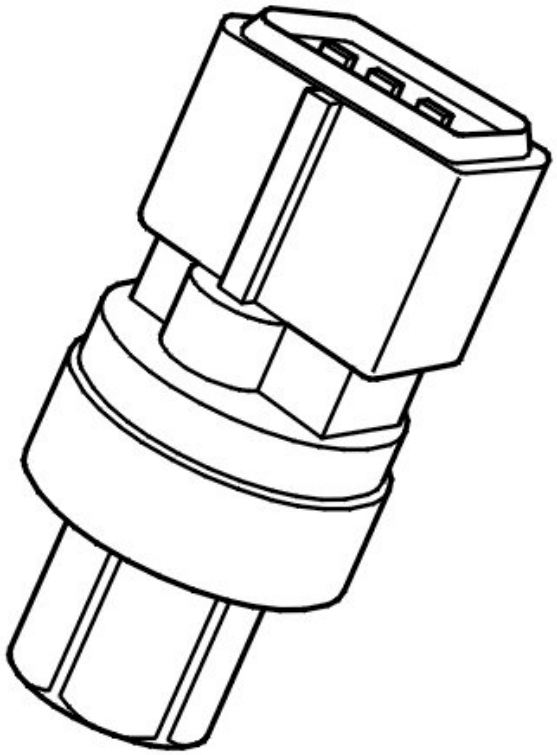
Diagnostic Trouble Code (DTC) Information

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

Diagnostic trouble code (DTC) information ECM-520C

Condition



The diagnostic trouble code (DTC) is stored if the engine control module (ECM) detects that the signal from the air conditioning (A/C) pressure sensor is higher than the normal operating range.
The diagnostic trouble code (DTC) can be diagnosed while the engine is running and while air conditioning (A/C) control is active.

Substitute value
- None.

Possible source
- Short-circuit to supply voltage in the signal cable
- Open-circuit in the power supply
- Open-circuit in the ground lead
- Damaged A/C pressure sensor.

Fault symptom[s]
- The air conditioning (A/C) system does not operate.

Signal Too High Permanent Fault

Signal too high. Permanent fault

Checking component and wiring

Check signal cable between engine control module (ECM) #A68 (#B8) and air conditioning (A/C) pressure sensor #2 for a short-circuit to supply voltage according to Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault.
Check power supply cable between engine control module (ECM) #A39 (#A39) and air conditioning (A/C) pressure sensor #3 for an open-circuit according to Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault.
Check power supply cable between engine control module (ECM) #A60 (#A60) and air conditioning (A/C) pressure sensor #1 for an open-circuit according to Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault.
Remedy as necessary.

Other information:

- Connecting the breakout box/accessing the control module, see Connecting the breakout box, B5244T5, B5254T2 See: Pinout Values and Diagnostic Parameters/Connecting the Breakout Box.
- Air conditioning (A/C) pressure sensor #2 is the signal cable, #3 is the power supply (5V) and #1 is the signal ground.
- For information about signals, see Signal specification See: Pinout Values and Diagnostic Parameters/Signal Description / Specification.

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information ECM-5300

Condition

Internal functions in the engine control module (ECM) check important parameters.
The diagnostic trouble code (DTC) is stored if the engine control module (ECM) detects an incorrect parameter.
The diagnostic trouble code (DTC) can be diagnosed when driving under specific driving conditions.

Substitute value
- None.

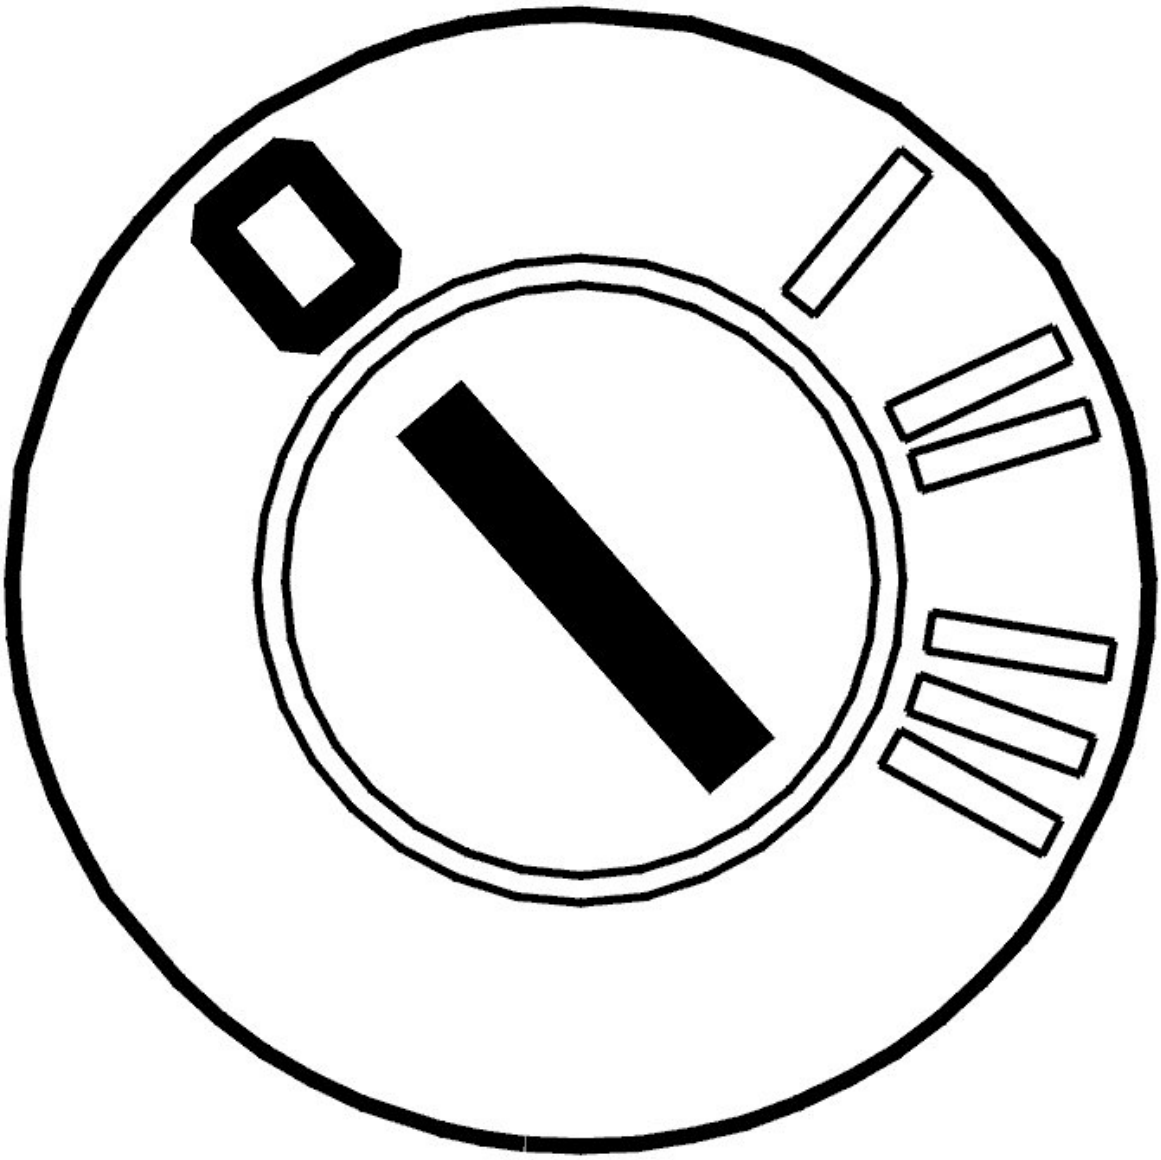
Possible source
- Damaged engine control module (ECM).

Fault symptom[s]
- Malfunction indicator lamp (MIL) lit.

Faulty Signal

Faulty signal

Programming/replacing the engine control module (ECM)



- Ignition off.

The engine control module (ECM) has registered an internal fault or a fault in the software. Try downloading new software into the control module.
To download new software or replace the engine control module (ECM), see:
Engine control module (ECM), replacing See: Engine Control Module/Service and Repair.
If software cannot be downloaded or new software does not solve the problem, replace the engine control module (ECM) and download the relevant software to the new control module.

Note! After downloading new software or replacing the engine control module (ECM), the throttle unit must be adapted according to VIDA Vehicle communication: "Throttle unit adaptation".

Remedy as necessary.

Diagnostic Trouble Code (DTC) Information

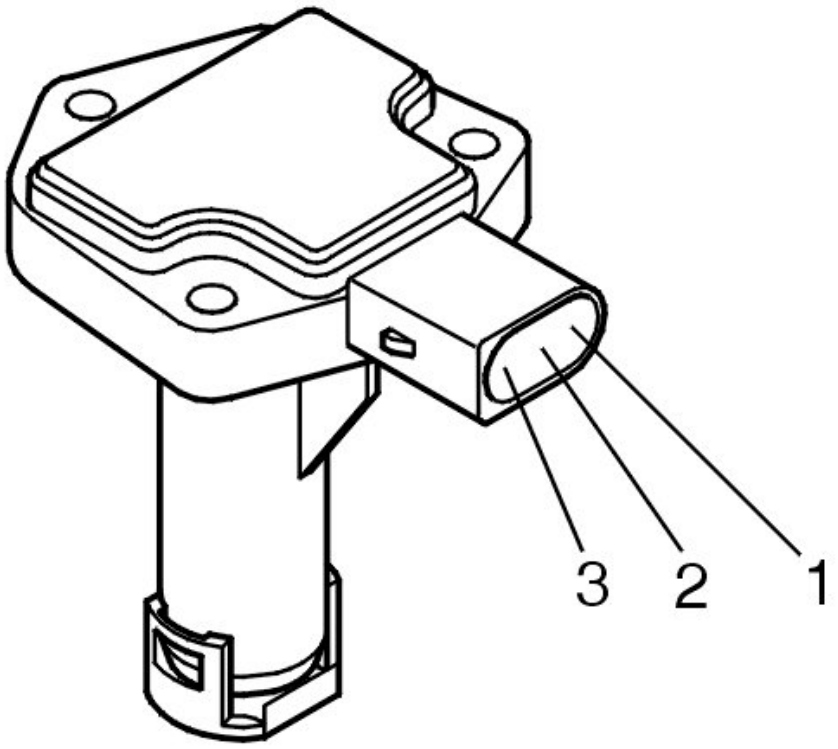
Diagnostic trouble code (DTC) information ECM-540B

Condition



The engine control module (ECM) checks the signal from the oil level sensor. The diagnostic trouble code (DTC) is stored if the engine control module (ECM) detects that there is no signal from the oil level sensor.
The diagnostic trouble code (DTC) can be diagnosed when the engine is running.

Substitute value
- None.

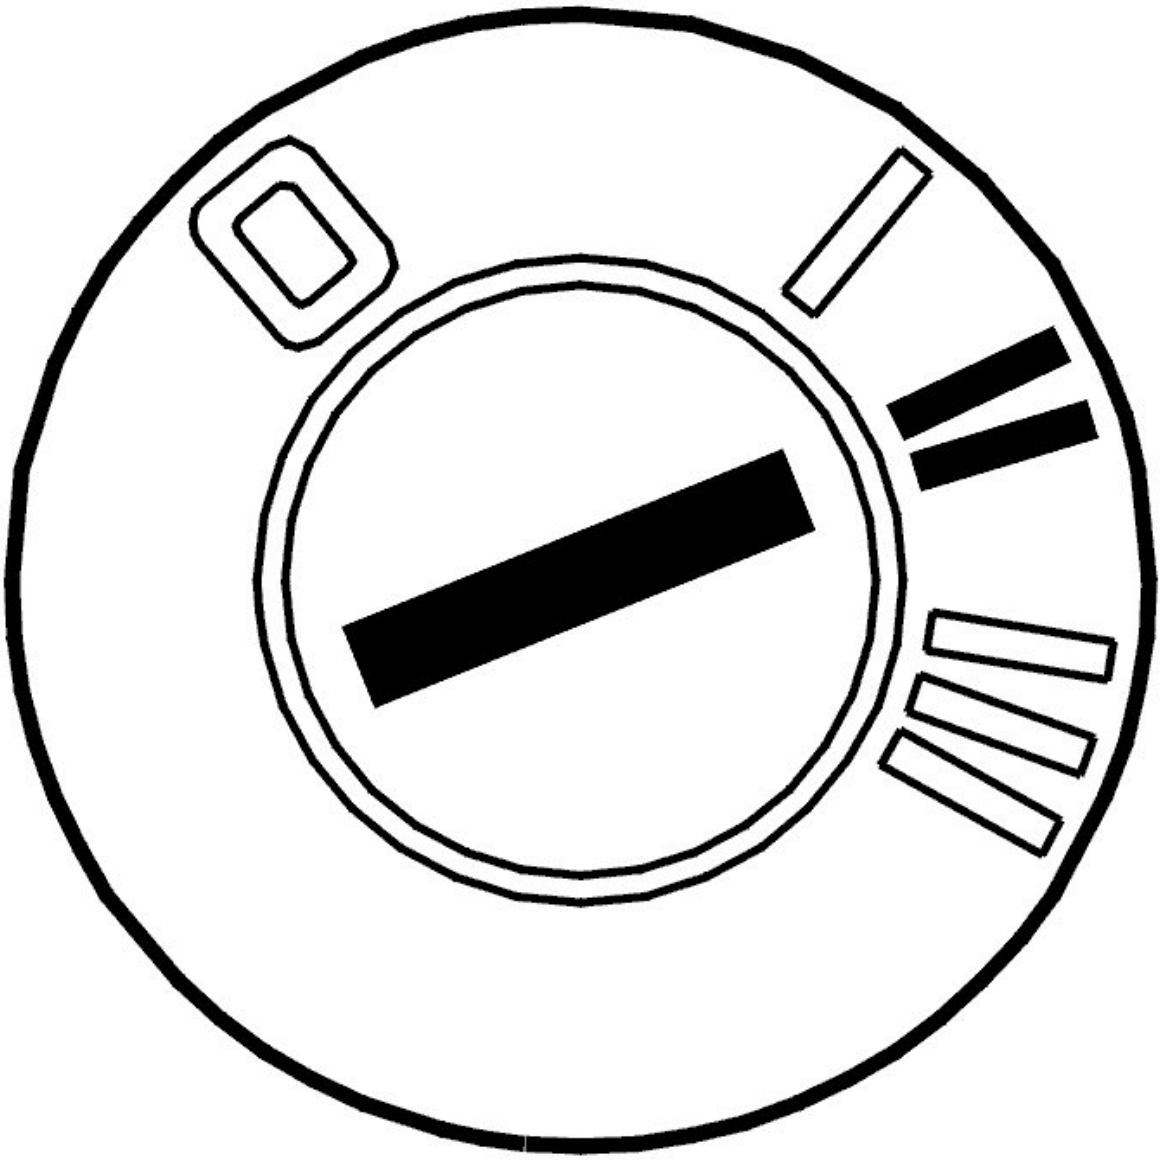
Possible source
- Loose connections, contact resistance or oxidation in the terminals
- Open-circuit in the signal cable
- Open-circuit in the power supply
- Damaged oil level sensor.

Fault symptom[s]
- None.

Faulty Signal

Faulty signal

Checking the status



- Ignition on
- Read off the oil level sensor signal.

Check that all three values for oil level, oil temperature and oil grade are between 17-83%. The fault is intermittent at the moment if all the values are OK.

Continue - Checking connectors and wiring

Checking connectors and wiring

Check the oil level sensor connector. Check for loose connections, contact resistance and oxidation.
Check the signal cable between engine control module (ECM) terminal #A40 and oil level sensor terminal #1. Check for an open-circuit.

Check the cable between engine control module (ECM) terminal #A39 and oil level sensor terminal #3. Check for an open-circuit.
Check the cable between engine control module (ECM) terminal #A60 and oil level sensor terminal #2. Check for an open-circuit.

Hint: With the ignition on, the voltage between terminals #2 and #3 must be 5 V, with the reading taken at the oil level sensor connector.

Try a new oil level sensor if no fault is found and the fault is permanent.
Remedy as necessary.

Diagnostic Trouble Code (DTC) Information

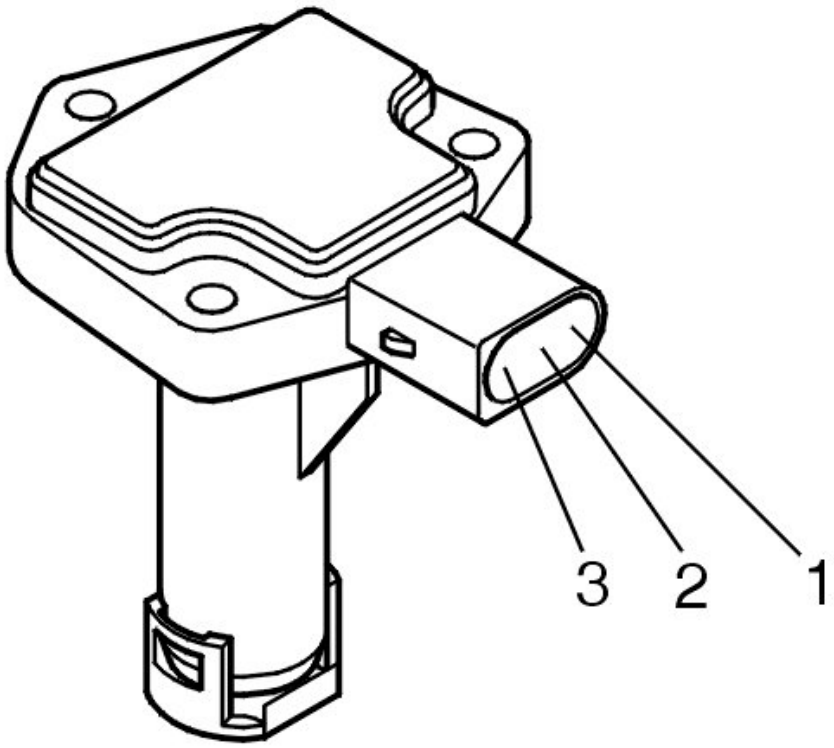
Diagnostic trouble code (DTC) information ECM-5500

Condition



The engine control module (ECM) checks the signal from the oil level sensor. The diagnostic trouble code (DTC) is stored if the engine control module (ECM) registers that the signal from the oil level sensor is outside a reasonable operating range.
The diagnostic trouble code (DTC) can diagnosed after a number of different criteria (engine speed (RPM), vehicle speed, etc.) have been reached.

Substitute value
- None.

Possible source
- Engine oil leak
- Loose connections, contact resistance or oxidation in the terminals
- Damaged oil level sensor.

Fault symptom[s]

- Warning lights and chimes/Oil pressure indication/no indication

Faulty Signal

Faulty signal

Checking for oil leakage and replacing the component

Note! If diagnostic trouble codes (DTCs) ECM-540X and ECM-550X are stored at the same time, codes ECM-540X must be remedied first.

- Checking the engine for oil leakage
- Also check the oil level sensor connector. Check for loose connections, contact resistance or oxidation.

Hint: This diagnostic trouble code (DTC) may be stored if the engine oil is significantly mixed with fuel or coolant for example.

Try a new oil level sensor if no fault is found and the fault is permanent.
Remedy as necessary.

Diagnostic Trouble Code (DTC) Information

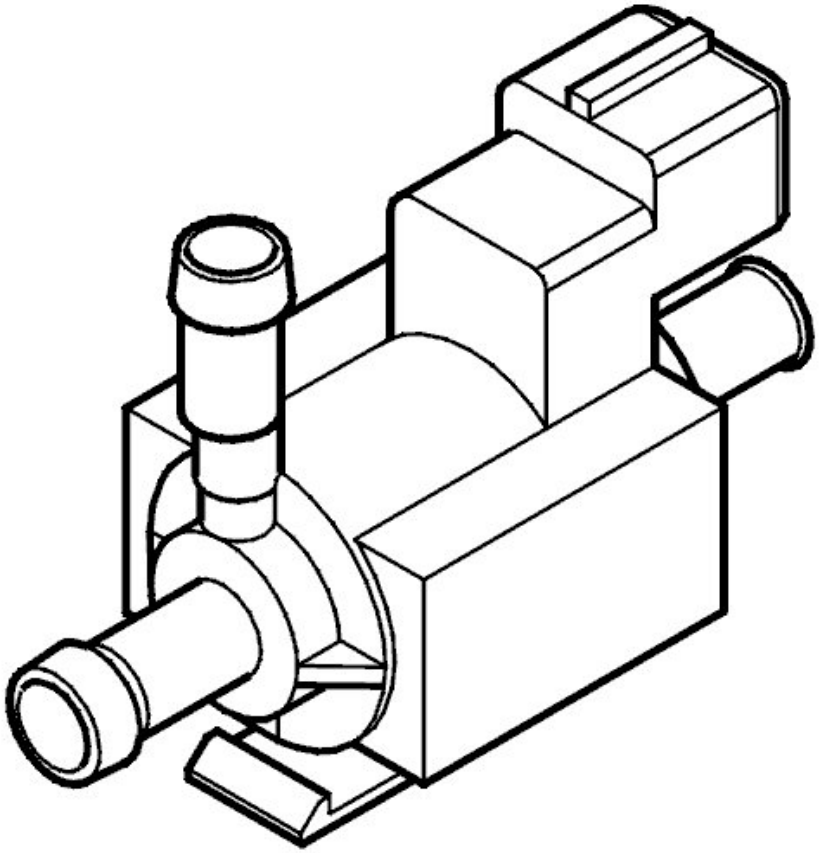
Diagnostic trouble code (DTC) information ECM-600B

Condition



The engine control module (ECM) checks the signal cable for the turbocharger (TC) control valve.
The diagnostic trouble code (DTC) is stored if the engine control module (ECM) detects an open-circuit in the signal cable for the turbocharger (TC) control valve.
The diagnostic trouble code (DTC) can be diagnosed during control of the boost pressure.

Substitute value
- None.

Possible source
- Open-circuit in the signal cable
- Open-circuit in the power cable
- Damaged turbocharger (TC) control valve.

Fault symptom[s]

- Malfunction indicator lamp (MIL) lit.

Signal Missing - Intermittent Fault

Signal missing. Intermittent fault

Checking the component, wiring and connector

Check turbocharger (TC) control valve connector for intermittent contact resistance or oxidation according to Checking wiring and terminals. Intermittent faults See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Intermittent Faults and intermittent loose connections according to Checking wiring and terminals. Intermittent faults See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Intermittent Faults.
Check signal cable between engine control module (ECM) #A38 (#A38) and turbocharger (TC) control valve #2 for an intermittent open-circuit according to Checking wiring and terminals. Intermittent faults See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Intermittent Faults.
Check power supply turbocharger (TC) control valve between turbocharger (TC) control valve #1 and system relay for an intermittent open-circuit according to Checking wiring and terminals. Intermittent faults See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Intermittent Faults.
Remedy as necessary

Other information

- To connect the breakout box, see Connecting the breakout box, B5244T5, B5254T2 See: Pinout Values and Diagnostic Parameters/Connecting the Breakout Box.
- To access/replace the turbocharger (TC) control valve, see Replacing the turbocharger (TC) control valve, B5244T5, B5254T2 See: Boost Solenoid/Service and Repair.
- Turbocharger (TC) control valve #1 has power supply via the system relay.

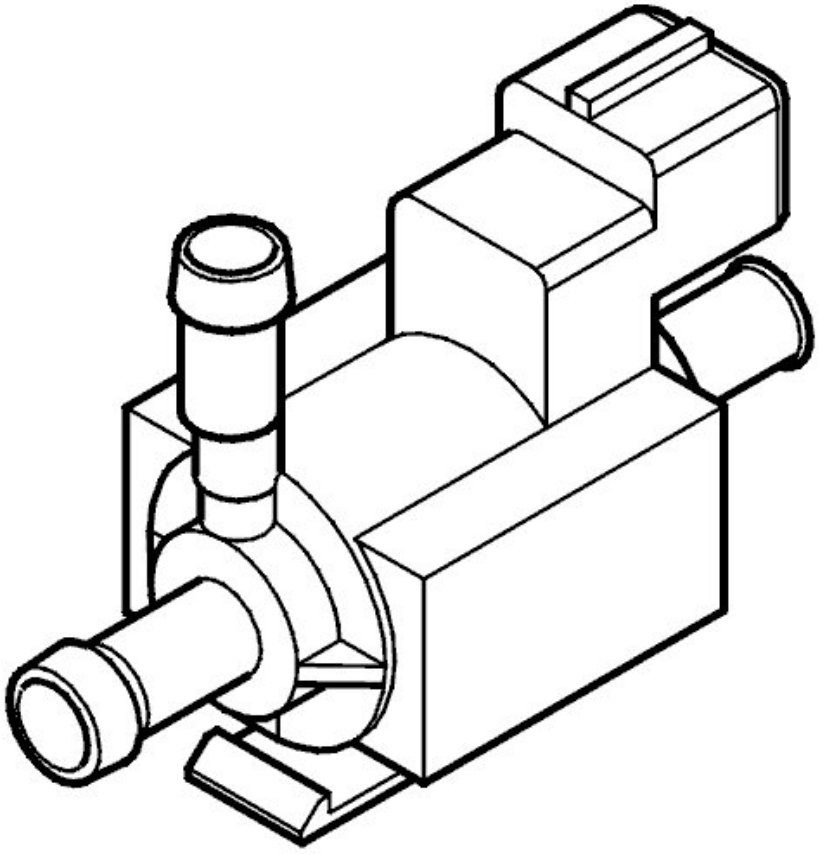
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information ECM-600C

Condition



The engine control module (ECM) checks the signal cable for the turbocharger (TC) control valve.
The diagnostic trouble code (DTC) is stored if the engine control module (ECM) detects that the voltage in the signal cable from the turbocharger (TC) control valve is too high.
The diagnostic trouble code (DTC) can be diagnosed during control of the boost pressure.

Substitute value
- None.

Possible source
- Short-circuit to supply voltage in the signal cable
- Damaged turbocharger (TC) control valve.

Fault symptom[s]
- Malfunction indicator lamp (MIL) lit.

Signal Too High - Intermittent Fault

Signal too high. Intermittent fault

Checking component and wiring

Check cables between engine control module (ECM) #A38 (#A38) and turbocharger (TC) control valve #2 for an intermittent short-circuit to supply voltage according to Checking wiring and terminals. Intermittent faults See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Intermittent Faults.
Remedy as necessary

Other information
- To connect the breakout box, see Connecting the breakout box, B5244T5, B5254T2 See: Pinout Values and Diagnostic Parameters/Connecting the Breakout Box.
- To access/replace the turbocharger (TC) control valve, see Replacing the turbocharger (TC) control valve, B5244T5, B5254T2 See: Boost Solenoid/Service and Repair.
- For information about signals, see Signal specification See: Pinout Values and Diagnostic Parameters/Signal Description / Specification.

