See: Fuel Delivery and Air Induction/Fuel Pressure/Testing and Inspection/Fuel Pressure Gauge
- Run the engine to operating temperature. Allow the engine to idle
- air conditioning (A/C) off
- Read off the relative fuel pressure.

The relative fuel pressure is calculated from the fuel pressure sensor and the atmospheric pressure sensor signal (= absolute pressure minus atmospheric pressure).
Check that the value on the manometer and the value displayed in VIDA are the same. If the values are different, the circuit for the fuel pressure sensor is defective.



Is the fuel pressure sensor correct?

Yes - Checking regulation of the fuel pressure

No - Checking components and wiring

Checking regulation of the fuel pressure

Warning! In this test, the pressure in the fuel injection system will reach approximately 650 kPa. Disconnect the pressure gauge, as it is not

intended to be used at such high pressures.

Hint: The method described below is used to check the control of the pressure in the fuel injection system by activating the quick test for the fuel pump (FP). If the pressure gauge for pressures up to 650 kPa is connected, the fuel pressure sensor can also be checked during this test.

Note! In this test, the complete flow capacity of the system is not tested.

- Disconnect the manometer unless it is adapted for pressures higher than 650 kPa
- Run the engine to operating temperature. Allow the engine to idle
- air conditioning (A/C) off
- Read off the fuel pressure and the fuel pressure desired value
- Start the quick test when the engine is running at idling.

During the course of the quick test, the control module will steer the pressure to different target values in different stages (400, 500, 600 and finally 700 kPa), after which the pressure will be decreased in stages to the same pressure. Each stage lasts for approximately 5 seconds.

Note! Because the by-pass valve in the fuel pump (FP) will be open at approximately 650 kPa, the pressure will not go higher than this.

Hint: The illustration to the left shows an example of normal regulation.

- The upper digital display and the graphic display (red font color) indicate the absolute fuel pressure, calculated from the fuel pressure sensor
- The lower digital display and the graphic display (yellow font color) indicate the control module target value for the absolute fuel pressure
- The lower digital display indicates the relative fuel pressure (white font color), calculated from the fuel pressure sensor and the atmospheric pressure sensor (= absolute pressure minus atmospheric pressure). If a manometer is connected during the test, it should indicate this pressure.

Check that the value for absolute fuel pressure is the same as the target value for absolute fuel pressure. If the values are not the same, this indicates a fault in the pressure regulation. The values may differ during the quick test when the target value is changed. This is due to sluggishness in the fuel regulation and is normal. In some cases, it can take up to 5 seconds before the fuel pressure reaches the target value for the fuel pressure.

Is the pressure regulation correct?

Yes - Checking components

No - Checking components

Checking components

Hint: The fault may be intermittent or be due to the flow capacity in the system being too low.

Check that the fuel level in the tank is not too low (almost no fuel).
Check the fuel lines between the fuel pump (FP) and the fuel rail for the injectors for leakage.
Check the fuel pressure sensor connectors. Check for contact resistance and oxidation.
Check the pump control module connector. Check for contact resistance and oxidation.
Check the fuel lines and fuel filter for blockage.
Remedy as necessary.
Try a new fuel pump (FP) if no fault is found during the above fault-tracing.

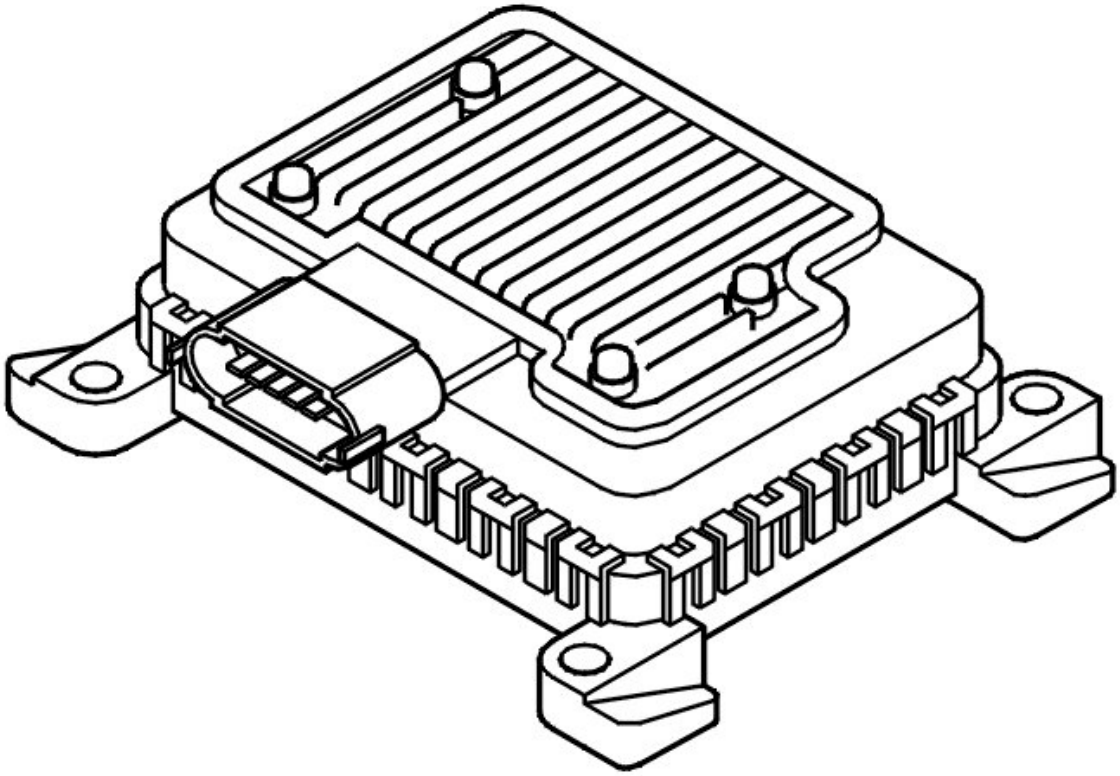
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information ECM-291B

Condition



The engine control module (ECM) controls the fuel pressure via the fuel pump (FP) control module using a pulse width modulation (PWM) signal.
The fuel pump (FP) control module then controls the fuel pump (FP) depending on the pressure requested by the engine control module (ECM).
The diagnostic trouble code (DTC) is stored if there is no PWM signal between the engine control module (ECM) and the fuel pump (FP) control module.
The diagnostic trouble code (DTC) can be diagnosed when the engine is running.
For information about fuel pressure regulation, see VIDA Design and Function.

Substitute value
- None.

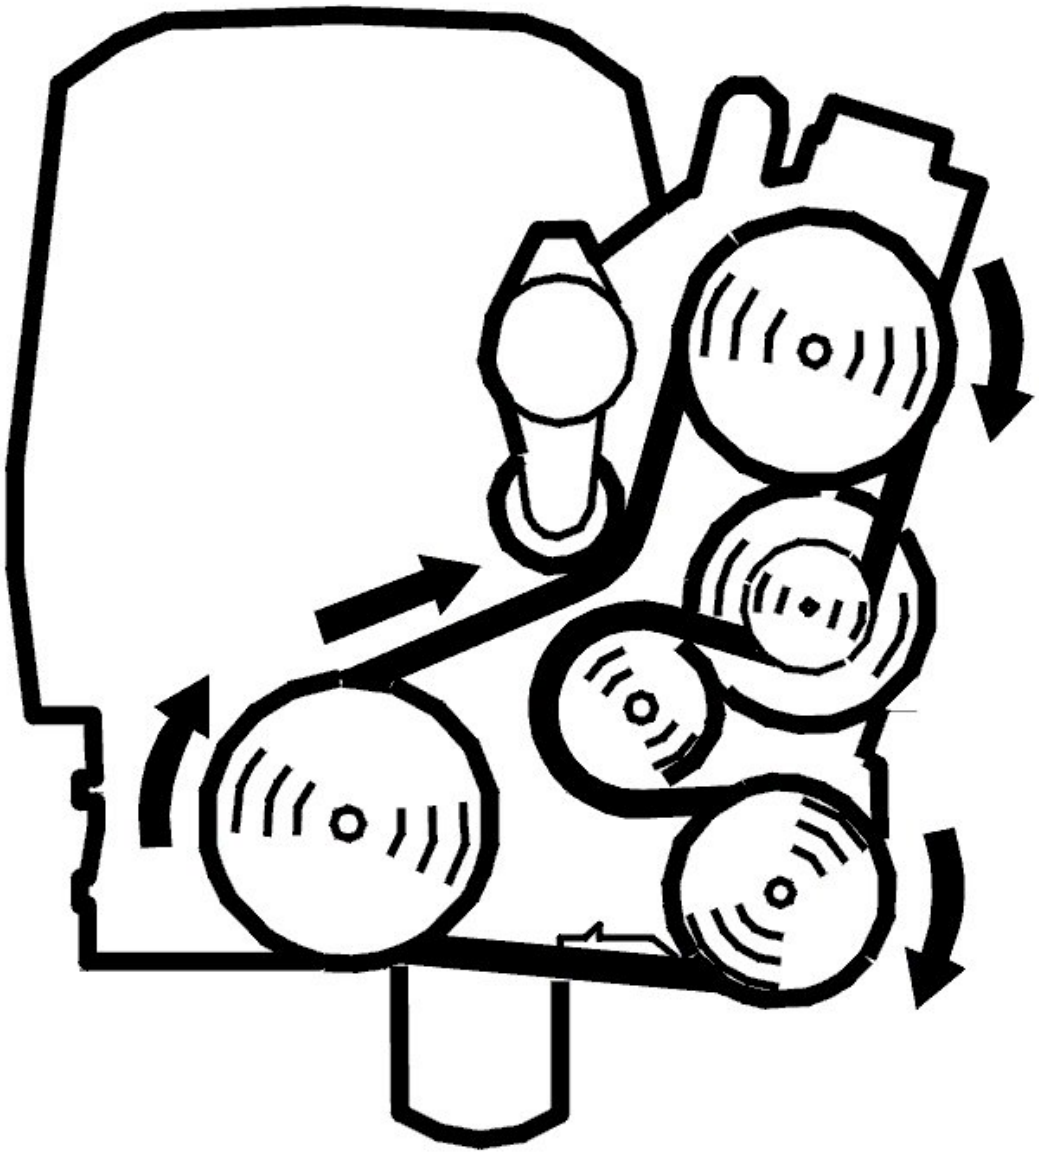
Possible source
- Short-circuit to supply voltage in the signal cable
- Damaged fuel pump control module.

Fault symptom[s]
- The starter motor turns but the engine does not start
- The engine stops.

Signal Too High/Signal Too Low/Signal Missing

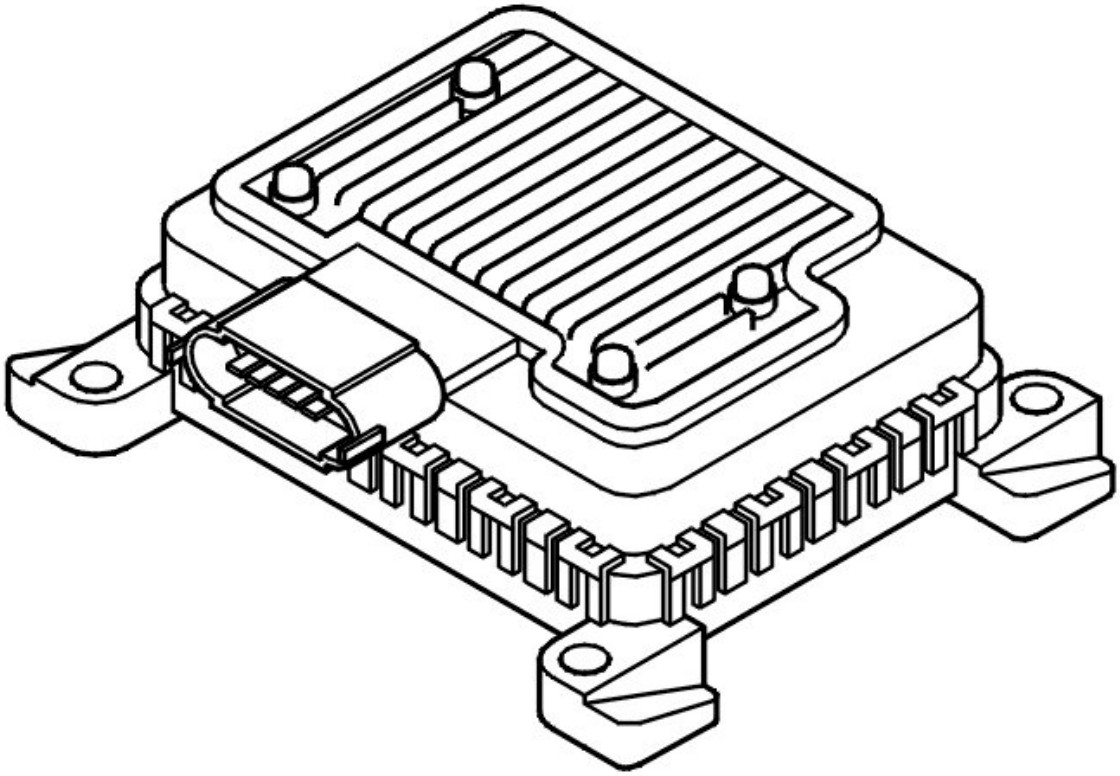
Signal too high/signal too low/signal missing

Checking the status



- Start the engine and run it to normal operating temperature
- Read off the fuel pump (FP) load.

Check whether the fault is permanent or intermittent by checking the value of the fuel pump (FP) load (signal from the engine control module (ECM) to the fuel pump (FP) control module).
Check that the signal is approximately 35% (±5%) with the engine idling at operating temperature.
The fault is permanent if the signal is incorrect or the engine will not start.
The fault is intermittent if the signal is correct.



Continue - Checking components and wiring

Checking components and wiring

Check the pump control module connector. Check for contact resistance and oxidation.
Check the cable between Engine Control Module (ECM) terminal #B47 (#B57) and pump control module terminal #1. Check for an open circuit, short circuit to ground and supply voltage.
Remedy as necessary.

Hint: The diagnostic trouble code (DTC) may be caused by a defective pump control module.

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information ECM-2B00

Condition

During the engine warm up phase the way the engine temperature should increase is calculated. Factors such as engine load and the start temperature are taken into account. This test takes place during the engine warm-up phase (under "normal operation") and continues until the engine temperature has reached 84 °C. For the test to start, the starting temperature of the engine must be below 35 °C, the outside temperature must be -7 to +35 °C and at least 15 minutes must have passed since the engine was last run.
The diagnostic trouble code (DTC) is stored if the calculated increase in temperature does not correspond to the actual increase (measured by the engine coolant temperature (ECT) sensor).

Hint: This diagnostic trouble code (DTC) can also be caused by faults that store diagnostic trouble codes (DTCs) for outside temperature sensors.

Substitute value
- None.

Possible source
- Damaged engine coolant temperature (ECT) sensor
- Damaged thermostat.

Fault symptom[s]
- Malfunction indicator lamp (MIL) lit.

Faulty Signal

Faulty signal

Replacing the thermostat

Note! This diagnostic trouble code (DTC) is stored if the engine coolant temperature (ECT) sensor freezes. This may happen if the coolant level is low or there is too little glycol in the coolant. Check the engine coolant level and its freezing point. Remedy as necessary.

The engine control module (ECM) has registered that the actual temperature increase has deviated from the calculated temperature increase. This deviation is due to a defective thermostat.
Try replacing the thermostat. See Temperature sensor engine coolant, replacing See: Coolant Temperature Sensor/Switch (For Computer)/Service and Repair.

- Malfunction indicator lamp (MIL) lit
- Poor performance.

Internal Fault

Internal fault

Replacing the component

The engine control module (ECM) has registered an internal fault.
If the fault is intermittent, it has been registered previously but is no longer present. Intermittent faults can be caused by interference at start up of the engine control module (ECM) or may be a different type of fault which occurs on different occasions. The fault is evaluated depending on how it occurs. Replace the engine control module (ECM) if the fault recurs.
Replace the engine control module (ECM) in the event of a permanent fault.
Engine control module (ECM), replacing See: Engine Control Module/Service and Repair
Remedy as necessary.

Diagnostic Trouble Code (DTC) Information

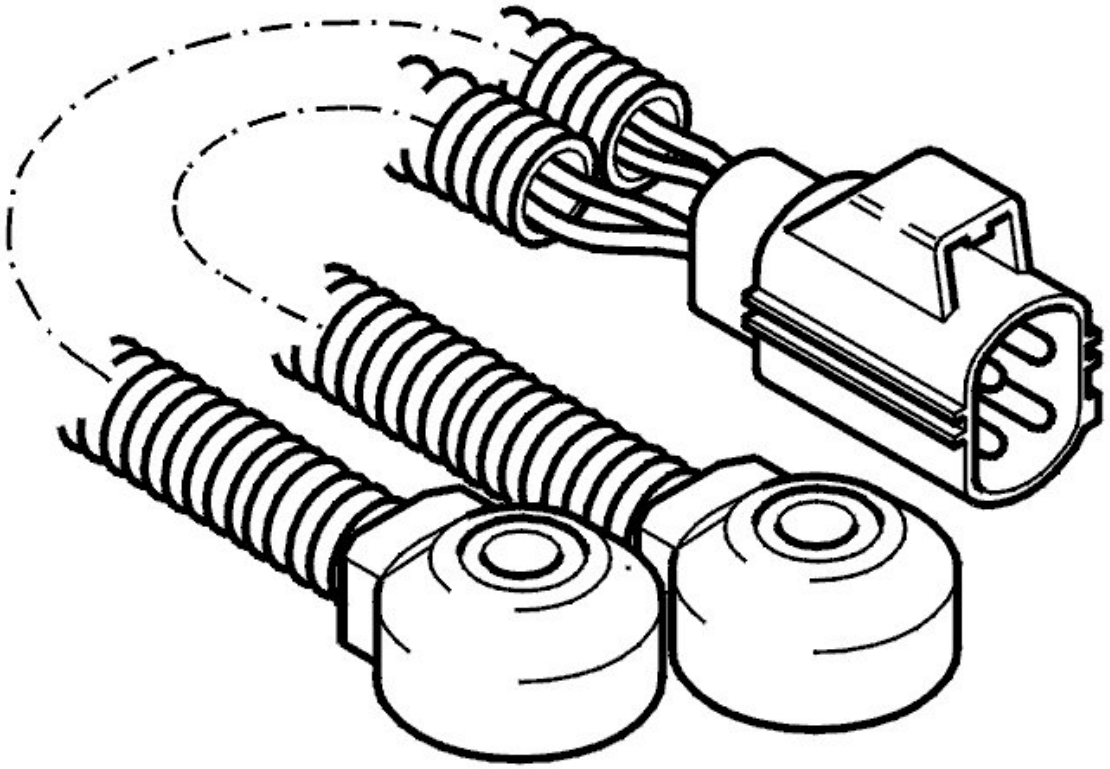
Diagnostic trouble code (DTC) information ECM-303C

Condition



In certain operating conditions the engine control module (ECM) checks the signal from the front knock sensor (KS). The diagnostic trouble code (DTC) is stored if the signal from the front knock sensor (KS) is too high.
The diagnostic trouble code (DTC) can be diagnosed when the engine is running.

Substitute value
- Safety retardation of ignition advance
- Reduced boost pressure.

Possible source
- Short-circuit to supply voltage in the signal cable
- Noise from the engine.

Fault symptom[s]
- Poor performance.

Signal Too High

Signal too high. Permanent fault

Checking components and wiring

Check the signal cable between knock sensor (KS) terminal #1 and control module terminal #A46 (#A46). Check the ground lead between knock sensor (KS) terminal #2 and control module terminal #A64 (#B4). Check for a short-circuit to supply voltage.
Check that the knock sensor (KS) is tightened to the correct torque.

Hint: The diagnostic trouble code (DTC) may be caused by a worn engine. Start the engine and listen for noise.

Remedy as necessary.

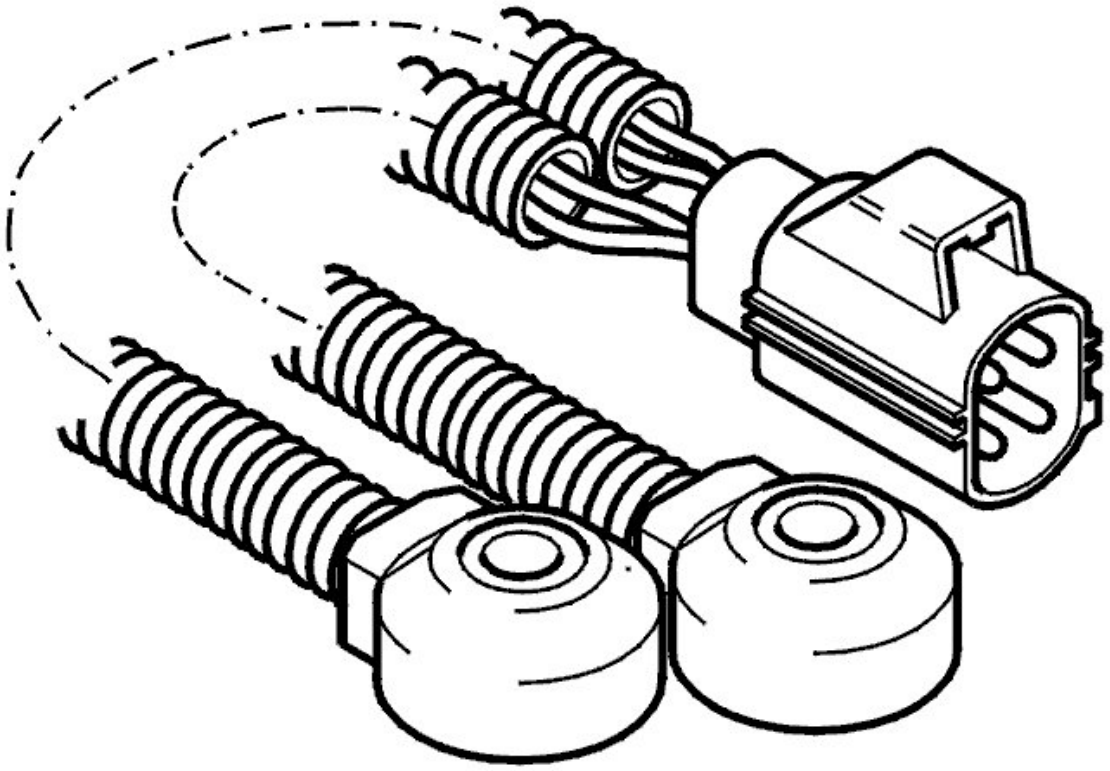
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information ECM-303D

Condition



In certain operating conditions the engine control module (ECM) checks the signal from the front knock sensor (KS). The diagnostic trouble code (DTC) is stored if the signal from the front knock sensor (KS) is too low.
The diagnostic trouble code (DTC) can be diagnosed when the engine is running.

Substitute value
- Safety retardation of ignition advance
- Reduced boost pressure.

Possible source
- Contact resistance in the knock sensor (KS) terminals
- Open-circuit in the signal cable
- Short-circuit between the knock sensor (KS) signal cables
- Damaged knock sensor (KS).

Fault symptom[s]
- Poor performance.

Signal Too Low

Signal too low. Permanent fault

Checking wiring and connectors

Check the knock sensor (KS) connector. Check for contact resistance and oxidation.
Check the signal cable between knock sensor (KS) terminal #1 and control module terminal #A46 (#A46). Check the ground lead between knock sensor (KS) terminal #2 and control module terminal #A64 (#B4). Check for an open-circuit. Check for a short-circuit to ground.
Check that the knock sensor (KS) is tightened to the correct torque.
Remedy as necessary.

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information ECM-3100

Condition

The diagnostic trouble code (DTC) is stored if the engine control module (ECM) detects a certain number of misfires during the first 1000 engine revolutions after the engine is started.
This diagnostic trouble code (DTC) is stored together with other diagnostic trouble codes (DTCs) which indicate which cylinders are misfiring.

Substitute value
- Rear heated oxygen sensor control shut off
- Fuel trim switched off.

Possible source
- Low fuel level
- Engine does not reach normal operating temperature between several cold starts
- Water in the spark plug wells
- Damaged spark plug
- Contaminated or incorrect fuel
- Poor fuel quality (summer fuel in winter).
- Blocked / leaking injector
- Air leakage
- Blocked crankcase ventilation.
- Damaged VVT-unit.
- Faulty fuel pressure
- Uneven compression

Fault symptom[s]
- Malfunction indicator lamp (MIL) lit
- The engine misfires
- The engine is difficult to start
- Deterioration in performance
- Uneven idle
- The engine is not firing on all cylinders.

Emissions Impact / Catalytic Converter Damage / Start Up

Emissions impact / Catalytic converter damage / Start up

Checking the fuel injection system, ignition system and components

Note! In the event of diagnostic trouble codes (DTCs), that affect camshaft control or camshaft reset valve, these must be fault-traced first.

Hint: In certain cases, the engine control module (ECM) can determine which cylinder has misfired.

Check the fuel level in the fuel tank.
Check that the engine oil level is correct.
Look for moisture in the electrical terminals for the ignition coils and in the spark plug wells.
Check the spark plugs. Check for damage in the insulation and for any other damage.
Check the engine intake system for leakage.
Check the crankcase ventilation. Check for blockage.
Check the fuel pressure and residual pressure.
Check the compression of the engine.
Remedy as necessary.

Diagnostic trouble code (DTC) information

Condition

The diagnostic trouble code (DTC) is stored if the engine control module (ECM) detects misfiring which affects emissions after the first 1000 engine revolutions after the engine is started. The diagnostic trouble code (DTC) indicates which cylinder is misfiring. The diagnostic trouble code (DTC) can be diagnosed when the engine is running.

- ECM-3110: cylinder 1
- ECM-3120: cylinder 2
- ECM-3130: cylinder 3
- ECM-3140: cylinder 4
- ECM-3150: cylinder 5.

Substitute value

- Rear heated oxygen sensor control shut off
- Fuel trim switched off.

Possible source

- Low fuel level
- Engine does not reach normal operating temperature between several cold starts
- Water in the spark plug wells
- Damaged spark plug
- Contaminated or incorrect fuel
- Poor fuel quality (summer fuel in winter).
- Air leakage
- Blocked crankcase ventilation.
- Damaged VVT-unit.
- Blocked / leaking injector
- Faulty fuel pressure
- Uneven compression

Fault symptom[s]

- Malfunction indicator lamp (MIL) lit
- The engine misfires
- The engine is difficult to start
- Deterioration in performance
- Uneven idle
- The engine is not firing on all cylinders.

Emissions Impact / Catalytic Converter Damage / Start Up

Emissions impact / Catalytic converter damage / Start up

Checking the fuel injection system, ignition system and components

Note! In the event of diagnostic trouble codes (DTCs), that affect camshaft control or camshaft reset valve, these must be fault-traced first.

Hint: In certain cases, the engine control module (ECM) can determine which cylinder has misfired.

Check the fuel level in the fuel tank.
Check that the engine oil level is correct.
Look for moisture in the electrical terminals for the ignition coils and in the spark plug wells.
Check the spark plugs. Check for damage in the insulation and for any other damage.
Check the engine intake system for leakage.
Check the crankcase ventilation. Check for blockage.
Check the fuel pressure and residual pressure.
Check the compression of the engine.
Remedy as necessary.

Other information

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition

The diagnostic trouble code (DTC) is stored if the engine control module (ECM) detects misfiring which affects emissions after the first 1000 engine revolutions after the engine is started. The diagnostic trouble code (DTC) indicates which cylinder is misfiring. The diagnostic trouble code (DTC) can be diagnosed when the engine is running.

- ECM-3110: cylinder 1
- ECM-3120: cylinder 2
- ECM-3130: cylinder 3
- ECM-3140: cylinder 4
- ECM-3150: cylinder 5.

Substitute value

- Rear heated oxygen sensor control shut off
- Fuel trim switched off.

Possible source

- Low fuel level
- Engine does not reach normal operating temperature between several cold starts
- Water in the spark plug wells
- Damaged spark plug
- Contaminated or incorrect fuel
- Poor fuel quality (summer fuel in winter).
- Air leakage
- Blocked crankcase ventilation.
- Damaged VVT-unit.
- Blocked / leaking injector
- Faulty fuel pressure
- Uneven compression

Fault symptom[s]

- Malfunction indicator lamp (MIL) lit
- The engine misfires
- The engine is difficult to start
- Deterioration in performance
- Uneven idle
- The engine is not firing on all cylinders.

Emissions Impact / Catalytic Converter Damage / Start Up

Emissions impact / Catalytic converter damage / Start up

Checking the fuel injection system, ignition system and components

Note! In the event of diagnostic trouble codes (DTCs), that affect camshaft control or camshaft reset valve, these must be fault-traced first.

Hint: In certain cases, the engine control module (ECM) can determine which cylinder has misfired.

Check the fuel level in the fuel tank.
Check that the engine oil level is correct.
Look for moisture in the electrical terminals for the ignition coils and in the spark plug wells.
Check the spark plugs. Check for damage in the insulation and for any other damage.
Check the engine intake system for leakage.
Check the crankcase ventilation. Check for blockage.
Check the fuel pressure and residual pressure.
Check the compression of the engine.
Remedy as necessary.

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information ECM-330B

Condition

If there is no signal from the engine speed (RPM) sensor or if its signal is lower than the engine speed signal from the camshaft position (CMP) sensor, the engine control module (ECM) interprets this as a fault and the diagnostic trouble code (DTC) is stored.
The diagnostic trouble code (DTC) can be diagnosed when the engine is running.

Substitute value

The engine control module (ECM) uses the signal from the camshaft position (CMP) sensor if the camshaft position (CMP) sensor has been adapted.

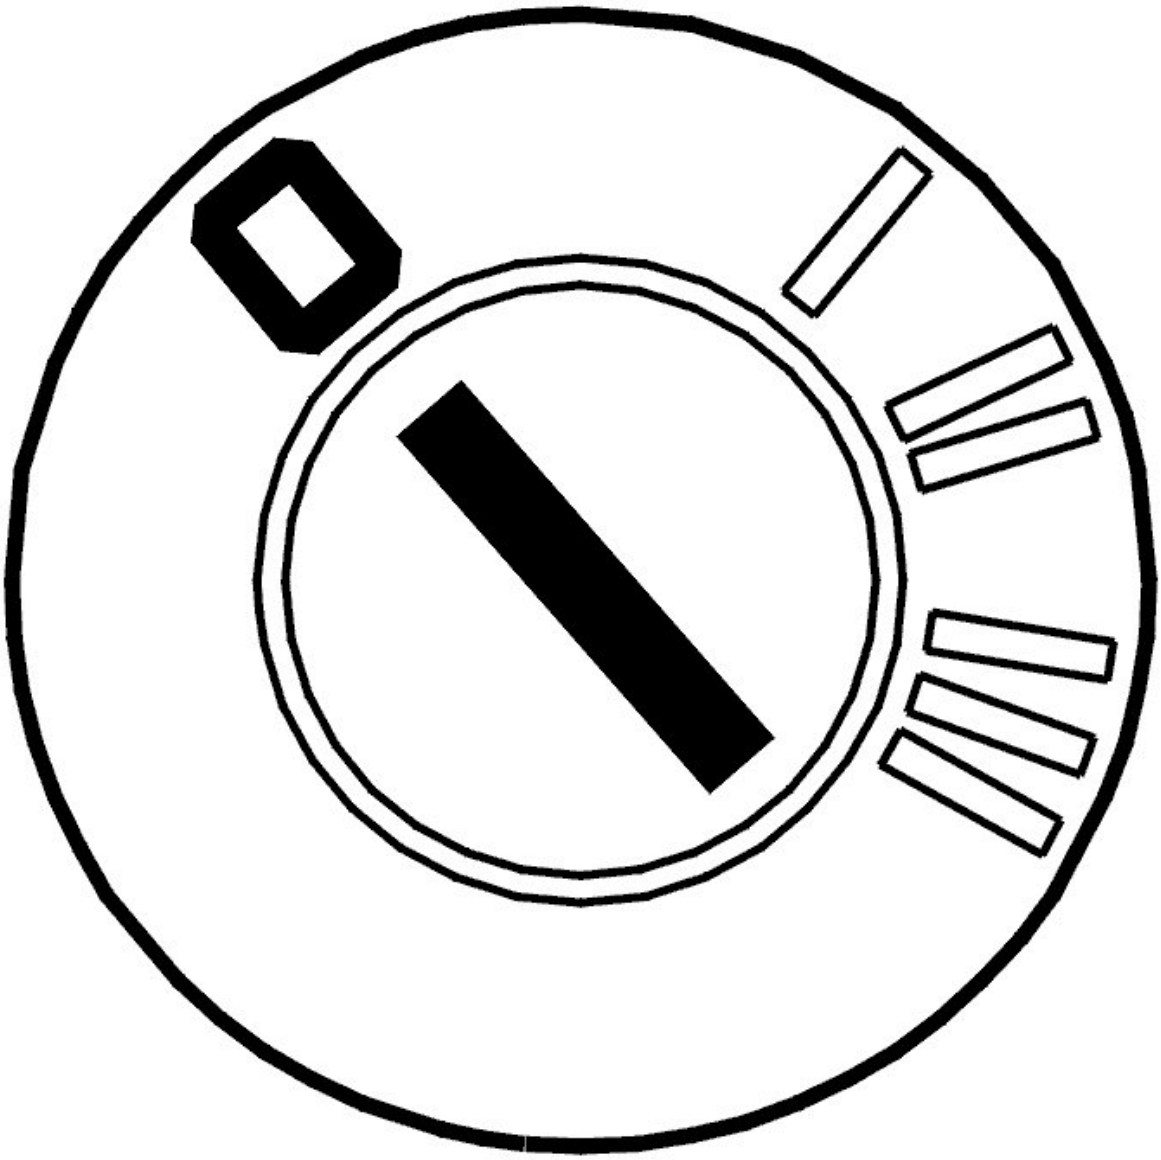
Possible source
- Open-circuit in the signal cable or ground lead
- Short-circuit to ground or supply voltage in the signal cable
- Contact resistance in the terminals
- Damaged engine speed (RPM) sensor
- Damaged carrier plate.

Fault symptom[s]
- The engine does not start
- The engine stops.

Signal Missing

Signal missing

Checking connectors and wiring



- Ignition off.

Check the engine speed (RPM) sensor connector. Check for contact resistance and oxidation.

Check the signal cable between:

- The engine speed (RPM) sensor terminal #1 and Engine control module (ECM) terminal #A48 (#A48).
- The engine speed (RPM) sensor terminal #2 and Engine control module (ECM) terminal #A66 (#B6).

Check the signal line for open circuit, short-circuit to ground and short-circuit to voltage.
Check the carrier plate.
Remedy as necessary.

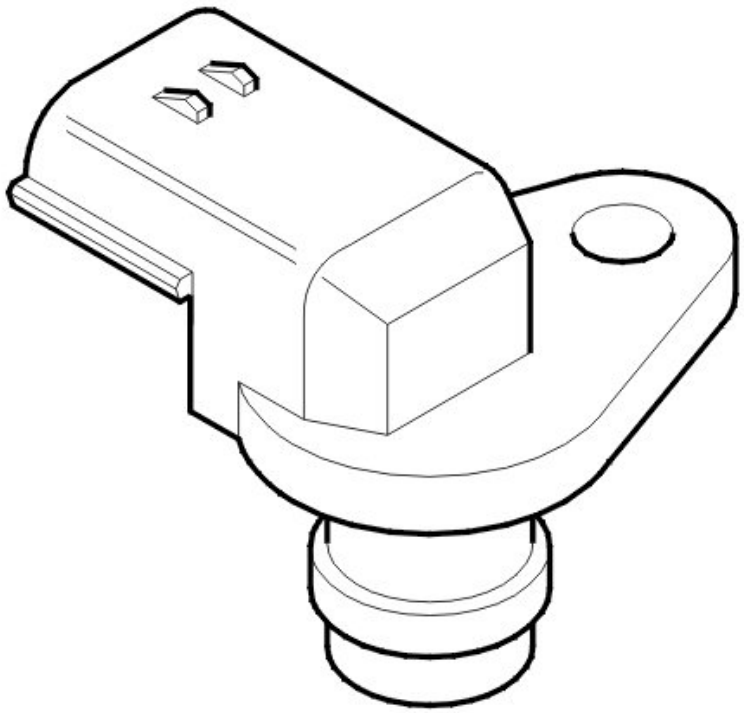
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition



Diagnostic trouble code (DTC) ECM-340B is for the camshaft position (CMP) sensor, intake.
Diagnostic trouble code (DTC) ECM-341B is for the camshaft position (CMP) sensor, exhaust.
The engine control module (ECM) checks the pulse width modulation (PWM) signal from the camshaft position (CMP) sensor.
If there is no signal from the camshaft position (CMP) sensor although it appears sporadically, the engine control module (ECM) interprets this as a fault and the diagnostic trouble code (DTC) is stored. The diagnostic trouble code (DTC) can be diagnosed when the engine is running.

Substitute value

- None.

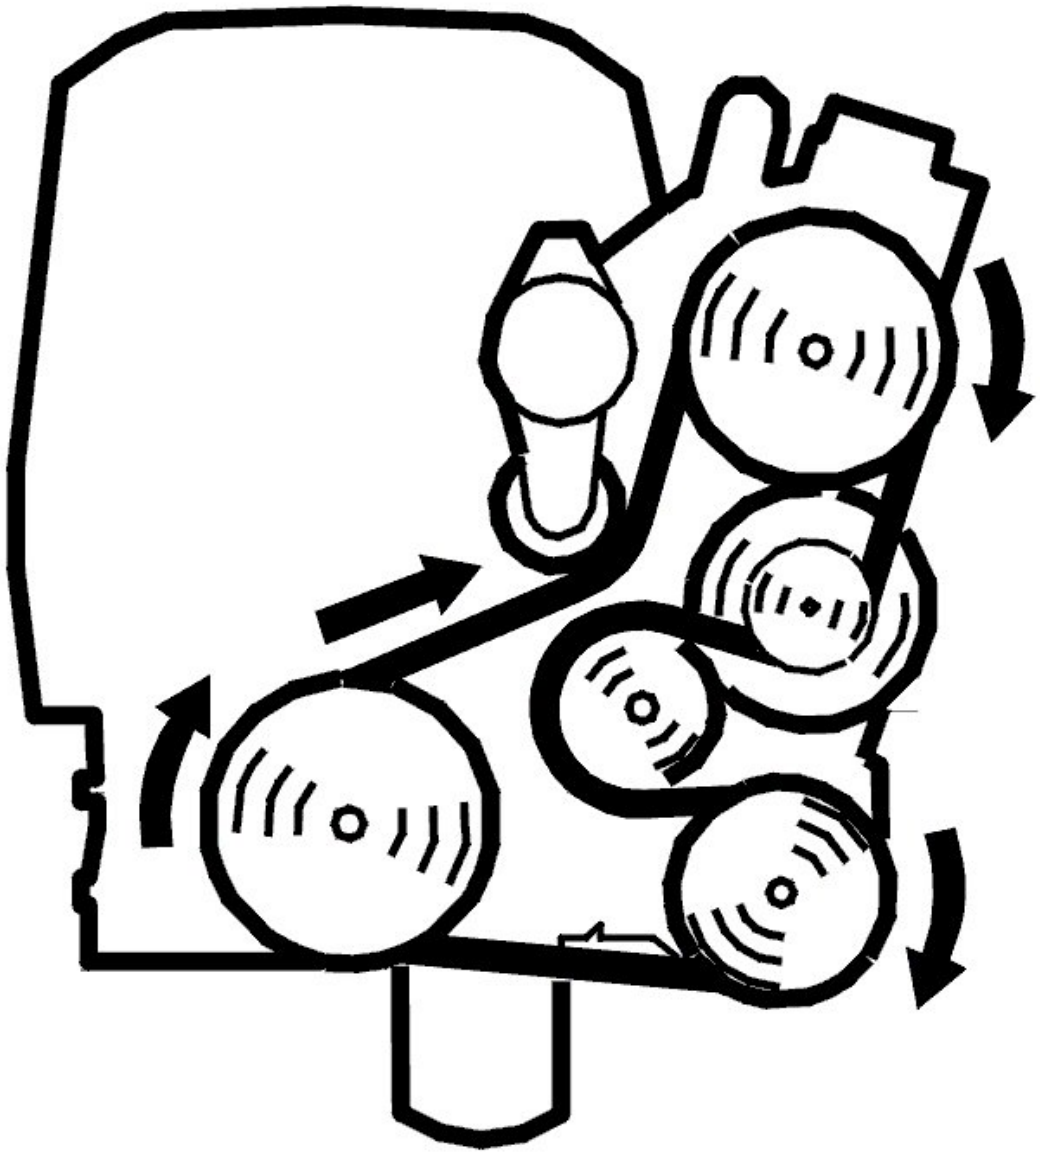
Possible source
- The camshaft position (CMP) sensor is in the wrong position
- Damaged camshaft position (CMP) sensor
- Loose connections.

Fault symptom[s]
- The engine is difficult to start.

Faulty Signal or Signal Missing

Faulty signal or signal missing

Checking the status

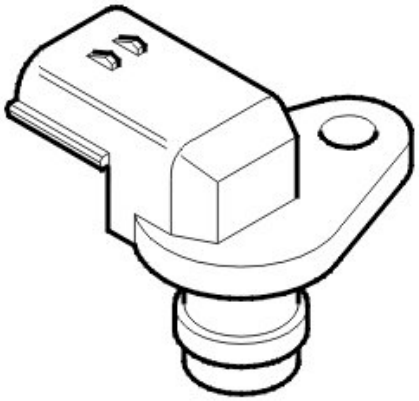


- Start the engine.

Read off the diagnostic status and fault status for the diagnostic trouble code (DTC) by selecting the relevant diagnostic trouble code (DTC) from the list.
Increase the engine speed a number of times until the diagnostic is "Complete".
Check whether the fault is permanent or intermittent. Read off the diagnostic trouble code (DTC) fault status when the diagnostic status is "Completed".

Hint: In some cases several functions of the component will be diagnosed. This affects the amount of time taken to run the diagnostic.

The fault is permanent if the fault status is "Fault found". If the fault status is "No fault found" the fault is intermittent and not presently active.



Continue - Checking components and wiring

Checking components and wiring

- Check the connector for the camshaft position (CMP) sensor. Check for contact resistance and oxidation.

Check that the camshaft position (CMP) sensor is correctly installed. Check that neither the camshaft position (CMP) sensor nor the housing is damaged. Damage may affect the position of the sensor in relation to the camshaft rotor.

Hint: This diagnostic trouble code (DTC) may be caused by a faulty camshaft position (CMP) sensor.

Remedy as necessary.

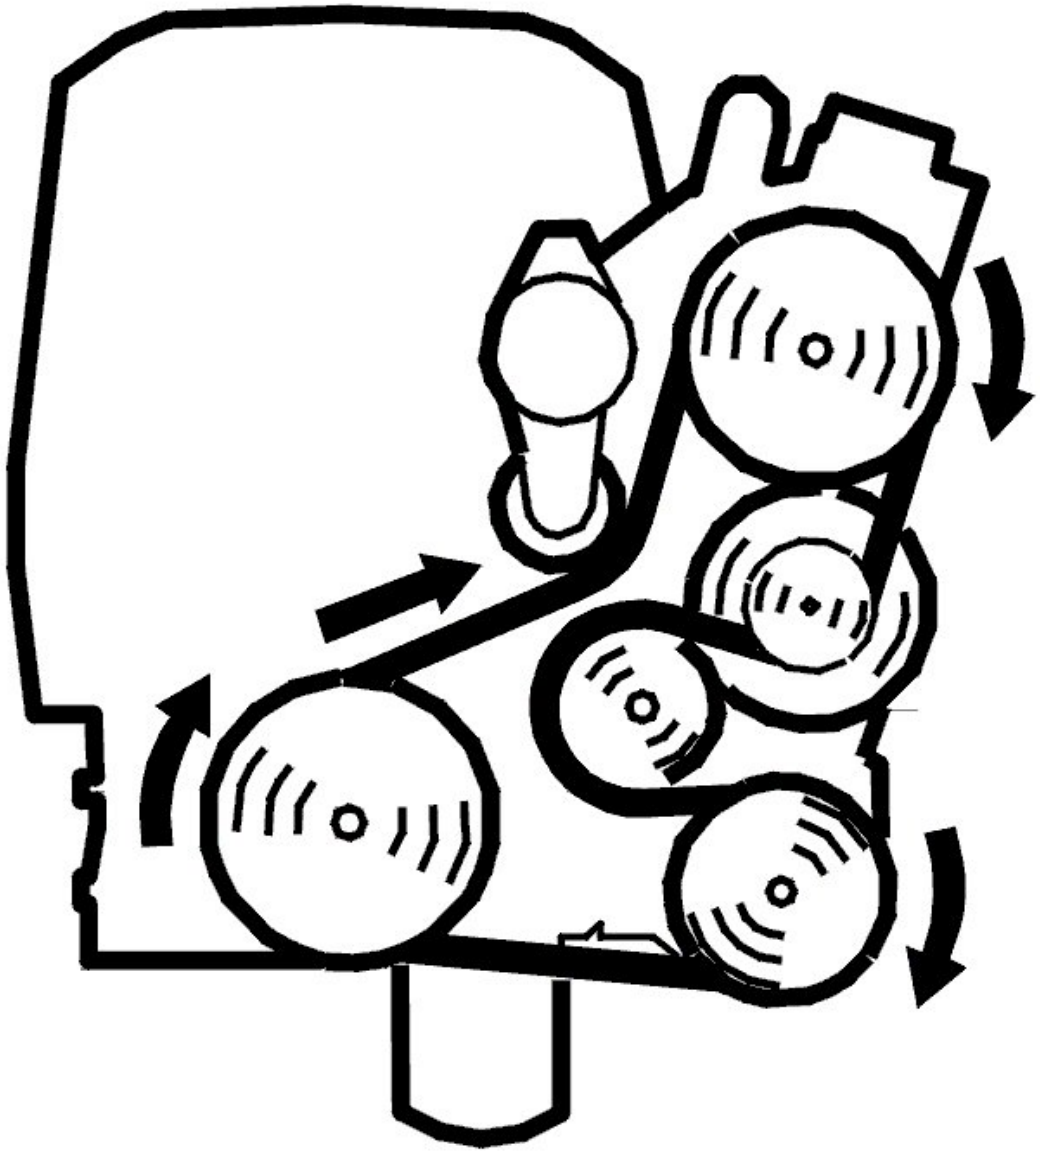
Checking the status



- Start the engine.

Read off the diagnostic status and fault status for the diagnostic trouble code (DTC) by selecting the relevant diagnostic trouble code (DTC) from the list.
Increase the engine speed a number of times until the diagnostic is "Complete".
Check whether the fault is permanent or intermittent. Read off the diagnostic trouble code (DTC) fault status when the diagnostic status is "Completed".

Hint: In some cases several functions of the component will be diagnosed. This affects the amount of time taken to run the diagnostic.

The fault is permanent if the fault status is "Fault found". If the fault status is "No fault found" the fault is intermittent and not presently active.

Continue - Checking components and wiring

Checking components and wiring

- Check the connector for the camshaft position (CMP) sensor. Check for contact resistance and oxidation.

Check that the camshaft position (CMP) sensor is correctly installed. Check that neither the camshaft position (CMP) sensor nor the housing is damaged. Damage may affect the position of the sensor in relation to the camshaft rotor.

Hint: This diagnostic trouble code (DTC) may be caused by a faulty camshaft position (CMP) sensor.

Remedy as necessary.

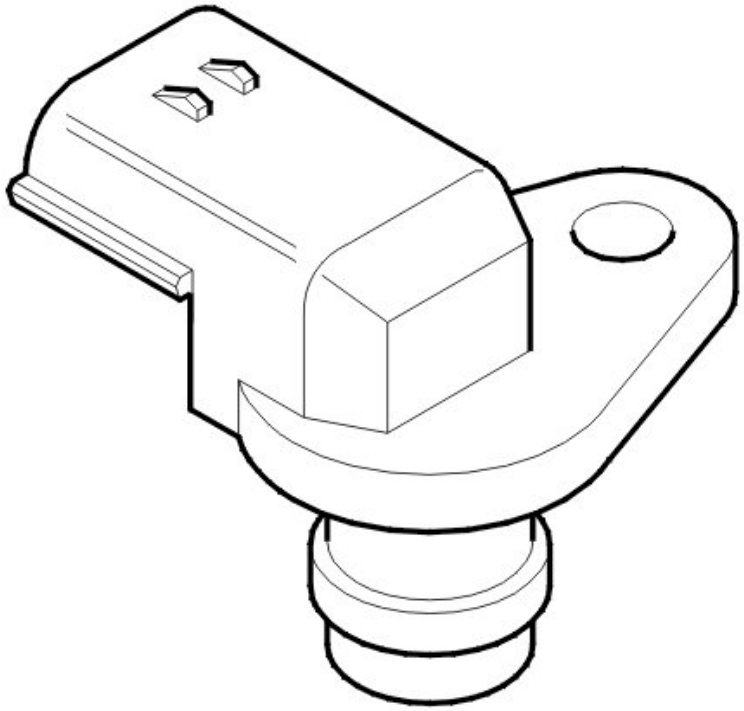
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition



Diagnostic trouble code (DTC) ECM-340C is for the camshaft position (CMP) sensor, intake.
Diagnostic trouble code (DTC) ECM-341C is for the camshaft position (CMP) sensor, exhaust.
The engine control module (ECM) checks the pulse width modulation (PWM) signal from the camshaft position (CMP) sensor.
The diagnostic trouble code (DTC) is stored if the signal from the camshaft position (CMP) sensor is constantly high. This is interpreted by the engine control module (ECM) as a fault. The diagnostic trouble code (DTC) can be diagnosed when the engine is running.

Substitute value

- None.

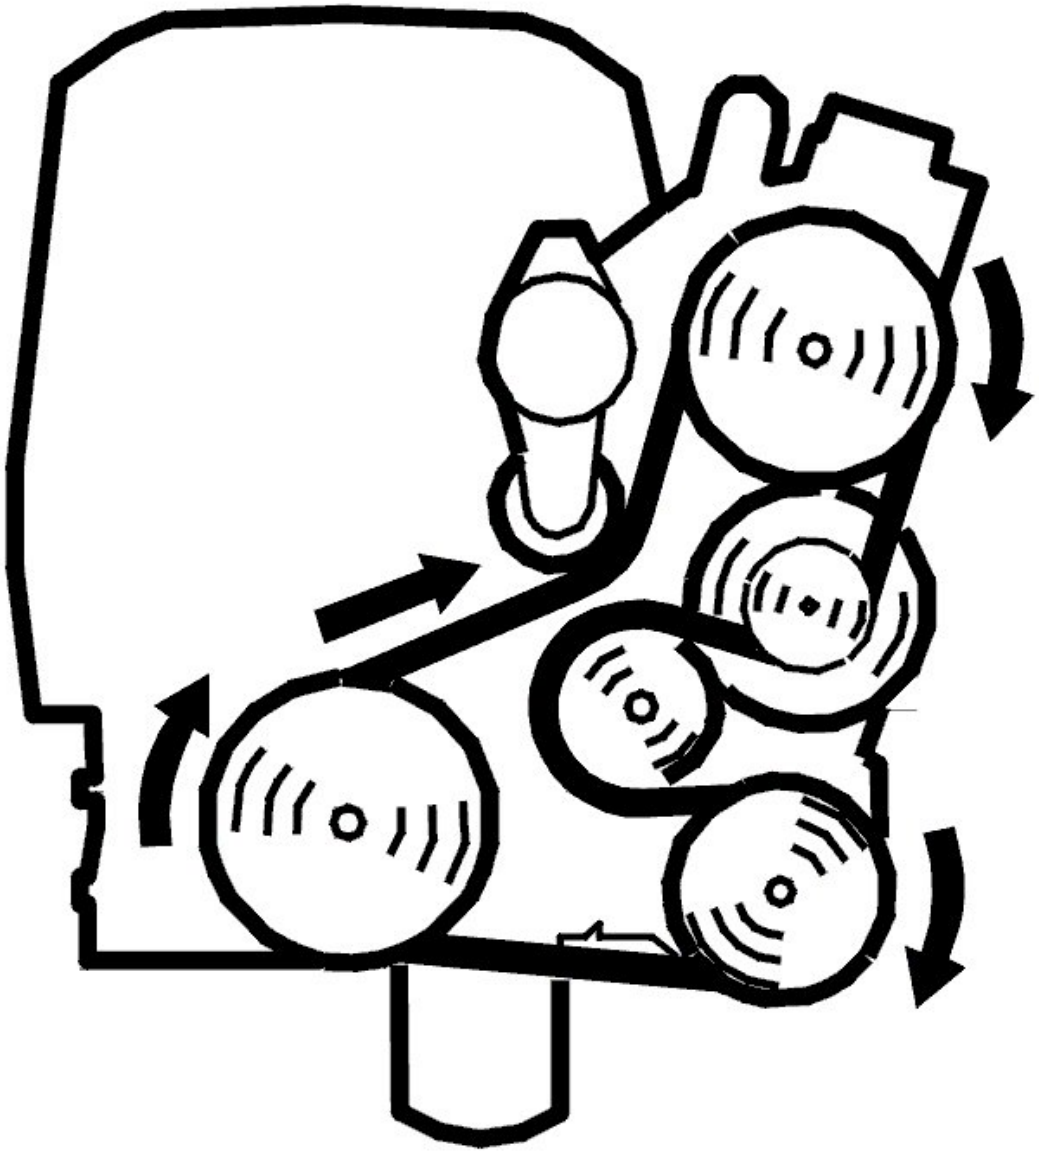
Possible source
- Open-circuit in the signal cable
- Short-circuit to supply voltage in the signal cable
- Short-circuit to ground in the power cable
- Open-circuit in the ground lead
- Damaged camshaft position (CMP) sensor.