- Turbocharger (TC) control valve terminal 1 has Ubat power supply from the system relay.

Diagnostic Trouble Code (DTC) Information

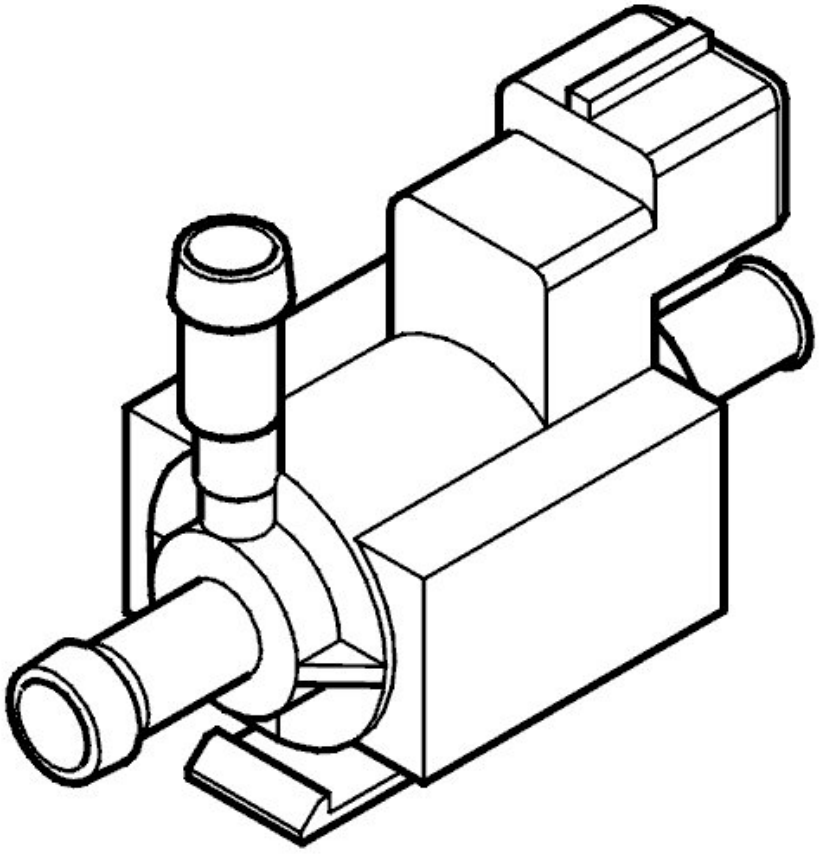
Diagnostic trouble code (DTC) information ECM-601C

Condition



The engine control module (ECM) checks the function of the turbocharger (TC) control system.
The diagnostic trouble code (DTC) is stored if the pressure measured by the boost pressure sensor is higher than a calculated desired value. This is interpreted as a fault by the control module.
The diagnostic trouble code (DTC) can be diagnosed when the engine is running.

Substitute value
- Reduced throttle angle.

Possible source
- Damaged turbocharger (TC) control valve
- The hoses between the pressure servo for the boost pressure control (BPC) valve and the turbocharger (TC) control valve have come loose or are blocked or damaged
- The hoses between the turbocharger (TC) control valve and the charge air pipe (between the turbocharger (TC) and the charge air cooler (CAC)) are blocked or damaged
- Pressure servo for the boost pressure control (BPC) valve is incorrectly adjusted
- Damaged boost pressure control (BPC) valve pressure servo
- Sticking boost pressure control (BPC) valve.

Fault symptom[s]
- Poor performance.

Signal Too High

Signal too high

Checking hoses and the turbocharger (TC) control valve

Check the hoses between the pressure servo for the boost pressure control (BPC) valve and the turbocharger (TC) control valve. Check that the hoses are not trapped, blocked or damaged.
Check the hoses between the turbocharger (TC) control valve and the charge air pipe (between the turbocharger (TC) and the charge air cooler (CAC)). Check that the hoses are not trapped, blocked or damaged.
Check the turbocharger (TC) control valve by activating it. The turbocharger (TC) control valve must click when it is activated.

5 cylinder engines:

Check the setting of the pressure servo for the boost pressure control (BPC) valve. Check the boost pressure control (BPC) valve. Check that the pressure servo and the boost pressure control (BPC) valve are functioning correctly and are not sticking:
Wastegate valve, adjusting, B5254T2 See: Fuel Delivery and Air Induction/Turbocharger/Wastegate Actuator/Adjustments

6 cylinder engines:

Check the setting of the pressure servo for the boost pressure control (BPC) valve. Check the boost pressure control (BPC) valve. Check that the pressure servo and the boost pressure control (BPC) valve are functioning correctly and are not sticking:

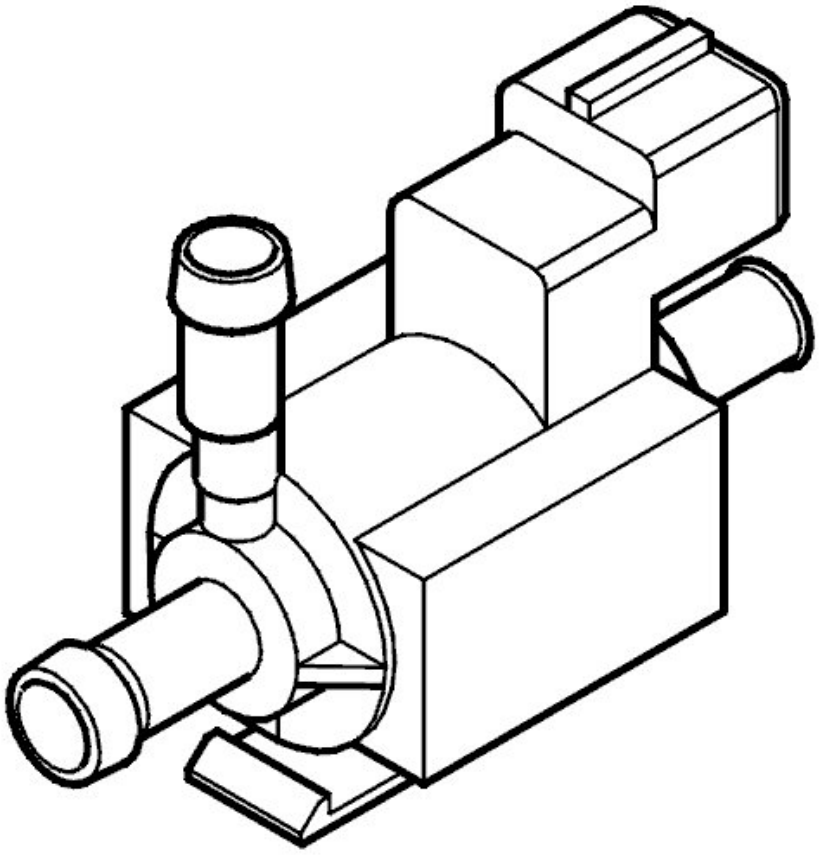
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information ECM-602D

Condition



The engine control module (ECM) checks the function of the turbocharger (TC) control system.
The diagnostic trouble code (DTC) is stored if the control module deployment of the turbocharger (TC) control valve is high (the control module requests maximum boost pressure) and the measured boost pressure (from the boost pressure sensor) is lower than a calculated desired value.
The diagnostic trouble code (DTC) can be diagnosed when the engine speed (RPM) and load are above a certain value.

Substitute value
- Reduced boost pressure.

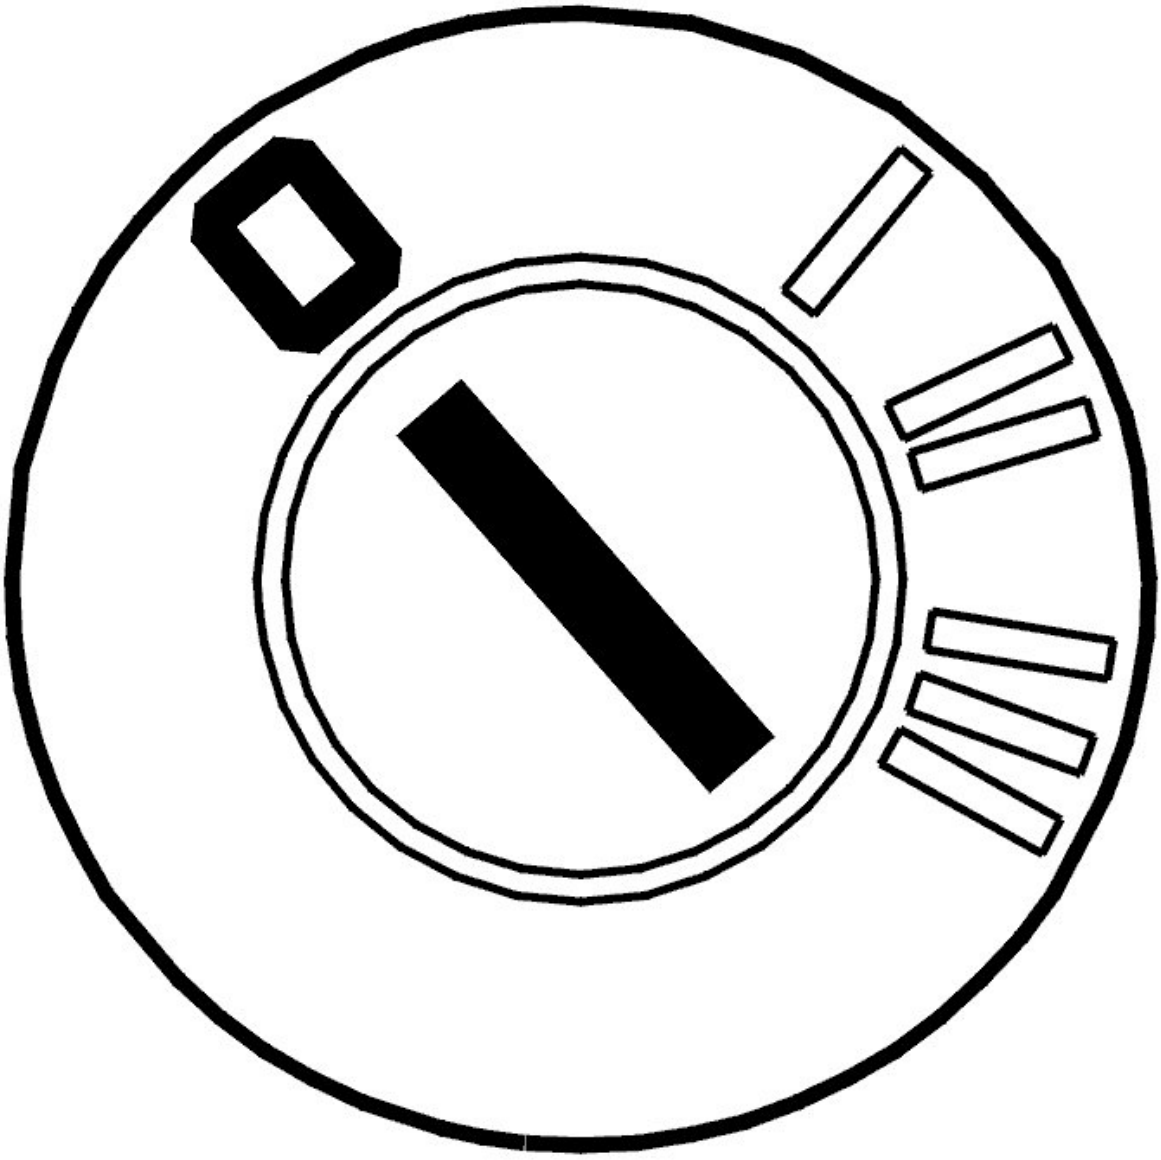
Possible source
- Air leakage in the intake system.
- Damaged turbocharger (TC) control valve.
- Incorrect adjustment of the pressure servo for the boost pressure control (BPC) valve
- Sticking boost pressure control (BPC) valve.
- Damaged turbo charger (TC).

Fault symptom[s]
- Poor performance.

Signal Too Low

Signal too low

Checking for air leakage



- Ignition off.

Check the intake system for air leakage and loose charge-air pipe.
Air leakage in the intake system, checking, B5244T5, B5254T2 See: Fuel Delivery and Air Induction/Testing and Inspection/Air Leaks in the Intake System, Checking

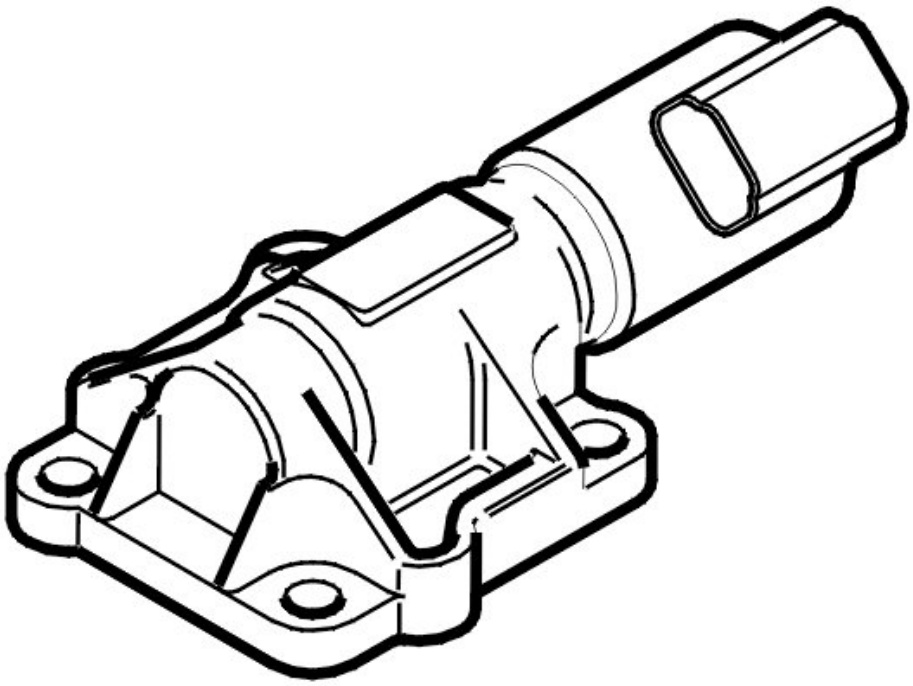
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information ECM-6110

Condition



The engine control module (ECM) checks that control of the intake camshaft is quick enough. This means that the intake camshaft (actual value) reaches the position requested by the engine control module (ECM) quickly enough. The diagnostic trouble code (DTC) is stored if the requested position is not reached within a certain time.
The diagnostic trouble code (DTC) can be diagnosed by the engine control module (ECM) when the engine is running and the camshaft control is active.

Substitute value
- None.

Possible source
- Low oil pressure
- Poor oil quality
- Damaged reset valve
- Mechanical fault in the variable valve timing (VVT) unit.

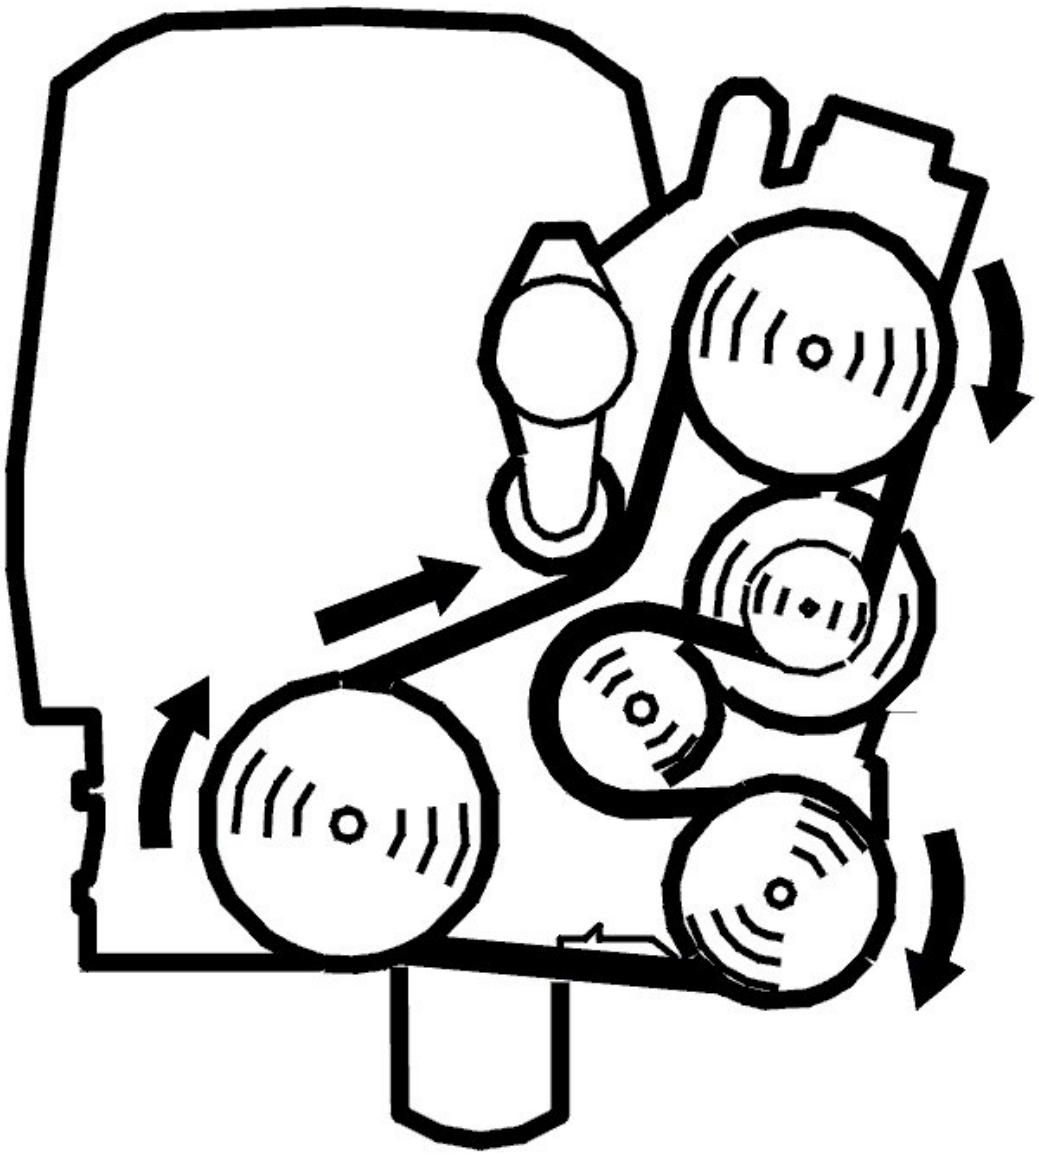
Fault symptom[s]
- Malfunction indicator lamp (MIL) lit.

Slow/Faulty

Slow/Faulty

Checking the status

Hint: Diagnostic trouble code (DTC) may be caused by a damaged fuse. If the engine does not start, check the fuse for the power supply to the camshaft reset valve.



- Start the engine
- Read off the value for the camshaft shift angle and the desired value for the camshaft shift angle
- Active the quick test of camshaft control by clicking the start button
- Increase the engine speed (RPM) to approximately 2500 rpm and keep the engine running at this speed.

When the engine speed (RPM) increases, the control module will start the quick test to control the shift angle of the camshaft to the different target values. There is a fault if the control module does not operate the camshaft shift angle to the different target values.
During the quick test, check that the shift angle of the camshaft (actual value) corresponds to the target values to an accuracy of ±10°. If the shift angle of the camshaft (target value) does not change, or if the actual value does not correspond to the target value, the function is faulty.

Deviation between the values can be read off in the lower display.
Carry out the check for approximately 15 seconds at an engine speed (RPM) of 2500 rpm. The test is completed when the shift angle of the camshaft returns to 0°. To restart the test, let the engine return to idle speed, then increase the engine speed to approximately 2500 rpm.
The fault is intermittent if the function is OK.

Note! The test is active until the ignition is switched off. Switch off the ignition before the vehicle is delivered to the customer.

Continue - Checking components

Checking components

Check the level and quality of the engine oil. Check for contaminants in particular.
Check the engine oil pressure.
Remove the camshaft reset valve. Check the oil ducts for the cylinder head for the camshaft reset valve (intake) for blockages and dirt.

Hint: The fault can be caused by contaminants in the camshaft reset valve. Try cleaning the valve.

Remedy as necessary.
Try a new intake camshaft reset valve if the above remedy does not solve the fault.

Hint: The fault may also have been caused by an internal fault in the variable valve timing unit. The variable valve timing unit may be damaged if the above fault-tracing and corrective action do not remedy the fault.

- Increase the engine speed (RPM) to approximately 2500 rpm and keep the engine running at this speed.

When the engine speed (RPM) increases, the control module will start the quick test to control the shift angle of the camshaft to the different target values. There is a fault if the control module does not operate the camshaft shift angle to the different target values.
During the quick test, check that the shift angle of the camshaft (actual value) corresponds to the target values to an accuracy of ±10°. If the shift angle of the camshaft (target value) does not change, or if the actual value does not correspond to the target value, the function is faulty.
Deviation between the values can be read off in the lower display.
Carry out the check for approximately 15 seconds at an engine speed (RPM) of 2500 rpm. The test is completed when the shift angle of the camshaft returns to 0°. To restart the test, let the engine return to idle speed, then increase the engine speed to approximately 2500 rpm.

Note! The test is active until the ignition is switched off. Switch off the ignition before the car is delivered to the customer.

Diagnostic Trouble Code (DTC) Information

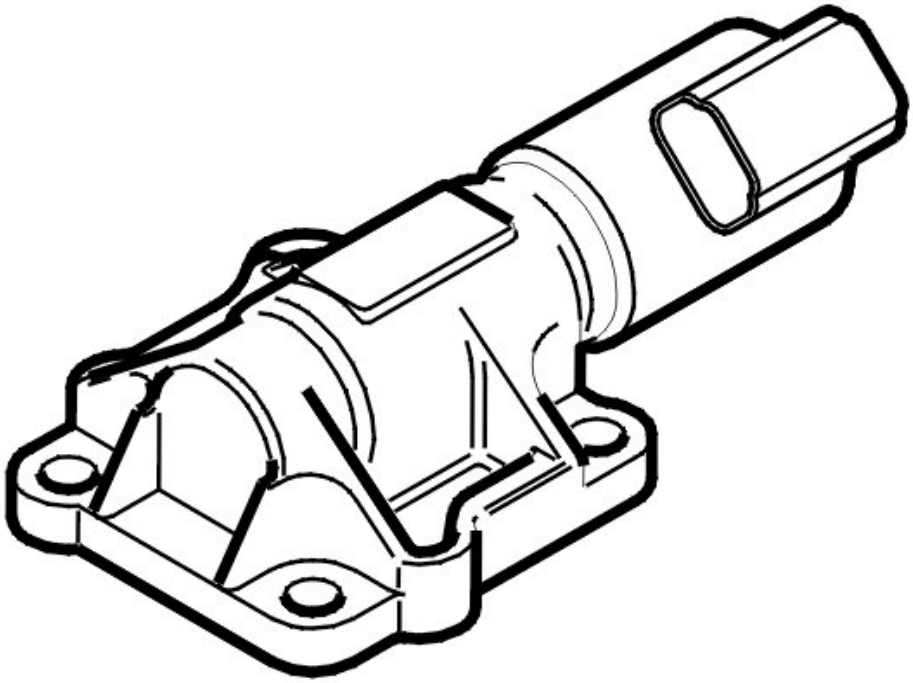
Diagnostic trouble code (DTC) information ECM-612C

Condition



The engine control module (ECM) checks the signal cable for the reset valve for the intake camshaft.
The diagnostic trouble code (DTC) is stored if the engine control module (ECM) detects that the signal from the signal cable for the reset valve is too high.
The diagnostic trouble code (DTC) can be diagnosed at ignition on and with the engine running.

Substitute value
- None.

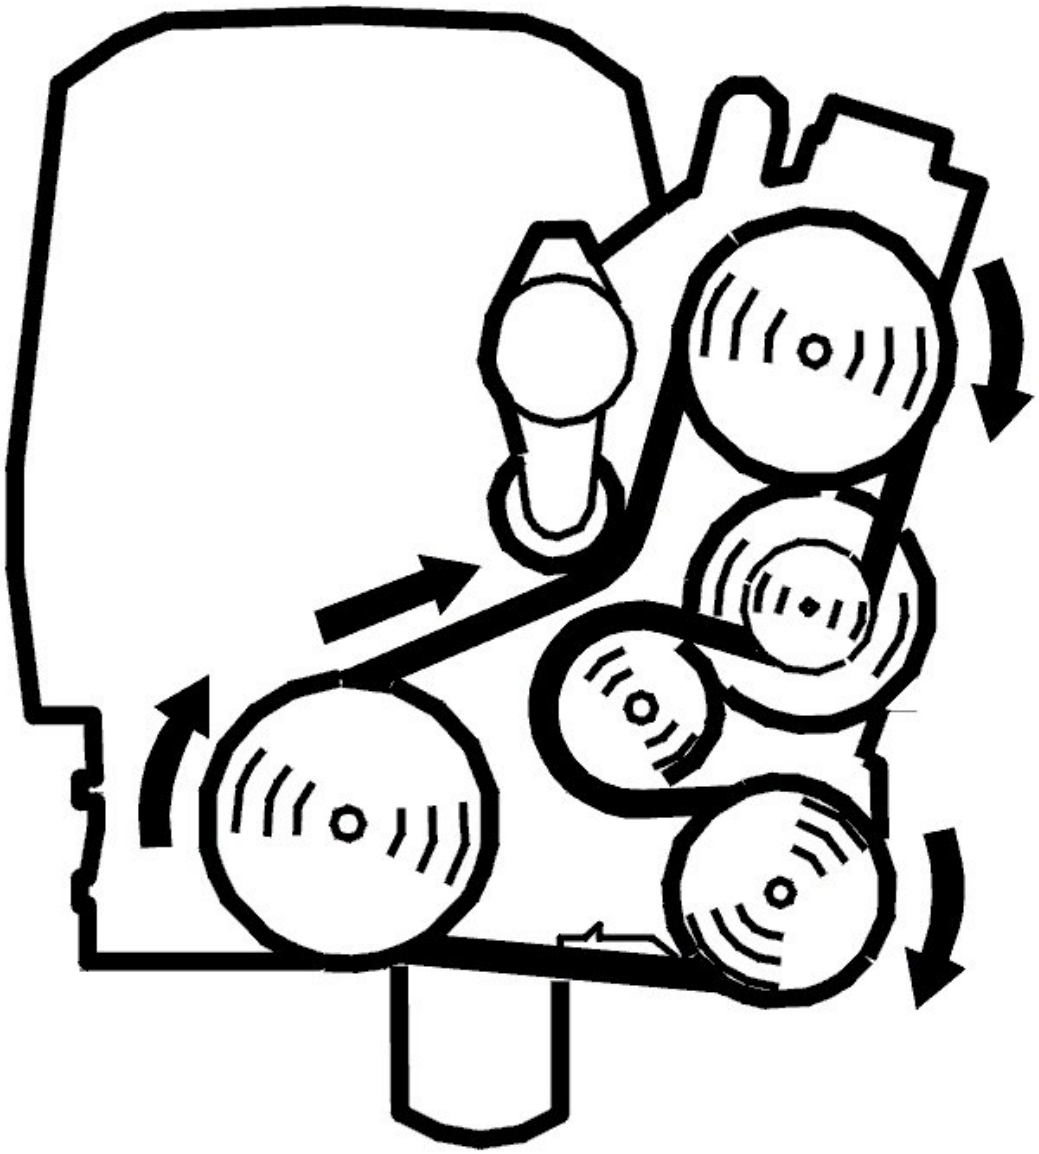
Possible source
- Short-circuit to supply voltage in the signal cable
- Open-circuit in the power supply
- Damaged camshaft reset valve.

Fault symptom[s]
- Malfunction indicator lamp (MIL) lit.

Signal Too High

Signal too high

Checking the status



- Start the engine
- Read off the value for the camshaft shift angle and the desired value for the camshaft shift angle
- Active the quick test of camshaft control by clicking the start button
- Increase the engine speed (RPM) to approximately 2500 rpm and keep the engine running at this speed.

When the engine speed (RPM) increases, the control module will start the quick test to control the shift angle of the camshaft to the different target values. There is a fault if the control module does not operate the camshaft shift angle to the different target values.
During the quick test, check that the shift angle of the camshaft (actual value) corresponds to the target values to an accuracy of ±10°. If the shift angle of the camshaft (target value) does not change, or if the actual value does not correspond to the target value, the function is faulty.
Deviation between the values can be read off in the lower display.
Carry out the check for approximately 15 seconds at an engine speed (RPM) of 2500 rpm. The test is completed when the shift angle of the camshaft returns to 0°. To restart the test, let the engine return to idle speed, then increase the engine speed to approximately 2500 rpm.
The fault is intermittent if the function is OK.

Note! The test is active until the ignition is switched off. Switch off the ignition before the car is delivered to the customer.

Continue - Checking the wiring

Checking the wiring

Check the resistance of the camshaft reset valve between terminals #1 and #2.
The resistance must be approximately 3.7 ohms.

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

Check the signal cable between engine control module (ECM) terminal #A13 (#A13) and camshaft reset valve terminal #2. Check for a short-circuit to supply voltage.
Remedy as necessary.

Diagnostic Trouble Code (DTC) Information

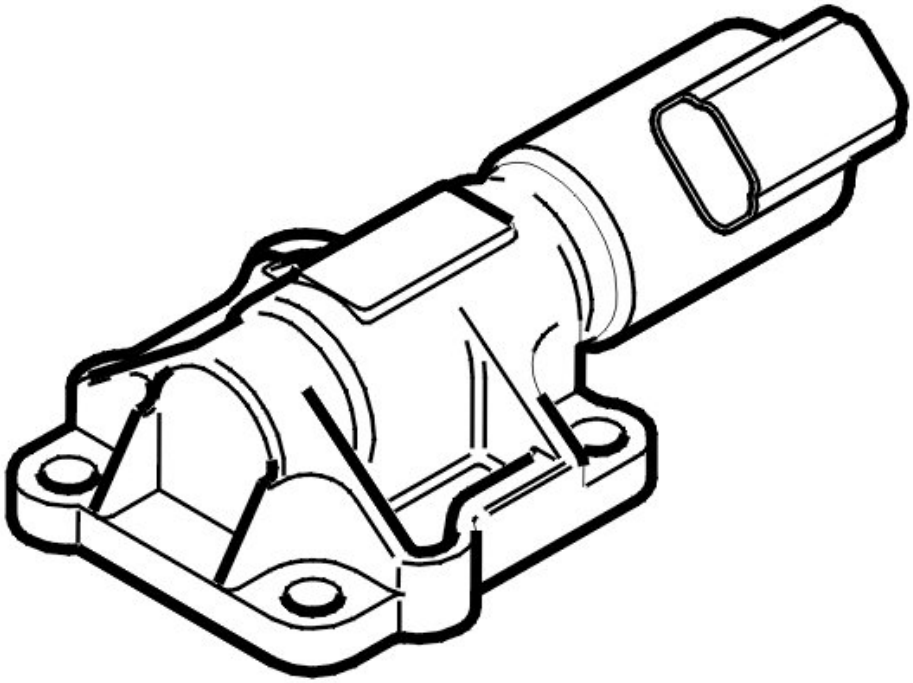
Diagnostic trouble code (DTC) information ECM-6140

Condition



The engine control module (ECM) checks that control of the exhaust camshaft is quick enough. This means that the exhaust camshaft (actual value) reaches the position requested by the engine control module (ECM) quickly enough. The diagnostic trouble code (DTC) is stored if the requested position is not reached within a certain time.
The diagnostic trouble code (DTC) can be diagnosed while the engine is running and while camshaft control is active.

Substitute value
- None.

Possible source
- Low oil pressure
- Poor oil quality
- Damaged reset valve
- Mechanical fault in the variable valve timing (VVT) unit.

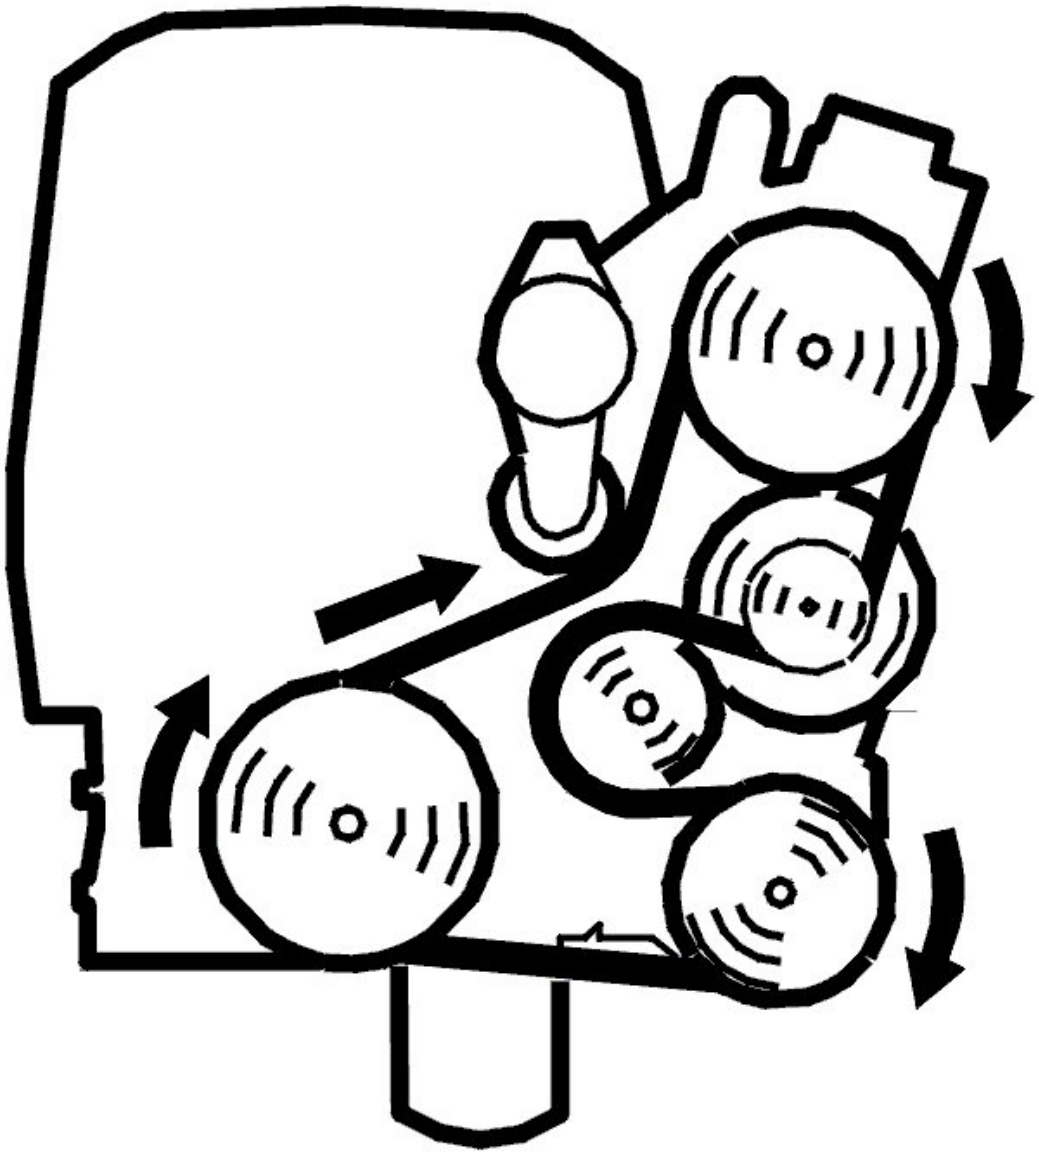
Fault symptom[s]
- Malfunction indicator lamp (MIL) lit.

Slow/Faulty

Slow/Faulty

Checking the status

Hint: Diagnostic trouble code (DTC) may be caused by a damaged fuse. If the engine does not start, check the fuse for the power supply to the camshaft reset valve.



- Start the engine
- Read off the value for the camshaft shift angle and the desired value for the camshaft shift angle
- Active the quick test of camshaft control by clicking the start button
- Increase the engine speed (RPM) to approximately 2500 rpm and keep the engine running at this speed.

When the engine speed (RPM) increases, the control module will start the quick test to control the shift angle of the camshaft to the different target values. There is a fault if the control module does not operate the camshaft shift angle to the different target values.
During the quick test, check that the shift angle of the camshaft (actual value) corresponds to the target values to an accuracy of ±10°. If the shift angle of the camshaft (target value) does not change, or if the actual value does not correspond to the target value, the function is faulty.

- Read off the value for the camshaft shift angle and the desired value for the camshaft shift angle
- Active the quick test of camshaft control by clicking the start button
- Increase the engine speed (RPM) to approximately 2500 rpm and keep the engine running at this speed.

When the engine speed (RPM) increases, the control module will start the quick test to control the shift angle of the camshaft to the different target values. There is a fault if the control module does not operate the camshaft shift angle to the different target values.
During the quick test, check that the shift angle of the camshaft (actual value) corresponds to the target values to an accuracy of ±10°. If the shift angle of the camshaft (target value) does not change, or if the actual value does not correspond to the target value, the function is faulty.
Deviation between the values can be read off in the lower display.
Carry out the check for approximately 15 seconds at an engine speed (RPM) of 2500 rpm. The test is completed when the shift angle of the camshaft returns to 0°. To restart the test, let the engine return to idle speed, then increase the engine speed to approximately 2500 rpm.

Note! The test is active until the ignition is switched off. Switch off the ignition before the car is delivered to the customer.

Diagnostic Trouble Code (DTC) Information

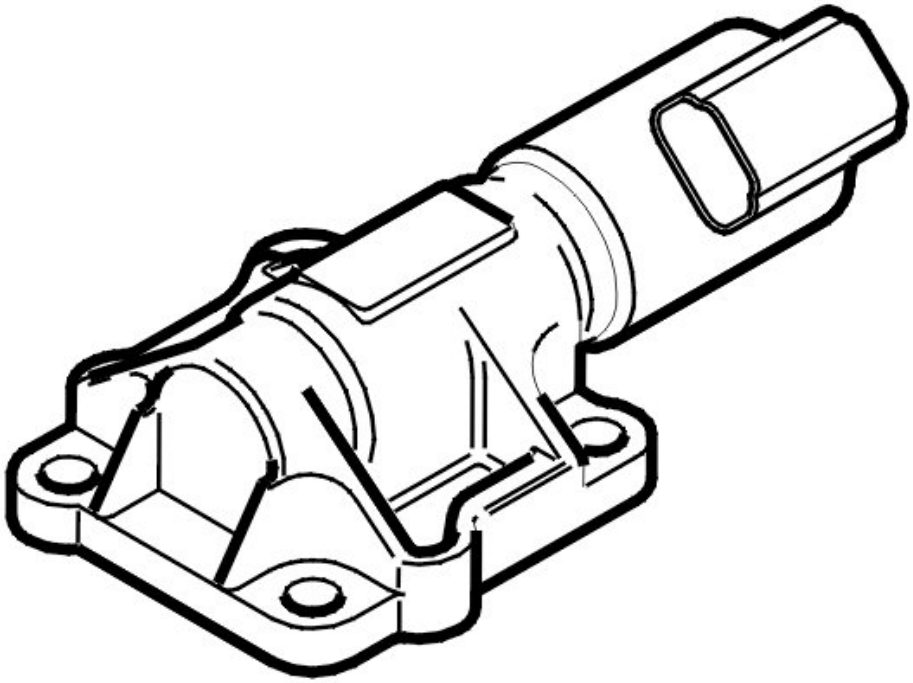
Diagnostic trouble code (DTC) information ECM-616D

Condition



The engine control module (ECM) checks the signal cable for the reset valve for the exhaust camshaft.
The diagnostic trouble code (DTC) is stored if the engine control module (ECM) detects that the signal from the signal cable for the reset valve is too low.
The diagnostic trouble code (DTC) can be diagnosed at ignition on and with the engine running.

Substitute value
- None.

Possible source
- Contact resistance in the terminals
- Short-circuit to ground in the signal cable
- Damaged camshaft reset valve.

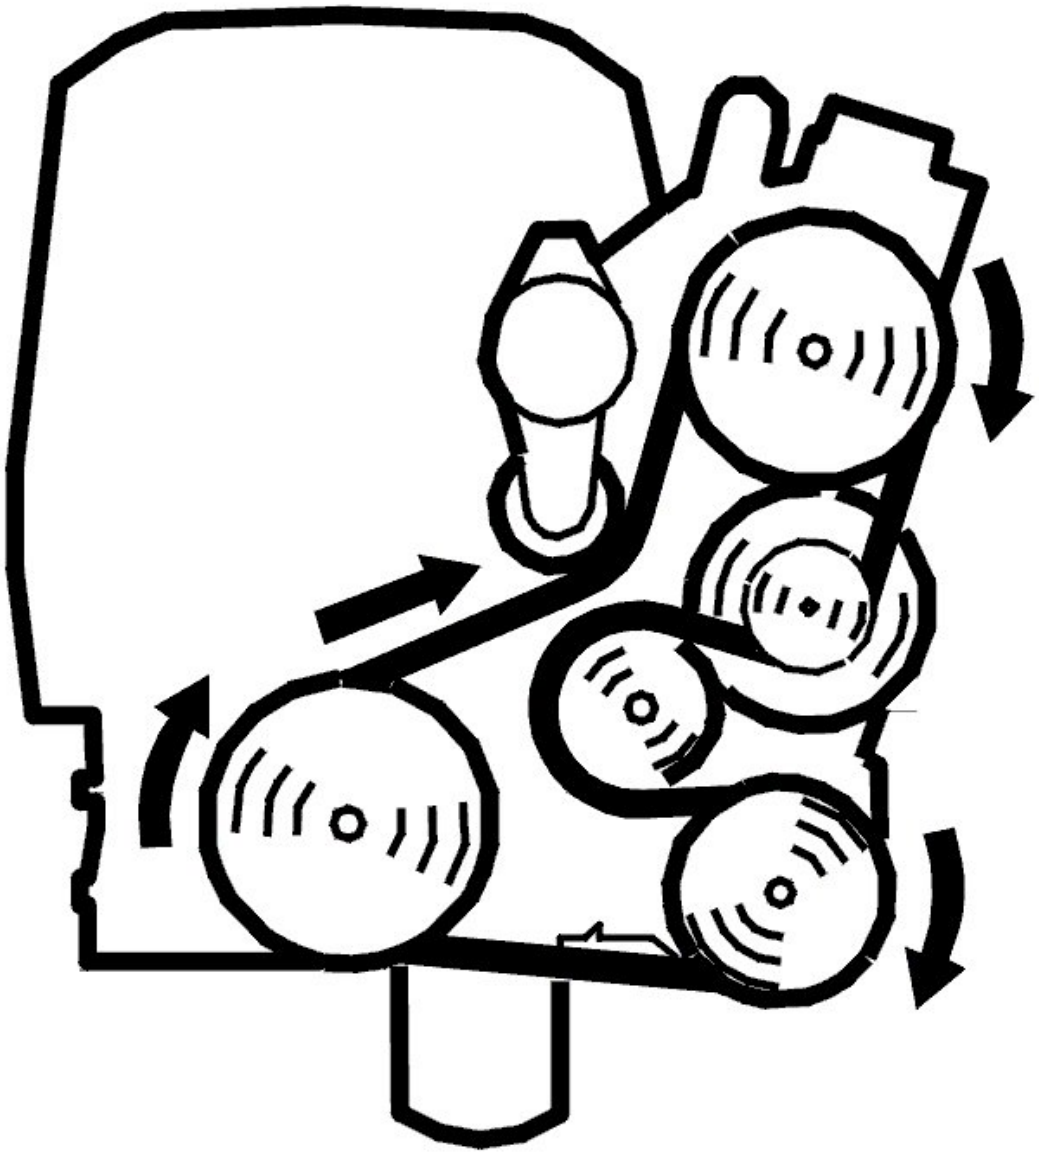
Fault symptom[s]
- Malfunction indicator lamp (MIL) lit.

Signal Too Low or Signal Missing

Signal too low or signal missing

Checking the status

Hint: The diagnostic trouble code (DTC) may be caused by a defective fuse. If the engine does not start, check the fuse for the power supply to the camshaft reset valve.



- Start the engine
- Read off the value for the camshaft shift angle and the desired value for the camshaft shift angle
- Active the quick test of camshaft control by clicking the start button
- Increase the engine speed (RPM) to approximately 2500 rpm and keep the engine running at this speed.

When the engine speed (RPM) increases, the control module will start the quick test to control the shift angle of the camshaft to the different target values. There is a fault if the control module does not operate the camshaft shift angle to the different target values.
During the quick test, check that the shift angle of the camshaft (actual value) corresponds to the target values to an accuracy of ±10°. If the shift angle of the camshaft (target value) does not change, or if the actual value does not correspond to the target value, the function is faulty.
Deviation between the values can be read off in the lower display.
Carry out the check for approximately 15 seconds at an engine speed (RPM) of 2500 rpm. The test is completed when the shift angle of the camshaft returns to 0°. To restart the test, let the engine return to idle speed, then increase the engine speed to approximately 2500 rpm.
The fault is intermittent if the function is OK.

Note! The test is active until the ignition is switched off. Switch off the ignition before the car is delivered to the customer.

Continue - Checking the wiring

Checking the wiring

Check the fuse before the circuit. If the fuse is blown, check the circuit for a short-circuit to ground.
Check the resistance of the camshaft reset valve between terminals #1 and #2.

The resistance must be approximately 3.7 ohms.
Check the signal cable between engine control module (ECM) terminal #A21 (#A21) and camshaft reset valve terminal #2. Check for an open-circuit. Check for a short-circuit to ground.
Check the power supply cable between system relay terminal #5 and camshaft reset valve terminal #1. Check for an open-circuit.

Hint: With the ignition on and the reset valve and camshaft connector disconnected, the voltage at connector terminal #1 must be approximately Ubat.

Remedy as necessary.

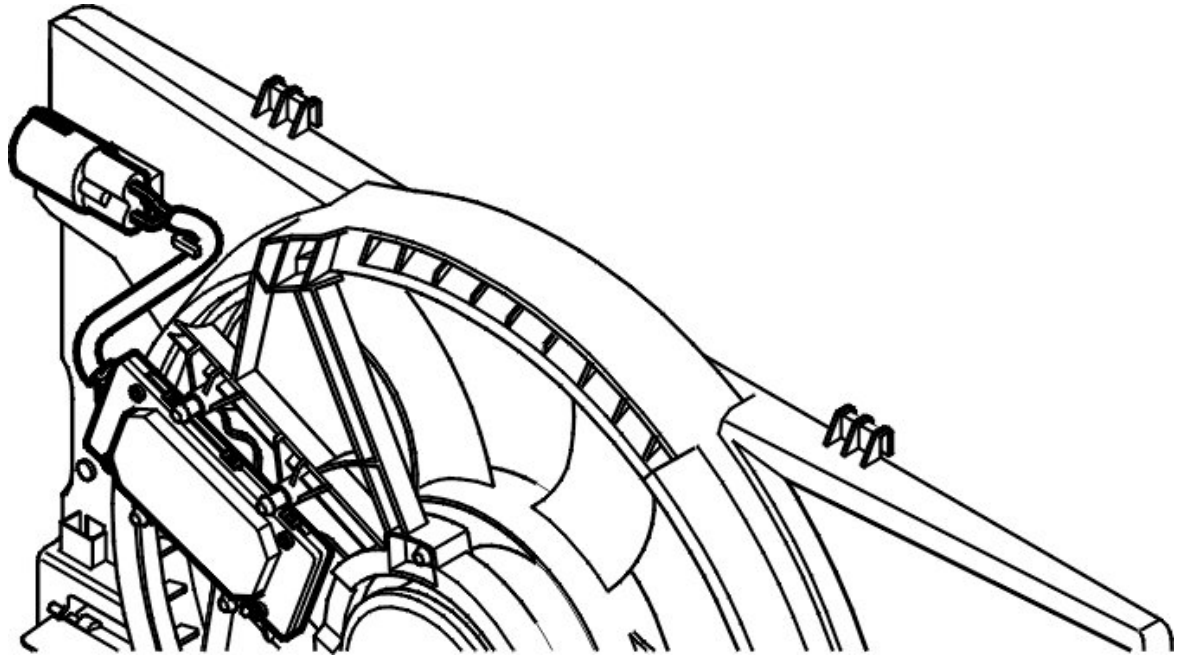
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information ECM-6200

Condition



The engine control module (ECM) checks the function of the engine cooling fan (FC). The diagnostic trouble code (DTC) is stored if an internal fault in the engine cooling fan (FC) is registered.
The diagnostic trouble code (DTC) can be diagnosed at ignition on or when the engine is running.

Note! The electric cooling fan may have a post-running time of up to approx. 6 minutes after the engine has been shut off. The time for the electric cooling fan's post-running depends on the engine's temperature, temperature in the engine compartment as well as the pressure level in the AC system.

Substitute value
- Engine cooling fan (FC) switched off.

Possible source
- Damaged engine cooling fan (FC).

Fault symptom[s]
- The engine cooling fan (FC) does not function.

Fault-Tracing Information

Caution! Avoid touching the pins in the control module and the corresponding connector on the cable harness. There is a risk of static discharge which could damage the control module. Discharge yourself and tools to be used by holding the tool's metal part and touching a body part on the car just before starting to work.

If the engine cooling fan (FC) cannot be activated at any speed:
- Check the fuse, power supply cable and ground lead for the engine cooling fan (FC).
- Check the connector and wiring between the engine control module (ECM) and engine cooling fan (FC) module. Check for damage. Check for an open circuit. Check for a short circuit.

If the engine cooling fan (FC) can be activated at one or more speeds:
- Check the connectors to the engine cooling fan (FC) control module and Engine Control Module (ECM). Check for damage to pins and connections.
- Also check other connectors and connections that connect cables between Engine Control Module (ECM) and the control module for electric cooling fan.
- Check the wiring between the engine control module (ECM) and the engine cooling fan (FC) module. Check for damage.

Remedy as necessary.

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information ECM-640C

Condition

The engine control module (ECM) checks the boost pressure.
The diagnostic trouble code (DTC) is stored if the ratio between the measured boost pressure (measured value from the boost pressure sensor before the throttle) and the calculated boost pressure (calculated value after the throttle) is incorrect.
The diagnostic trouble code (DTC) can be diagnosed when the engine is running.

Substitute value
- Reduced boost pressure.

Possible source
- Damaged boost pressure sensor
- Loose boost pressure sensor (the engine control module (ECM) measures the atmospheric pressure)
- Air leakage downstream of the turbocharger (TC) (between the turbocharger (TC) and the electronic throttle unit)
- Large air leak at the intake manifold (after the electronic throttle unit).

Fault symptom[s]
- Poor performance.

Signal Too High/Signal Too Low

Signal too high / Signal too low

Checking hoses and the turbocharger (TC) control valve

Check particularly that the boost pressure sensor is correctly installed and has not come loose.
Check the intake system for air leakage. Check in particular the hose between the turbocharger (TC) and the throttle unit.
The boost pressure sensor is damaged if no fault is found in the above fault-tracing.

Other information:
- Check for air leaks in the intake system See: Fuel Delivery and Air Induction/Testing and Inspection/Air Leaks in the Intake System, Checking
- Temperature and pressure sensor, replacing See: Coolant Temperature Sensor/Switch (For Computer)/Service and Repair.