Fault symptom[s]
- The engine is difficult to start.

Signal Too High

Signal too high

Checking the status



- Start the engine.

Read off the diagnostic status and fault status for the diagnostic trouble code (DTC) by selecting the relevant diagnostic trouble code (DTC) from the list.
Increase the engine speed a number of times until the diagnostic is "Complete".
Check whether the fault is permanent or intermittent. Read off the diagnostic trouble code (DTC) fault status when the diagnostic status is "Completed".

Fault-tracing information

The fault should have been detected and remedied. As this is not the case fault-tracing has failed.
Exit fault-tracing for this diagnostic trouble code (DTC) or make another attempt.

Do you want to exit fault-tracing?

Yes - FAULT-TRACING FAILED

No - Attempt New Test

FAULT-TRACING FAILED - FAULT-TRACING FAILED

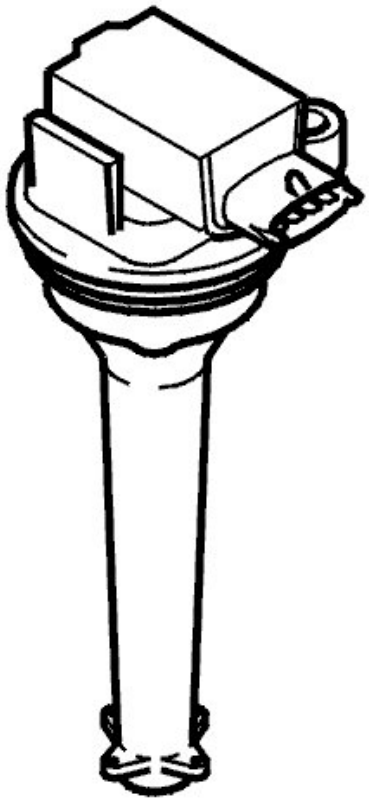
Attempt New Test - Checking components and wiring

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition



The engine control module (ECM) checks the signal cable for the ignition coil primary winding.
The diagnostic trouble code (DTC) is stored if the engine control module (ECM) detects that the signal for the primary winding for the ignition coil is too high.
The diagnostic trouble code (DTC) indicates which ignition coil is being referred to.
- ECM-350C: ignition coil 1
- ECM-351C: ignition coil 2
- ECM-352C: ignition coil 3
- ECM-353C: ignition coil 4
- ECM-354C: ignition coil 5.

The diagnostic trouble code (DTC) can be diagnosed when the engine is running.

Substitute value
- None.

Possible source
- Short-circuit to supply voltage in the signal cable
- Damaged ignition coil.

Fault symptom[s]
- Malfunction indicator lamp (MIL) lit
- The engine is not firing on all cylinders.

Signal Too High

Signal too high

Checking components and wiring

Check the cable that relates to the diagnostic trouble code (DTC). Check for a short-circuit to supply voltage.
Check between:
- Engine control module (ECM) #A50 (#A50) and ignition coil pin #2 (ECM-350C: ignition coil A, cylinder 1).
- Engine control module (ECM) #A31 (#A31) and ignition coil pin #2 (ECM-351C: ignition coil B, cylinder 2).
- Engine control module (ECM) #A51 (#A51) and ignition coil pin #2 (ECM-352C: ignition coil E, cylinder 3).
- Engine control module (ECM) #A30 (#A30) and ignition coil pin #2 (ECM-353C: ignition coil C, cylinder 4).

- Engine control module (ECM) #A52 (#A52) and ignition coil pin #2 (ECM-354C: ignition coil D, cylinder 5).

Remedy as necessary.

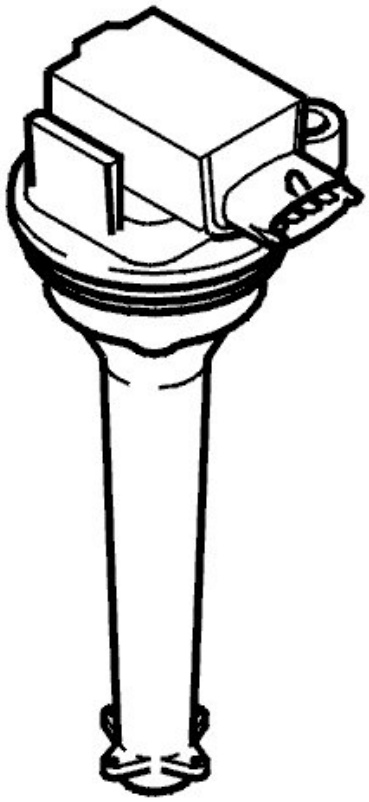
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition



The engine control module (ECM) checks the signal cable for the ignition coil primary winding.
The diagnostic trouble code (DTC) is stored if the engine control module (ECM) detects that the signal for the primary winding for the ignition coil is too low.
The diagnostic trouble code (DTC) indicates which ignition coil is being referred to.
- ECM-350D: ignition coil 1
- ECM-351D: ignition coil 2
- ECM-352D: ignition coil 3
- ECM-353D: ignition coil 4
- ECM-354D: ignition coil 5.

The diagnostic trouble code (DTC) can be diagnosed when the engine is running.

Substitute value
- None.

Possible source
- Short-circuit to ground in the signal cable
- Damaged ignition coil.

Fault symptom[s]
- Malfunction indicator lamp (MIL) lit
- The engine is not firing on all cylinders.

Signal Too Low

Signal too low

Checking components and wiring
- Check the connector for the ignition coil. Check for contact resistance. Check for oxidation.

Check the cable that relates to the diagnostic trouble code (DTC). Check for a short-circuit to ground.
Check between:
- Engine control module (ECM) #A50 (#A50) and ignition coil pin #2 (ECM-350D: ignition coil A, cylinder 1).
- Engine control module (ECM) #A31 (#A31) and ignition coil pin #2 (ECM-351D: ignition coil B, cylinder 2).
- Engine control module (ECM) #A51 (#A51) and ignition coil pin #2 (ECM-352D: ignition coil E, cylinder 3).
- Engine control module (ECM) #A30 (#A30) and ignition coil pin #2 (ECM-353D: ignition coil C, cylinder 4).

- Engine control module (ECM) #A52 (#A52) and ignition coil pin #2 (ECM-354D: ignition coil D, cylinder 5).

Remedy as necessary.

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information ECM-400C

Condition

The engine control module (ECM) continuously checks three-way catalytic converter (TWC) efficiency (bank 1) by comparing signals from the rear heated oxygen sensor (HO2S) with the signal from the front heated oxygen sensor (HO2S). The diagnostic trouble code (DTC) is stored if the efficiency of the three-way catalytic converter (TWC) deviates too much.
The diagnostic trouble code (DTC) is diagnosed when driving under specific driving conditions.

Substitute value
- The rear long-term fuel trim is disabled.

Possible source
- Misfiring
- Leakage in the intake system
- Leakage in the exhaust system
- Faulty fuel pressure
- Uneven compression
- Damaged catalytic converter.

Fault symptom[s]
- Malfunction indicator lamp (MIL) lit.

Signal Too High

Signal too high

Checking the components and wiring

Check the intake system for air leakage.
Check the exhaust system for air leakage.
Checking fuel and residual pressure.
Check the compression of the engine.
Remedy as necessary.

Note! Try a new heated oxygen sensor (HO2S) if the above fault-tracing does not remedy the fault.

Other information
- Check for air leaks in the intake system See: Fuel Delivery and Air Induction/Testing and Inspection/Air Leaks in the Intake System, Checking
- Checking for air leakage in the exhaust system See: Diagnostic Trouble Code Tests and Associated Procedures/Related Tests, Information and Procedures/Air Leakage Exhaust System, Check
- Cylinder leakage test See: Engine, Cooling and Exhaust/Engine/Testing and Inspection/Cylinder Leakage Test
- Three-way catalytic converter (TWC), replacing See: Emission Control Systems/Catalytic Converter/Service and Repair

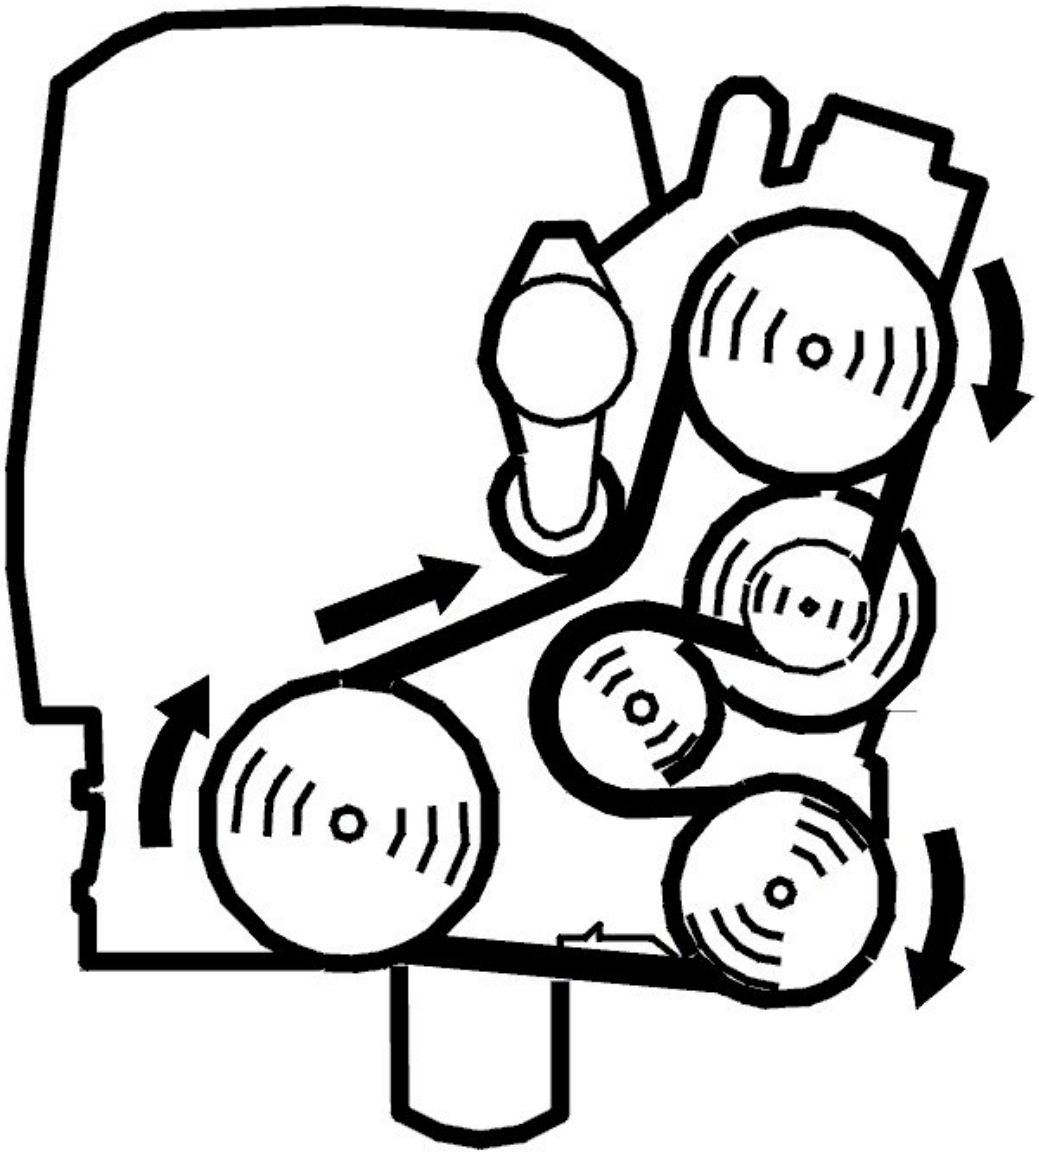
Continue - Verification

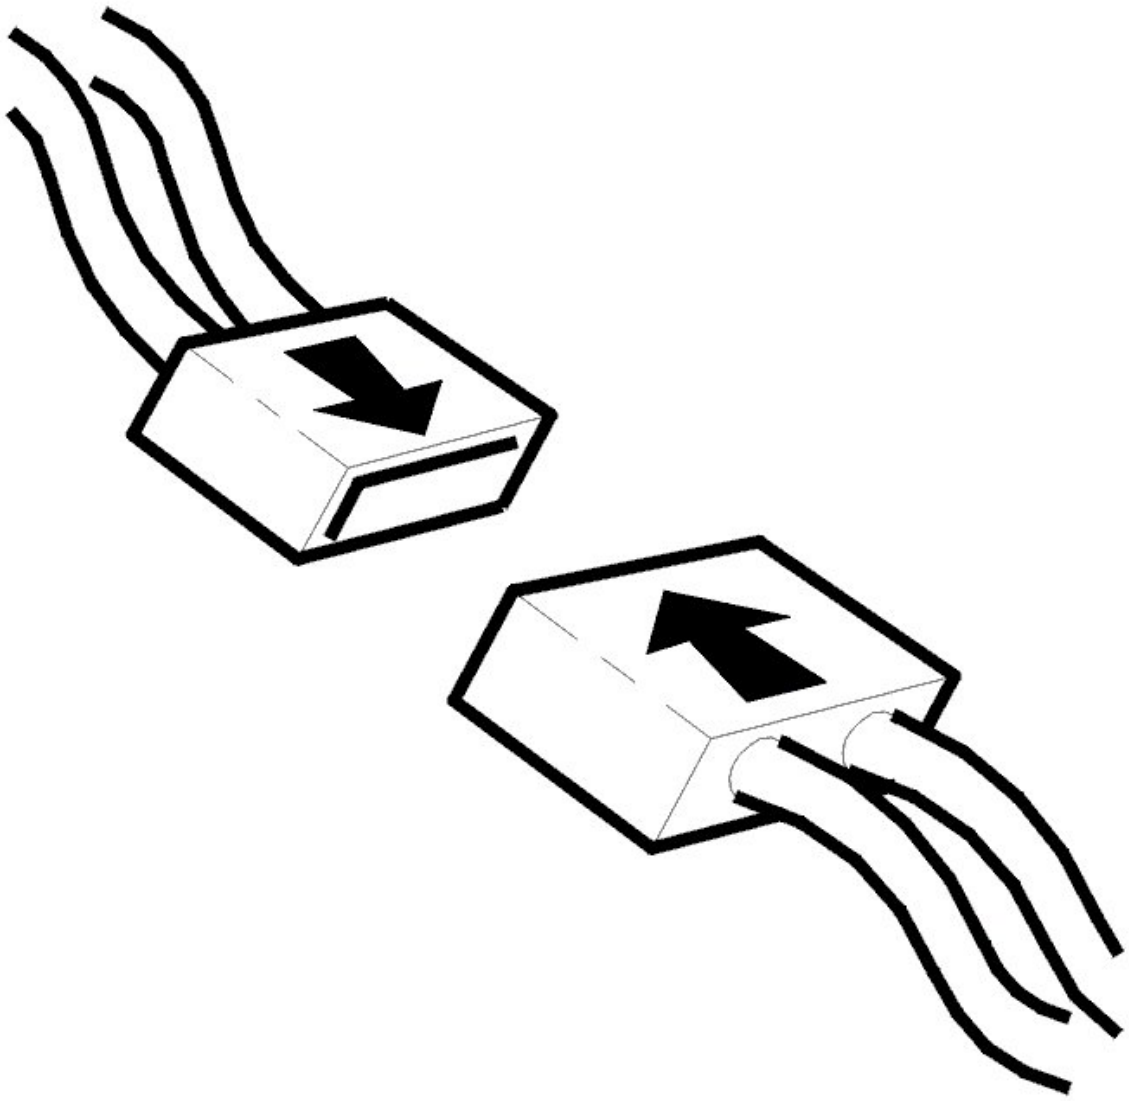
Verification

Verification

Verification

Hint: After carrying out the repair, check that the fault has been remedied.





- Ignition off
- Reconnect the connectors, reinstall components etc.
- Test drive the vehicle on the road. Run a TRIP schedule so that the engine control module (ECM) compares the diagnostics. To run a TRIP schedule, see: Verifying repairs See: Monitors, Trips, Drive Cycles and Readiness Codes/Verifying Repairs
- Connect VCT2000 to the data link connector (DLC) without switching off the engine.

Note! If the engine is switched off, the stored fault status will be erased and the test drive will have to be repeated.

Read off the diagnostic status and fault status for the diagnostic trouble code (DTC) by selecting the relevant diagnostic trouble code (DTC) from the list.
Check the fault status for the diagnostic trouble code (DTC) when the diagnostic is "Complete". If the function is correct, the fault status must be "No fault found" when the diagnostic is complete.

Diagnostic Trouble Code (DTC) Information

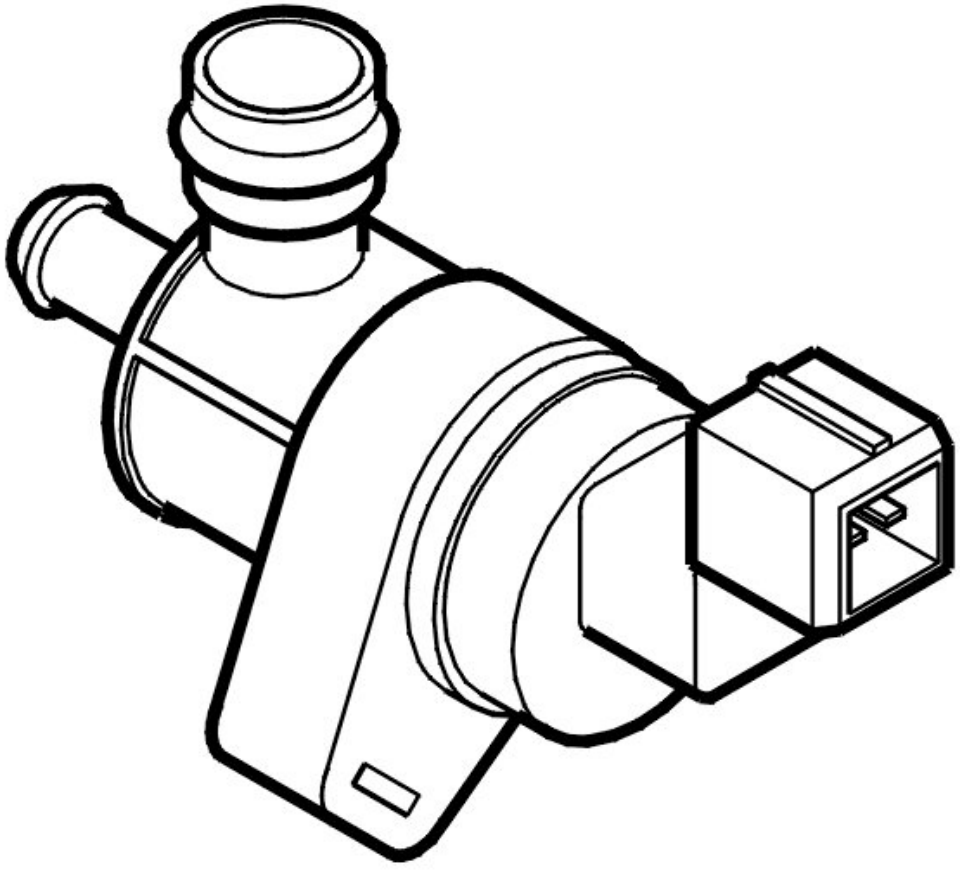
Diagnostic trouble code (DTC) information ECM-420C

Condition



When the control module activates evaporative emission system (EVAP) control, the idle air trim or short-term fuel trim will change. The diagnostic trouble code (DTC) is stored if the engine control module (ECM) does not detect any change in the idle air trim or the long term fuel trim when evaporative emission (EVAP) control is active. The engine control module (ECM) interprets this as a damaged evaporative emission (EVAP) system.

Substitute value
- None.

Possible source
- Damaged evaporative emission system (EVAP) valve.

Fault symptom[s]
- Malfunction indicator lamp (MIL) lit.

Open

Open

Checking the component
- Slacken off the evaporative emission system (EVAP) valve
- Connect a vacuum pump to the evaporative emission system (EVAP) valve terminal (B). Pump a vacuum. Check that there is no leakage through the evaporative emission system (EVAP) valve by listening to and checking via the pump gauge that the pressure is stable
- Connect the Evaporative emission system (EVAP) valve connector
- Ignition on
- Activate the evaporative emission system (EVAP) valve. When the Evaporative emission system (EVAP) valve is activated, the valve opens and clicks. Check on the pump gauge that the vacuum drops (the pressure evens out) when the evaporative emission system (EVAP) valve opens.

If the function is OK, there must be no leakage when the evaporative emission system (EVAP) valve is closed (stable pressure on the pump gauge) and the vacuum must drop when the evaporative emission system (EVAP) valve opens (the pressure evens out).
The evaporative emission system (EVAP) valve is damaged if the function is faulty.
If the function of the evaporative emission system (EVAP) valve is correct, check the hose and hose connections between the evaporative emission system (EVAP) valve for leakage.
Remedy as necessary.

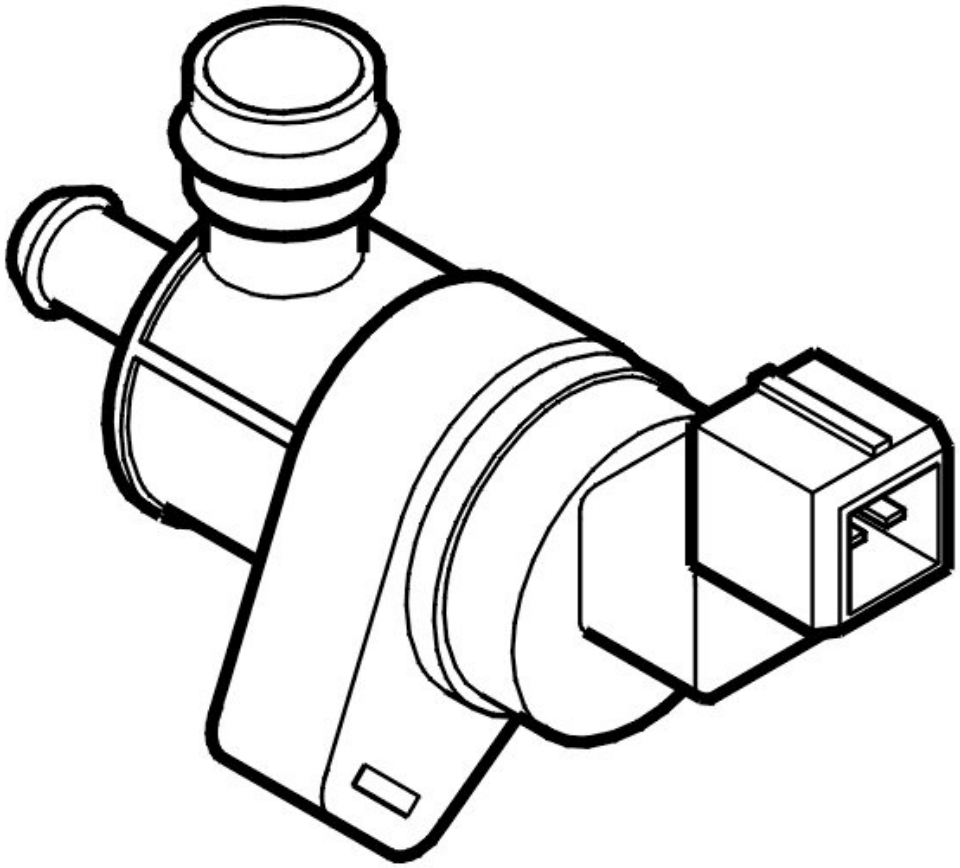
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information ECM-420D

Condition



When the control module activates evaporative emission system (EVAP) control, the idle air trim or short-term fuel trim will change. The diagnostic trouble code (DTC) is stored if the engine control module (ECM) does not detect any change in the idle air trim or the long term fuel trim when evaporative emission (EVAP) control is active. The engine control module (ECM) interprets this as a damaged evaporative emission (EVAP) system.

Substitute value
- None.

Possible source
- Blocked hose between the EVAP canister and the evaporative emission system (EVAP) valve
- Blocked hose between the evaporative emission system (EVAP) valve and the intake manifold
- Damaged evaporative emission system (EVAP) valve.

Fault symptom[s]
- Malfunction indicator lamp (MIL) lit.

Closed

Closed

Checking the component
- Slacken off the evaporative emission system (EVAP) valve
- Connect a vacuum pump to the evaporative emission system (EVAP) valve terminal (B). Pump a vacuum. Check that there is no leakage through the evaporative emission system (EVAP) valve by listening to and checking via the pump gauge that the pressure is stable
- Connect the Evaporative emission system (EVAP) valve connector
- Ignition on
- Activate the evaporative emission system (EVAP) valve. When the Evaporative emission system (EVAP) valve is activated, the valve opens and clicks. Check on the pump gauge that the vacuum drops (the pressure evens out) when the evaporative emission system (EVAP) valve opens.

If the function is OK, there must be no leakage when the evaporative emission system (EVAP) valve is closed (stable pressure on the pump gauge) and the vacuum must drop when the evaporative emission system (EVAP) valve opens (the pressure evens out).
The evaporative emission system (EVAP) valve is damaged if the function is faulty.
If the function of the Evaporative emission system (EVAP) valve is OK, check:
- The hose and hose terminals between the Evaporative emission system (EVAP) valve and the intake manifold. Check for leakage and blockages
- Check the hose and hose terminals between the EVAP canister and the Evaporative emission system (EVAP) valve. Check for leakage and blockages.

Remedy as necessary.

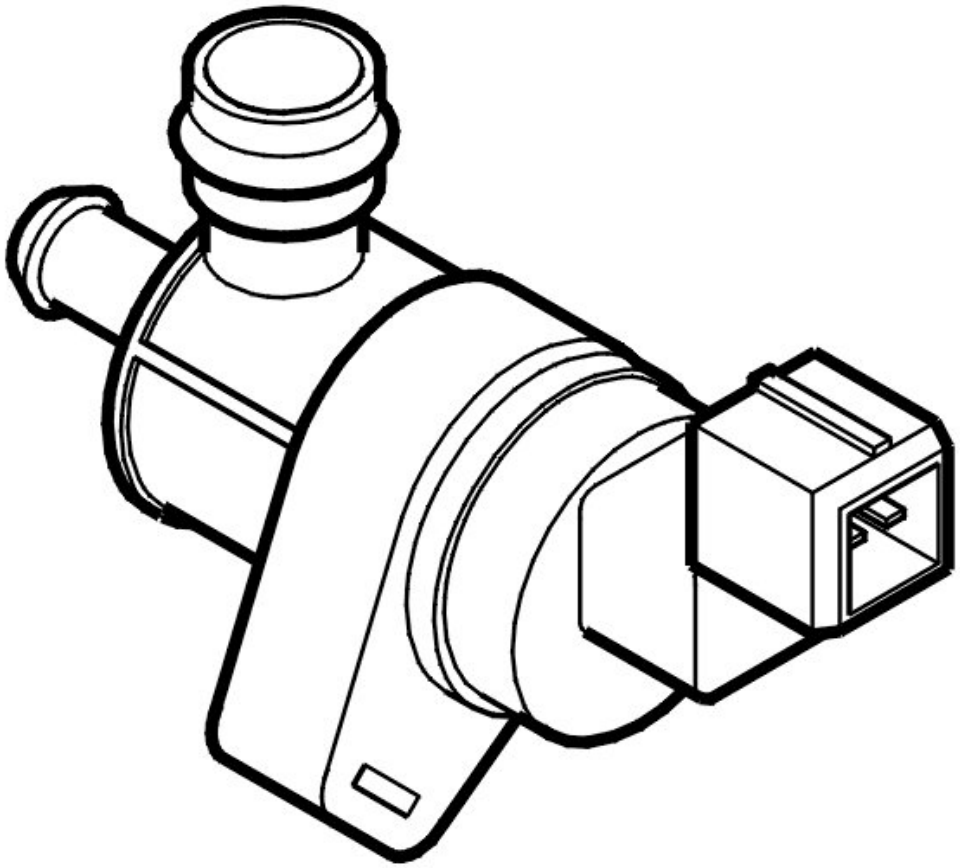
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information ECM-421B

Condition



The diagnostic trouble code (DTC) is stored if the engine control module (ECM) detects that there is no signal from the evaporative emission system (EVAP) valve.
The diagnostic trouble code (DTC) can be diagnosed when the ignition is switched on.

Substitute value
- twin heated oxygen sensor (HO2S) control disabled.

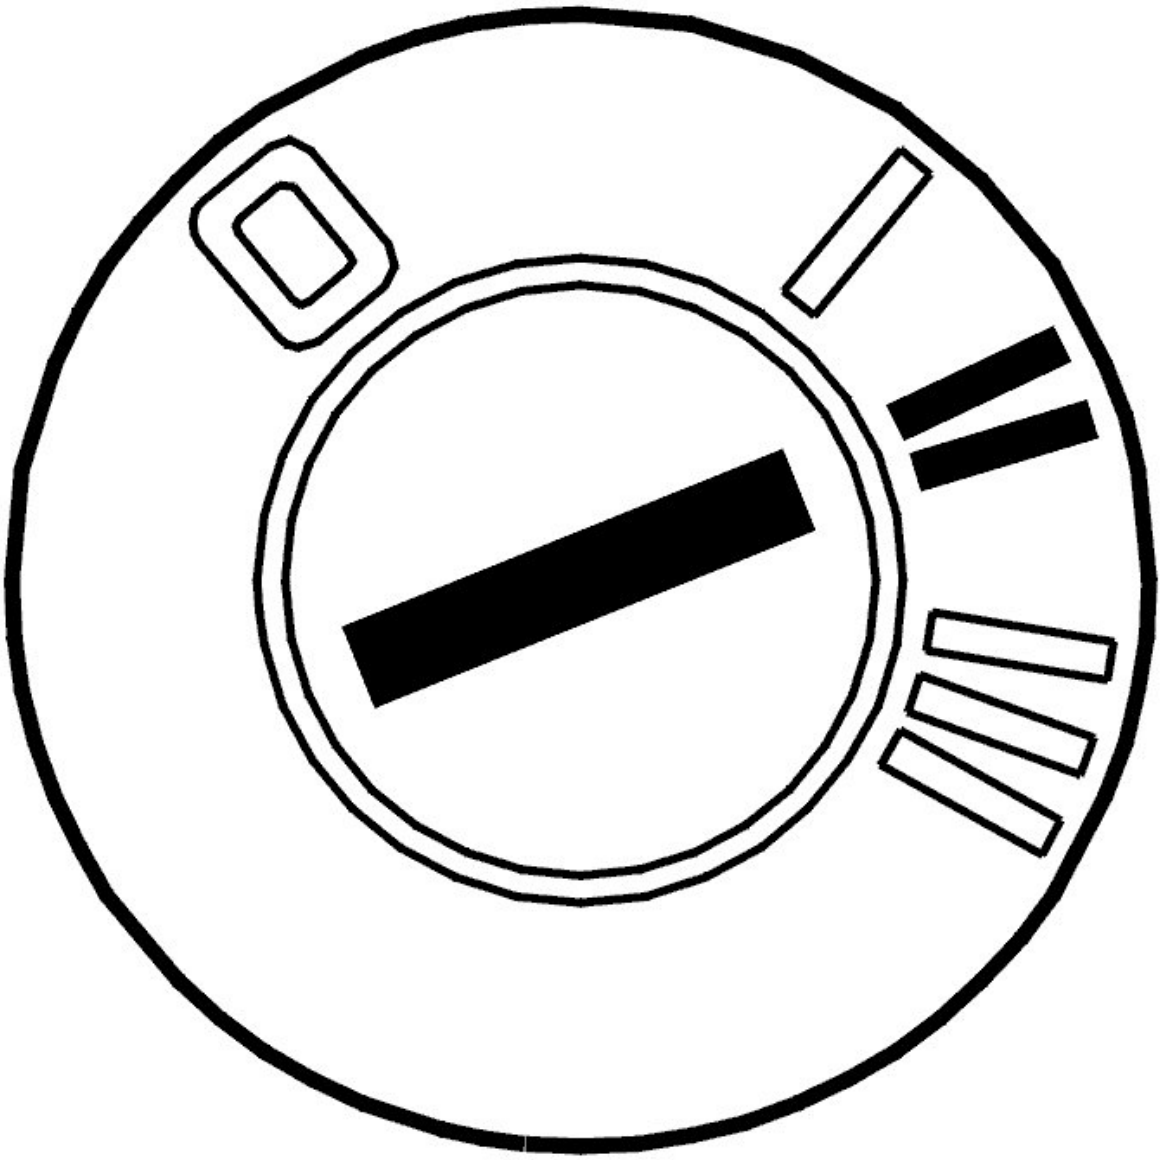
Possible source
- Open-circuit in the signal cable
- Damaged evaporative emission system (EVAP) valve
- Contact resistance in the terminals
- Open-circuit in the power cable.

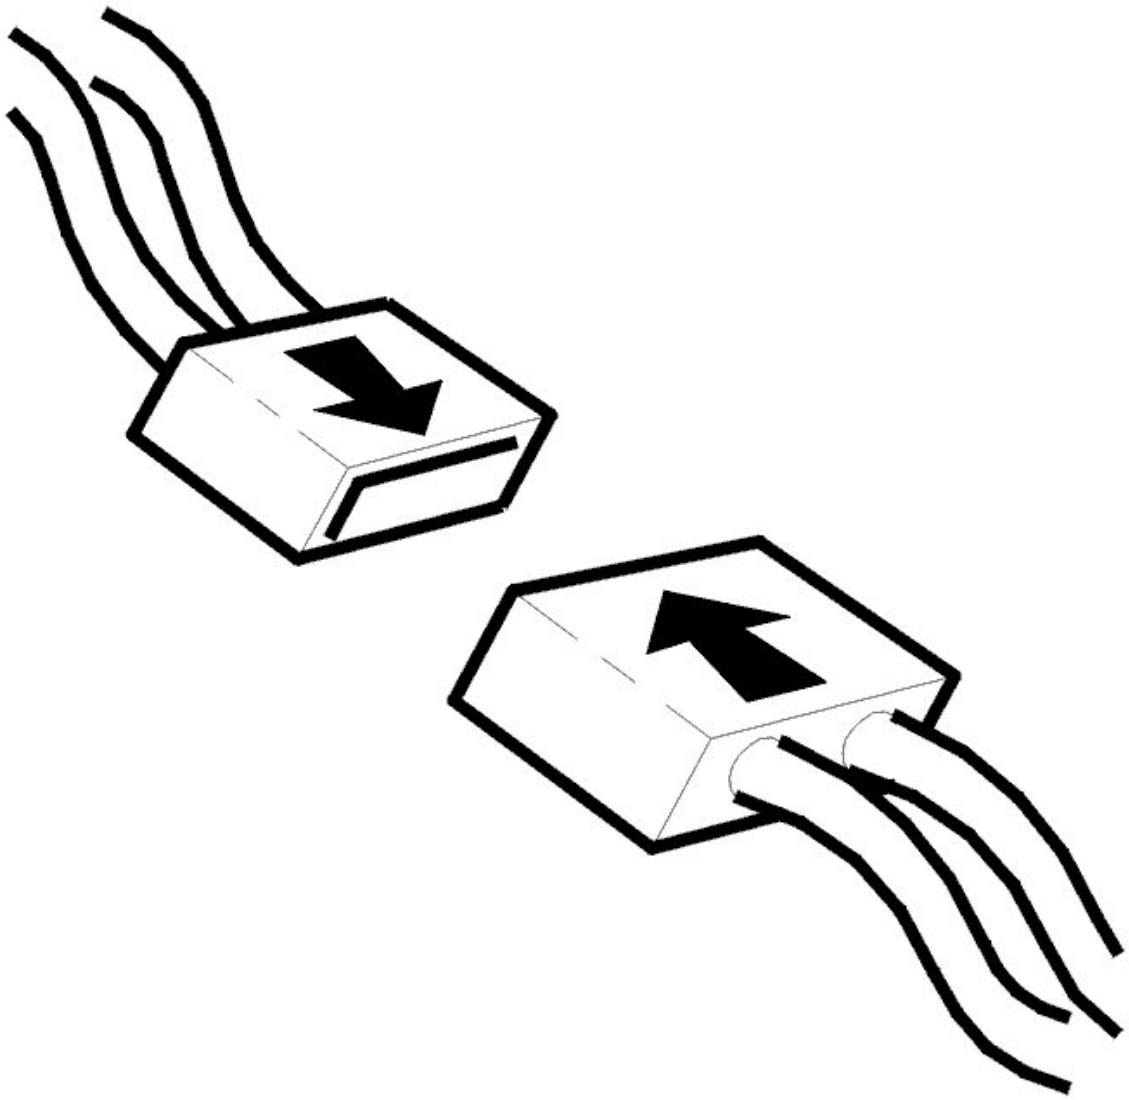
Fault symptom[s]
- Malfunction indicator lamp (MIL) lit.

Signal Missing

Signal missing

Checking the connector





- Ignition off
- Check the evaporative emission system (EVAP) valve connector. Check for contact resistance and oxidation
- Reinstall the components, reconnect the connectors etc.
- Ignition on
- Activate the evaporative emission system (EVAP) valve.

A click should be heard when the evaporative emission system (EVAP) valve is activated.
If the evaporative emission system (EVAP) valve is now OK this indicates that the fault was caused by poor contact in the connector.

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information ECM-430C

Condition

If the engine control module (ECM) registers that fuel filling has been carried out through the fuel level being changed, the position and installation of the fuel tank filler cap is checked. This is carried out by quicker leak diagnostics.
The check is carried out a few minutes after start if the vehicle speed is constant and exceeds 30 km/h and only if no fault is detected on the leak diagnostic unit.
The diagnostic trouble code (DTC) is stored if the engine control module (ECM) detects a leak after filling. This is interpreted as fuel tank filler cap missing or loosely installed.

Substitute value

None.

Possible source
- The fuel tank filler cap is missing or not properly tightened.

Fault symptom[s]
- None.

Fuel Tank Filler Cap Missing

Fuel tank filler cap missing

Checking other diagnostic trouble codes (DTCs), engine control module (ECM)

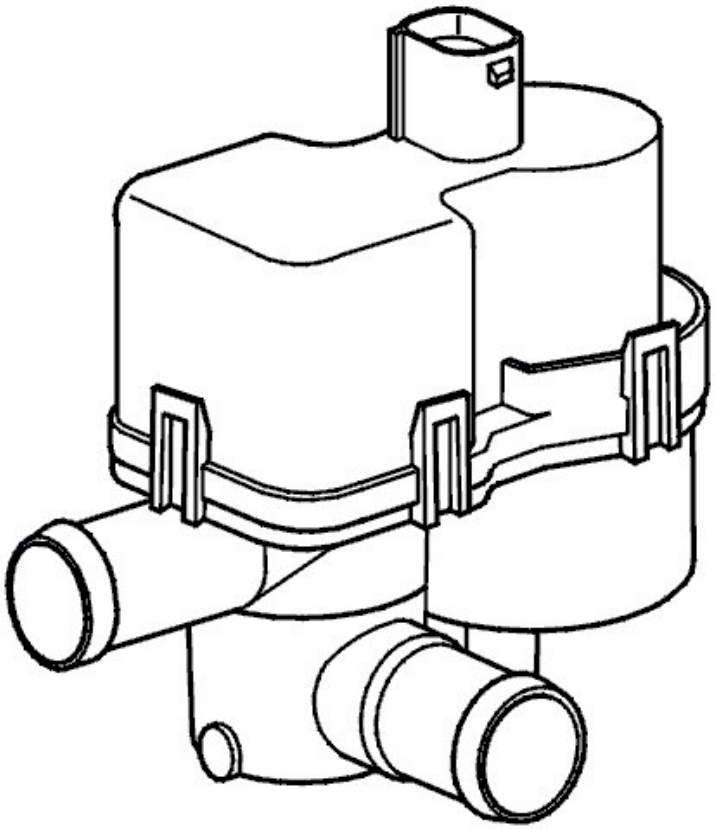
Hint: This diagnostic trouble code (DTC) can only be stored after a refueling. The diagnostic detects major leaks in the fuel tank system. The most likely cause is that the fuel tank filler cap has not been installed correctly. For further information about this diagnostic trouble code (DTC), see Diagnostic Trouble Code (DTC) Information.
In the event of a permanent fault, a diagnostic trouble code (DTC) for a "Major leak" will also be stored after the major leak diagnostic is complete.

- Check if the diagnostic trouble code (DTC) for "Major leak" is stored in the engine control module (ECM), if so, fault-trace from it instead.
- If no diagnostic trouble code for "Major leak" is stored, perform a quick test of the tank system via VEHICLE COMMUNICATION to ensure that the fault was intermittent and probably caused by the fuel tank filler cap.

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information ECM-431B

Condition



The engine control module (ECM) checks the control signal to the heater element in the leak diagnostic unit.
The diagnostic trouble code (DTC) is stored if the engine control module (ECM) detects that the signal is too high.
The diagnostic trouble code (DTC) can be diagnosed when the leak diagnostic system is run.

Substitute value
- None.

Possible source
- Open-circuit in the signal cable.
- Damaged leak diagnostic pump.

Fault symptom[s]
- None.

Signal Missing

Signal missing

Checking the wiring

Check the cable between engine control module (ECM) terminal #B34 (#B44) and leak diagnostic unit terminal #2. Check for an open-circuit. Remedy as necessary.

Diagnostic Trouble Code (DTC) Information

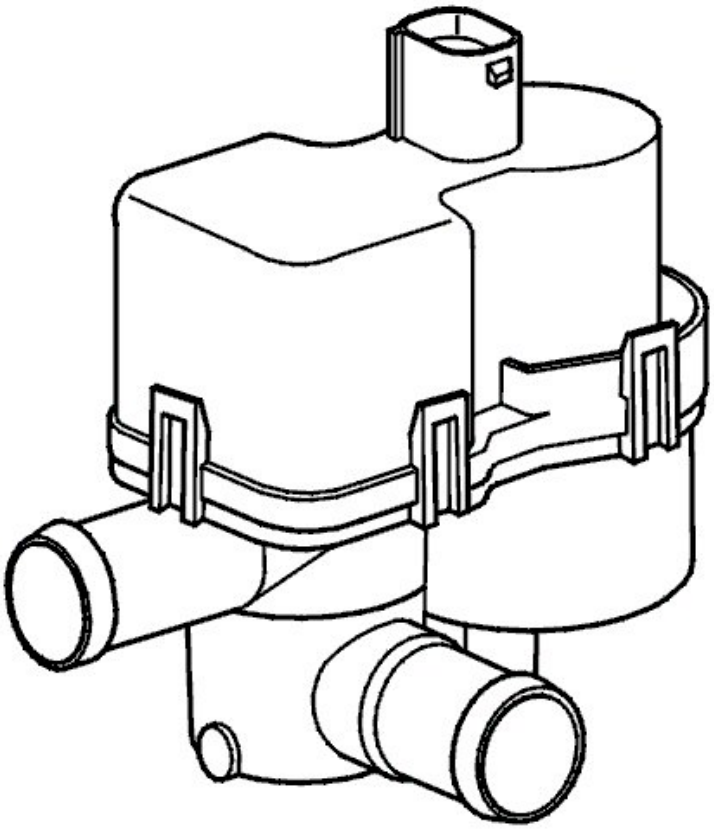
Diagnostic trouble code (DTC) information ECM-431D

Condition



The engine control module (ECM) checks the control signal to the heater element in the leak diagnostic unit.
The diagnostic trouble code (DTC) is stored if the engine control module (ECM) detects that the signal is too low.
The diagnostic trouble code (DTC) can be diagnosed when the engine is running.

Substitute value
- None.

Possible source
- Short-circuit to ground in the signal cable.

- Damaged leak diagnostic pump.

Fault symptom[s]
- None.

Signal Too Low

Signal too low

Checking the wiring

Check the signal cable. Check for a short-circuit to ground. Take readings between:
- Engine control module (ECM) #B34 (#C44) and leakage diagnostic unit #2.

Remedy as necessary.

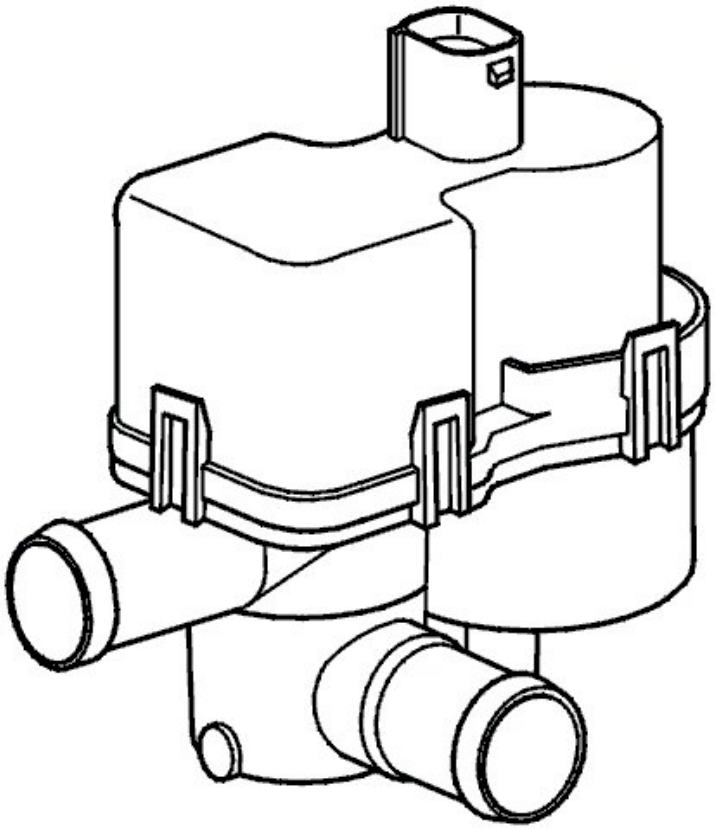
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information ECM-432B

Condition



The diagnostic trouble code (DTC) is stored if the engine control module (ECM) registers that there is no signal from the valve in the pump for the leak diagnostic when the valve is activated.
The diagnostic trouble code (DTC) can be diagnosed when the leak diagnostic system is run.

Substitute value
- The leak diagnostic is disabled.

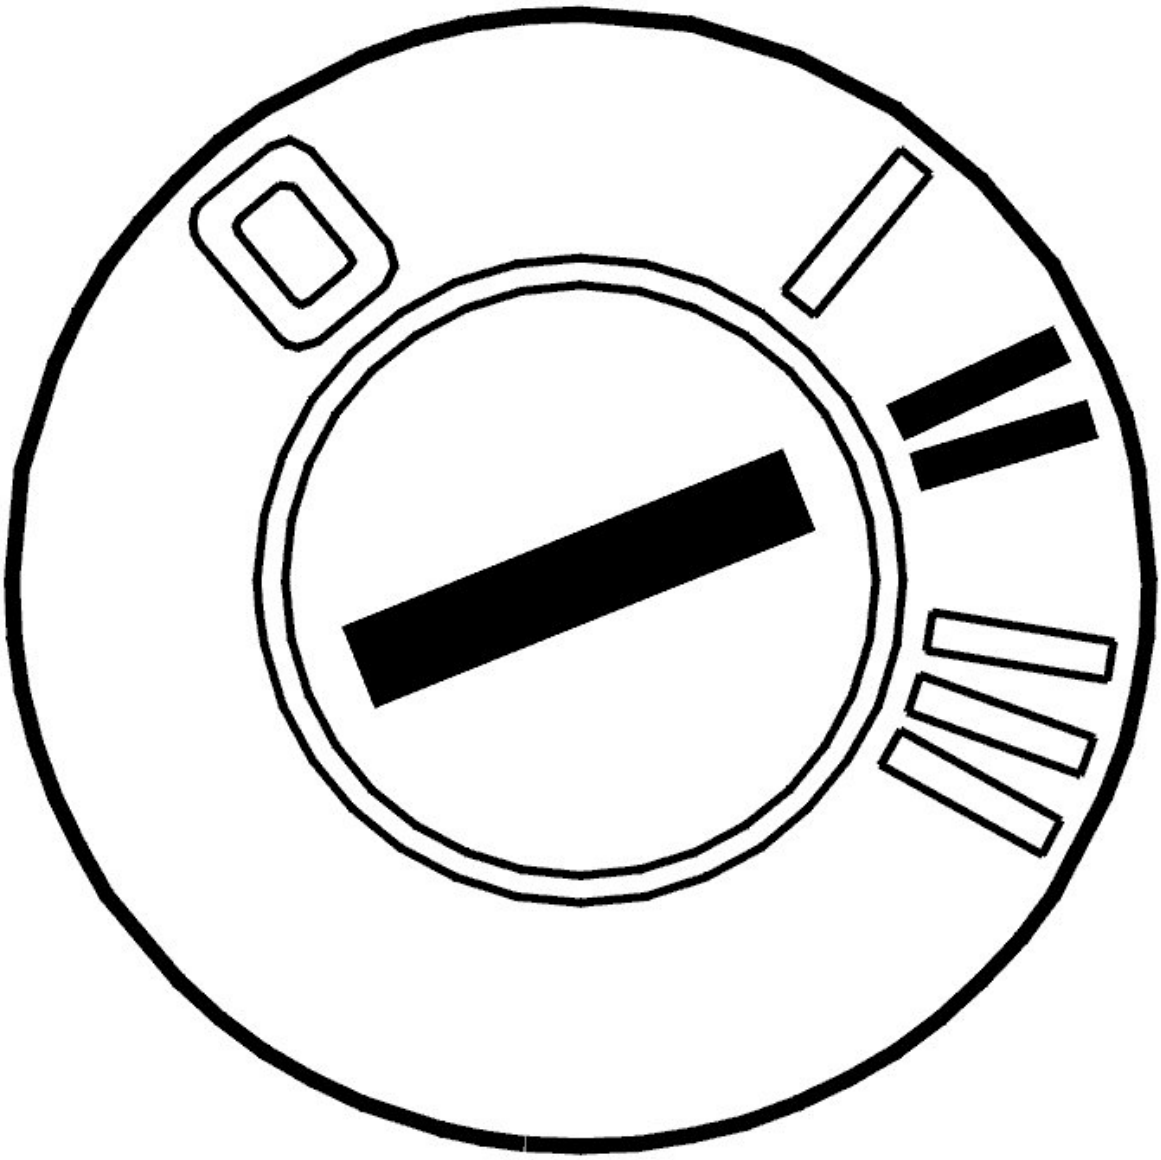
Possible source
- Contact resistance in the terminals
- Open-circuit in the signal cable
- Open-circuit in the power cable
- Damaged valve.

Fault symptom[s]
- Malfunction indicator lamp (MIL) lit.

Signal Missing

Signal missing

Checking the status



- Ignition on.

Activate the valve in the leak diagnostic unit to check whether the fault is permanent or intermittent.
The valve clicks when it is activated.
The fault is permanent if the valve does not activate.
The fault is intermittent if the valve activates.

Continue - Checking components and wiring

Checking components and wiring

Check the fuse before the circuit.
Check the leak diagnostic unit connectors. Check for contact resistance and oxidation.
Check the resistance of the valve between the leak diagnostic pump connector terminals #3 and #4 (leak diagnostic unit side).
Check the signal cable between control module terminal #B40 (#B50) and leak diagnostic unit terminal #3. Check for an open-circuit.
Check the power supply cable between system relay terminal #5 and leak diagnostic unit terminal #4. Check for an open-circuit.
Remedy as necessary.