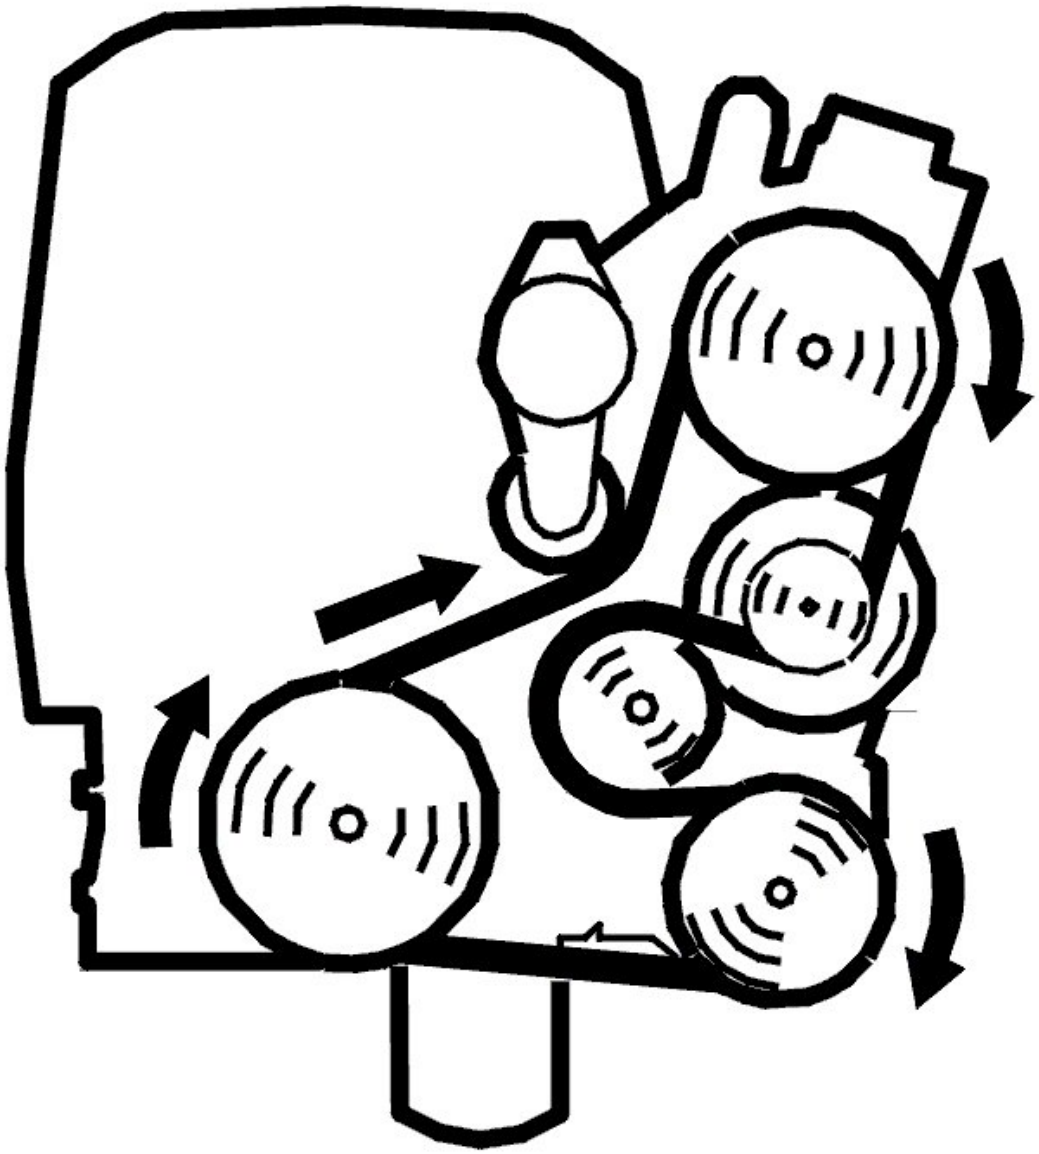
Continue - Verification

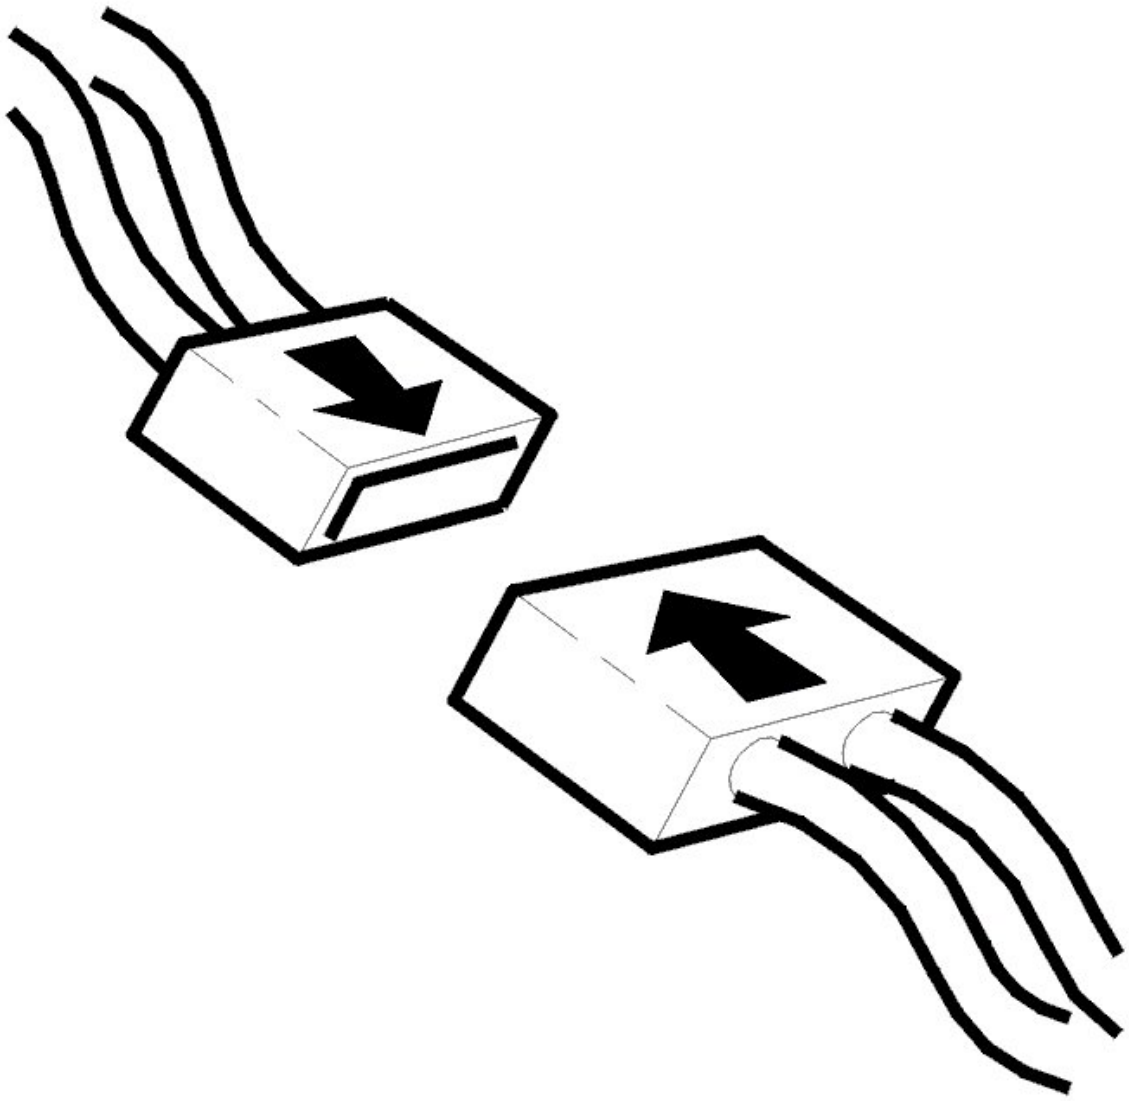
Verification

Verification

Verification

Hint: After carrying out the repair, check that the fault has been remedied.





- Ignition off
- Reconnect the connectors, reinstall components etc.
- Test drive the vehicle on the road. Ensure that high boost pressure is reached (high load) so that the engine control module (ECM) can run the diagnostic
- Connect VCT2000 to the data link connector (DLC) without switching off the engine.

Note! If the engine is switched off, the stored fault status will be erased and the test drive will have to be repeated.

Read off the diagnostic status and fault status for the diagnostic trouble code (DTC) by selecting the relevant diagnostic trouble code (DTC) from the list.
Check the fault status for the diagnostic trouble code (DTC) when the diagnostic is "Complete". If the function is correct, the fault status must be "No fault found" when the diagnostic is complete.

Diagnostic Trouble Code (DTC) Information

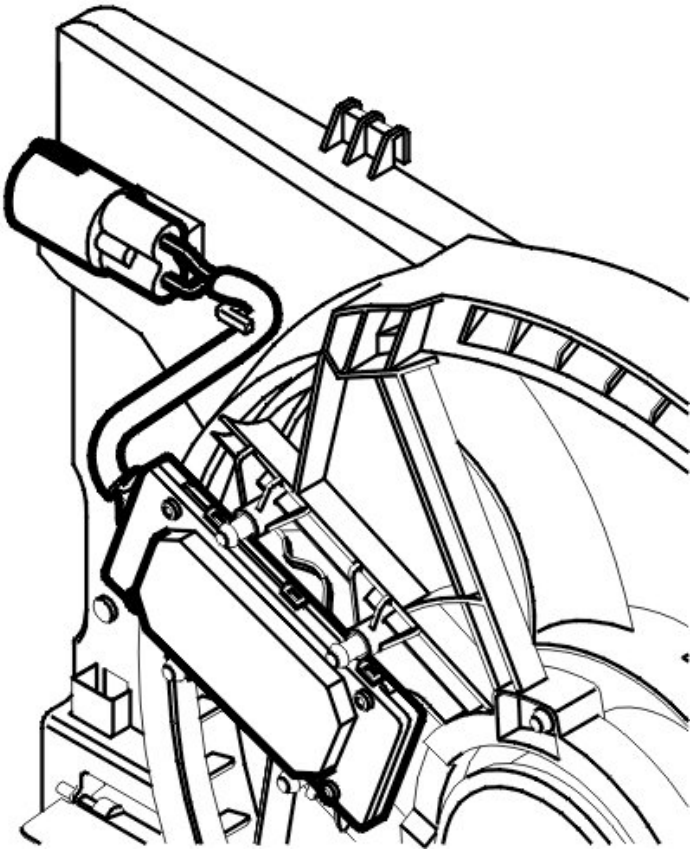
Diagnostic trouble code (DTC) information ECM-650B

Condition



The engine control module (ECM) checks the signal cable for the engine cooling fan (FC).
The diagnostic trouble code (DTC) is stored if the engine control module (ECM) detects that the signal for the engine cooling fan (FC) is missing.
The diagnostic trouble code (DTC) can be diagnosed at ignition on or when the engine is running.

Note! The electric cooling fan may have a post-running time of up to approx. 6 minutes after the engine has been shut off. The time for the

electric cooling fan's post-running depends on the engine's temperature, temperature in the engine compartment as well as the pressure level in the AC system.

Substitute value
- None.

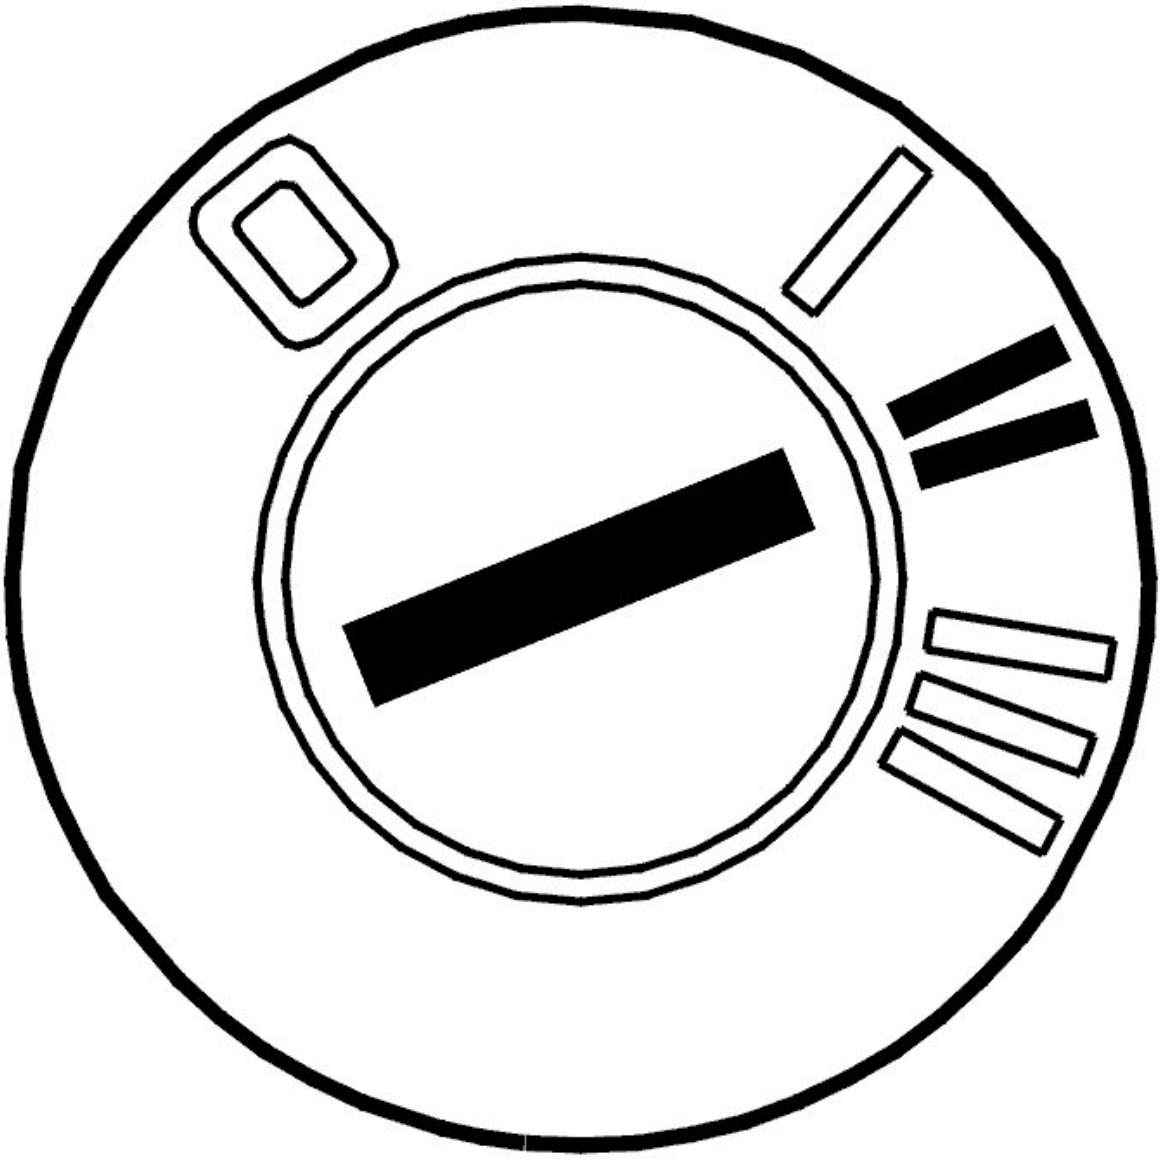
Possible source
- Open-circuit in the signal cable
- Damaged engine cooling fan (FC).

Fault symptom[s]
- Electric cooling fan does not operate
- The engine cooling fan (FC) operates constantly.

Signal Missing

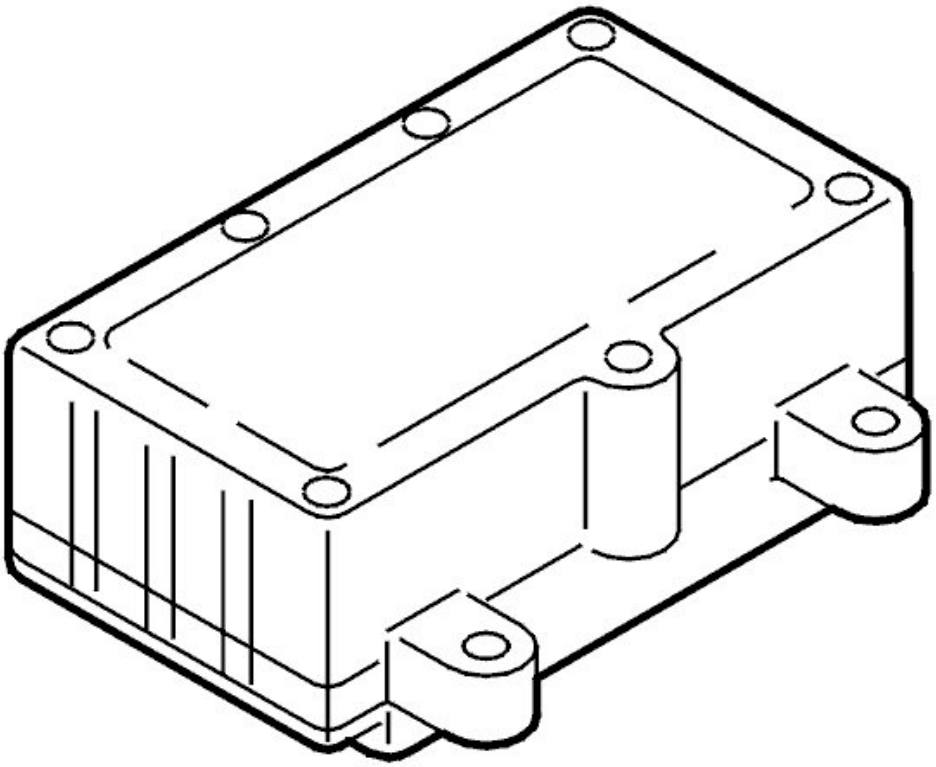
Signal missing

Checking the component



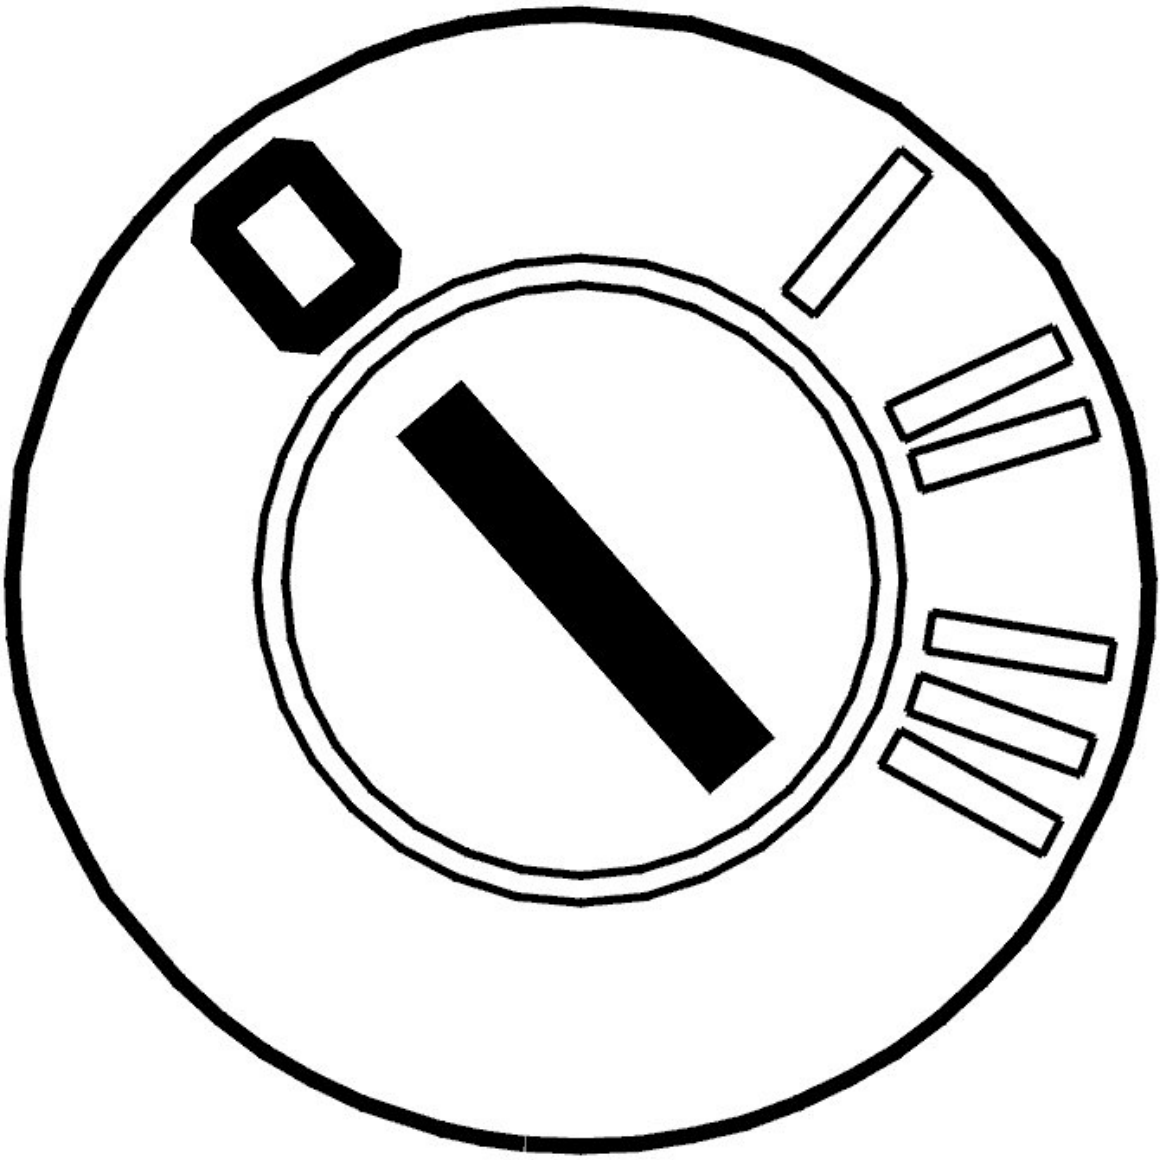
- Ignition off.
- Check that the engine cooling fan (FC) blade rotates easily. Check that nothing is obstructing the engine cooling fan (FC) blade.
- Remedy as necessary.
- Ignition on.
- Check all speeds of the engine cooling fan (FC).

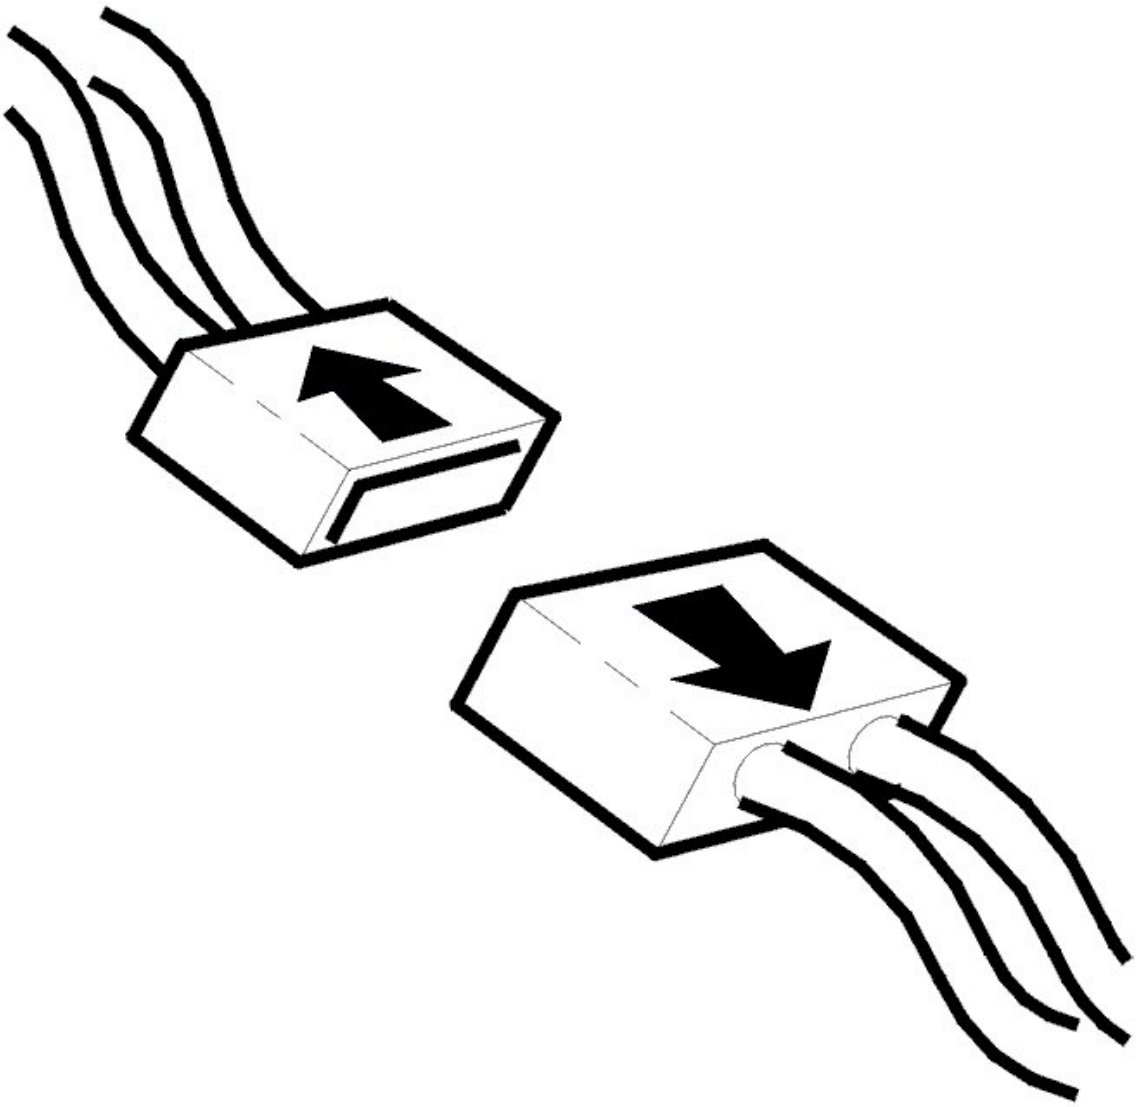
Activate the engine cooling fan (FC) by clicking the VCT2000 symbol.



Continue - Checking the component and wiring

Replacing a component





- Ignition off.

Caution! Avoid touching the pins in the control module and the corresponding connector on the cable harness. There is a risk of static discharge which could damage the control module. Discharge yourself and tools to be used by holding the tool's metal part and touching a body part on the car just before starting to work.

Replace the engine cooling fan (FC) control module if the engine cooling fan (FC) cannot be activated at all speeds and no faults have been found on wiring and connections.
Remedy as necessary.

Other information

Diagnostic Trouble Code (DTC) Information

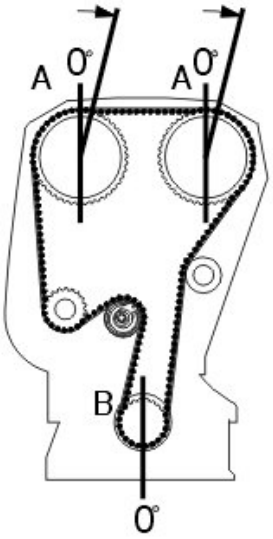
Diagnostic trouble code (DTC) information ECM-6700

Condition



The engine control module (ECM) checks the angle of the camshaft (its position in relation to the crankshaft).
If the Engine control module (ECM) detects that the intake camshaft's angle position changes dramatically when idling, the Engine control module (ECM) interprets this as a fault and stores a DTC.
The diagnostic trouble code (DTC) can be diagnosed when the engine is hot and the camshaft is in position 0.
For more information, see Design and Function.