FAULT FOUND - Fault Found

Diagnostic Trouble Code (DTC) Information

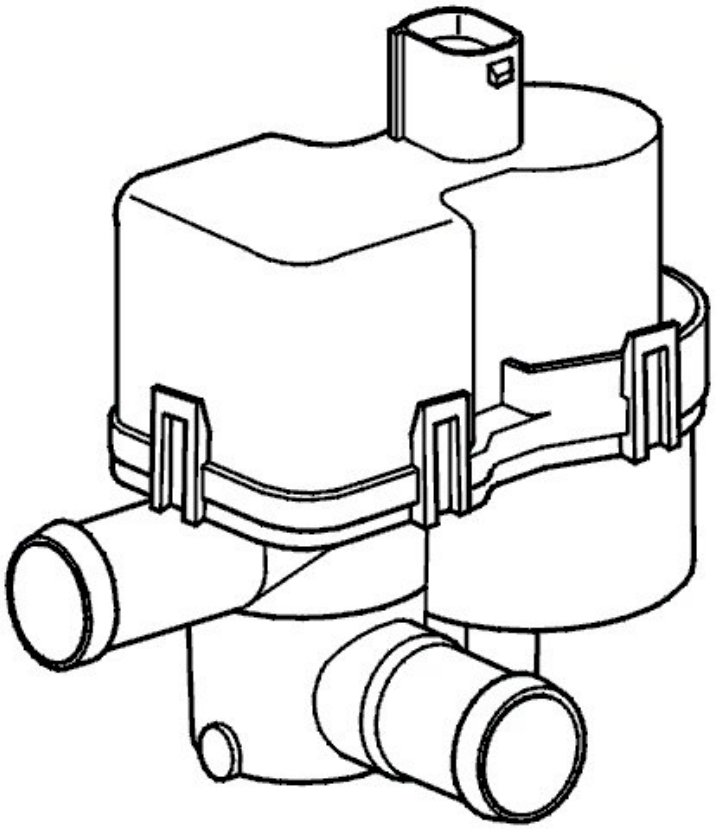
Diagnostic trouble code (DTC) information ECM-434C

Condition



If no fault has been detected in the leak diagnostic unit, the engine control module (ECM) carries out a leak diagnostic of the fuel tank system. The diagnostic trouble code (DTC) is stored if the engine control module (ECM) detects a leak which is 0.5-1.0 mm.
For further information about leak diagnostics, see VIDA Design and Function.

Substitute value

None.

Possible source

- A leak that is 0.5-1.0 mm or smaller in the fuel tank, fuel filler pipe, fuel tank filler cap, EVAP canister, evaporative emission system (EVAP) valve, or in the hoses between these components.

Fault symptom[s]

- Malfunction indicator lamp (MIL) lit.

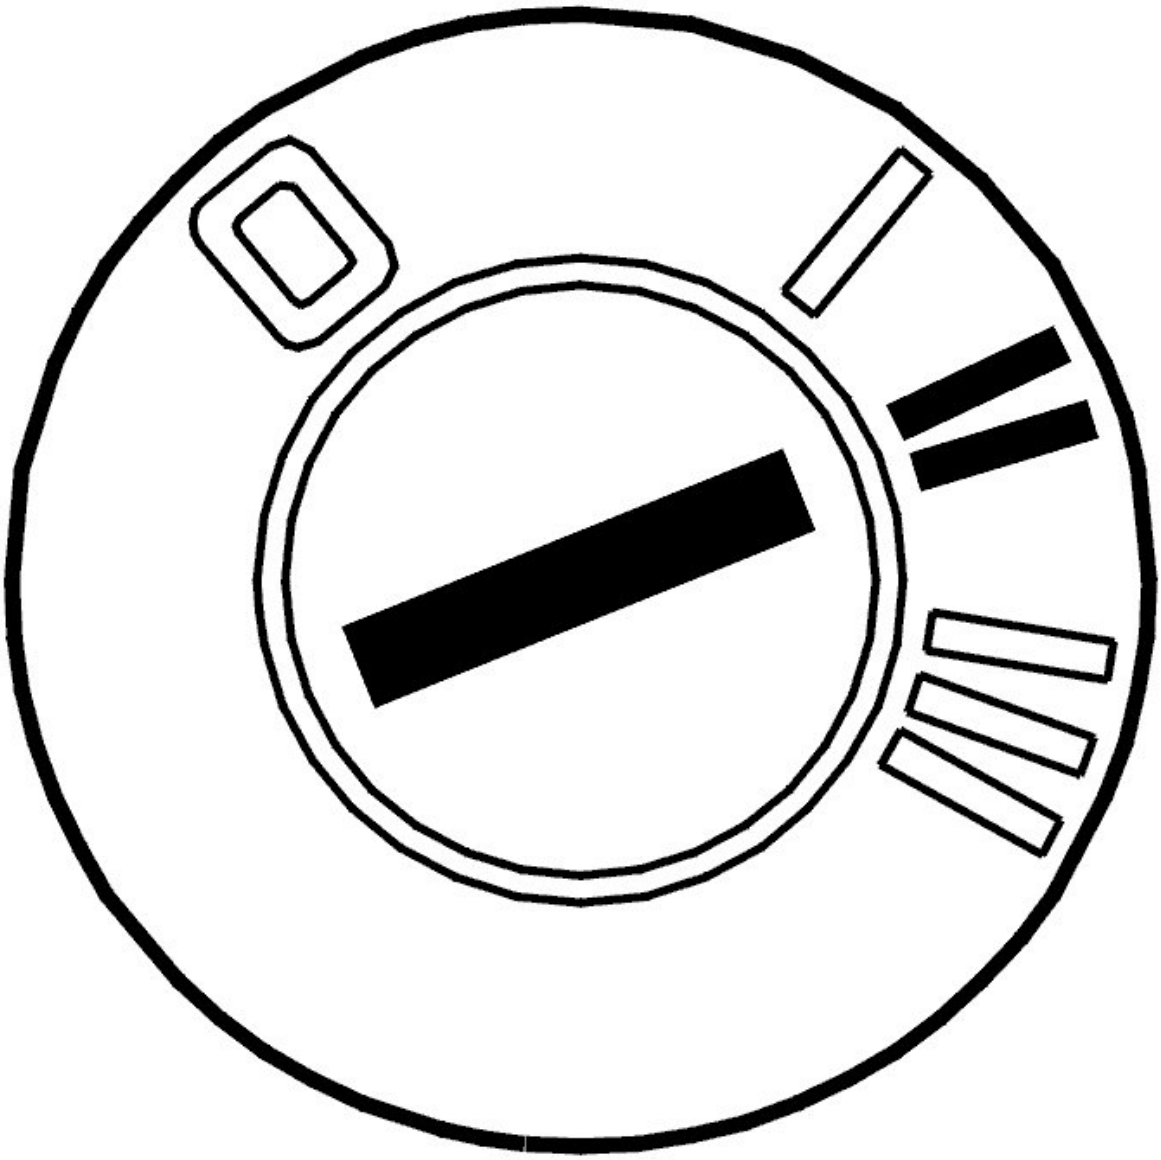
Leakage

Leakage

Checking software

Hint: For vehicles of model year 2003-2008, the software in engine control module (ECM) should be checked before fault tracing of the fault relating to the leak from the tank system is carried out.

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2



- Ignition on.

Click on the VCT2000 symbol to start the read out and check the software version in the Engine control module (ECM).

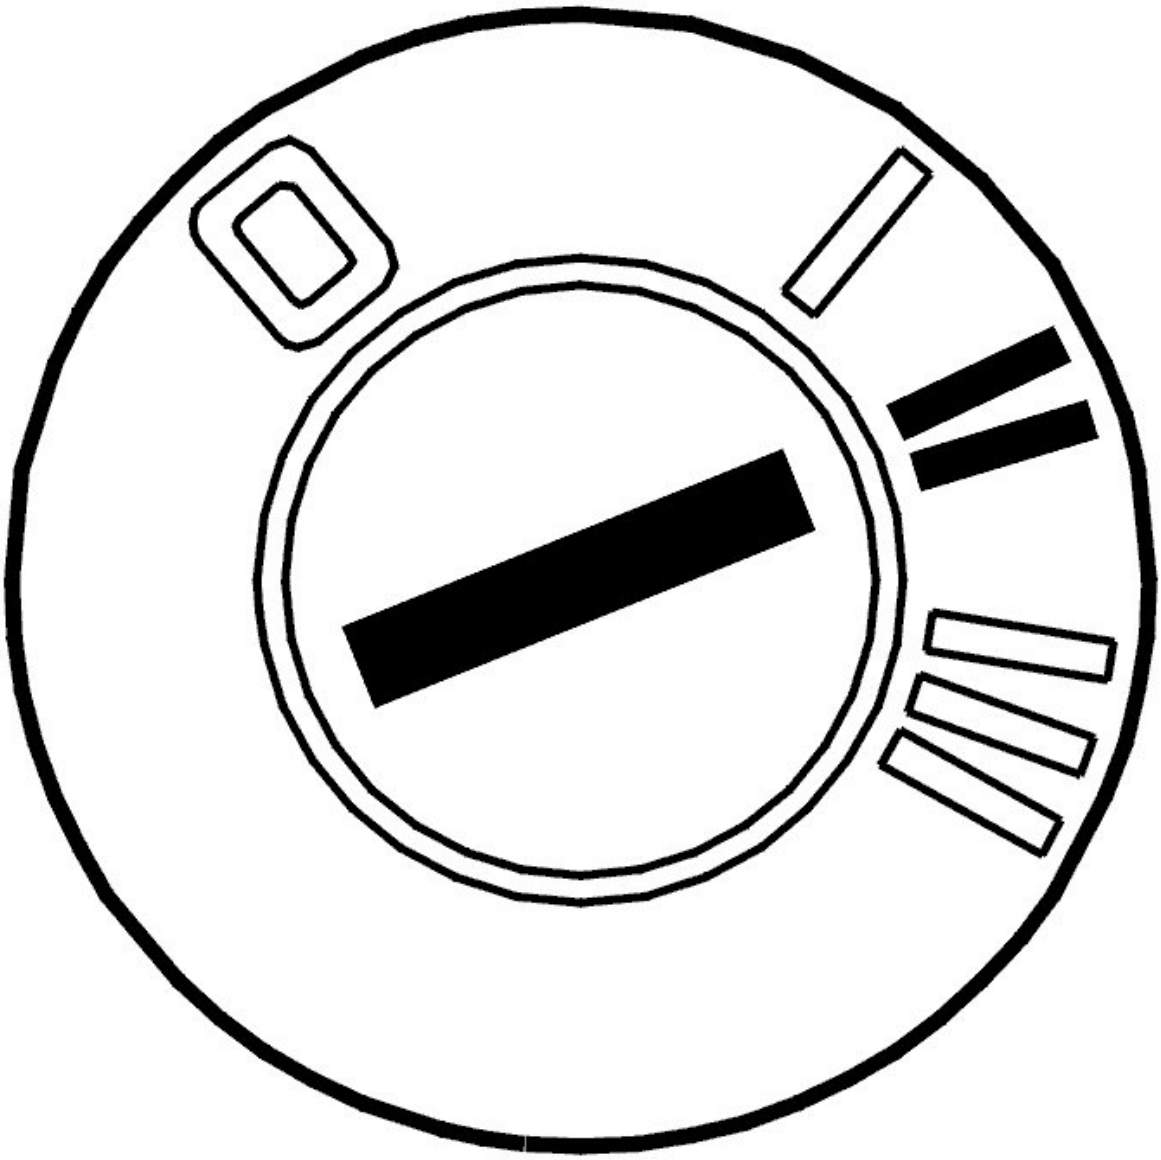
Note! More instructions follow together with the read out.

Has the latest software been downloaded to the control module?

Yes - Perform quick-test tank system

No - **ANOTHER TEST**

Perform quick-test tank system



- Activate the test by pressing on the symbol for VCT2000.
- Read off initial parameters and check them according to start conditions for performing the test.
- Press the button "Start" to start the quick-test.
- Check that the test has started. Parameters run status shall go to "In progress" and the test phase shall go to "Reference".

Note! If the test does not start, check that the start conditions are fulfilled.

When the reference phase is finished, check of the tank system starts. The pressure in the tank starts to increase, see graph. Within 15 minutes the Engine control module (ECM) makes a decision as to whether there is leakage in the tank system or not. The test is finished.

- Check parameters for test result and follow relevant instructions below.

Note! Estimated leakage shall be used to get an idea of the proximity to the diagnostic trouble code limit. If the estimated leakage is very near the diagnostic trouble code limit, troubleshooting should probably be performed despite the Tank system, test result shows "No leakage found", especially if diagnostic trouble code for leakage has been stored earlier.

Note! Use diagnostic trouble code counter to see the frequency of the problem. Also use frozen values to get an idea if external conditions may have affected the result. Compare with current conditions in the workshop.

Conditions for starting the quick test of the fuel tank system

- No DTCs related to EVAP purge valve or ambient air pressure sensor set.
- Battery voltage 11-15 V.
- Atmospheric pressure higher than 750 hPa, appr. 2500 m (8200 ft).
- Fuel level 0-85 %.
- Ambient air temperature 4-35 °C (39-95 °F).

Note! The battery voltage must be correct throughout the entire test. The test can take up to 15 minutes, depending on the quantity of fuel in the fuel tank. It is highly recommended to use the constant voltage charger, Midtronics PSC-550, during the test. For more information, see TNN 30-04 (USA/CDN).

Other information

- Description of parameters, quick test of the fuel tank system, B5244T5, B5254T2 See: Diagnostic Trouble Code Tests and Associated Procedures/Related Tests, Information and Procedures/Description of Parameters, Quick Test of the Fuel Tank System

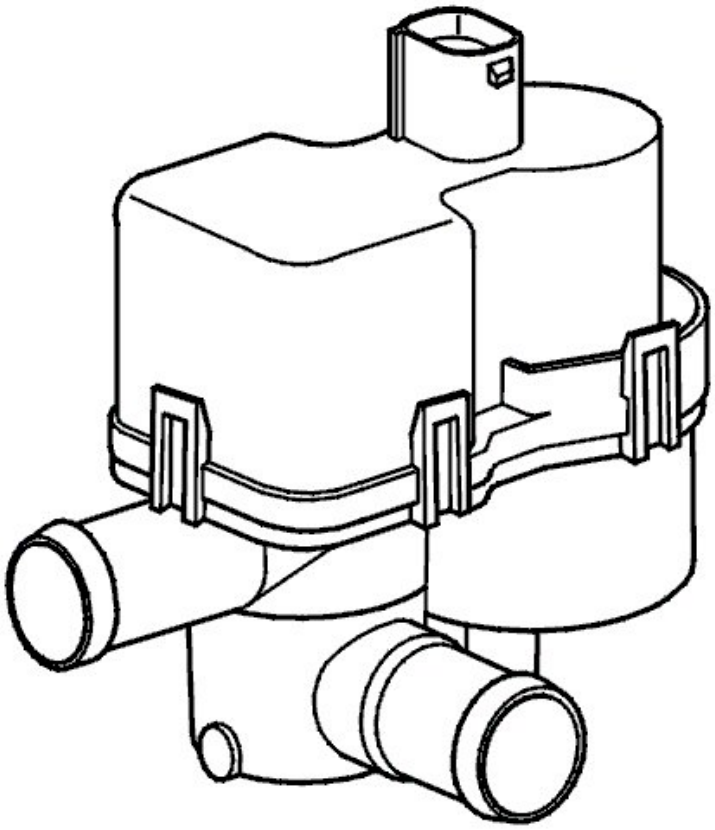
- Fuel tank system, check See: Fuel Delivery and Air Induction/Fuel Tank/Testing and Inspection/Fuel Tank System, Check
- Test pressurizing the tank system See: Fuel Delivery and Air Induction/Fuel Tank/Testing and Inspection/Test Pressurizing the Tank System

Select alternative according to relevant test results:

1. DMTL, test result = "Problem found"
2. Tank system, test result = "No leakage found"
3. Tank system, test result = "Minor leakage found"
4. Tank system, test result = "Major leakage found"
5. DMTL, test result and Tank system, test result = "Unknown"
6. Cancel fault-tracing.



1 - test result = "Problem found"

2 - test result = "No leakage found"

3 - test result = "Minor leakage found"

4 - test result = "Major leakage found"

5 - test result and Tank system, test result = "Unknown"

6 - **No Fault Found**

DMTL, test result = "Problem found"

If a problem is detected on the leakage diagnostics unit (DMTL), this may have been caused during the test itself. Checks on DMTL are normal electric checks of leakage diagnostics unit and cabling and is no indication of if there is leakage or not.

- Cancel troubleshooting for this problem.
- Read off diagnostic trouble codes again and start troubleshooting for the new diagnostic trouble code.

Note! The tank system's status is unknown since the test was interrupted.

Continue - **ANOTHER TEST**

Tank system, test result = "No leakage found"

Diagnostic trouble code limit (minor leakage): Estimated leakage = 0.40 mm
If no leakage was found, the Engine control module (ECM) has detected leakage in the tank system earlier, but the problem is not active at this time. The fault could be caused by leakage in the tank, filler pipe, fuel tank filler cap, canister, EVAP valve, leakage diagnosis unit or hoses between these components.

Note! Problems caused by a loose tank cap or loose hose connections may be difficult to find. If no leakage was found in the quick-test of the tank system after completed checks and actions according to the above, the problem has likely been repaired.

Note! The parameter estimated leakage does not necessarily have to show 0 mm for a sealed system.

Select "Continue" to exit.

Continue - **Fault Found**

Tank system, test result = "Minor leakage found"

Diagnostic trouble code limit: Estimated leakage = 0.40 mm

- Check that the tank cap is properly fitted and that its seal is undamaged.
- Check the hoses and connections on the leak diagnostic unit, the canister,EVAP-valve and the fuel filler pipe visually. Check for damage or incorrect/loose installation.
- Remedy as necessary.
- Restart the test.

Note! Problems caused by a loose tank cap or loose hose connections may be difficult to find. If no leakage was found in the quick-test of the tank system after completed checks and actions according to the above, the problem has likely been repaired.

Note! By blocking the hose between canister and EVAP-valve and then repeating quick-test tank system, leakage through the EVAP-valve can be detected. If leakage was detected in a previous quick test of the fuel tank system but is not now detected when the hose between the canister and the EVAP valve is blocked, the leakage may be through the EVAP valve.

- Disconnect the hose between the EVAP canister purge valve and the EVAP canister from the connection to the EVAP canister purge valve.
- Block the hose while running the quick test of the fuel tank system.

Continue - Perform quick-test tank system

DMTL, test result and Tank system, test result = "Unknown"

Engine control module (ECM) cannot perform check of tank system. This may be due to the conditions for start of the quick-test not being fulfilled,that they have changed during the course of the test, or that a problem has occurred during troubleshooting.

- Check that all conditions for start of the quick-test are fulfilled.
- Visually check hoses and connections on leakage diagnostics unit, canister, EVAP-valve, and filler pipe. Check for damage or incorrect/loose installation.
- Remedy as necessary.
- Restart the test.

Continue - Perform quick-test tank system

Tank system, test result = "Major leakage found"

Diagnostic trouble code limit: Tank pressure lower than 1500 Pa after 450 seconds in test phase "Major leakage".

- Check that the tank cap is properly fitted and that its seal is undamaged.

- Check the hoses and connections on the leak diagnostic unit, the canister,EVAP-valve and the fuel filler pipe visually. Check for damage or incorrect/loose installation.
- Remedy as necessary.
- Restart the test.

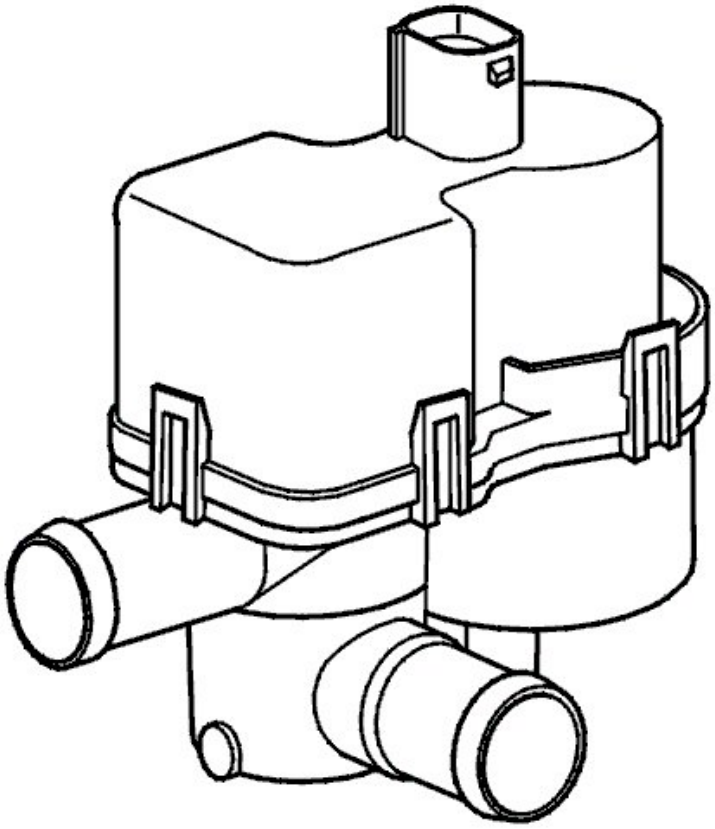
Note! Problems caused by a loose tank cap or loose hose connections may be difficult to find. If no leakage was found in the quick-test of the tank system after completed checks and actions according to the above, the problem has likely been repaired.

Continue - Perform quick-test tank system

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information ECM-4360

Condition



The power consumption of the pump must drop when the leak diagnostic pump valve moves from the reference check to pressurizing the fuel tank system. Diagnostic trouble code is stored if the value for the power consumption of the pump drops too quickly, slowly or not at all.
The diagnostic trouble code (DTC) can be diagnosed when the leak diagnostic system is run.
For further information about leak diagnostics, see VIDA Design and Function.

Substitute value

The leak diagnostic is disabled.

Possible source
- Contact resistance in the terminals
- Damaged leak diagnostic unit
- Damaged control heater pad.

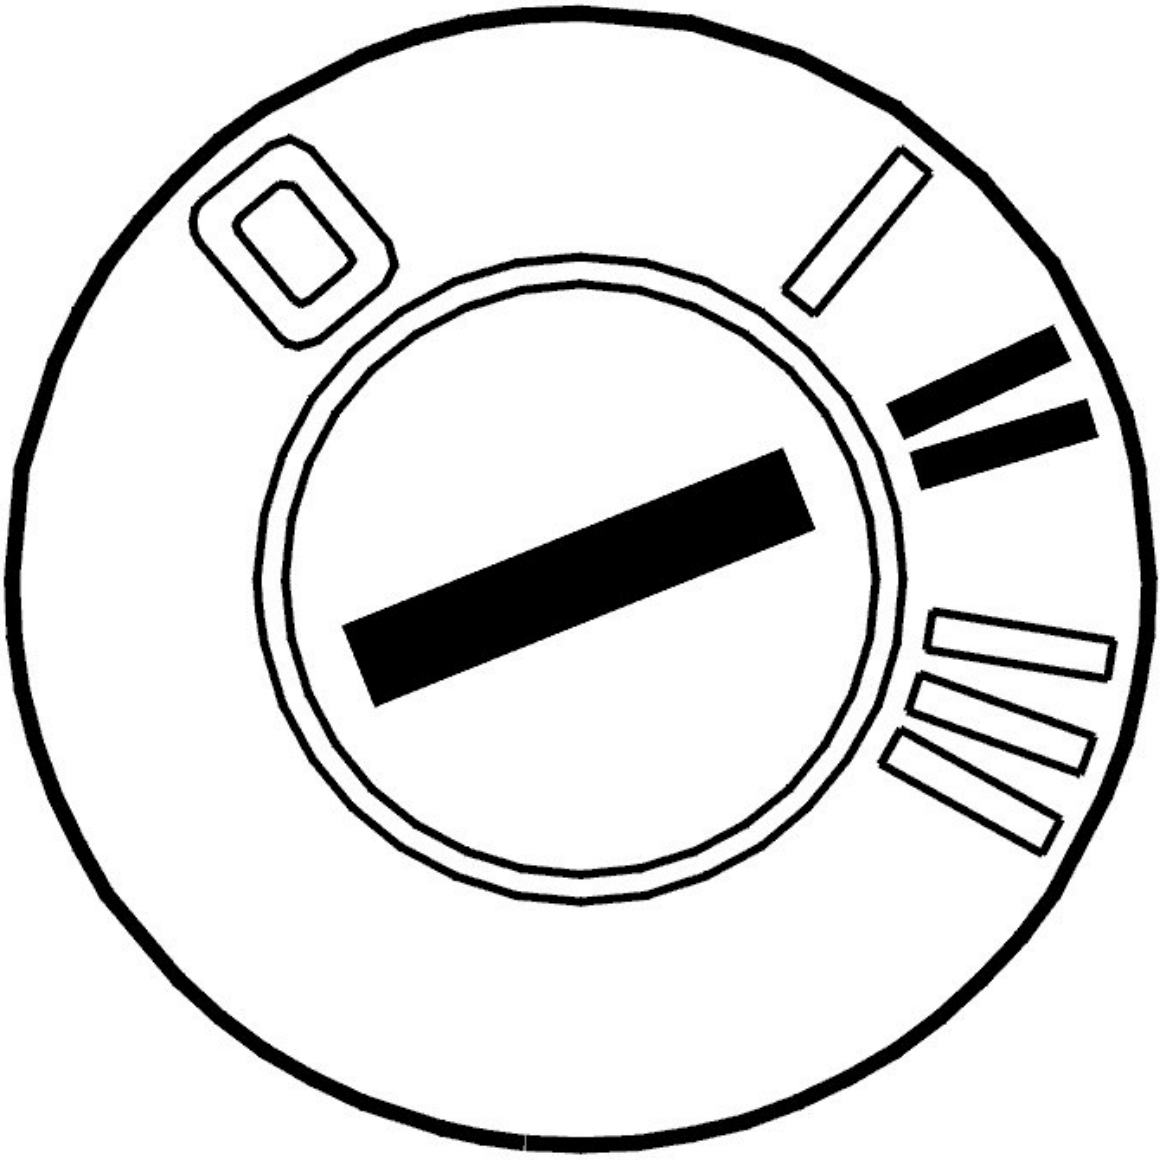
Fault symptom[s]
- Malfunction indicator lamp (MIL) lit.

Fault-Tracing

Fault-tracing

Checking software

Hint: For vehicles of model year 2003-2008, the software in engine control module (ECM) should be checked before fault tracing of the fault relating to the leak from the tank system is carried out.



- Ignition on.

Click on the VCT2000 symbol to start the read out and check the software version in the Engine control module (ECM).

5 - **No Fault Found**

DMTL, test result = "Problem found"

Check the leak diagnostic unit connectors. Check for contact resistance and oxidation.
Check the hose between the leak diagnostic unit and the EVAP canister. Check for blockages.
Try a new leak diagnostic unit if no fault is found during the above fault-tracing.

- Perform "Quick-test tank system" again to verify that the problem has been solved.

Note! The tank system's status is unknown since the test was interrupted.

Continue - Perform quick-test tank system

Tank system, test result = "No leakage found"

Diagnostic trouble code limit (minor leakage): Estimated leakage = 0.40 mm
No problem has been detected on leakage diagnostics unit and fuel tank system is OK. The vehicle is ready to be delivered back to customer.

Note! The parameter estimated leakage does not necessarily have to show 0 mm for a sealed system.

Select "Continue" to exit.

Continue - Fault Found

Tank system, test result = "Major leakage found" or "Minor leakage found"

If a leakage is detected during this test, it indicates that the problem with the leakage diagnostics unit (DMTL) is solved. Now the Engine control module (ECM) has the possibility to check the fuel tank system. A leakage has been found.
- Cancel troubleshooting for this problem.
- Read off diagnostic trouble codes again and start troubleshooting for the new diagnostic trouble code.

Select "Continue" to exit.

Continue - ANOTHER TEST

DMTL, test result and Tank system, test result = "Unknown"

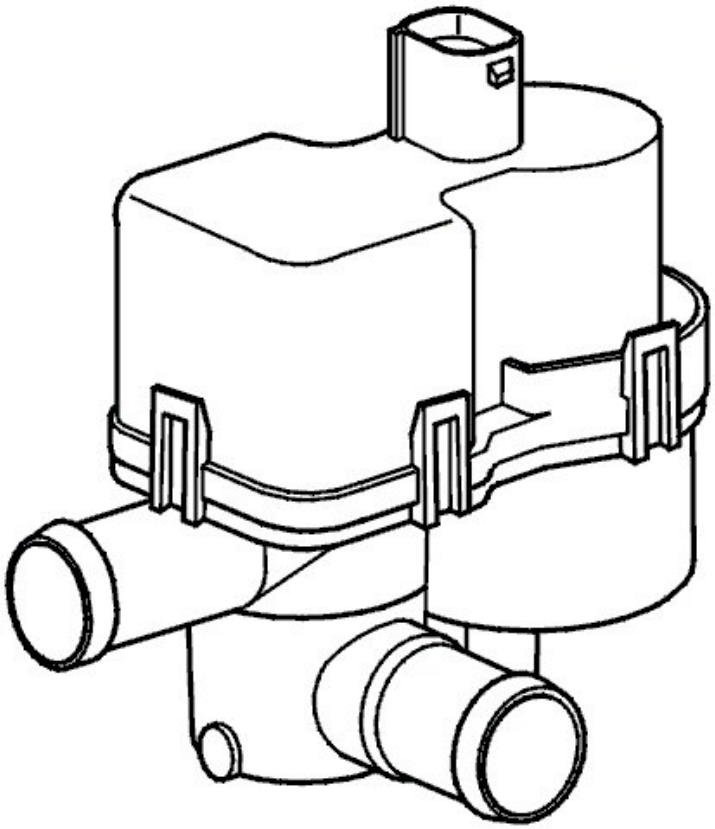
Engine control module (ECM) cannot perform check of tank system. This may be due to the conditions for start of the quick-test not being fulfilled,that they have changed during the course of the test, or that a problem has occurred during troubleshooting.
- Check that all conditions for start of the quick-test are fulfilled.
- Visually check hoses and connections on leakage diagnostics unit, canister, EVAP-valve, and filler pipe. Check for damage or incorrect/loose installation.
- Remedy as necessary.
- Restart the test.

Continue - Perform quick-test tank system

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information ECM-436B

Condition



The engine control module (ECM) checks power consumption on the leak diagnostic unit pump.
A diagnostic trouble code is stored if the current consumption of the pump in the leak diagnostic unit varies too much during the reference phase.
The diagnostic trouble code (DTC) can be diagnosed when the leak diagnostic system is run.
For further information about leak diagnostics, see VIDA Design and Function.

Substitute value

The leak diagnostic is disabled.

Possible source
- Contact resistance in the terminals
- Blocked hose between the filter and the leak diagnostic unit
- Damaged leak diagnostic unit.

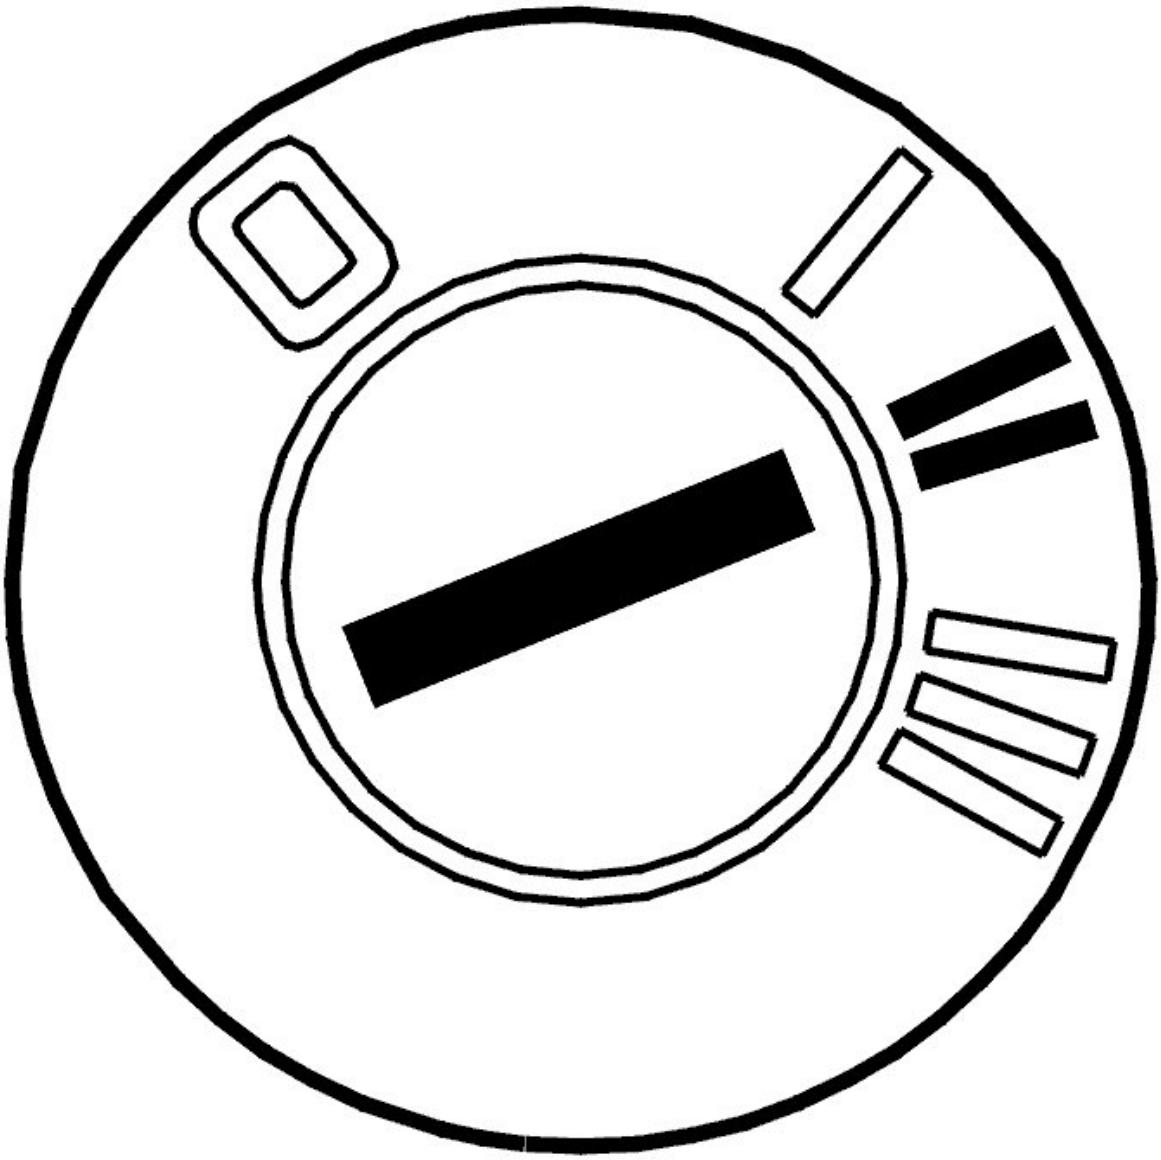
Fault symptom[s]
- Malfunction indicator lamp (MIL) lit.

Signal Missing

Fault-tracing

Checking software

Hint: For vehicles of model year 2003-2008, the software in engine control module (ECM) should be checked before fault tracing of the fault relating to the leak from the tank system is carried out.



- Ignition on.

Click on the VCT2000 symbol to start the read out and check the software version in the Engine control module (ECM).

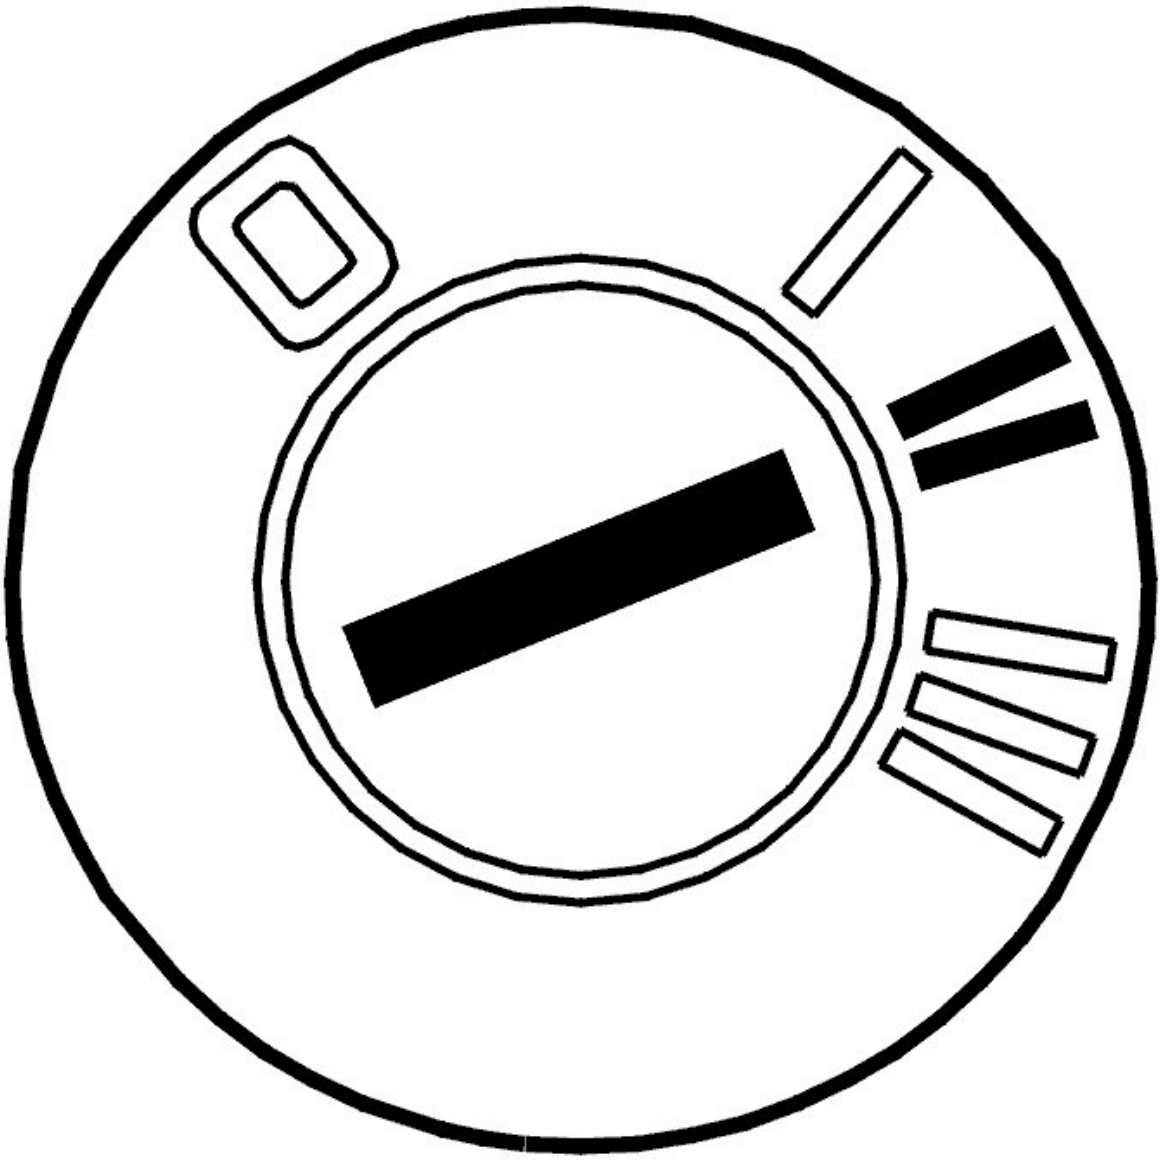
Note! More instructions follow together with the read out.

Has the latest software been downloaded to the control module?

Yes - Perform quick-test tank system

No - **ANOTHER TEST**

Perform quick-test tank system



- Activate the test by pressing on the symbol for VCT2000.
- Read off initial parameters and check them according to start conditions for performing the test.
- Press the button "Start" to start the quick-test.
- Check that the test has started. Parameters run status shall go to "In progress" and the test phase shall go to "Reference".

Note! If the test does not start, check that the start conditions are fulfilled.

When the reference phase is finished, check of the tank system starts. The pressure in the tank starts to increase, see graph. Within 15 minutes the Engine control module (ECM) makes a decision as to whether there is leakage in the tank system or not. The test is finished.

- Check parameters for test result and follow relevant instructions below.

Note! Estimated leakage shall be used to get an idea of the proximity to the diagnostic trouble code limit. If the estimated leakage is very near the diagnostic trouble code limit, troubleshooting should probably be performed despite the Tank system, test result shows "No leakage found", especially if diagnostic trouble code for leakage has been stored earlier.

Note! Use diagnostic trouble code counter to see the frequency of the problem. Also use frozen values to get an idea if external conditions may have affected the result. Compare with current conditions in the workshop.

Conditions for starting the quick test of the fuel tank system

- No DTCs related to EVAP purge valve or ambient air pressure sensor set.
- Battery voltage 11-15 V.
- Atmospheric pressure higher than 750 hPa, appr. 2500 m (8200 ft).
- Fuel level 0-85 %.
- Ambient air temperature 4-35 °C (39-95 °F).

Note! The battery voltage must be correct throughout the entire test. The test can take up to 15 minutes, depending on the quantity of fuel in the fuel tank. It is highly recommended to use the constant voltage charger, Midtronics PSC-550, during the test. For more information, see TNN 30-04 (USA/CDN).

Select "Continue" to exit.

Continue - ANOTHER TEST

DMTL, test result and Tank system, test result = "Unknown"

Engine control module (ECM) cannot perform check of tank system. This may be due to the conditions for start of the quick-test not being fulfilled,that they have changed during the course of the test, or that a problem has occurred during troubleshooting.
- Check that all conditions for start of the quick-test are fulfilled.
- Visually check hoses and connections on leakage diagnostics unit, canister, EVAP-valve, and filler pipe. Check for damage or incorrect/loose installation.
- Remedy as necessary.
- Restart the test.

Continue - Perform quick-test tank system

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information ECM-4380

Condition

If the engine control module (ECM) registers that fuel filling has been carried out through the fuel level being changed, the position and installation of the fuel tank filler cap is checked. This is carried out by quicker leak diagnostics.
The check is carried out a few minutes after start if the vehicle speed is constant and exceeds 30 km/h and only if no fault is detected on the leak diagnostic unit.
The diagnostic trouble code (DTC) is stored if the engine control module (ECM) detects a leak after filling. This is interpreted as fuel tank filler cap missing or loosely installed.
This diagnostic trouble code (DTC) cannot occur alone but follows another stored diagnostic trouble code (DTC) for the fuel tank filler cap. The diagnostic trouble code (DTC) only remains during one operating cycle and lights a message in the display indicating that the fuel tank filler cap is not correctly positioned.

Substitute value
- None.

Possible source
- The diagnostic trouble code (DTC) is caused by another diagnostic trouble code (DTC) being stored in the engine control module (ECM).

Fault symptom[s]
- Message in the display.

Fault-Tracing Information

Fault-tracing information

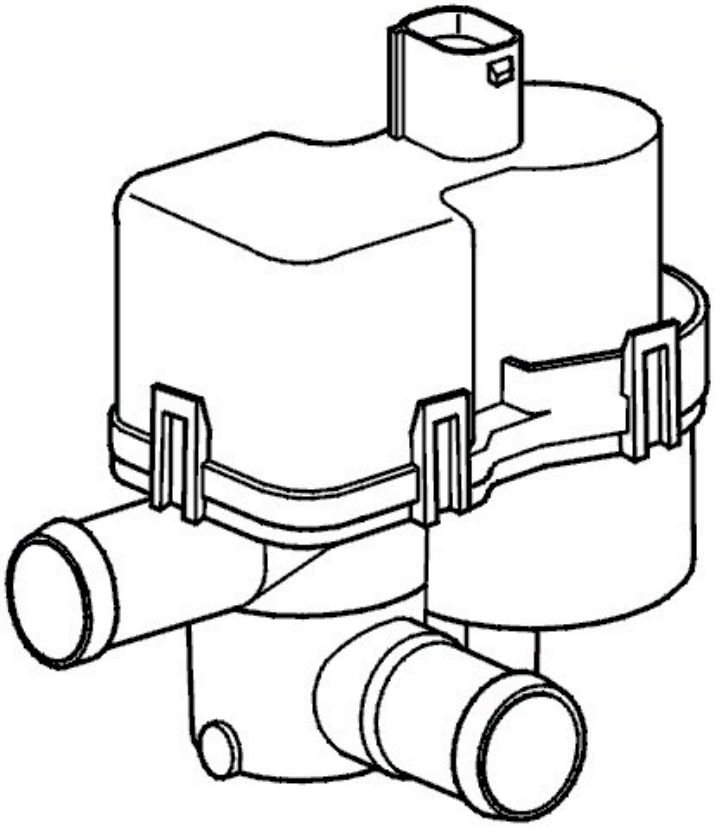
Information

There is no fault-tracing for this diagnostic fault code (DTC).
For further information on this diagnostic trouble code, see Diagnostic trouble code (DTC) information.

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information ECM-439C

Condition



If no fault has been detected in the leak diagnostic unit, the engine control module (ECM) carries out a leak diagnostic of the fuel tank system. The diagnostic trouble code (DTC) is stored if the engine control module (ECM) detects a leak which is larger than 1.0 mm.
For further information about leak diagnostics, see VIDA Design and Function.

Substitute value

None.

Possible source
- The fuel tank filler cap is missing or not properly tightened
- Leakage that is 1.0 mm or greater in the fuel tank, fuel filler pipe, fuel tank filler cap, EVAP canister, canister purge (CP) valve, or in the hoses between these components.

Fault symptom[s]
- Malfunction indicator lamp (MIL) lit.

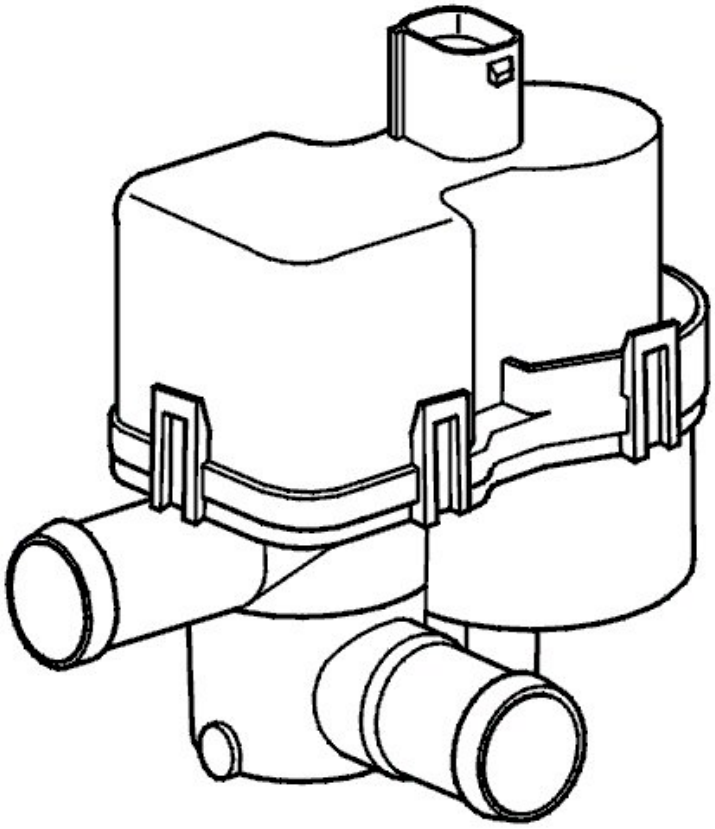
Select alternative according to relevant test results:

1. DMTL, test result = "Problem found"
2. Tank system, test result = "No leakage found"
3. Tank system, test result = "Minor leakage found"
4. Tank system, test result = "Major leakage found"
5. DMTL, test result and Tank system, test result = "Unknown"
6. Cancel fault-tracing.



1 - test result = "Problem found"

2 - test result = "No leakage found"

3 - test result = "Minor leakage found"

4 - test result = "Major leakage found"

5 - test result and Tank system, test result = "Unknown"

6 - **No Fault Found**

DMTL, test result = "Problem found"

If a problem is detected on the leakage diagnostics unit (DMTL), this may have been caused during the test itself. Checks on DMTL are normal electric checks of leakage diagnostics unit and cabling and is no indication of if there is leakage or not.

- Cancel troubleshooting for this problem.
- Read off diagnostic trouble codes again and start troubleshooting for the new diagnostic trouble code.

Note! The tank system's status is unknown since the test was interrupted.

Continue - ANOTHER TEST

Tank system, test result = "No leakage found"

Diagnostic trouble code limit (minor leakage): Estimated leakage = 0.40 mm
If no leakage was found, the Engine control module (ECM) has detected leakage in the tank system earlier, but the problem is not active at this time. The fault could be caused by leakage in the tank, filler pipe, fuel tank filler cap, canister, EVAP valve, leakage diagnosis unit or hoses between these components.

Note! Problems caused by a loose tank cap or loose hose connections may be difficult to find. If no leakage was found in the quick-test of the tank system after completed checks and actions according to the above, the problem has likely been repaired.

Note! The parameter estimated leakage does not necessarily have to show 0 mm for a sealed system.

Select "Continue" to exit.

Continue - Fault Found

Tank system, test result = "Minor leakage found"

Diagnostic trouble code limit: Estimated leakage = 0.40 mm

- Check that the tank cap is properly fitted and that its seal is undamaged.
- Check the hoses and connections on the leak diagnostic unit, the canister,EVAP-valve and the fuel filler pipe visually. Check for damage or incorrect/loose installation.
- Remedy as necessary.
- Restart the test.

Note! Problems caused by a loose tank cap or loose hose connections may be difficult to find. If no leakage was found in the quick-test of the tank system after completed checks and actions according to the above, the problem has likely been repaired.

Note! By blocking the hose between canister and EVAP-valve and then repeating quick-test tank system, leakage through the EVAP-valve can be detected. If leakage was detected in a previous quick test of the fuel tank system but is not now detected when the hose between the canister and the EVAP valve is blocked, the leakage may be through the EVAP valve.

- Disconnect the hose between the EVAP canister purge valve and the EVAP canister from the connection to the EVAP canister purge valve.
- Block the hose while running the quick test of the fuel tank system.

Continue - Perform quick-test tank system

DMTL, test result and Tank system, test result = "Unknown"

Engine control module (ECM) cannot perform check of tank system. This may be due to the conditions for start of the quick-test not being fulfilled,that they have changed during the course of the test, or that a problem has occurred during troubleshooting.

- Check that all conditions for start of the quick-test are fulfilled.
- Visually check hoses and connections on leakage diagnostics unit, canister, EVAP-valve, and filler pipe. Check for damage or incorrect/loose installation.
- Remedy as necessary.
- Restart the test.

Continue - Perform quick-test tank system

Tank system, test result = "Major leakage found"

Diagnostic trouble code limit: Tank pressure lower than 1500 Pa after 450 seconds in test phase "Major leakage".

- Check that the tank cap is properly fitted and that its seal is undamaged.
- Check the hoses and connections on the leak diagnostic unit, the canister,EVAP-valve and the fuel filler pipe visually. Check for damage or incorrect/loose installation.
- Remedy as necessary.
- Restart the test.