Substitute value
- The Engine control module (ECM) switches off camshaft control.

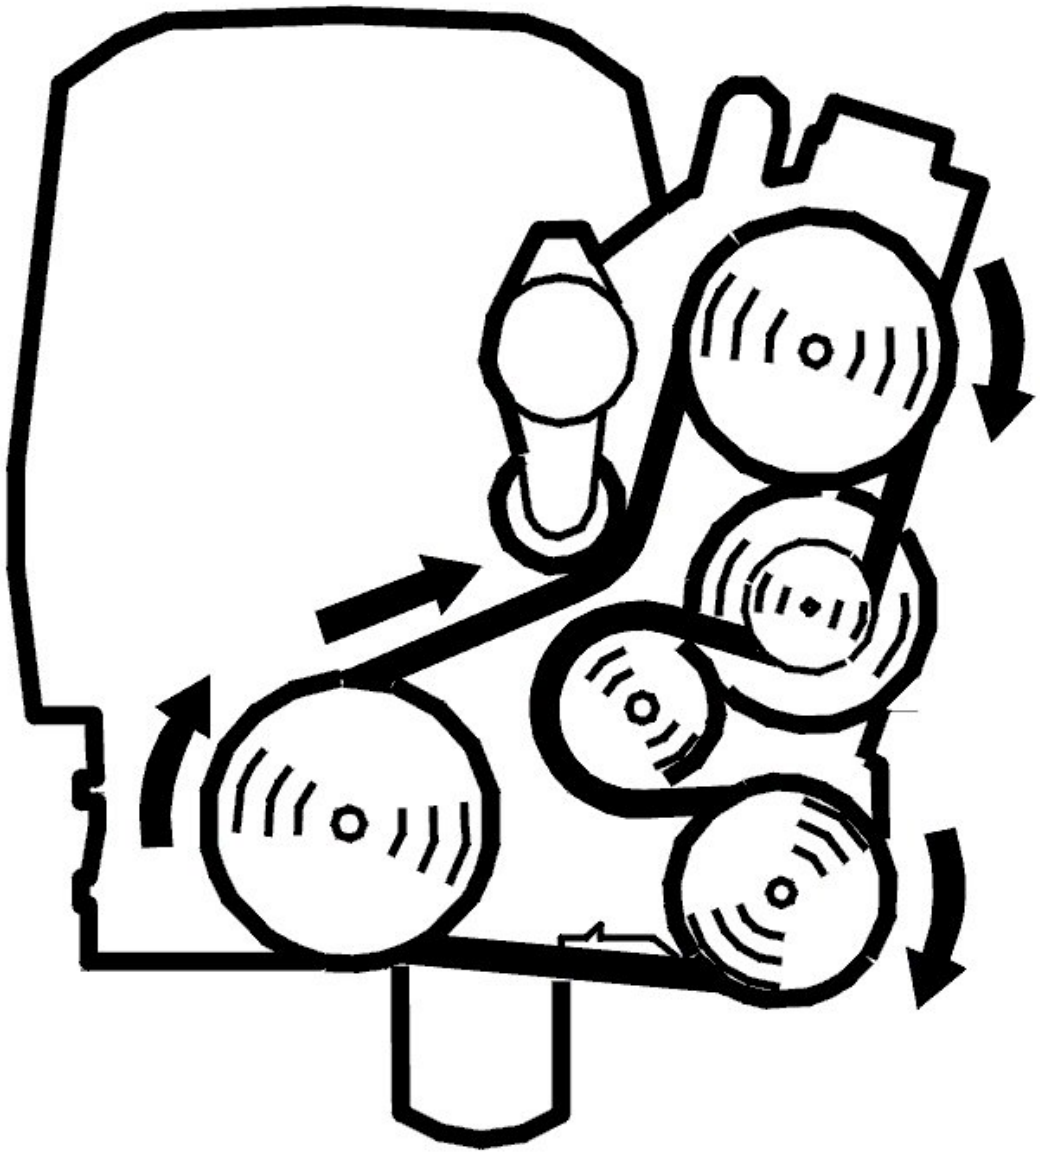
Possible source
- Incorrectly adjusted camshafts
- The timing gear belt has jumped off the cogs
- Damaged camshaft reset valve
- Mechanical fault in the variable valve timing (VVT) unit.

Fault symptom[s]
- Malfunction indicator lamp (MIL) lit.

Fault-tracing

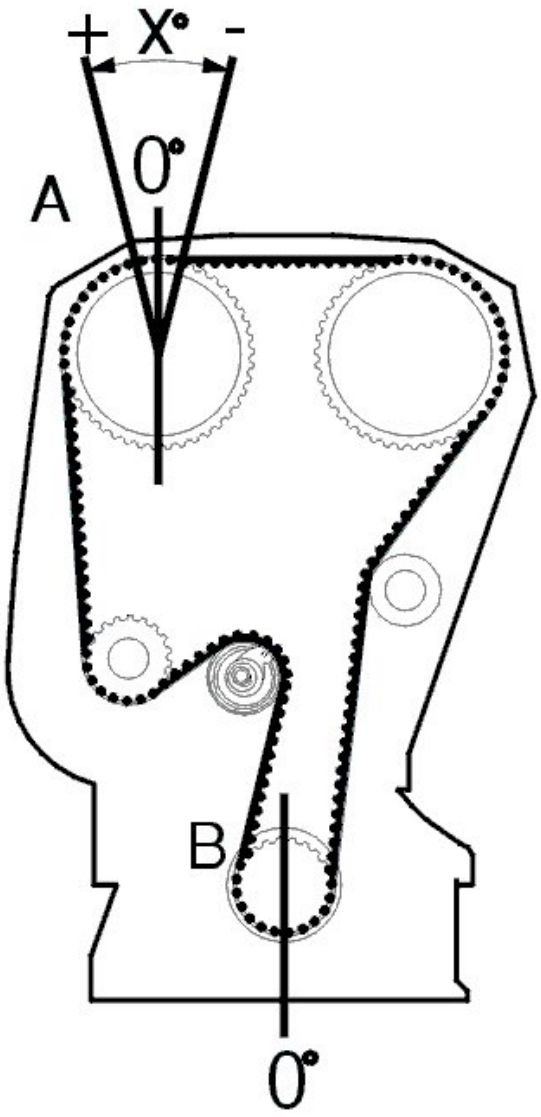
Fault-tracing

Checking the status



- Start the engine and run it to normal operating temperature
- Read off and note the adaptation value for the camshaft at idle speed. The value must be between -8° and +8°.

The fault is intermittent if the adaptation value is between -8° and +8°. The fault is permanent if the adaptation value is lower than -8° or higher than +8°.



Is the adaptation value correct?

Yes - Intermittent fault

No - Checking components

Checking components

For the variable valve timing control to work, the engine oil must be at the correct level, of the correct grade and free of contaminants. Check the level and quality of the engine oil. Check for contaminants in particular.
If the adaptation value is too high (higher than +8°) when the engine is at operating temperature, the cause of the fault is probably one of the following:

- Camshaft belt incorrectly seated
- Incorrect basic setting of the timing belt
- Faulty camshaft reset valve (the slide in the valve has stuck).

Try to adjust the basic setting of the camshaft. Then read off the adaptation value for the camshaft with the engine idling and at operating temperature. The value must be between -8° and +8°. If the adaptation value is incorrect when the basic setting of the camshaft is correct, try cleaning the camshaft reset valve.

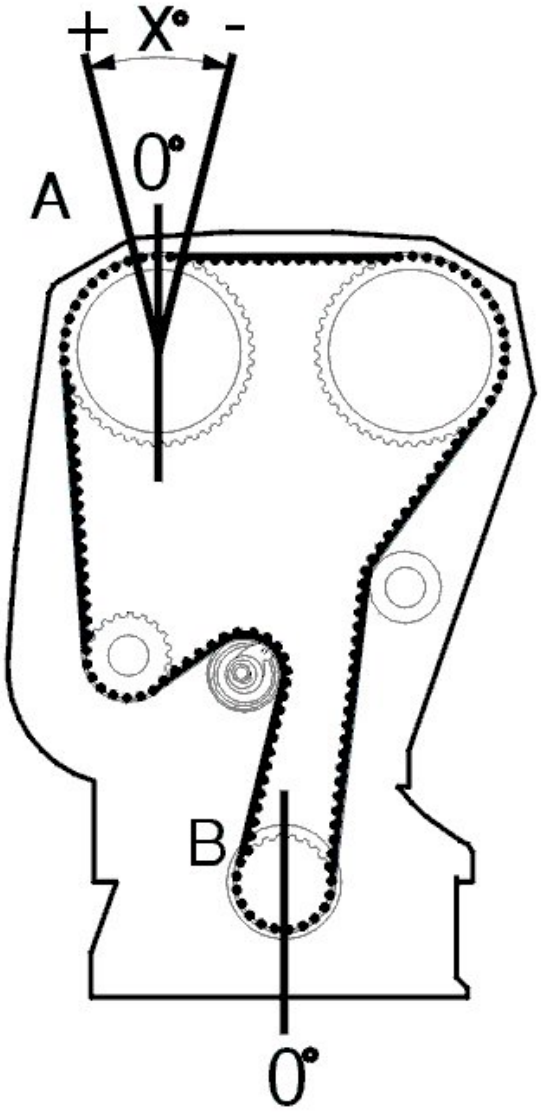
Note! The camshafts must be adjusted using the adjustment tool for the camshafts and crankshaft in the prescribed manner.

Try a new camshaft reset valve if the above fault-tracing does not solve the fault.
Remedy as necessary.

Hint: The fault can also be caused by a damaged variable valve timing unit. The variable valve timing unit may be damaged if the above fault-tracing and corrective action do not remedy the fault.

Other information:

- VVT solenoid, inspection and cleaning See: Variable Valve Timing Solenoid/Service and Repair/Procedures/VVT Solenoid, Inspection and Cleaning
- To adjust camshaft settings: Camshaft seal/variable valve timing (VVT) unit, replacing See: Variable Valve Timing Actuator/Service and Repair/Camshaft Seal/Variable Valve Timing (VVT) Unit, Replacing
- Variable valve timing solenoid, replacing See: Variable Valve Timing Actuator/Service and Repair/Variable Valve Timing Solenoid, Replacing



Continue - Verification

Intermittent fault

If the diagnostic trouble code (DTC) for this fault is stored but the adaptation value is correct, the fault is intermittent. Cause of the intermittent fault is probably a damaged camshaft reset valve.

Hint: The fault can be caused by contaminants in the camshaft reset valve. Try cleaning the valve.

Other information:

- VVT solenoid, inspection and cleaning See: Variable Valve Timing Solenoid/Service and Repair/Procedures/VVT Solenoid, Inspection and Cleaning
- Variable valve timing solenoid, replacing See: Variable Valve Timing Actuator/Service and Repair/Variable Valve Timing Solenoid, Replacing

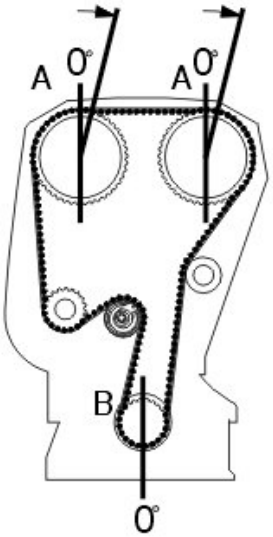
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information ECM-670C

Condition



The engine control module (ECM) checks the angle of the camshaft (its position in relation to the crankshaft).
If the inlet camshaft's angle position deviates and is too high during adaption (camshaft is ahead of crankshaft), the Engine control module (ECM) will interpret this as a failure and store a diagnostic trouble code.
The diagnostic trouble code (DTC) can be diagnosed when the engine is hot and the camshaft is in position 0.
For more information, see Design and Function.

Substitute value

- The Engine control module (ECM) switches off camshaft control.

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

Possible source

- Poor engine oil quality
- Incorrectly adjusted camshafts
- The timing gear belt has jumped off the cogs
- Damaged camshaft reset valve
- Mechanical fault in the variable valve timing (VVT) unit.

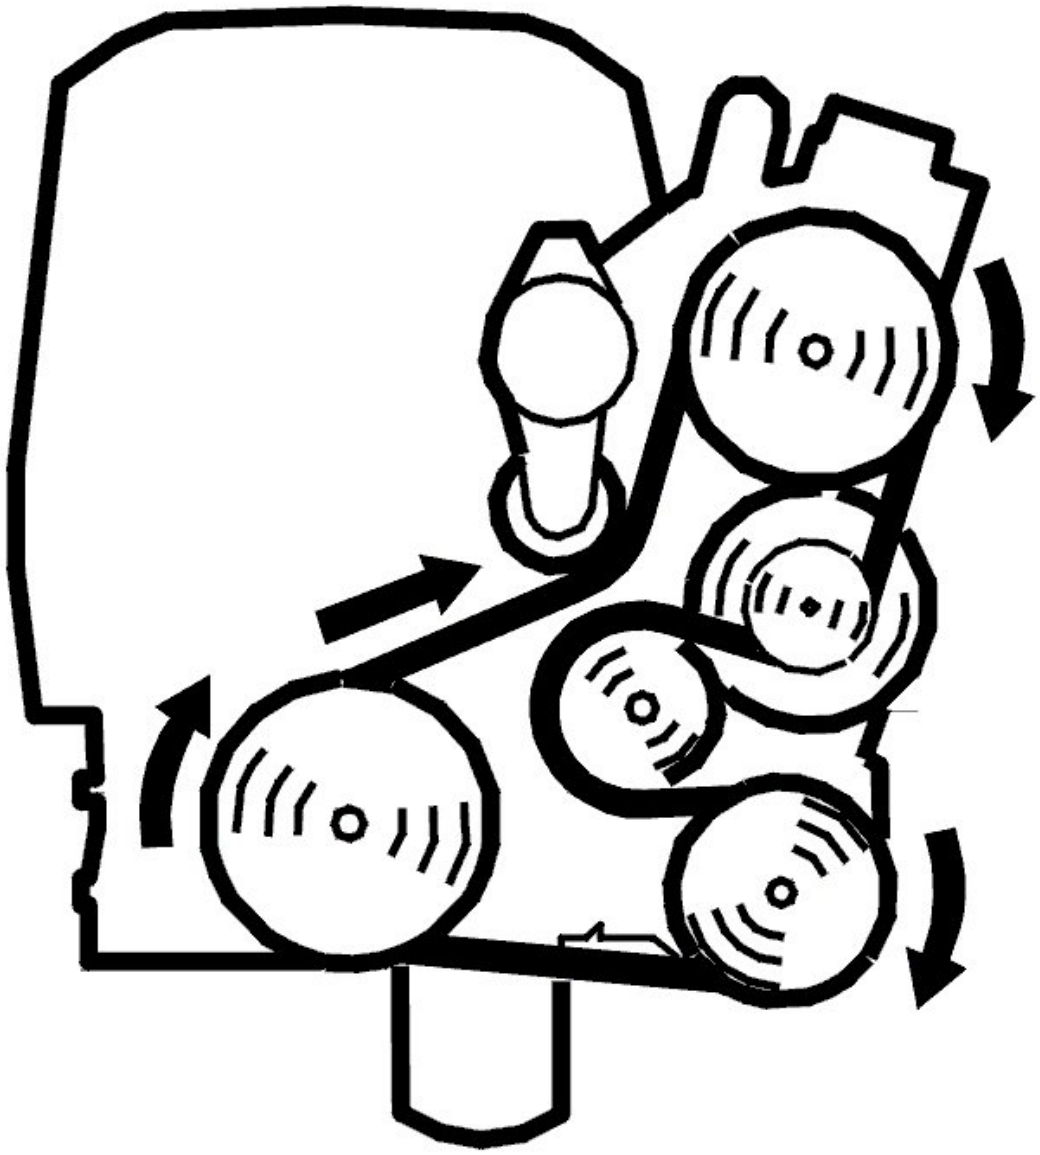
Fault symptom[s]

- Malfunction indicator lamp (MIL) lit.

High

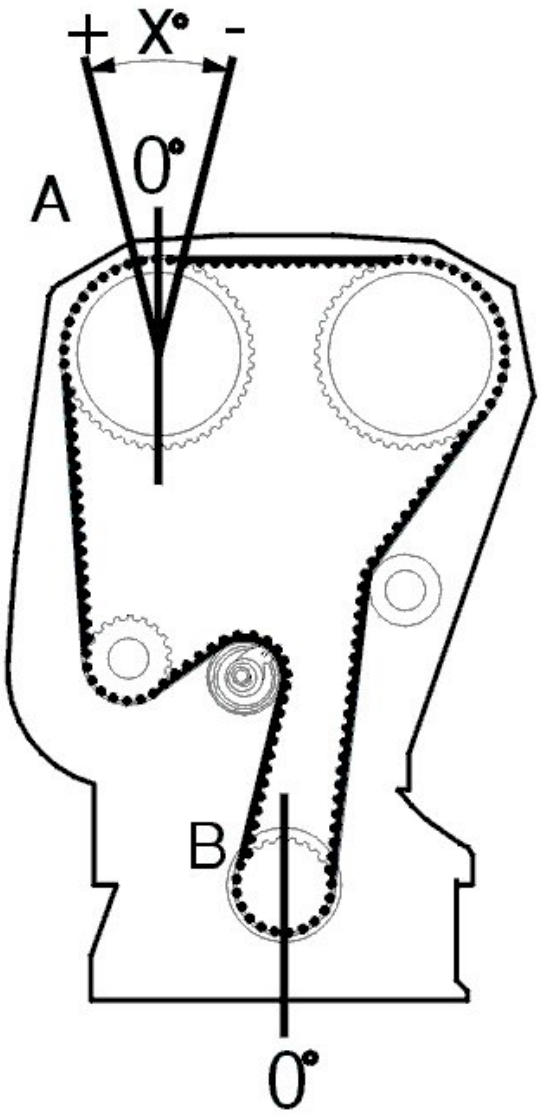
High

Checking the status



- Start the engine and run it to normal operating temperature
- Read off and note the adaptation value for the camshaft at idle speed. The value must be between -8° and +8°.

The fault is intermittent if the adaptation value is between -8° and +8°. The fault is permanent if the adaptation value is lower than -8° or higher than +8°.



Is the adaptation value correct?

Yes - Intermittent fault

No - Checking components

Checking components

For the variable valve timing control to work, the engine oil must be at the correct level, of the correct grade and free of contaminants. Check the level and quality of the engine oil. Check for contaminants in particular.
If the adaptation value is too high (higher than +8°) when the engine is at operating temperature, the cause of the fault is probably one of the following:

- Camshaft belt incorrectly seated
- Incorrect basic setting of the timing belt
- Faulty camshaft reset valve (the slide in the valve has stuck).

Try to adjust the basic setting of the camshaft. Then read off the adaptation value for the camshaft with the engine idling and at operating temperature. The value must be between -8° and +8°. If the adaptation value is incorrect when the basic setting of the camshaft is correct, try cleaning the camshaft reset valve.

Note! The camshafts must be adjusted using the adjustment tool for the camshafts and crankshaft in the prescribed manner.

Try a new camshaft reset valve if the above fault-tracing does not solve the fault.
Remedy as necessary.

Hint: The fault can also be caused by a damaged variable valve timing unit. The variable valve timing unit may be damaged if the above fault-tracing and corrective action do not remedy the fault.

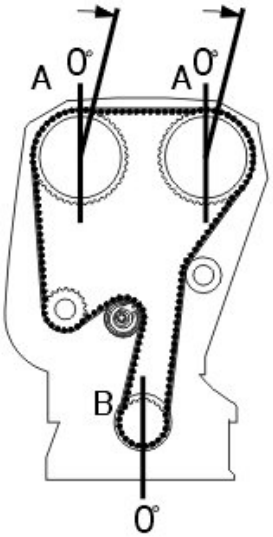
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information ECM-670D

Condition



The engine control module (ECM) checks the angle of the camshaft (its position in relation to the crankshaft).
If the intake camshaft's angle position deviates and is too low (the camshaft is "after" the crankshaft) during fuel trim, the Engine control module (ECM) interprets this as a fault and stores a DTC.
The diagnostic trouble code (DTC) can be diagnosed when the engine is hot and the camshaft is in position 0.
For more information, see Design and Function.

Substitute value

- None. The Engine control module (ECM) switches off camshaft control.

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

Possible source

- Poor engine oil quality
- Incorrectly adjusted camshafts
- The timing gear belt has jumped off the cogs.
- Air conditioning (A/C) compressor. Damaged camshaft reset valve.
- Mechanical fault in the variable valve timing (VVT) unit.

Fault symptom[s]

FAULT FOUND - DONE

Diagnostic Trouble Code (DTC) Information

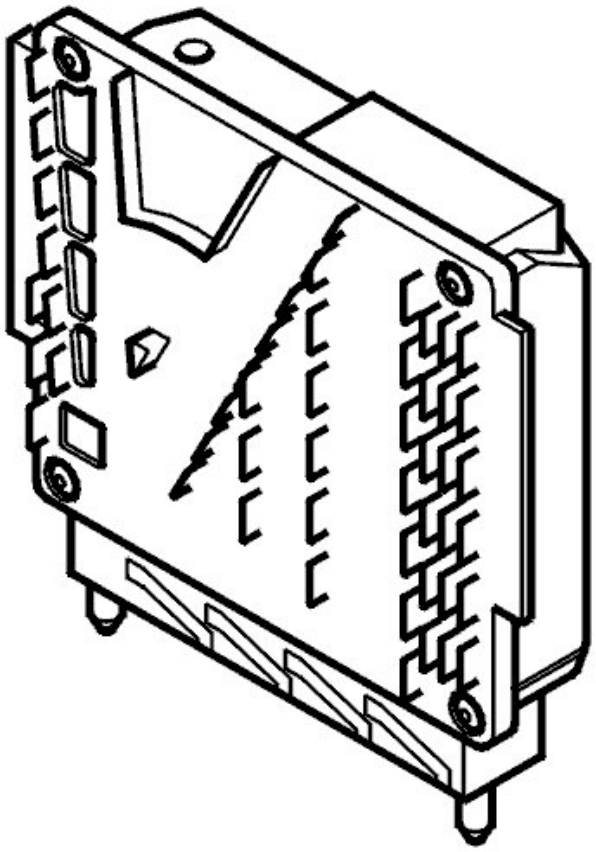
Diagnostic trouble code (DTC) information ECM-7010

Condition



The diagnostic trouble code (DTC) is stored if the temperature in the engine control module (ECM) exceeds 95 °C.
The diagnostic trouble code (DTC) can be diagnosed when the ignition is switched on.

Substitute value
- The engine cooling fan (FC) runs at low-speed.

Possible source
- Air supply is blocked.

Fault symptom[s]
- None.

Faulty Signal

Faulty signal

Checking the component

Hint: The diagnostic trouble code (DTC) may due to a damaged cooling fan for the control module boxes. If diagnostic trouble code (DTC) ECM-680X is stored it must be remedied first.

Activate the cooling fan for the control module box. Check the function. There must be a buzzing noise from the cooling fan when the fan for the control module box is activated.
Check that the air ducts for the control module box are not blocked.
Remedy as necessary.

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information ECM-7100

Condition

The engine control module (ECM) contains a code for the immobilizer which is unique to each car. Before the engine can be started, the immobilizer code is checked to ensure that it corresponds to both the central electronic module (CEM) and the engine control module (ECM). The diagnostic trouble code (DTC) is stored if the immobilizer code does not correspond.
The diagnostic trouble code (DTC) can be diagnosed when the ignition is switched on.

Substitute value

None

Possible source
- The engine control module (ECM) is not programmed and has no immobilizer code
- The immobilizer code in the engine control module (ECM) is incorrect
- The immobilizer code in the central electronic module (CEM) is incorrect
- The central electronic module (CEM) is not programmed and has no immobilizer code
- Damaged central electronic module (CEM)
- Damaged engine control module (ECM).

Fault symptom[s]
- The engine does not start.

Faulty Signal - Permanent Fault

Faulty signal. Permanent fault

Information

This diagnostic trouble code (DTC) indicates that the immobilizer code does not match between the engine control module (ECM) and the central electronic module (CEM). This may be because:
- the immobilizer code in the engine control module (ECM) is incorrect i.e. the code does not correspond to the code stored in the central electronic module (CEM)
- the engine control module (ECM) is not programmed and has no immobilizer code
- the immobilizer code in the central electronic module (CEM) is incorrect
- the central electronic module (CEM) is not programmed and has no immobilizer code
- the engine control module (ECM) is damaged
- the central electronic module (CEM) is damaged.

Note! A programmed engine control module (ECM) or central electronic module (CEM) cannot be moved from one vehicle to another.

Hint: Read off the diagnostic trouble codes (DTCs) for the central electronic module (CEM).

For further information about this diagnostic trouble code (DTC), see Diagnostic Trouble Code (DTC) Information.

Other information:
- To access and replace the engine control module (ECM), see Engine control module (ECM), replacing See: Engine Control Module/Service and Repair
- To access or replace the central electronic module (CEM), see Central electronic module (CEM), replacing See: Body Control Module/Service and Repair/Central Electronic Module (CEM), Replacing
- For information about signals, see Signal specification See: Pinout Values and Diagnostic Parameters/Signal Description / Specification

- Reinstall connectors, components etc.
- Start the engine.

Did the engine start?

Yes - Fault Found

No - Fault-tracing information

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information ECM-710B

Condition

The engine control module (ECM) contains a code for the immobilizer which is unique to each car. Before the engine can be started, the immobilizer code is checked to ensure that it corresponds to both the central electronic module (CEM) and the engine control module (ECM).
The diagnostic trouble code (DTC) will be stored if there is no communication between the central electronic module (CEM) and the engine control module (ECM) so that the immobilizer code cannot be checked.
The diagnostic trouble code (DTC) can be diagnosed when the ignition is switched on.

Substitute value

None

Possible source
- Open-circuit in the communication between the central electronic module (CEM) and the engine control module (ECM).

Fault symptom[s]
- The engine does not start.

Signal Missing, Permanent Fault

Signal missing. Permanent fault

Checking the component

The immobilizer function is integrated in the central electronic module (CEM).
This diagnostic trouble code (DTC) can be caused by missing CAN communication. If there is a diagnostic trouble code (DTC) stored in the central electronic module (CEM) fault trace accordingly.
If no diagnostic trouble codes (DTCs) are stored in the central electronic module (CEM), try a new central electronic module (CEM).