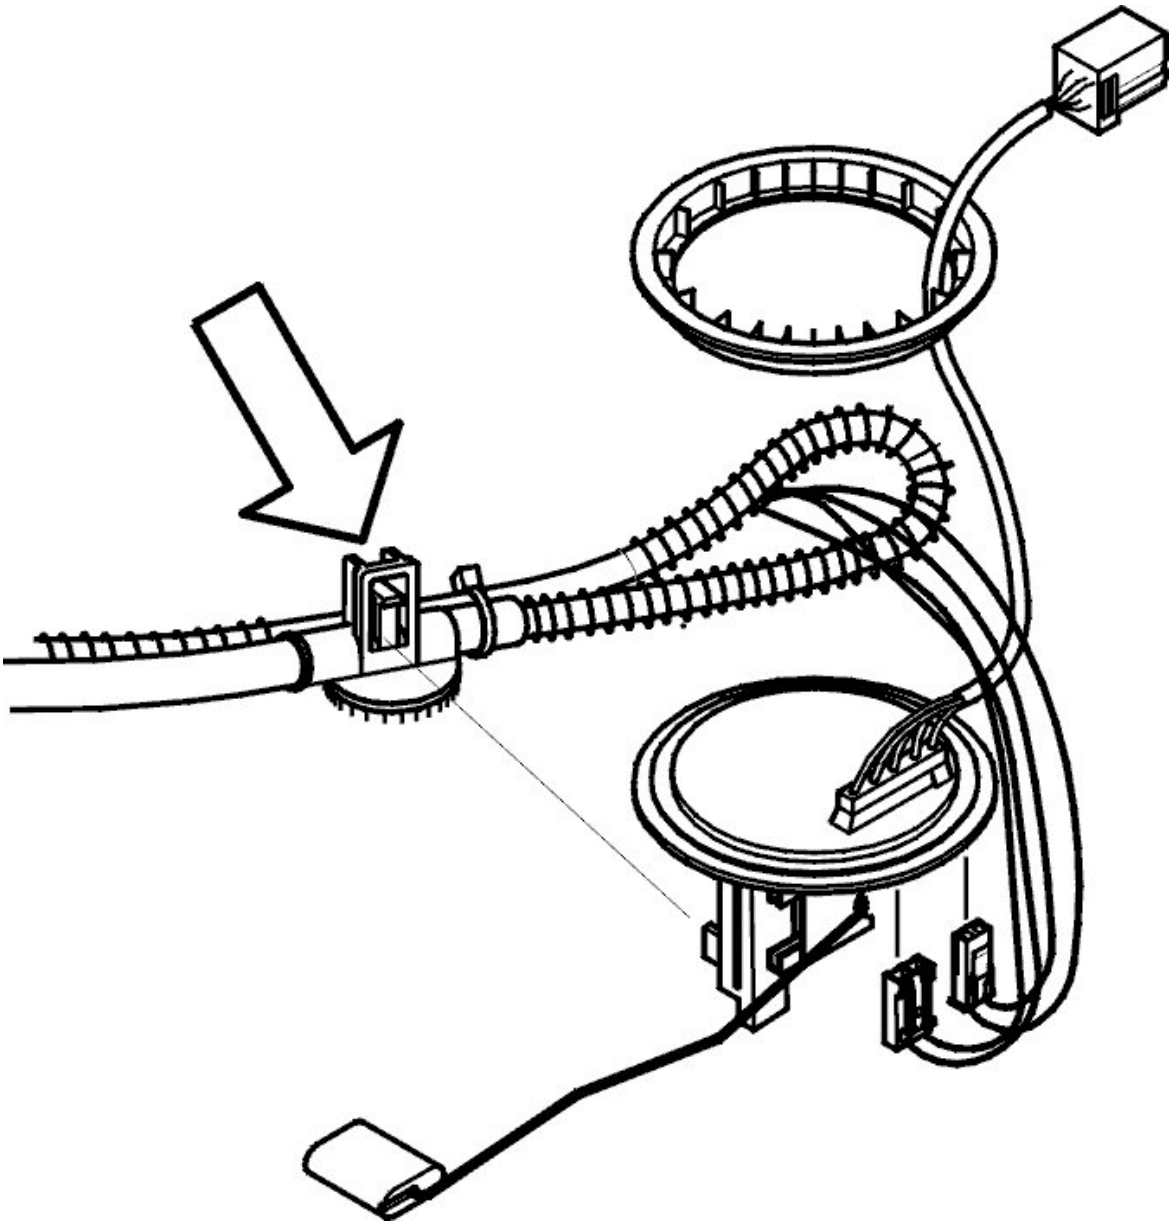
Note! Problems caused by a loose tank cap or loose hose connections may be difficult to find. If no leakage was found in the quick-test of the tank system after completed checks and actions according to the above, the problem has likely been repaired.

Continue - Perform quick-test tank system

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information ECM-4400

Condition



The rear electronic module (REM) transmits information about the fuel level and fault status of the fuel level sensor to the central electronic module (CEM). The central electronic module (CEM) then transmits this information on to the engine control module (ECM).
The engine control module (ECM) compares the engine fuel consumption with the change in fuel level over a set period of time. The diagnostic trouble code (DTC) is stored if the engine control module (ECM) registers an implausibly small reduction in the fuel level compared with calculated fuel consumption.

Substitute value

- None.

Possible source
- Fault trace the rear electronic module (REM)
- Damaged fuel level sensor.

Fault symptom[s]
- Gauges/Fuel level not accurate/Value too low

Fault-Tracing Information

Fault-tracing information

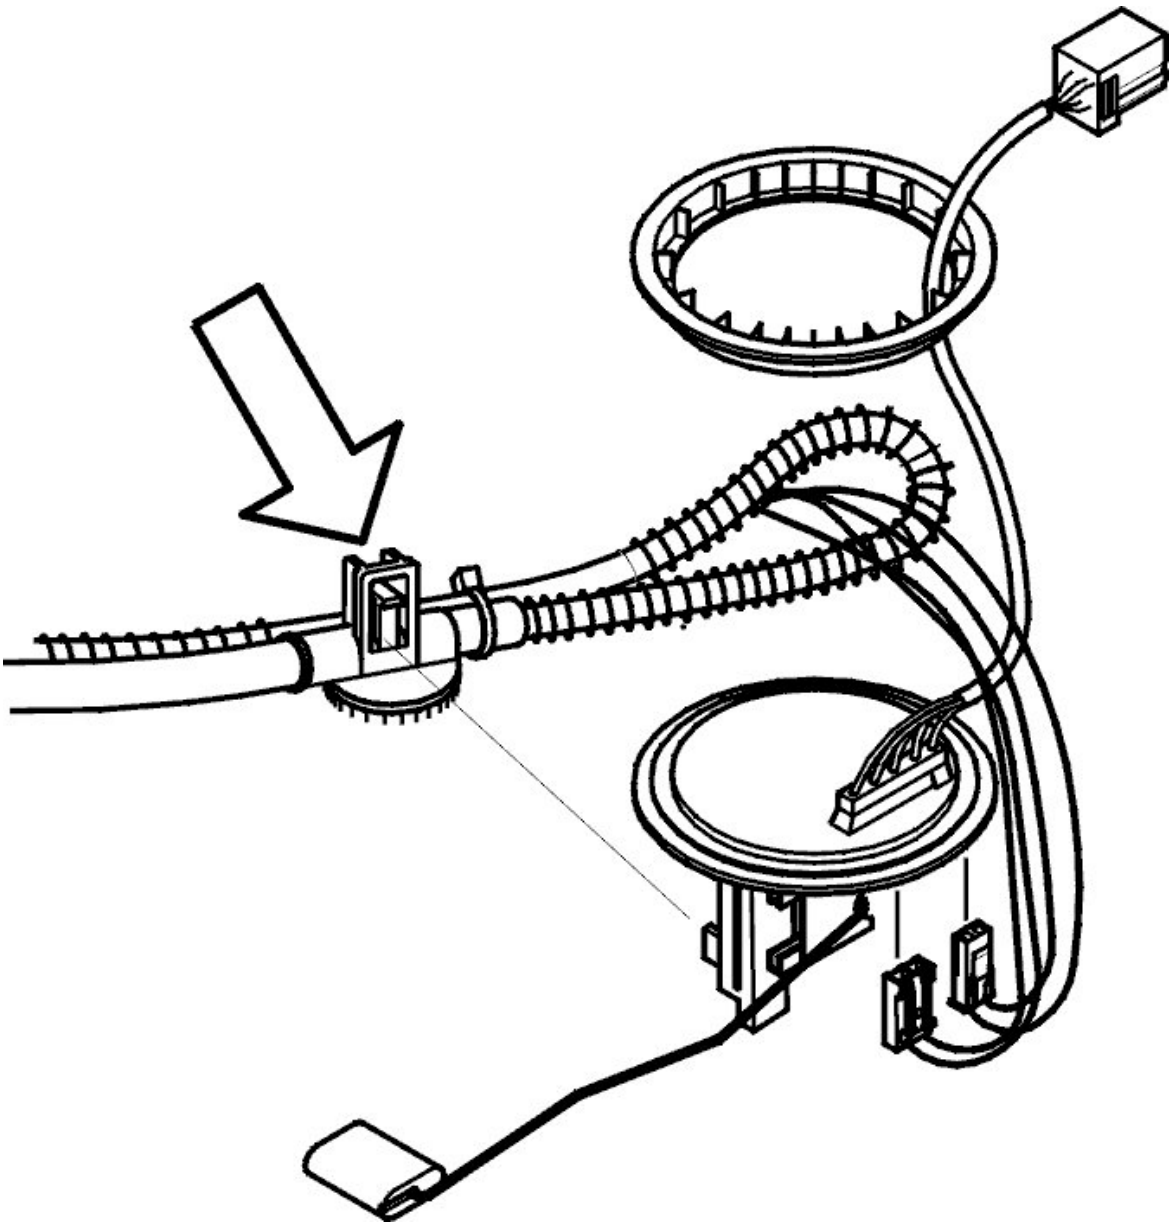
Information

The diagnostic trouble code (DTC) indicates that the primary fault is in another unit. The fault-tracing is carried out from the primary diagnostic trouble code.
For further information on this diagnostic trouble code, see Diagnostic trouble code (DTC) information.

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information ECM-440B

Condition



The rear electronic module (REM) transmits information about the fuel level and fault status of the fuel level sensor to the central electronic module

(CEM). The central electronic module (CEM) then transmits this information on to the engine control module (ECM).
The diagnostic trouble code (DTC) is stored if the engine control module (ECM) registers a communication problem with the central electronic module (CEM).
The diagnostic trouble code (DTC) can be diagnosed when the ignition is switched on.

Substitute value
- None.

Possible source
- Open-circuit in the control area network (CAN) wiring
- Short-circuit between the control area network (CAN) wiring
- Internal fault in another control module in the same part of the control area network (CAN).

Fault symptom[s]
- Gauges/Fuel level not accurate/Value too low

Fault-Tracing Information

Fault-tracing information

Information

No fault-tracing has been developed for this diagnostic trouble code (DTC). A diagnostic trouble code for CAN communication can also be generated in the Central Electronic Module (CEM). This diagnostic trouble code shall not be cleared until the trouble code in the central electronic module (CEM) and in other affected control modules has been remedied and cleared. Therefore, first read the diagnostic trouble codes in the Central Electronic Module (CEM) and other affected control modules, perform fault tracing and remedy as necessary. This diagnostic trouble code (DTC) can then be erased. For further information on this diagnostic trouble code, see Diagnostic trouble code (DTC) information.

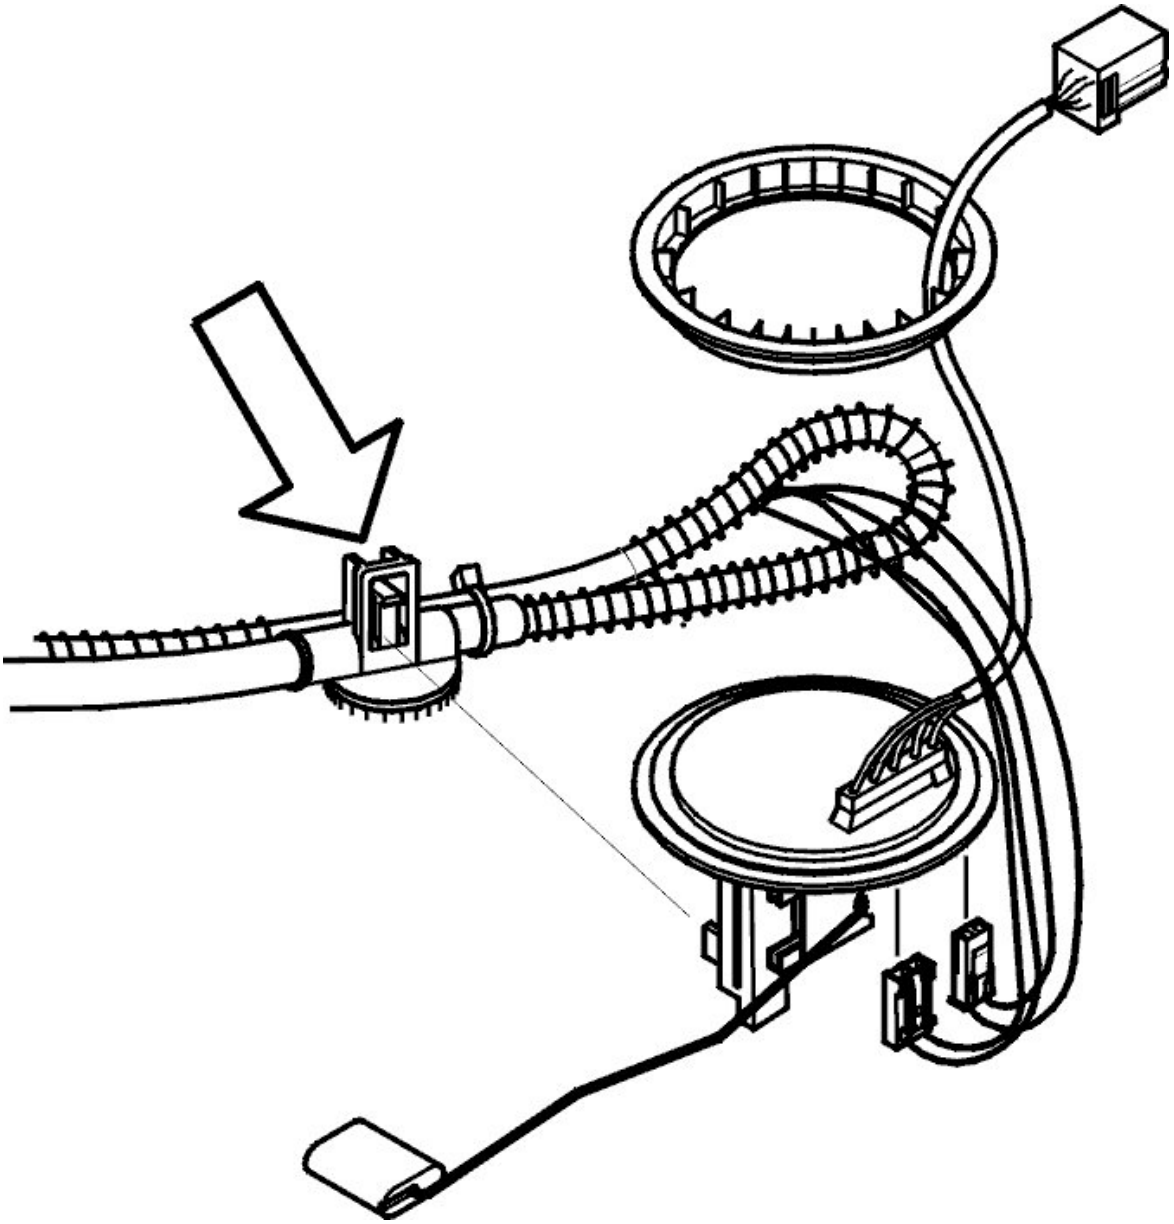
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information ECM-440C

Condition



The rear electronic module (REM) transmits information about the fuel level and fault status of the fuel level sensor to the central electronic module (CEM). The central electronic module (CEM) then transmits this information on to the engine control module (ECM).
A diagnostic trouble code (DTC) is stored in the rear electronic module (REM) if it registers an electrical fault with the fuel level sensor. A diagnostic trouble code (DTC) will be stored in the engine control module (ECM) at the same time.
The diagnostic trouble code (DTC) can be diagnosed when the ignition is switched on.

Substitute value
- None.

Possible source
- Fault trace the rear electronic module (REM).

Fault symptom[s]
- Gauges/Fuel level not accurate/Value too low

Fault-Tracing Information

Fault-tracing information

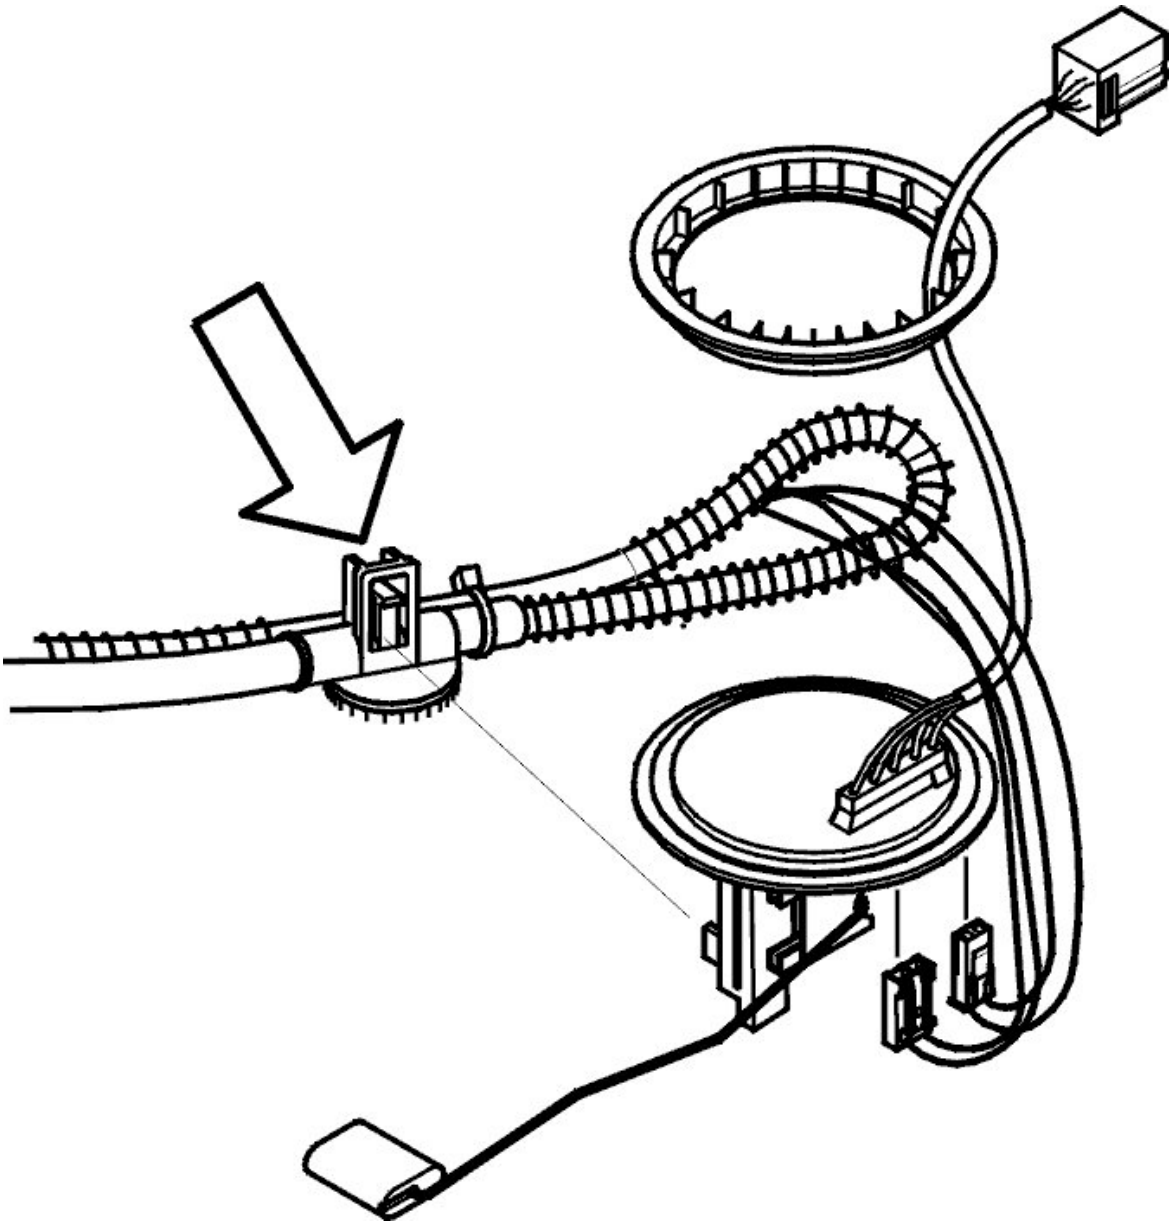
Information

The diagnostic trouble code (DTC) indicates that the primary fault is in another unit. The fault-tracing is carried out from the primary diagnostic trouble code.
For further information on this diagnostic trouble code, see Diagnostic trouble code (DTC) information.

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information ECM-440D

Condition



The rear electronic module (REM) transmits information about the fuel level and fault status of the fuel level sensor to the central electronic module (CEM). The central electronic module (CEM) then transmits this information on to the engine control module (ECM).
A diagnostic trouble code (DTC) is stored in the rear electronic module (REM) if it registers an electrical fault with the fuel level sensor. A diagnostic trouble code (DTC) will be stored in the engine control module (ECM) at the same time.
The diagnostic trouble code (DTC) can be diagnosed when the ignition is switched on.

Substitute value
- None.

Possible source
- Fault trace the rear electronic module (REM).

Fault symptom[s]
- Gauges/Fuel level not accurate/Value too low

Fault-Tracing Information

Fault-tracing information

Information

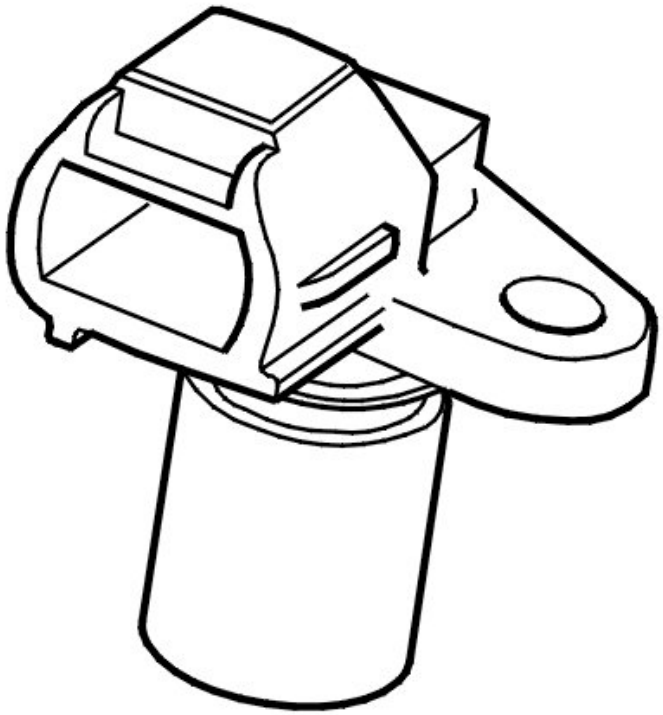
The diagnostic trouble code (DTC) indicates that the primary fault is in another unit. The fault-tracing is carried out from the primary diagnostic trouble code.

For further information on this diagnostic trouble code, see Diagnostic trouble code (DTC) information.

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information ECM-5000

Condition



The engine control module (ECM) detects the flywheel position for TDC using the signal from the engine speed (RPM) sensor. The diagnostic trouble code (DTC) is stored if the position for TDC is missing sporadically. The diagnostic trouble code (DTC) can be diagnosed when the engine is running.

Substitute value
- The engine control module (ECM) uses the signal from the camshaft position (CMP) sensor if the camshaft position (CMP) sensor has been adapted
- Variable valve timing control is blocked.

Possible source
- Signal interference
- Contact resistance and oxidation
- Intermittent fault causes in the engine speed (RPM) sensor wiring.

Fault symptom[s]
- The engine is difficult to start
- Poor performance.

Faulty Signal

Faulty signal

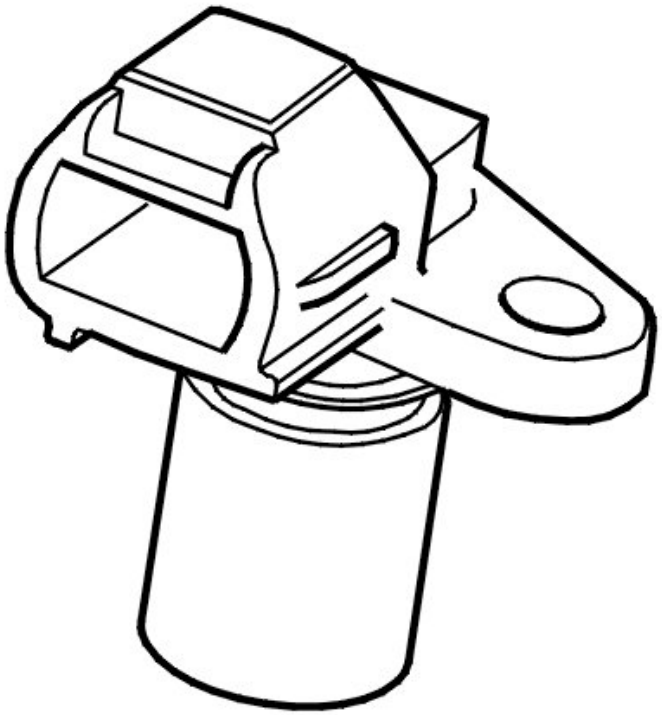
Checking components

Check that the engine speed (RPM) sensor is correctly installed.
Check the engine speed (RPM) sensor. Check that it is not damaged or dirty.

Hint: The diagnostic trouble code (DTC) can be caused by damage in the flywheel / carrier plate. Look for damage to the flywheel / carrier plate.