Other information:
- To access or replace the central electronic module (CEM), see Central electronic module (CEM), replacing See: Body Control Module/Service and Repair/Central Electronic Module (CEM), Replacing
- To access and replace the engine control module (ECM), see Engine control module (ECM), replacing See: Engine Control Module/Service and Repair

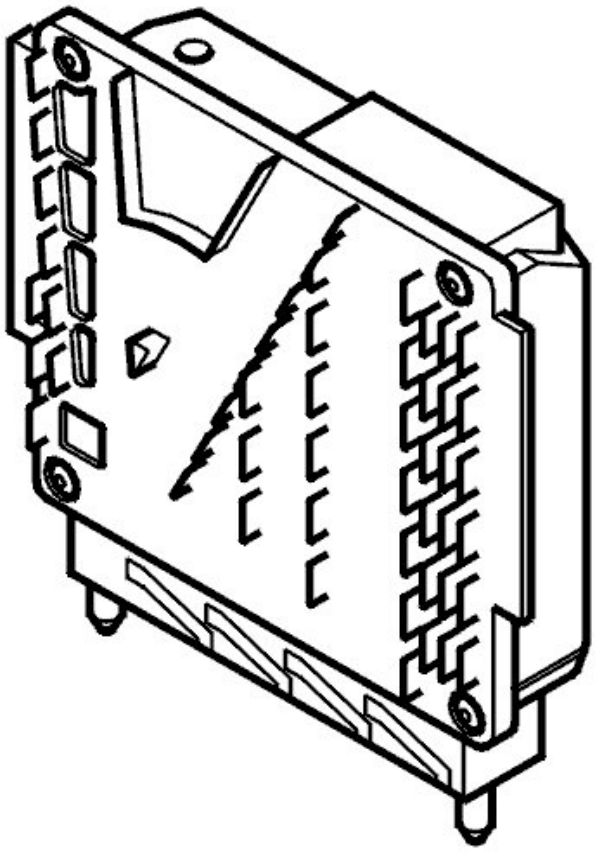
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information ECM-720B

Condition



The diagnostic trouble code (DTC) is stored if the engine control module (ECM) registers a fault in the circuit for the timer functions.

Substitute value
- None.

Possible source
- Damaged engine control module (ECM).

Fault symptom[s]
- Malfunction indicator lamp (MIL) lit.

Internal Fault

Internal fault

Replacing the component

The engine control module (ECM) has registered an internal fault.
If the fault is intermittent, it has been registered previously but is no longer present. Intermittent faults can be caused by interference at start up of the engine control module (ECM) or may be a different type of fault which occurs on different occasions. The fault is evaluated depending on how it occurs. Replace the engine control module (ECM) if the fault recurs.
Replace the engine control module (ECM) in the event of a permanent fault.
Engine control module (ECM), replacing See: Engine Control Module/Service and Repair
Remedy as necessary.

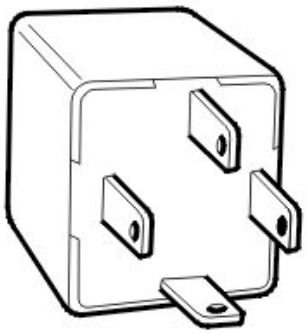
There is no fault-tracing for this diagnostic fault code (DTC).
For further information on this diagnostic trouble code, see Diagnostic trouble code (DTC) information.

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information ECM-800B

Condition



The engine control module (ECM) checks the function of the system relay. The diagnostic trouble code (DTC) is stored if the engine control module (ECM) registers that the voltage from the system relay is too low when the relay is activated.
The diagnostic trouble code (DTC) can be diagnosed when the ignition is switched on.

Substitute value
- None.

Possible source
- Contact resistance in the terminals
- Open-circuit in the signal cable for the system relay
- Damaged system relay.

Fault symptom[s]
- The engine does not start.

Signal Too Low

Signal too low

Checking connectors and components

Check the engine control module (ECM) and the system relay connectors. Check for contact resistance. Check for oxidation.
Check the cable between system relay terminal #5 and the engine control module (ECM). Check for an open-circuit.
Remedy as necessary.
Try a new system relay if no fault is found during the above fault-tracing.

Hint: Read off the voltage from the system relay to the engine control module (ECM) by clicking on the VCT2000 symbol.

Diagnostic Trouble Code (DTC) Information

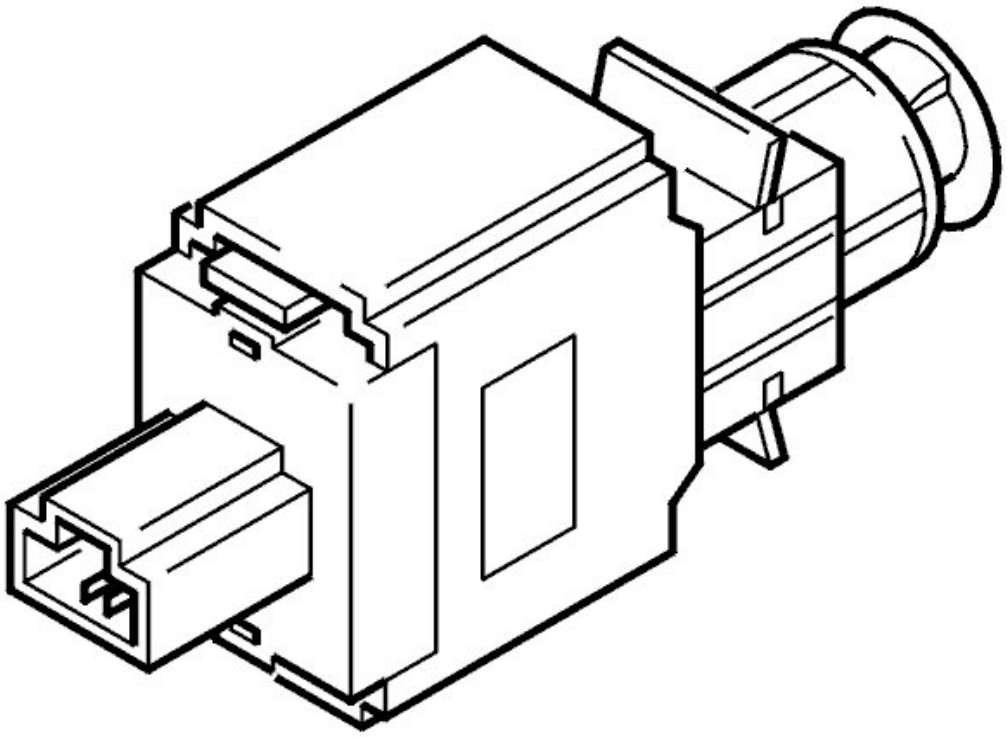
Diagnostic trouble code (DTC) information ECM-9000

Condition



The diagnostic trouble code (DTC) is stored if the engine control module (ECM) registers a fault in the circuit for the brake pedal position sensor, the circuit for the stop lamp switch or in the CAN communication between the brake control module (BCM) and the engine control module (ECM). The diagnostic trouble code (DTC) can be diagnosed when the engine is running.

Substitute value

Cruise control switched off.

Possible source
- Fault in the brake control module (BCM) or the central electronic module (CEM)
- Contact resistance or oxidation in the terminals between the engine control module (ECM) and the stop lamp switch
- Open-circuit in the power supply to the stop lamp switch
- Open-circuit or short-circuit to ground or supply voltage in the cable for the stop lamp switch
- Incorrectly installed stop lamp switch
- Damaged stop lamp switch.

Fault symptom[s]
- Cruise control/Does not engage
- Text window and warning symbol/Text message

Signal Missing or Faulty Signal

Signal missing or faulty signal

Checking the diagnostic trouble codes (DTCs)

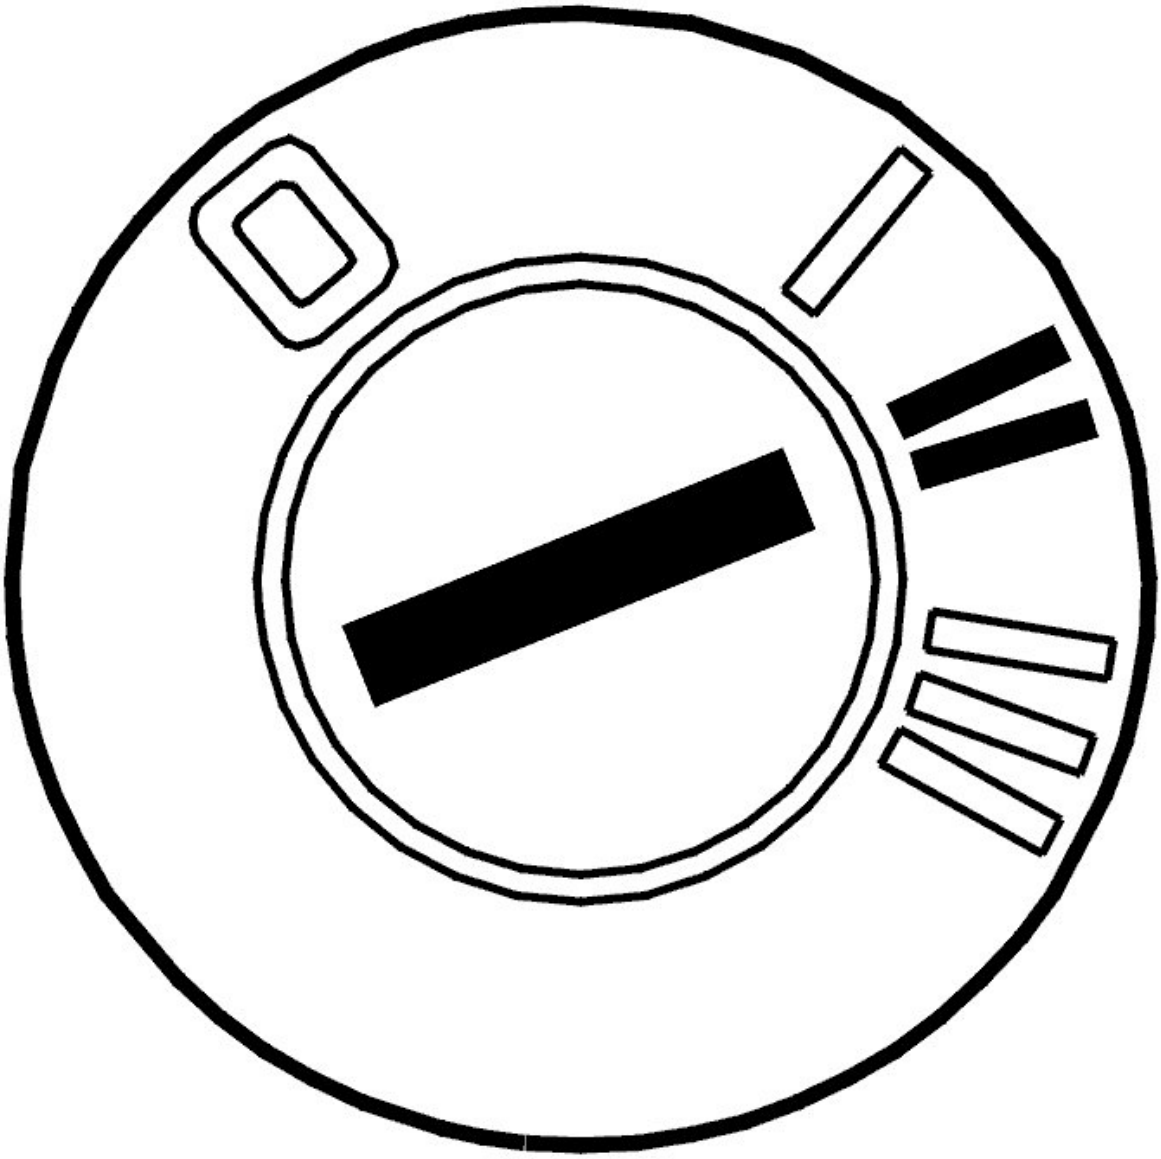
Check whether any diagnostic trouble codes (DTCs) are stored in the brake control module (BCM) or in the central electronic module (CEM). Any diagnostic trouble codes (DTCs) stored in the brake control module (BCM) or central electronic module (CEM) must be remedied first.

Have fault causes been traced or remedied in the brake control module (BCM) and the central electronic module (CEM)?

Yes - Checking the status

No - DONE

Checking the status

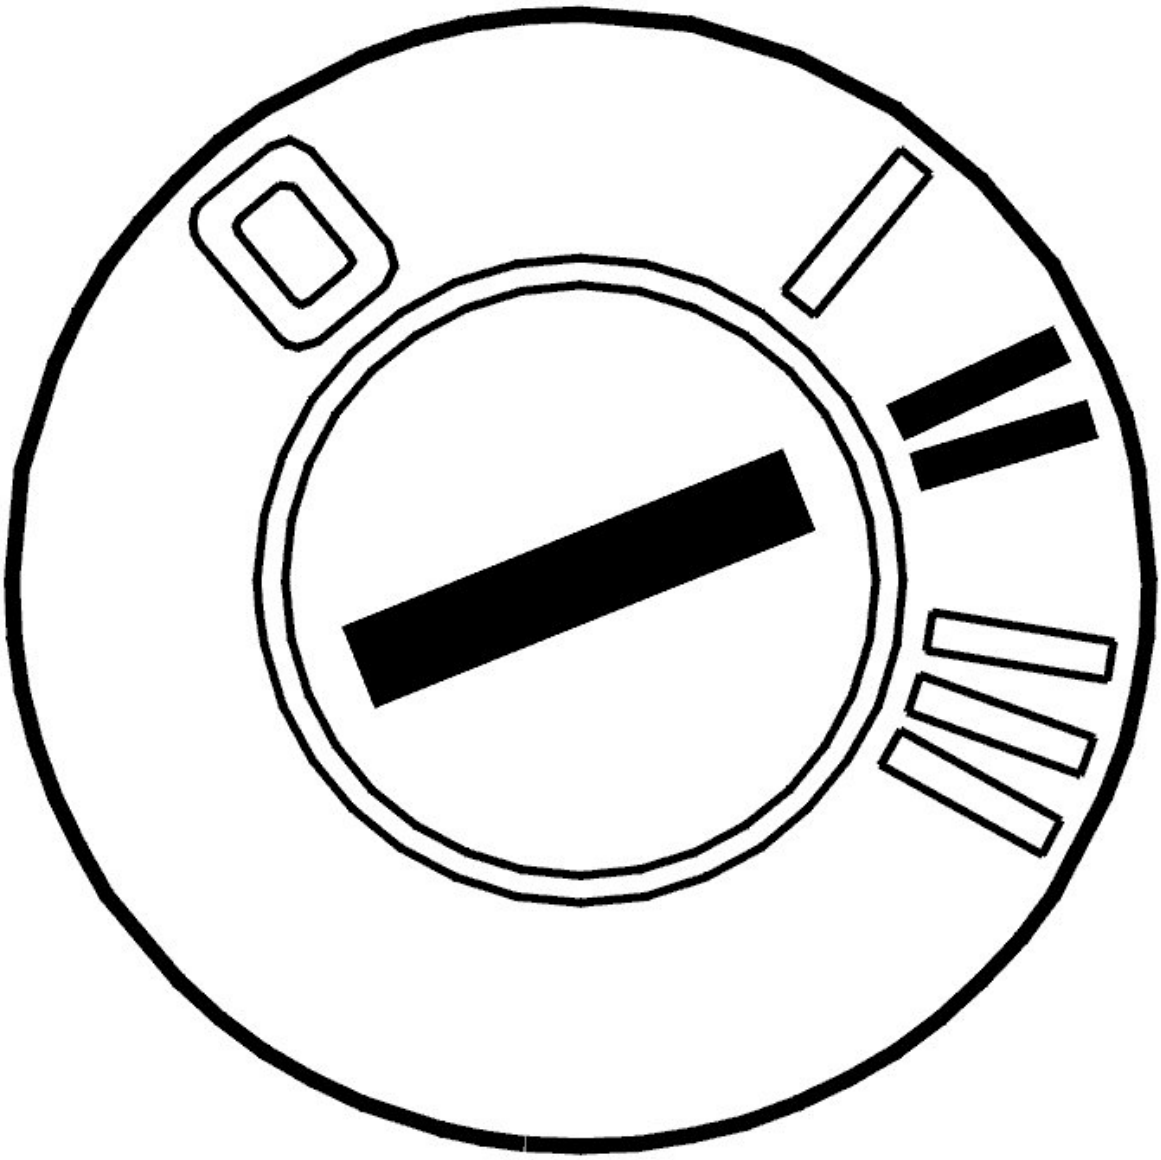


- Ignition on
- Read off the status from the stop lamp switch.

Check the function of the stop lamp switch by carefully pressing and releasing the brake pedal.
Check that the status changes between "OFF" when the brake pedal is unaffected and "ON" when the brake pedal is depressed.
If the status of the stop lamp switch changes as described above when the brake pedal is depressed, the fault is intermittent at the moment.

Continue - Checking the power supply

Checking the power supply



- Ignition on.

Check the power supply to the stop lamp switch. Take readings between stop lamp switch terminal #1 (cable harness side) and the ground terminal. The power supply must be approximately 12 V.

If there is no power supply:

Check the power supply circuit for stop lamp switch terminal #1 (cable harness side). Check for an open-circuit. Check for a short-circuit to ground. Check for a blown fuse in the circuit.
Remedy as necessary.

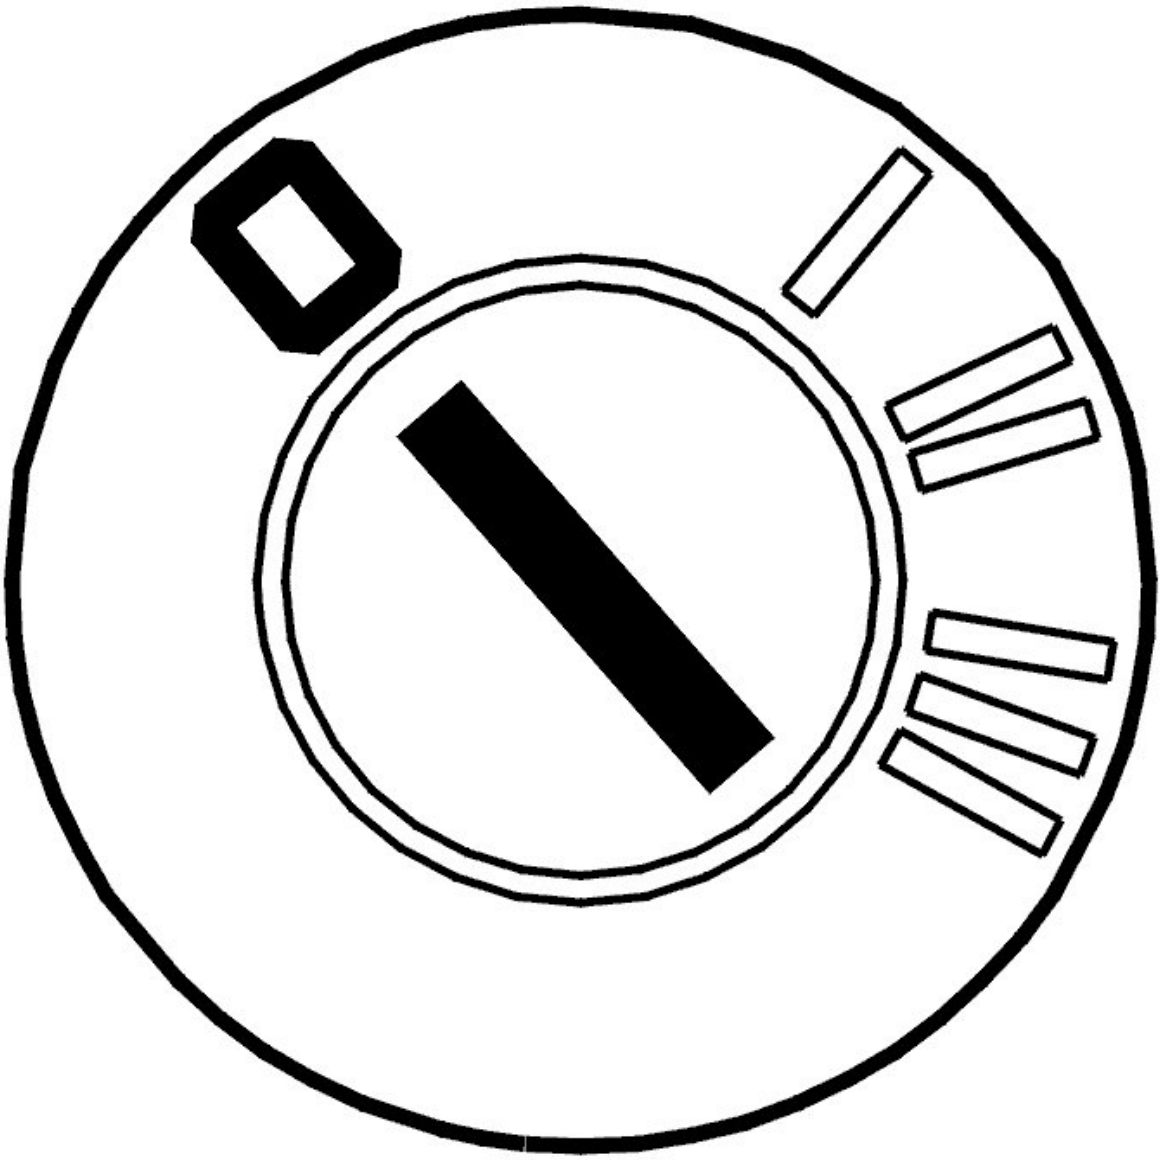
Continue - Checking components and wiring

Checking components and wiring



- Ignition off
- Check that the stop lamp switch is correctly installed.

Check the resistance of the stop lamp switch with the switch pressed in and with the switch released. Take readings between terminals #1 and #5 (component side) on the stop lamp switch.

Hint: The stop lamp switch must be closed when the brake pedal is depressed. The resistance of the stop lamp switch must be infinite when the brake pedal is unaffected.

Check the stop lamp switch and engine control module (ECM) connectors. Check for contact resistance and oxidation.
Check the cable between stop lamp switch terminal #5 (cable harness side) and engine control module (ECM) terminal #B26 (#B36). Check for an open-circuit. Check for a short-circuit to ground. Check for a short-circuit to supply voltage.
Check central electronic module (CEM) connector B. Check for contact resistance and oxidation.
Check the cable between stop lamp switch terminal #5 (cable harness side) and central electronic module (CEM) terminal #4B. Check for an open-circuit. Check for a short-circuit to ground. Check for a short-circuit to supply voltage.
Remedy as necessary.

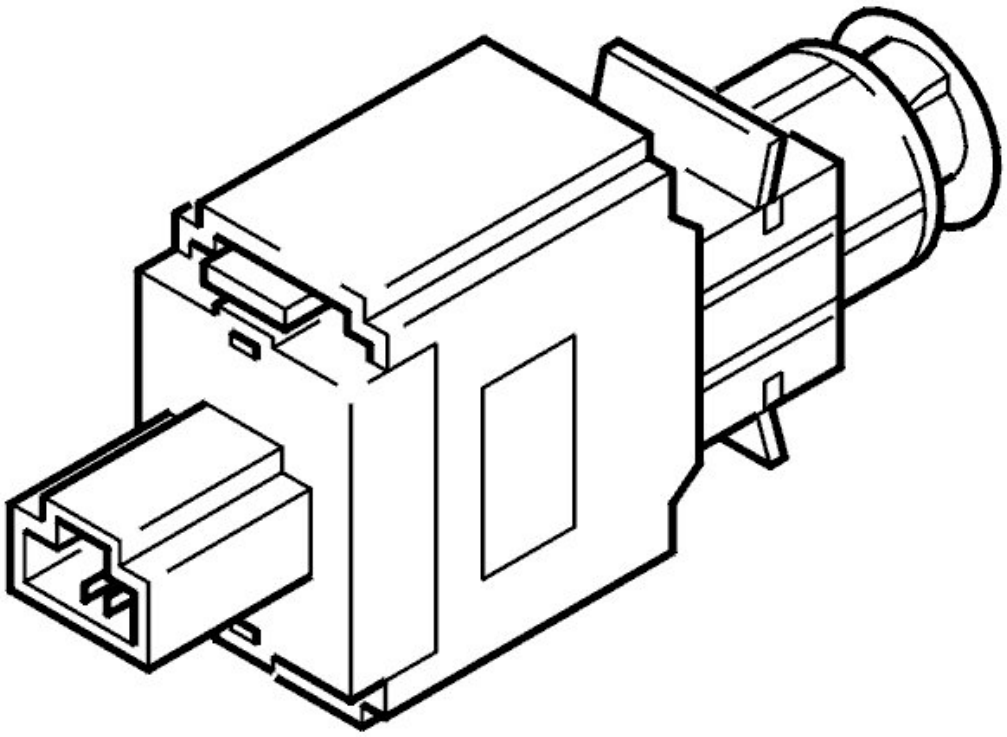
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information ECM-900B

Condition



The diagnostic trouble code (DTC) is stored if the engine control module (ECM) registers a fault in the circuit for the brake pedal position sensor, the circuit for the stop lamp switch or in the CAN communication between the brake control module (BCM) and the engine control module (ECM). The diagnostic trouble code (DTC) can be diagnosed when the engine is running.

Substitute value

Cruise control switched off.

Possible source

- Fault trace the brake control module (BCM) and the central electronic module (CEM).

Fault symptom[s]

- Cruise control does not function at all.

Signal Missing or Faulty Signal

Signal missing or faulty signal

Checking the diagnostic trouble codes (DTCs)

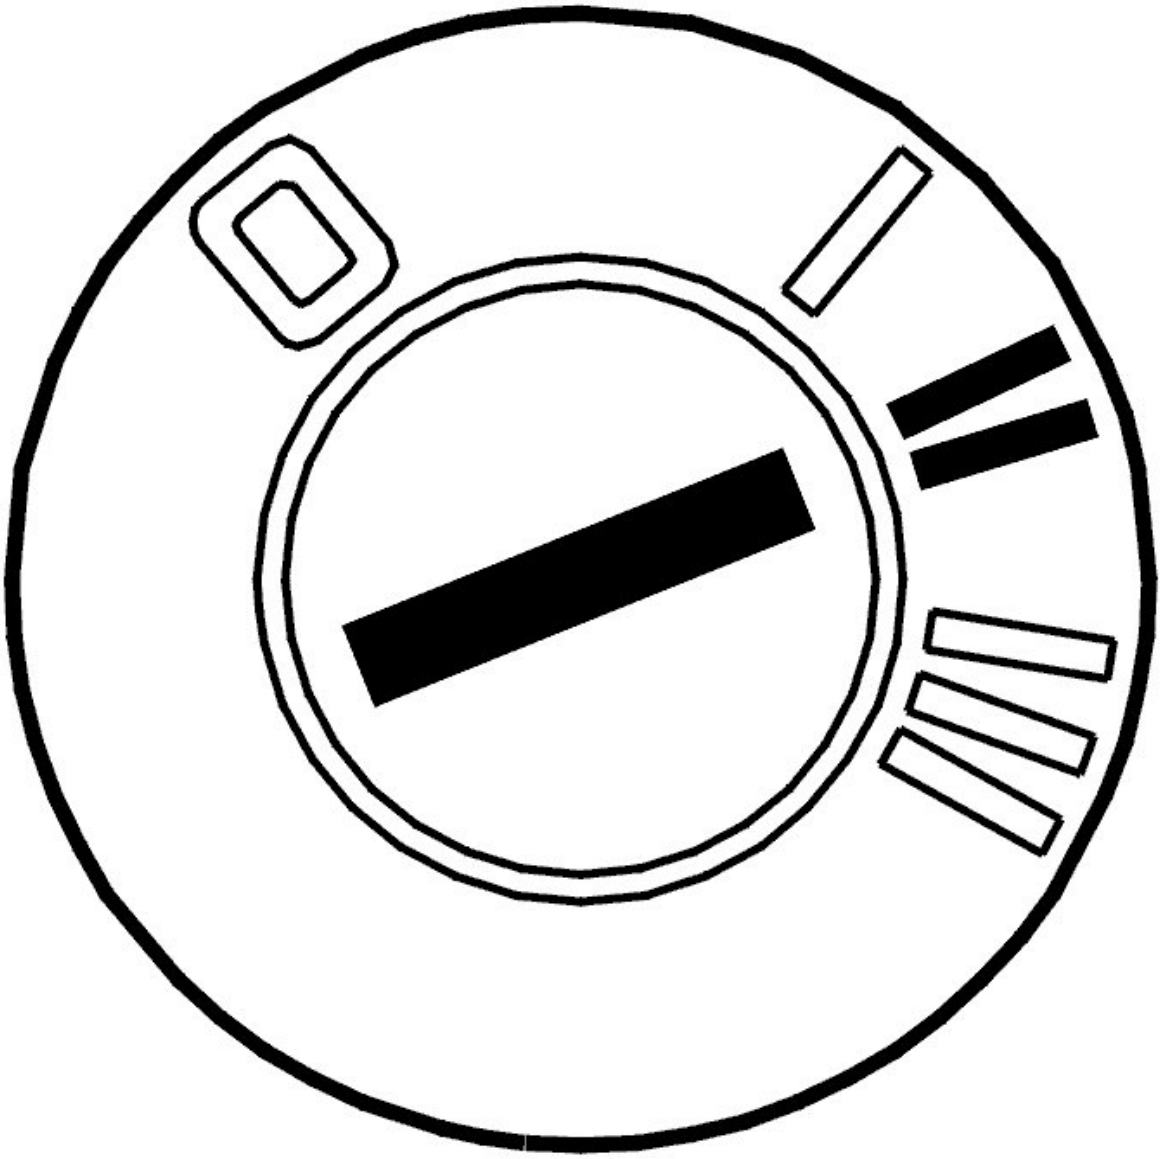
Check whether any diagnostic trouble codes (DTCs) are stored in the brake control module (BCM) or in the central electronic module (CEM).
Any diagnostic trouble codes (DTCs) stored in the brake control module (BCM) or central electronic module (CEM) must be remedied first.

Have fault causes been traced or remedied in the brake control module (BCM) and the central electronic module (CEM)?

Yes - Checking the status

No - DONE

Checking the status

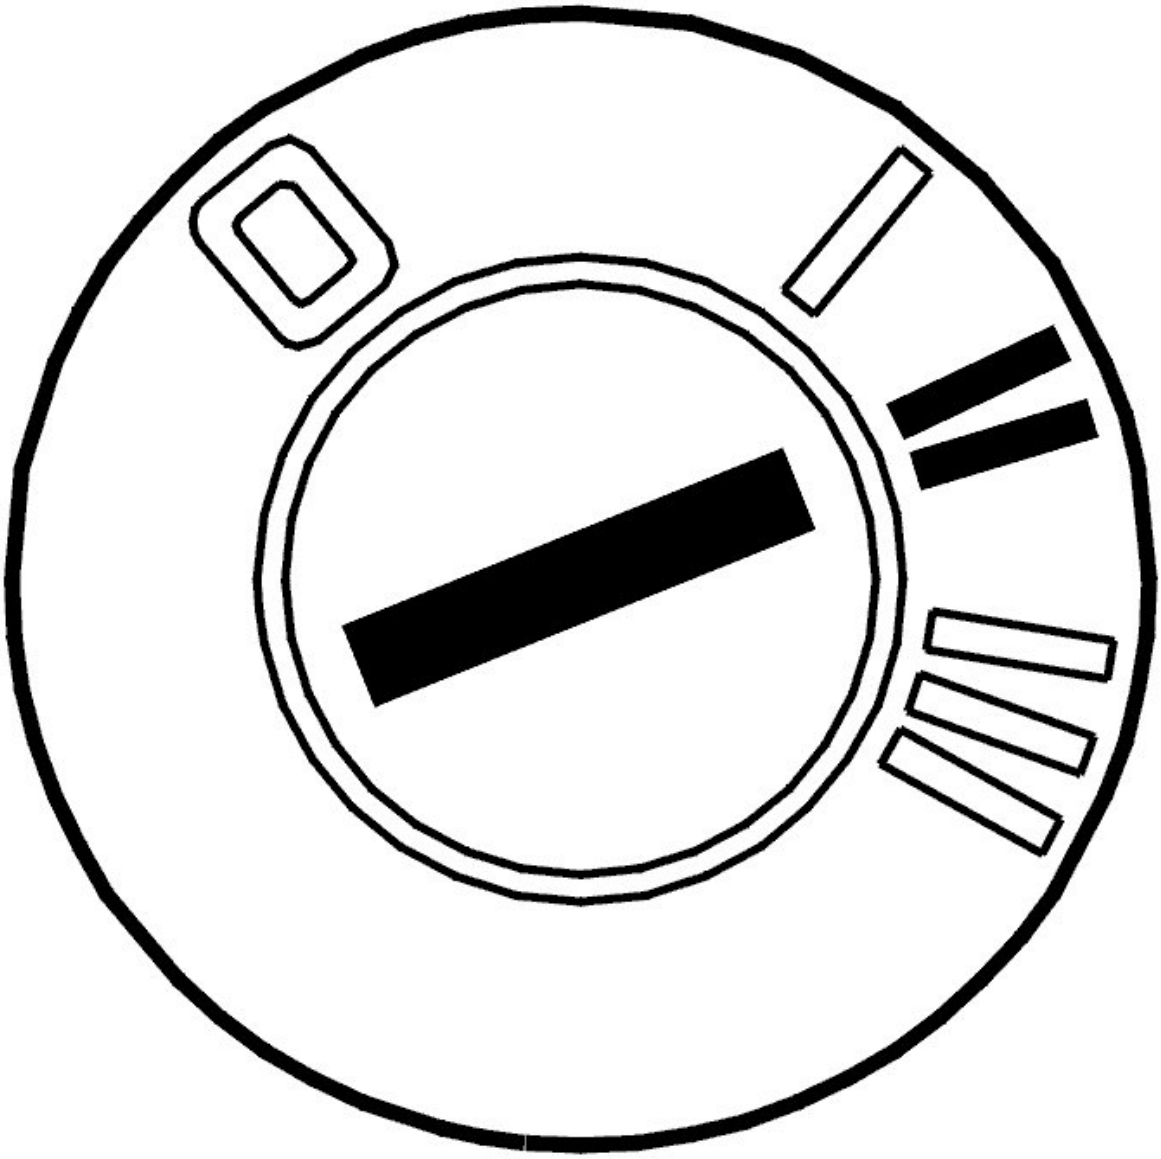


- Ignition on
- Read off the status from the stop lamp switch.

Check the function of the stop lamp switch by carefully pressing and releasing the brake pedal.
Check that the status changes between "OFF" when the brake pedal is unaffected and "ON" when the brake pedal is depressed.
If the status of the stop lamp switch changes as described above when the brake pedal is depressed, the fault is intermittent at the moment.

Continue - Checking the power supply

Checking the power supply



- Ignition on.

Check the power supply to the stop lamp switch. Take readings between stop lamp switch terminal #1 (cable harness side) and the ground terminal. The power supply must be approximately 12 V.

If there is no power supply:

Check the power supply circuit for stop lamp switch terminal #1 (cable harness side). Check for an open-circuit. Check for a short-circuit to ground. Check for a blown fuse in the circuit.
Remedy as necessary.

Diagnostic Trouble Code (DTC) Information

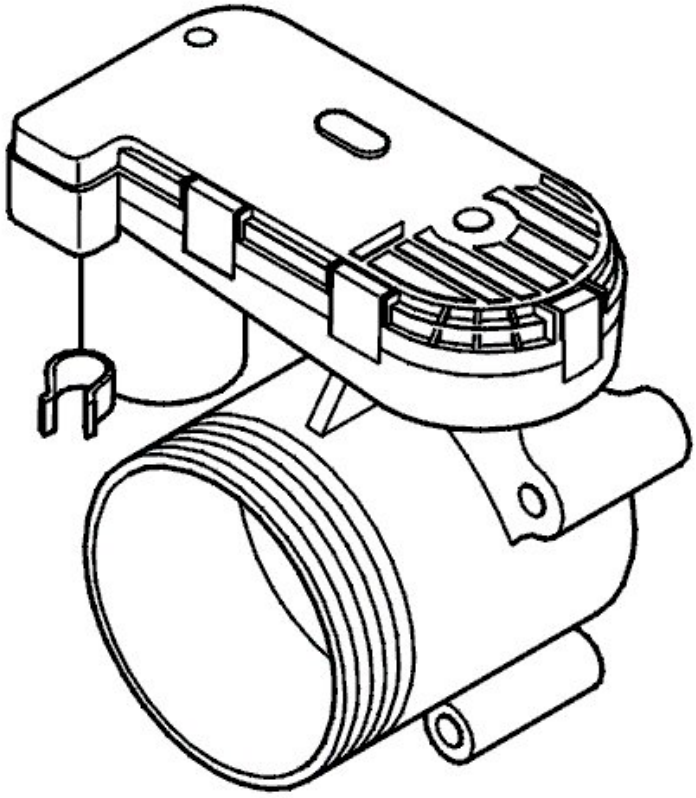
Diagnostic trouble code (DTC) information ECM-9200

Condition



This diagnostic trouble code (DTC) is never stored on its own. This diagnostic trouble code (DTC) will also be stored if the engine control module (ECM) registers that one of the diagnostic trouble codes (DTCs) for the throttle position sensor circuit is stored.
The diagnostic trouble code (DTC) can be diagnosed when the ignition is switched on.

Substitute value

None.

Possible source

- Fault in the throttle position (TP) sensor circuit for the electronic throttle unit.

Fault symptom[s]
- Malfunction indicator lamp (MIL) lit.

Fault-Tracing Information

Fault-tracing information

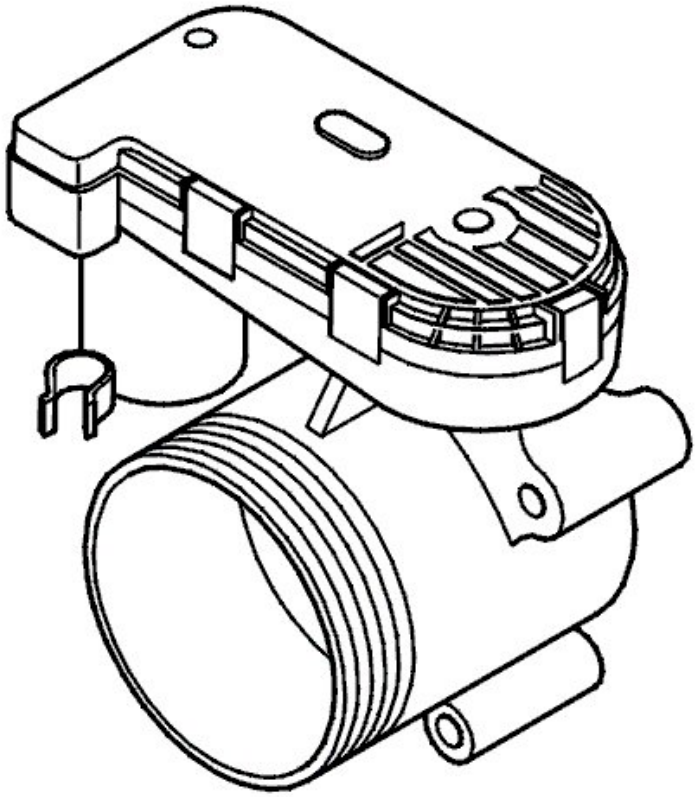
Information

There is no fault-tracing for this diagnostic fault code (DTC).
For further information on this diagnostic trouble code, see Diagnostic trouble code (DTC) information.

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information ECM-9210

Condition



The diagnostic trouble code (DTC) is stored if the engine control module (ECM) registers a fault in the signal from the throttle position (TP) sensor, potentiometer 1 (circuit 1) in the electronic throttle unit.
The diagnostic trouble code (DTC) can be diagnosed when the ignition is switched on.

Substitute value

The throttle angle is calculated using potentiometer 2 (circuit 2) in the throttle position (TP) sensor for the throttle unit. If the diagnostic trouble codes (DTCs) for both potentiometers 1 and 2 are stored at the same time, the supply to the damper motor in the throttle unit will be disabled. The throttle will set itself to the return position.

Possible source
- Contact resistance or oxidation in the terminals between the engine control module (ECM) and the electronic throttle unit
- The signal cables are short-circuited to each other
- Damaged throttle unit.

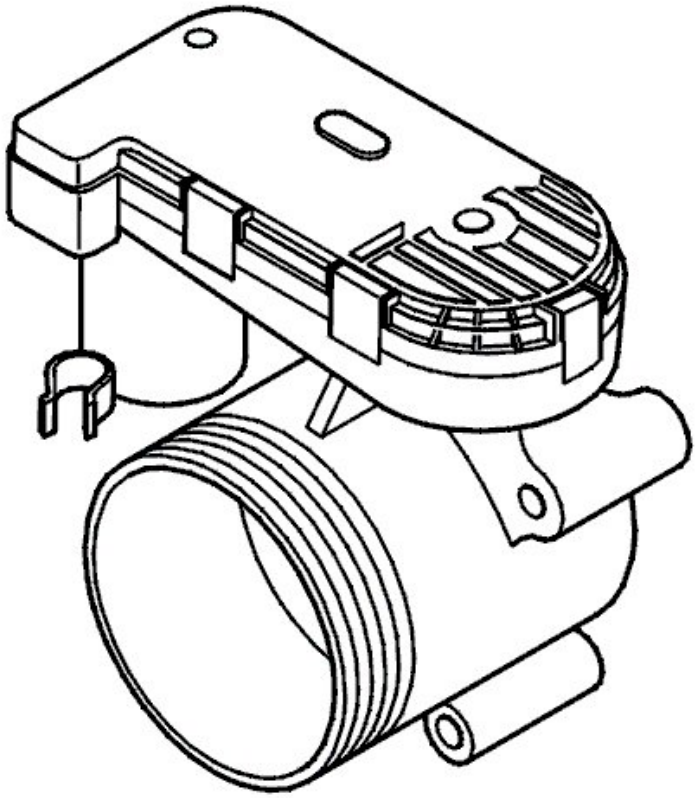
Fault symptom[s]
- Poor performance.

Faulty Signal

Faulty signal

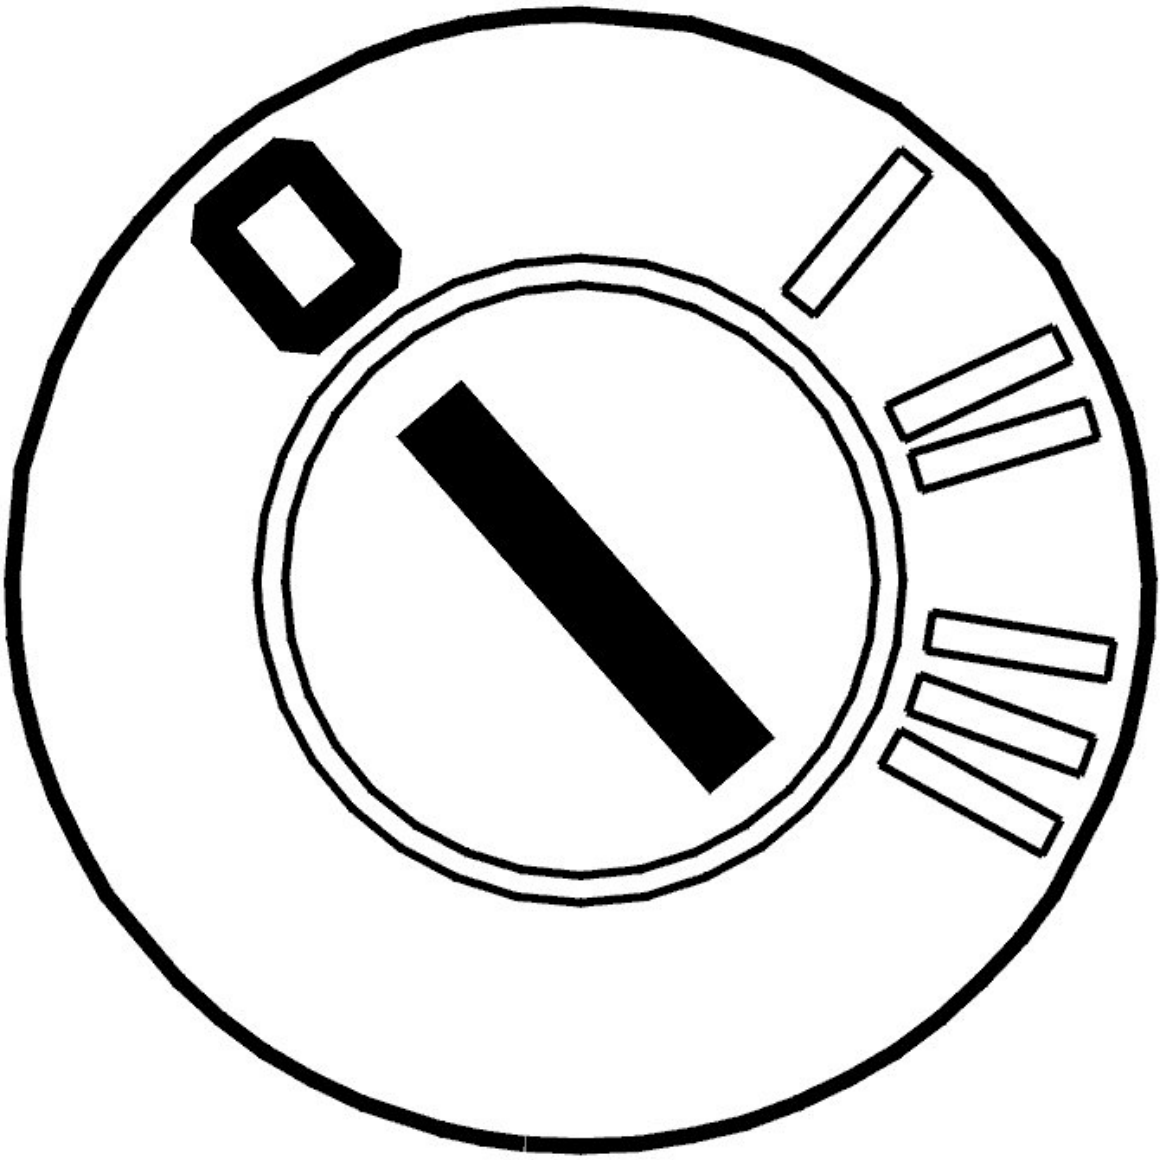
Fault-tracing information

Caution! The male and female pins on the electronic throttle unit connectors are gold plated. Great care must be taken when measuring. Damage to the gold plating can result in operating difficulties.



Continue - Checking components and wiring

Checking components and wiring



- Ignition off.

Check the throttle unit and engine control module (ECM) connectors. Check for contact resistance and oxidation.
Check the resistance values of the potentiometers in the throttle unit.
Check the signal cable (potentiometer 1) between engine control module (ECM) terminal #A1 (#A1) and throttle unit terminal #6 (wiring side). Check for an open-circuit.
Check the signal cable (potentiometer 2) between engine control module (ECM) terminal #A20 (#A20) and throttle unit terminal #5 (wiring side). Check for an open-circuit.
Check the signal cables (potentiometer 1) terminal #A1 (#A1) and (potentiometer 2) terminal #A20 (#A20). Check for a short-circuit to each other.

Hint: With the ignition on, the power supply to the throttle unit potentiometers must be approximately 5 V measured between throttle unit connector terminals #2 and #3 (wiring side).

If no faults are found during the checks and the diagnostic trouble code (DTC) recurs, try replacing the throttle unit.

Note! When replacing the throttle unit, the throttle unit must be adapted. See Throttle unit adaptation in the vehicle communication socket.

Remedy as necessary.

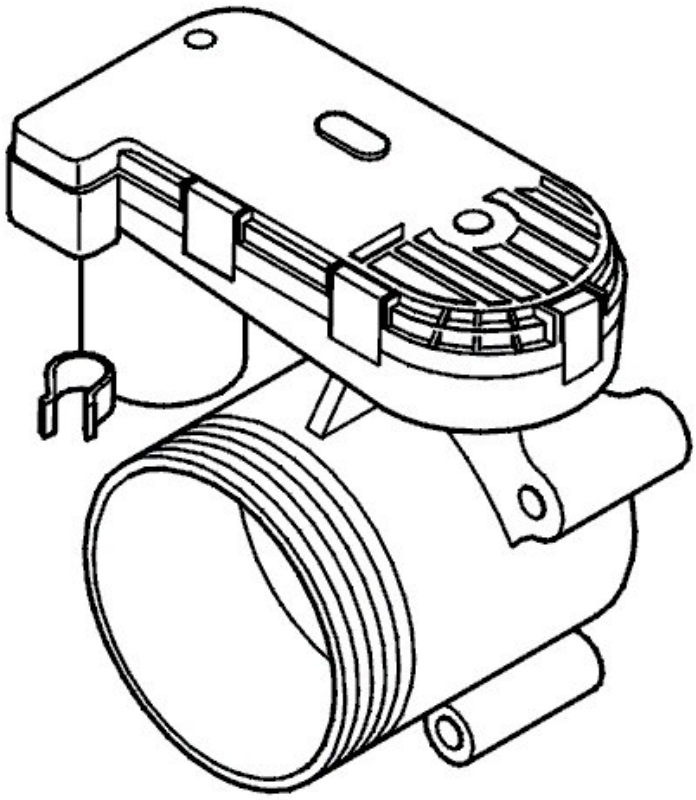
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information ECM-921C

Condition



The diagnostic trouble code (DTC) is stored if the engine control module (ECM) registers a fault in the signal from the throttle position (TP) sensor, potentiometer 1 (circuit 1) in the electronic throttle unit.
The diagnostic trouble code (DTC) can be diagnosed when the ignition is switched on.

Substitute value

The throttle angle is calculated using potentiometer 2 (circuit 2) in the throttle position (TP) sensor for the throttle unit. If the diagnostic trouble codes (DTCs) for both potentiometers 1 and 2 are stored at the same time, the supply to the damper motor in the throttle unit will be disabled. The throttle will set itself to the return position.

Possible source

- Contact resistance or oxidation in the terminals between the engine control module (ECM) and the electronic throttle unit
- Open-circuit or short-circuit to supply voltage in the signal cable

- Open-circuit in the signal ground cable for potentiometers 1 and 2
- Damaged throttle unit.

Fault symptom[s]
- Poor performance.

Signal Too High

Signal too high

The diagnostic trouble code (DTC) is stored if the engine control module (ECM) registers that the movement of the throttle is impeded, or that the return spring in the throttle unit is not functioning correctly, when attempting to adapt the electronic throttle unit.

Substitute value

Depending on the fault, the engine control module (ECM) can cut off the supply to the damper motor in the electronic throttle unit. The throttle will then attempt to set itself to the return position.

Possible source

- The throttle is sticking or is blocked (e.g. oil film, dust)
- Contact resistance or oxidation in the terminals between the engine control module (ECM) and the electronic throttle unit
- Open-circuit, short-circuit to ground or short-circuit to supply voltage in the wiring for the damper motor in the throttle unit
- Short-circuit to each other in the wiring for the damper motor in the throttle unit
- Damaged throttle unit.

Fault symptom[s]

- Malfunction indicator lamp (MIL) lit
- Poor performance.