Other information

- Engine speed (RPM) sensor, replacing See: Crankshaft Position Sensor/Service and Repair



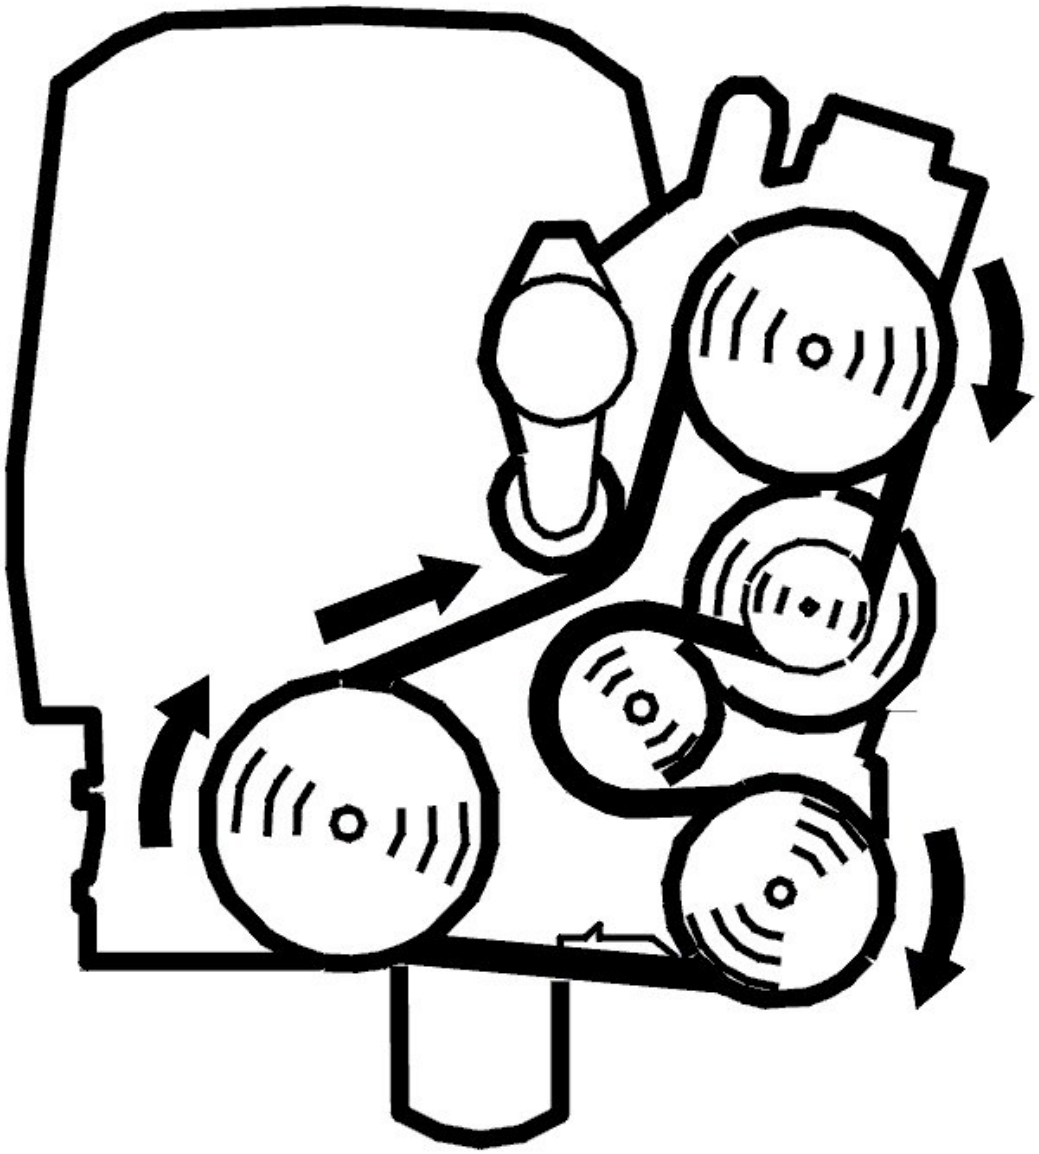
Continue - Verification

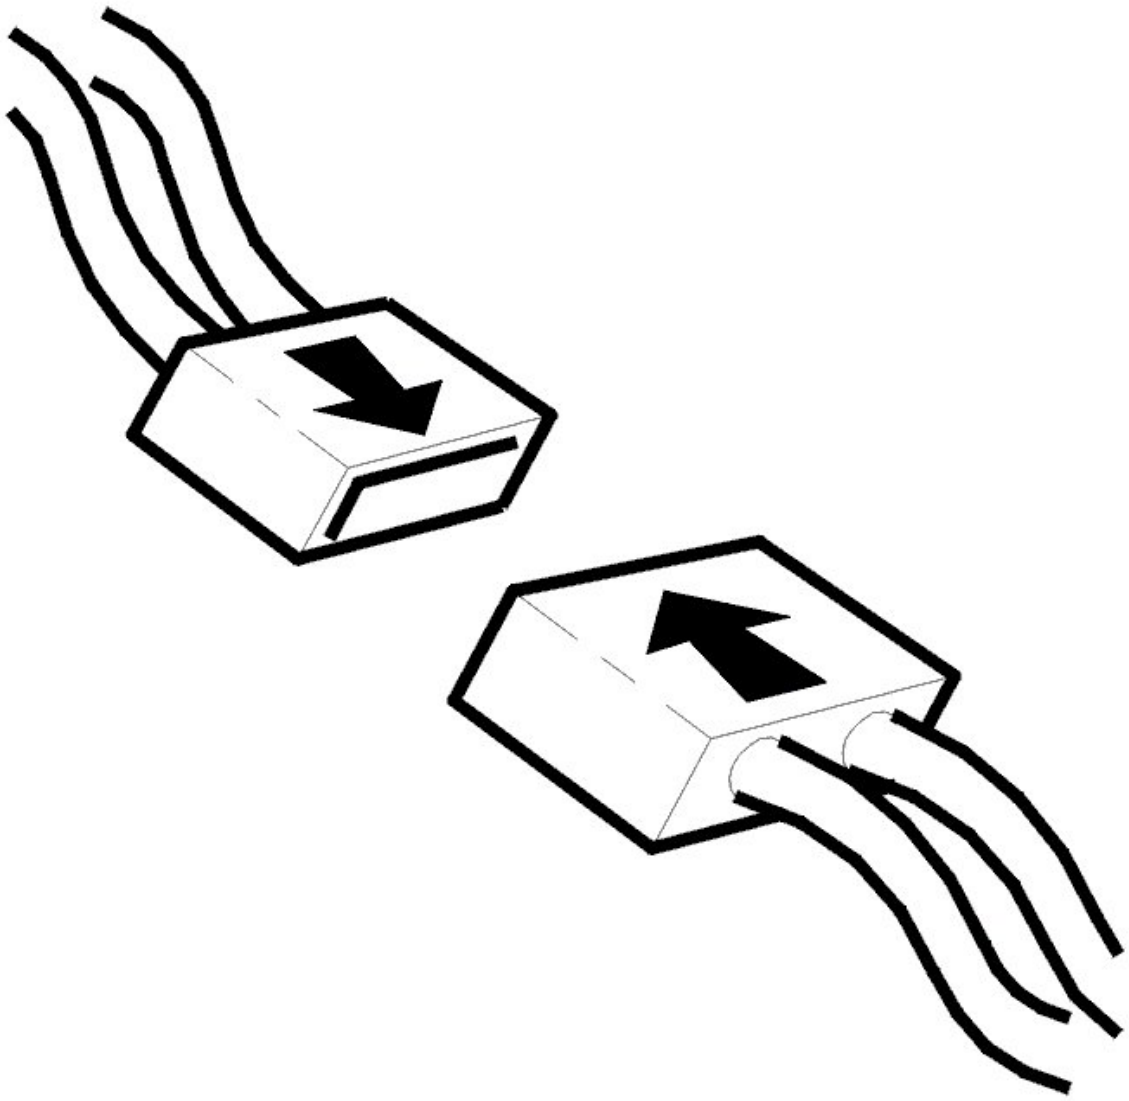
Verification

Verification

Verification

Hint: After carrying out the repair, check that the fault has been remedied.





- Ignition off
- Reconnect the connectors, reinstall components etc.
- Start the engine
- Read off the diagnostic status and fault status for the diagnostic trouble code (DTC) by selecting the relevant diagnostic trouble code (DTC) from the list.

Increase the engine speed a number of times until the diagnostic is "Complete".
Check the fault status for the diagnostic trouble code (DTC) when the diagnostic is "Complete". If the function is correct, the fault status must be "No fault found" when the diagnostic is complete.

Hint: In some cases several functions of the component will be diagnosed. The affects the amount of time taken to run the diagnostic.

Is the function OK?

Yes - VERIFIED

No - VERIFICATION FAILED

VERIFICATION FAILED - Fault-tracing information

VERIFIED - Fault Found

Fault-tracing information

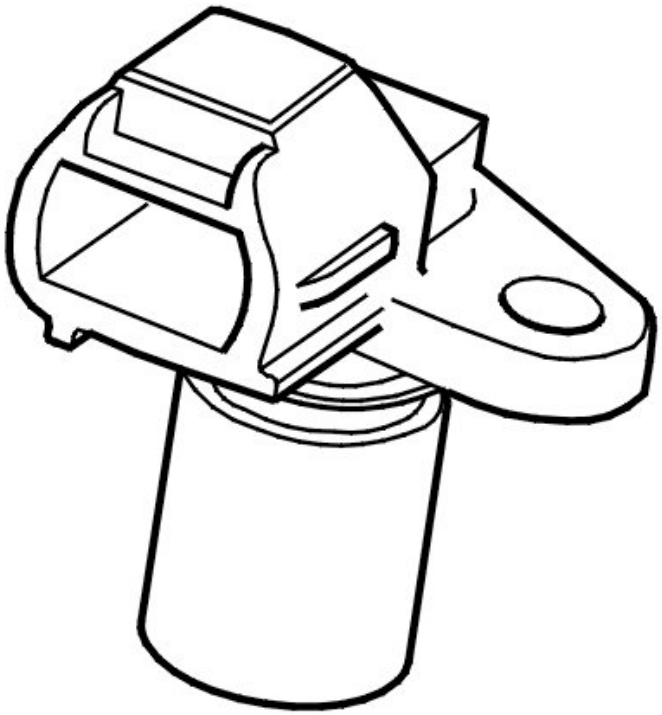
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information ECM-500B

Condition



The engine control module (ECM) detects the flywheel position for TDC using the signal from the engine speed (RPM) sensor. The diagnostic trouble code (DTC) is stored if the engine control module (ECM) is unable to detect TDC at the flywheel. The diagnostic trouble code (DTC) can be diagnosed when the engine is running.

Substitute value

- The control module uses the signal from the camshaft position (CMP) sensor if the camshaft position (CMP) sensor has been adapted
- Variable valve timing control is blocked.

Possible source
- Signal interference
- Contact resistance in the terminals
- Incorrectly installed engine speed (RPM) sensor
- Intermittent fault causes in the engine speed (RPM) sensor wiring.

Fault symptom[s]
- The engine is difficult to start
- Poor performance.

Signal Missing

Signal missing

Checking components and wiring

Check the engine speed (RPM) sensor connector. Check for intermittent contact resistance and oxidation.

Hint: The engine speed (RPM) sensor and its wiring are sensitive to interference from surrounding cables, the starter motor cable for example, or similar high amperage cables.

Interference can cause difficulty in starting the engine, prevent the engine starting at all, or cause intermittent operation of the tachometer, etc. Check whether any cables with high power consumption are incorrectly installed, i.e. too close to the engine speed (RPM) sensor or its wiring. Remedy as necessary.

Other information
- Engine speed (RPM) sensor, replacing See: Crankshaft Position Sensor/Service and Repair

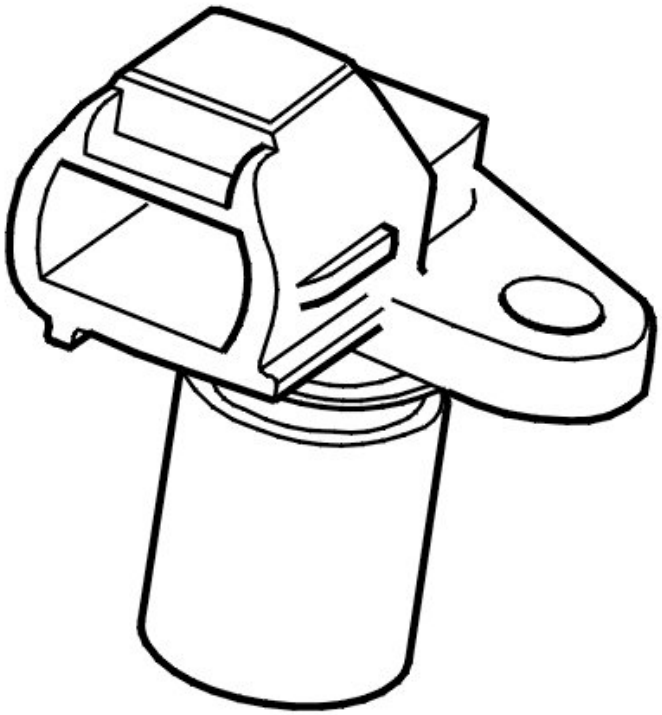
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information ECM-500C

Condition



The engine control module (ECM) counts the number of teeth on the flywheel using the signal for the engine speed (RPM) sensor. The diagnostic trouble code (DTC) is stored if the engine control module (ECM) detects at least one tooth too many during a certain number of engine revolutions. The diagnostic trouble code (DTC) can be diagnosed when the engine is running.

Substitute value

- The engine control module (ECM) uses the signal from the camshaft position (CMP) sensor if the camshaft position (CMP) sensor has been adapted

- Variable valve timing control is blocked.

Possible source
- Signal interference
- Damaged flywheel or ring gear.

Fault symptom[s]
- The engine is difficult to start
- Poor performance.

Signal Too High

Signal too high

Checking the component and wiring
- Check the engine speed (RPM) sensor connector. Check for intermittent contact resistance and oxidation.

Hint: The engine speed (RPM) sensor and its wiring are sensitive to interference from surrounding cables, the starter motor cable for example, or similar high amperage cables.

Interference can cause difficulty in starting the engine, prevent the engine starting at all, or cause intermittent operation of the tachometer, etc. Check whether any cables with high power consumption are incorrectly installed, i.e. too close to the engine speed (RPM) sensor or its wiring. Diagnostic Trouble Code (DTC) Information

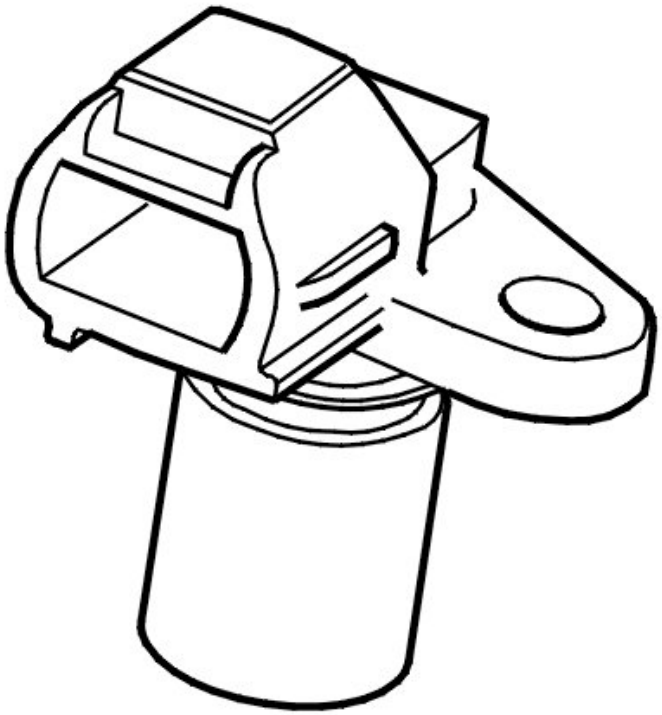
Diagnostic trouble code (DTC) information ECM-500D

Condition



The engine control module (ECM) counts the number of teeth on the flywheel using the signal for the engine speed (RPM) sensor. The diagnostic trouble code (DTC) is stored if the engine control module (ECM) detects at least one tooth too few during a certain number of engine revolutions. The diagnostic trouble code (DTC) can be diagnosed when the engine is running.

Substitute value

- The control module uses the signal from the camshaft position (CMP) sensor if the camshaft position (CMP) sensor has been adapted
- Variable valve timing control is blocked.

Possible source
- Signal interference
- Incorrectly installed engine speed (RPM) sensor
- Damaged flywheel or ring gear.

Fault symptom[s]
- The engine is difficult to start
- Poor performance.

Signal Too Low

Signal too low

Checking components

Check that the engine speed (RPM) sensor is correctly installed.
Check the engine speed (RPM) sensor connector. Check for intermittent contact resistance and oxidation.

Hint: The engine speed (RPM) sensor and its wiring are sensitive to interference from surrounding cables, the starter motor cable for example, or similar high amperage cables.

Interference can cause difficulty in starting the engine, prevent the engine from starting at all or cause the tachometer to flicker during start attempts etc.

Causes of interference can be:
- nearby cables, such as an incorrectly routed cable for the starter motor
- incorrectly tightened bolted joints securing the transmission to the engine.

Checking power cable

Check for incorrectly routed cables (routed too close to the engine speed (RPM) sensor).

Checking bolted joints

When removing and installing the transmission it is important that all the bolts for the engine are correctly tightened. Incorrectly tightened bolts can cause poor ground connection and interfere with the engine speed (RPM) sensor. Check that all the bolts from the transmission to the engine are correctly tightened.

Checking the wiring

Check the signal cable between the engine speed (RPM) sensor terminal #1 and engine control module (ECM) terminal #A48 (#A48) and between the engine speed (RPM) sensor terminal #2 and engine control module (ECM) terminal #A66 (#B6). Check for an intermittent short-circuit to supply voltage. Check for an intermittent short-circuit to ground. Check for an intermittent open-circuit.

Other information:

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information ECM-5100

Condition

One or more diagnostic trouble codes (DTCs) which affect emissions are stored in the transmission control module (TMC).
The diagnostic trouble code (DTC) is stored if the engine control module (ECM) registers that the transmission control module (TCM) has transmitted a request to light the malfunction indicator lamp (MIL).
The diagnostic trouble code (DTC) can be diagnosed when the ignition is switched on.

Substitute value
- None.

Possible source
- Fault trace the transmission control module (TCM).

Fault symptom[s]
- Malfunction indicator lamp (MIL) lit.

Fault-Tracing Information

Fault-tracing information

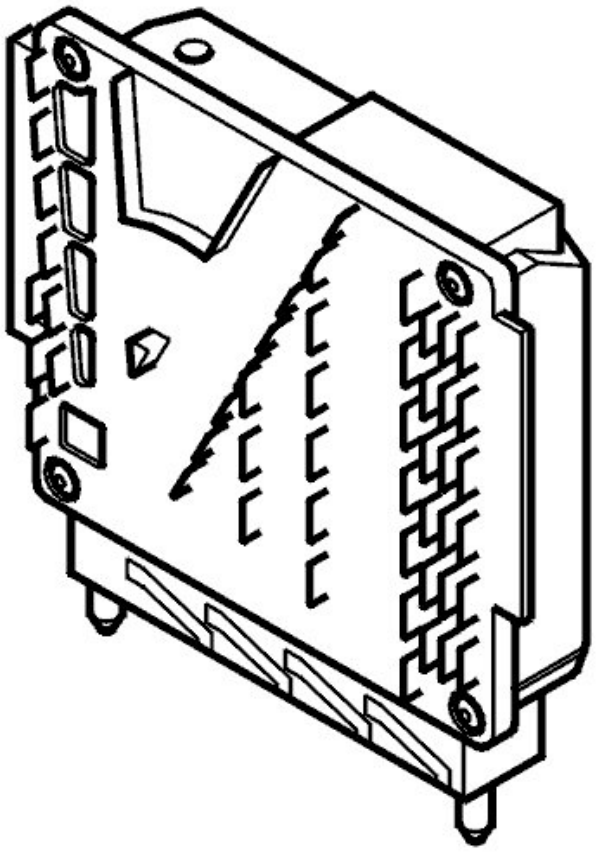
Information

No fault-tracing has been developed for this diagnostic trouble code (DTC). A diagnostic trouble code (DTC) for this fault is stored in the transmission control module (TCM) first and then in the engine control module (ECM). This diagnostic trouble code (DTC) can not be erased before the diagnostic trouble code (DTC) in the transmission control module (TCM) has been erased and remedied.
First read off the diagnostic trouble codes (DTCs) in the transmission control module (TCM). Fault-trace and remedy as required. This diagnostic trouble code (DTC) can then be erased. For further information about this diagnostic trouble code (DTC), see Diagnostic Trouble Code (DTC) Information.

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information ECM-5110

Condition



The diagnostic trouble code (DTC) is stored if the central electronic module (CEM) detects a fault in the software for the engine control module (ECM) (incorrect check sum).

Substitute value
- None.

Possible source
- Incorrect engine control module (ECM) for this vehicle
- Changed software in the engine control module (ECM)
- Damaged engine control module (ECM).

Fault symptom[s]
- None.

Fault-Tracing Information

Fault-tracing information

Information

There is no fault-tracing for this diagnostic fault code (DTC).
For further information on this diagnostic trouble code, see Diagnostic trouble code (DTC) information.

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information ECM-512B

Condition

The diagnostic trouble code (DTC) is stored if the engine control module (ECM) registers a fault in the CAN communication between the transmission control module (TCM) and the engine control module (ECM).
The diagnostic trouble code (DTC) is diagnosed with the engine running and with battery voltage above 10.5 V.

Substitute value
- None.

Possible source

- Open-circuit in the control area network (CAN) wiring
- Short-circuit between the control area network (CAN) wiring
- Internal fault in the engine control module (ECM)
- Internal fault in the transmission control module (TCM)
- Internal fault in another control module in the same part of the control area network (CAN).

Fault symptom[s]
- Malfunction indicator lamp (MIL) lit
- No accelerator pedal (AP) response.

Fault-Tracing Information

Fault-tracing information

There is no fault-tracing for this diagnostic fault code (DTC).
For further information on this diagnostic trouble code, see Diagnostic trouble code (DTC) information.

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information ECM-5130

Condition

The diagnostic trouble code (DTC) is stored if the engine control module (ECM) registers that the transmission control module (TCM) has transmitted a request to save the frozen values.
The diagnostic trouble code (DTC) can be diagnosed when the ignition is switched on.

Substitute value
- None.

Possible source
- Fault trace the transmission control module (TCM).

Fault symptom[s]
- Warning lights and chimes/Malfunction Indicator Light ("Check engine" light) indication/no indication

Fault-Tracing Information

Fault-tracing information

Information

No fault-tracing has been developed for this diagnostic trouble code (DTC). A diagnostic trouble code (DTC) for this fault is stored in the transmission control module (TCM) first and then in the engine control module (ECM). This diagnostic trouble code (DTC) can not be erased before the diagnostic trouble code (DTC) in the transmission control module (TCM) has been erased and remedied.
First read off the diagnostic trouble codes (DTCs) in the transmission control module (TCM). Fault-trace and remedy as required. This diagnostic trouble code (DTC) can then be erased. For further information about this diagnostic trouble code (DTC), see Diagnostic Trouble Code (DTC) Information.

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information ECM-513B

Condition

The diagnostic trouble code (DTC) is stored if the engine control module (ECM) registers that the transmission control module (TCM) has transmitted a request to save the frozen values.
The diagnostic trouble code (DTC) can be diagnosed when the ignition is switched on.

Substitute value
- None.

Possible source
- Fault trace the transmission control module (TCM).

Fault symptom[s]
- Varies depending on the diagnostic trouble code (DTC) stored in the transmission control module (TCM).

Fault-Tracing Information

Fault-tracing information

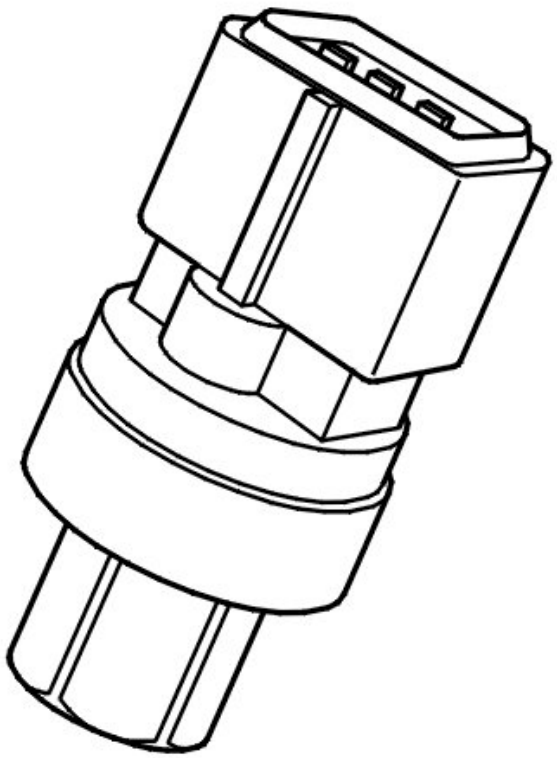
No fault-tracing has been developed for this diagnostic trouble code (DTC). A diagnostic trouble code (DTC) for this fault is stored in the transmission control module (TCM) first and then in the engine control module (ECM). This diagnostic trouble code (DTC) can not be erased before the diagnostic trouble code (DTC) in the transmission control module (TCM) has been erased and remedied.
First read off the diagnostic trouble codes (DTCs) in the transmission control module (TCM). Fault-trace and remedy as required. This diagnostic trouble code (DTC) can then be erased. For further information about this diagnostic trouble code (DTC), see Diagnostic Trouble Code (DTC) Information.

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information ECM-5200

Condition



The diagnostic trouble code (DTC) is stored if the engine control module (ECM) detects that the pressure in the air conditioning (A/C) system has not increased for a certain time following activation of the air conditioning (A/C) compressor.
The diagnostic trouble code (DTC) can be diagnosed while the engine is running and air conditioning (A/C) control is active.

Substitute value
- None.

Possible source
- Damaged A/C pressure sensor
- Low pressure in the air conditioning (A/C) system.

Fault symptom[s]
- The air conditioning (A/C) system does not operate.

Fault-Tracing Information

Fault-tracing information

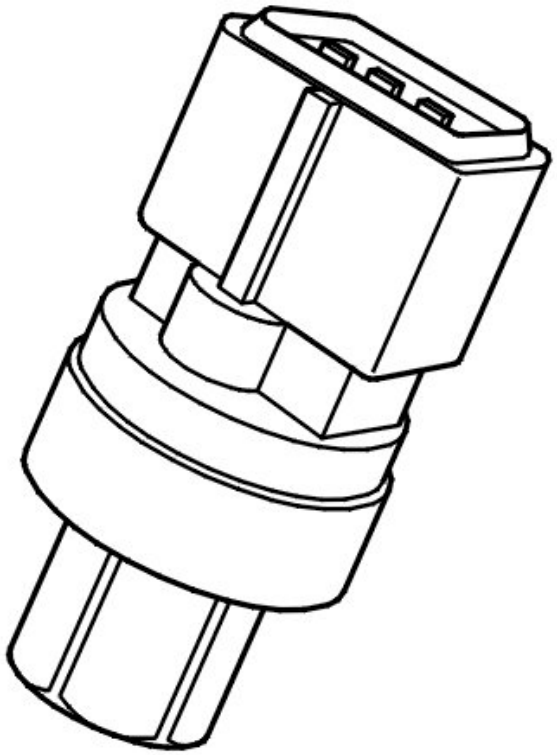
Information

There is no fault-tracing for this diagnostic fault code (DTC).
For further information on this diagnostic trouble code, see Diagnostic trouble code (DTC) information.

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information ECM-520B

Condition



The diagnostic trouble code (DTC) is stored if the engine control module (ECM) detects that there is no signal from the air conditioning (A/C) pressure sensor.
The diagnostic trouble code (DTC) can be diagnosed while the engine is running and while air conditioning (A/C) control is active.

Substitute value
- Predefined value for the air conditioning pressure.

Possible source
- Open-circuit in the signal cable
- Damaged A/C pressure sensor.

Fault symptom[s]
- The air conditioning (A/C) system does not operate.

Signal Missing Permanent Fault

Signal missing. Permanent fault

Checking component and wiring

Check if there is any refrigerant in the air conditioning (A/C).

Hint: If there is refrigerant in the A/C system there is probably a fault in the A/C pressure sensor.

Check air conditioning (A/C) system for damage and leakage.
Remedy as necessary.