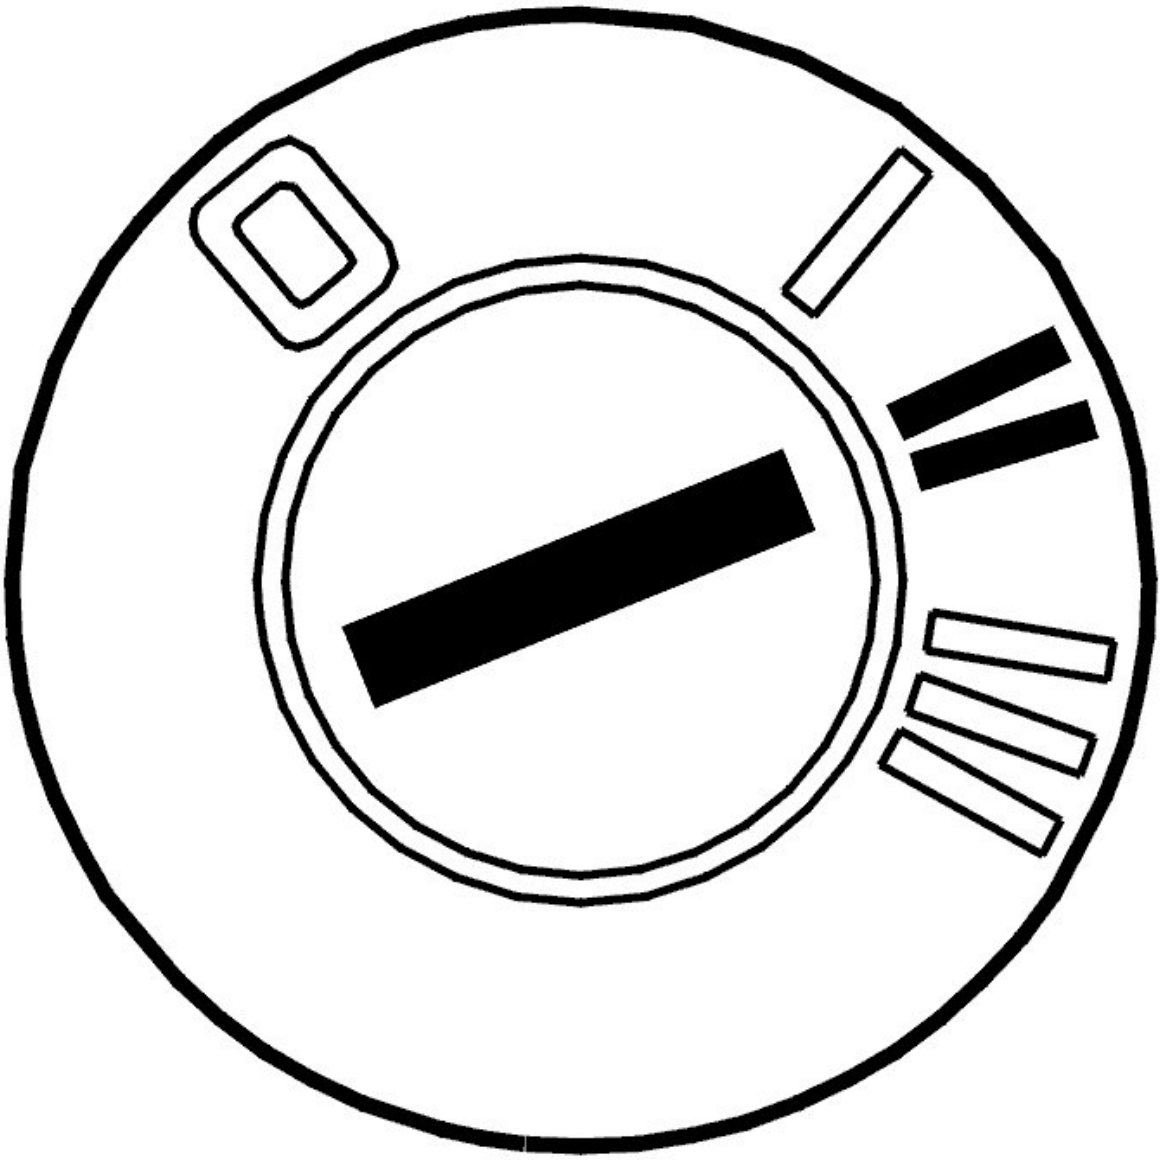
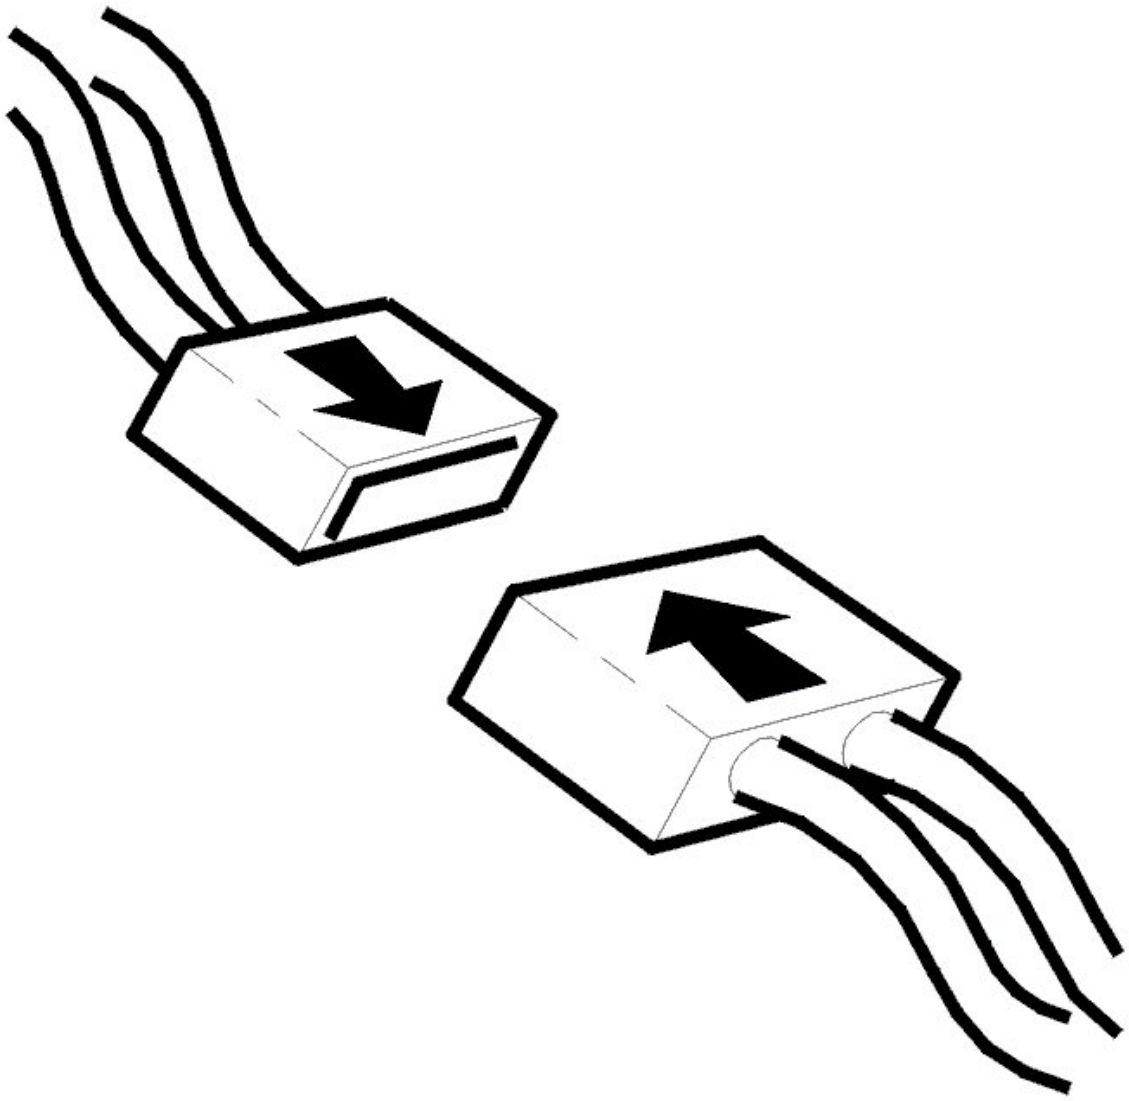
Continue - Adaptation of the throttle unit

Adaptation of the throttle unit

Hint: Faults which caused this diagnostic trouble code (DTC) may affect the adaptation values for the throttle unit. Carry out adaptation of the throttle unit to update the adaptation values.

Note! The ignition must be switched on for at least 30 seconds after the basic conditions are met in order for the adaptation to start. It takes approximately 10 seconds to run the adaptation.





- Ignition off
- Reinstall the components and connectors etc.
- Ignition on
- Read off the parameters.

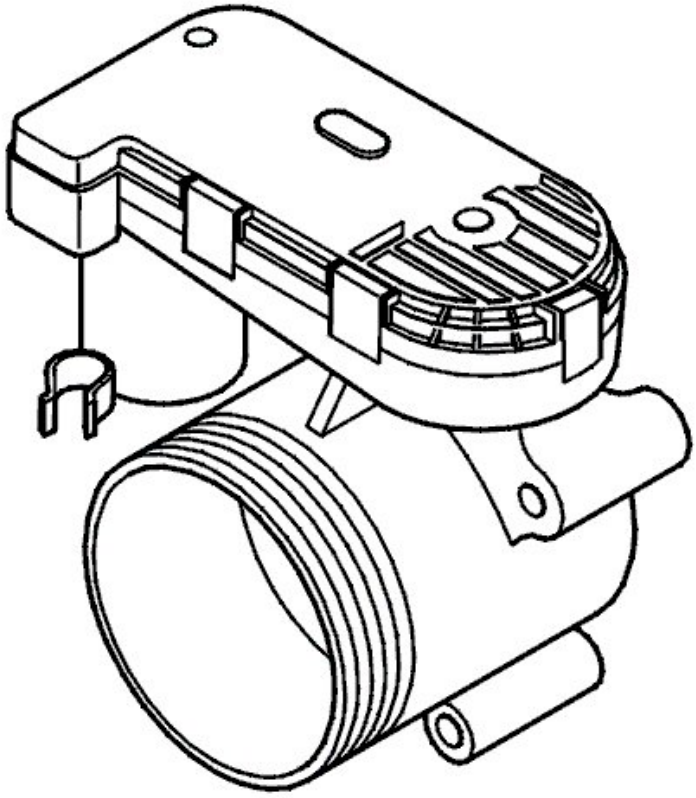
Check that the following basic conditions for adaptation of the throttle unit are met.

1. Ignition on / engine off
2. Battery voltage above 10 V
3. Accelerator pedal (AP) unaffected
4. The vehicle must be stationary (no vehicle speed signal)
5. Engine coolant temperature (ECT) between 5-100°C
6. Intake air temperature (IAT) above 5 °C.

Remedy as necessary.

Check that the adaptation is correctly run after the "Adaptation of the throttle unit running" parameter changes status from "YES" to "NO". When all basic conditions are met, the adaptation must be completed after approximately 40 seconds. When the adaptation has been run correctly, the following information will be displayed:

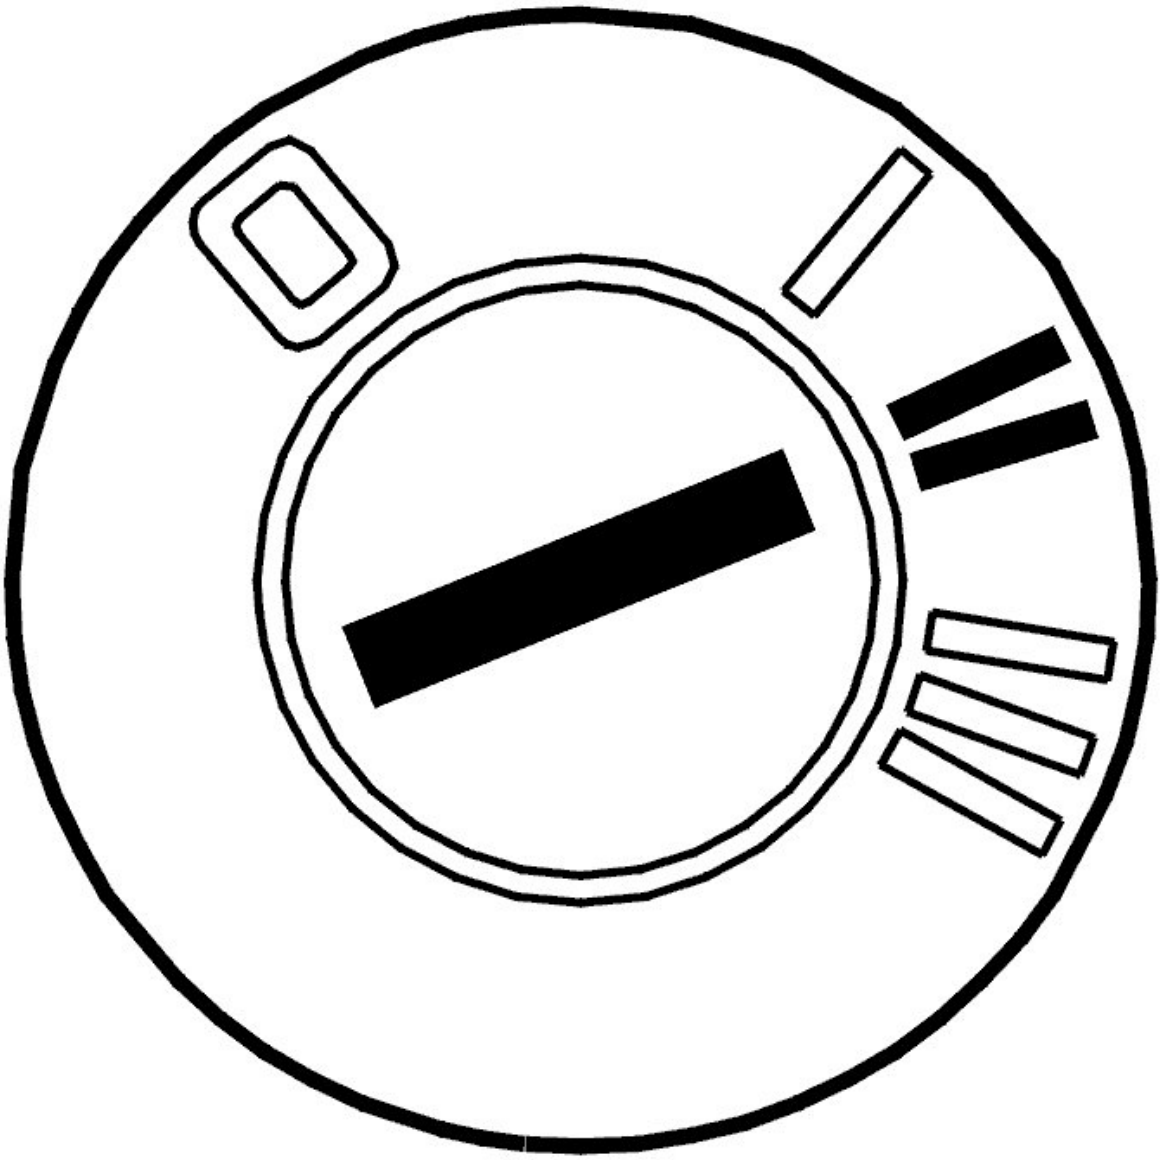
- Adaptation of the throttle unit: OK
- Adaptation of the throttle unit running: NO.



Select Continue without switching off the ignition when the adaptation is OK.

Continue - Checking the function

Checking the function



- Ignition on.

Read off the diagnostic status and fault status for the diagnostic trouble code (DTC) by selecting the relevant diagnostic trouble code (DTC) from the list.
Check whether the fault is permanent or intermittent. Read off the diagnostic trouble code (DTC) fault status when the diagnostic status is "Completed".

Hint: In some cases several functions of the component will be diagnosed. The affects the amount of time taken to run the diagnostic.

The fault is permanent if the fault status is "Fault found". If the fault status is "No fault found" the fault is intermittent and not presently active.

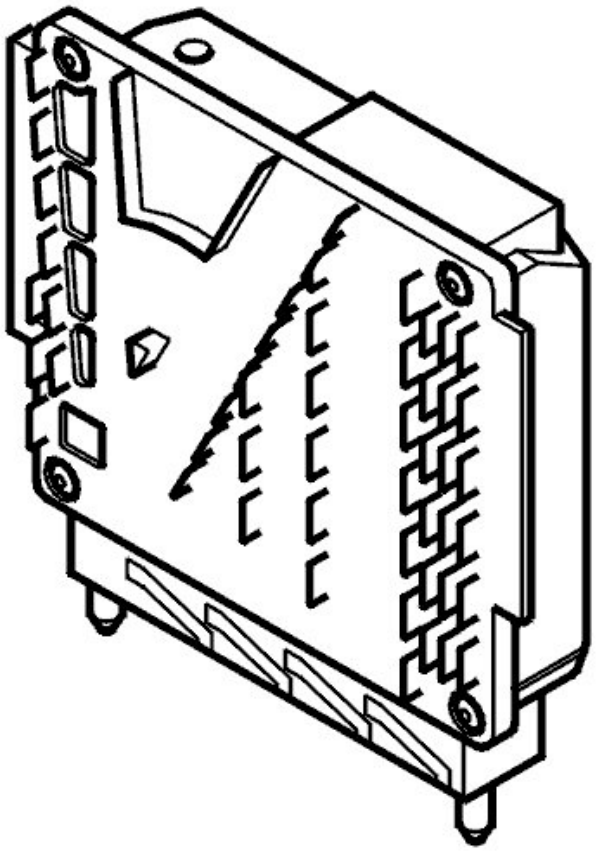
Diagnostic trouble code (DTC) information ECM-929C

Condition



The diagnostic trouble code (DTC) is stored if the engine control module (ECM) registers that the internal governor for control of the throttle angle in the throttle unit is damaged or that the control signal for the governor is too low when controlling the throttle.
The diagnostic trouble code (DTC) can be diagnosed when the engine is running.

Substitute value

The engine control module (ECM) shuts down the supply to the damper motor for the electronic throttle unit. The throttle will set itself to the return position.

Possible source

- The throttle is sticking or is blocked (e.g. oil film, dust)

- Contact resistance or oxidation in the terminals between the engine control module (ECM) and the electronic throttle unit
- Open-circuit, short-circuit to ground or short-circuit to supply voltage in the wiring for the damper motor in the throttle unit
- Short-circuit to each other in the wiring for the damper motor in the throttle unit
- Damaged throttle unit
- Faulty software in the engine control module (ECM).

Fault symptom[s]
- Malfunction indicator lamp (MIL) lit
- Poor performance.

Signal Too High

Signal too high

Fault-tracing information

Fault-tracing information

Fault-tracing information

Caution! The male and female pins on the electronic throttle unit connectors are gold plated. Great care must be taken when measuring. Damage to the gold plating can result in operating difficulties.

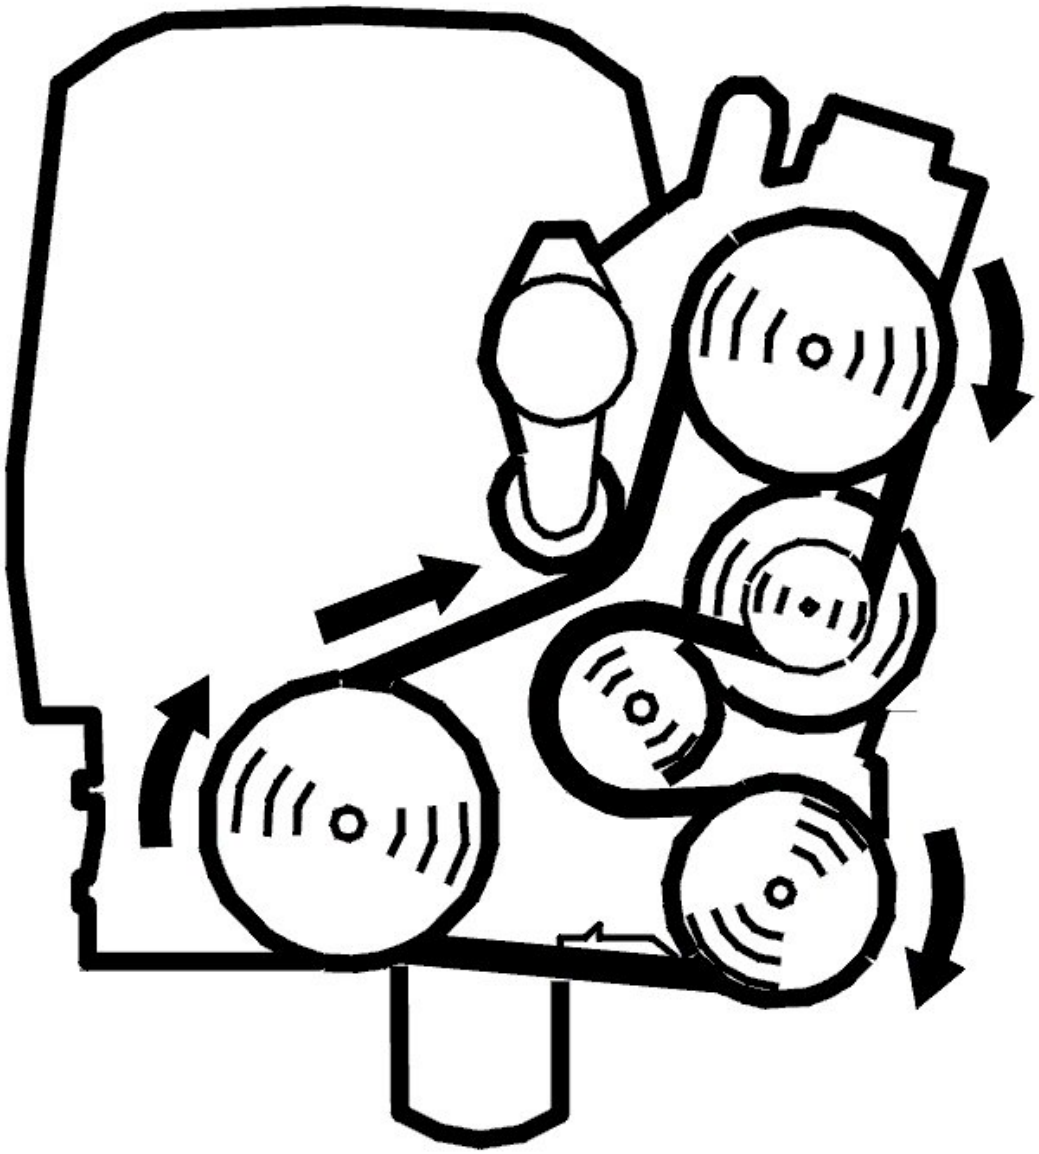
cont - Checking the fault status

Checking the fault status



- Start the engine.

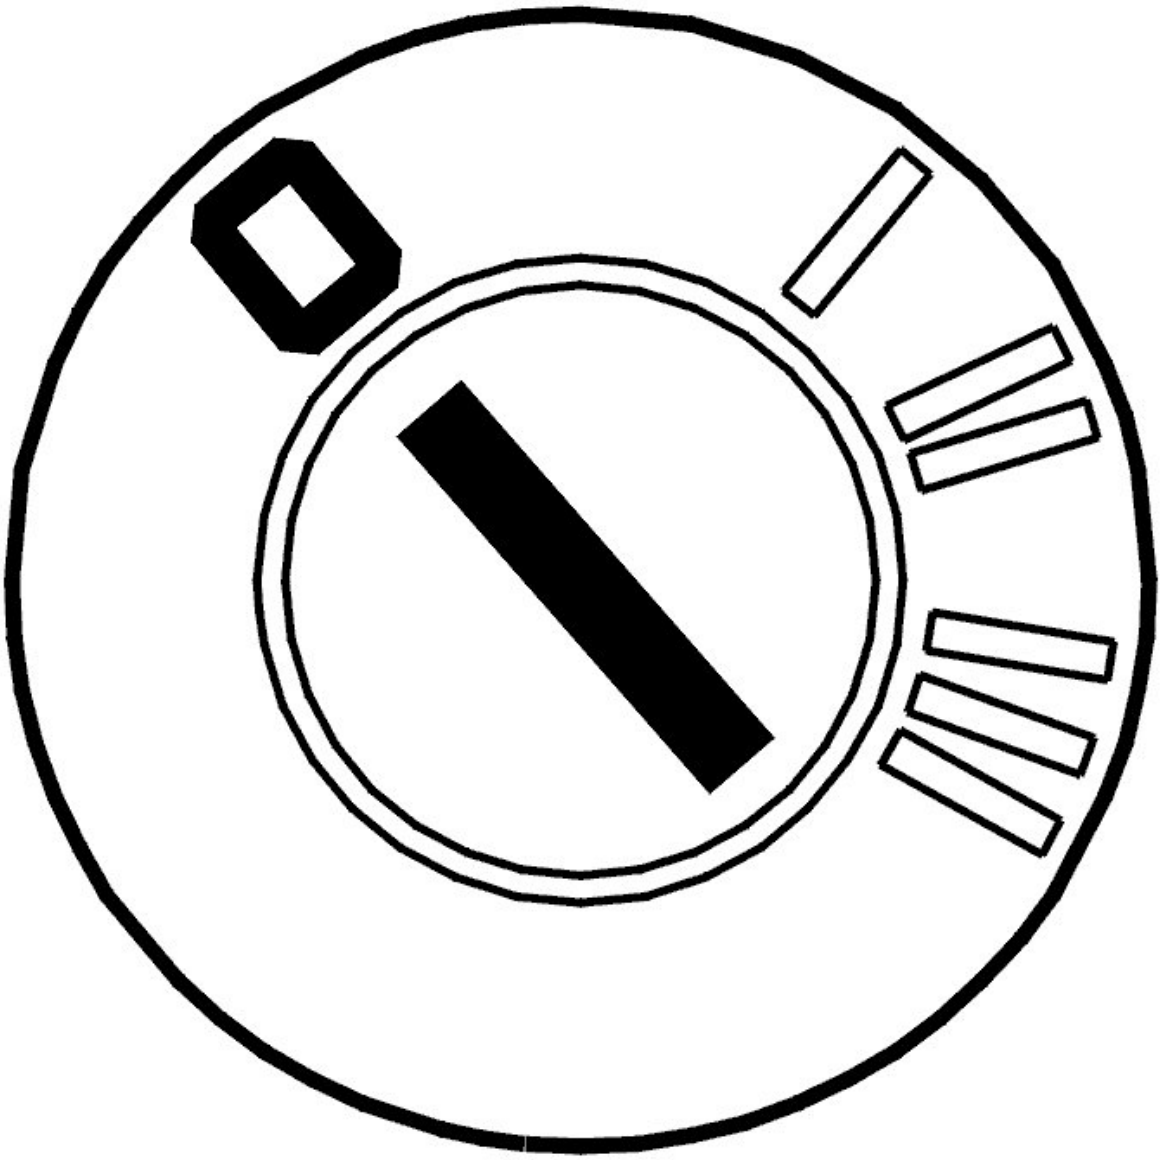
Read off the diagnostic status and fault status for the diagnostic trouble code (DTC) by selecting the relevant diagnostic trouble code (DTC) from the list.
Check whether the fault is permanent or intermittent. Read off the diagnostic trouble code (DTC) fault status when the diagnostic status is "Completed".

Hint: In some cases several functions of the component will be diagnosed. The affects the amount of time taken to run the diagnostic.

The fault is permanent if the fault status is "Fault found". If the fault status is "No fault found" the fault is intermittent and not presently active.

Continue - Checking components and wiring

Checking components and wiring



- Ignition off
- Check the throttle unit and engine control module (ECM) connectors. Check for contact resistance and oxidation.

Check the resistance value of the damper motor winding in the throttle unit. Take readings between throttle unit terminals #1 and #4 (component side). Check for an open-circuit. Check for a short-circuit.

Note! The resistance of the motor winding in the damper motor is very low.

Check the cable (+) for the damper motor between engine control module (ECM) terminal #A35 (#A35) and throttle unit terminal #4 (cable harness side). Check for an open-circuit. Check for a short-circuit to ground. Check for a short-circuit to supply voltage.
Check the cable (-) for the damper motor between engine control module (ECM) terminal #A36 (#A36) and throttle unit terminal #1 (cable harness side). Check for an open-circuit. Check for a short-circuit to ground. Check for a short-circuit to supply voltage.
Also check the damper motor cables (+) and (-). Check for a short-circuit to each other.
Check that the shutter in the throttle unit is not blocked or sticking. Clean as necessary.
Remedy as necessary.

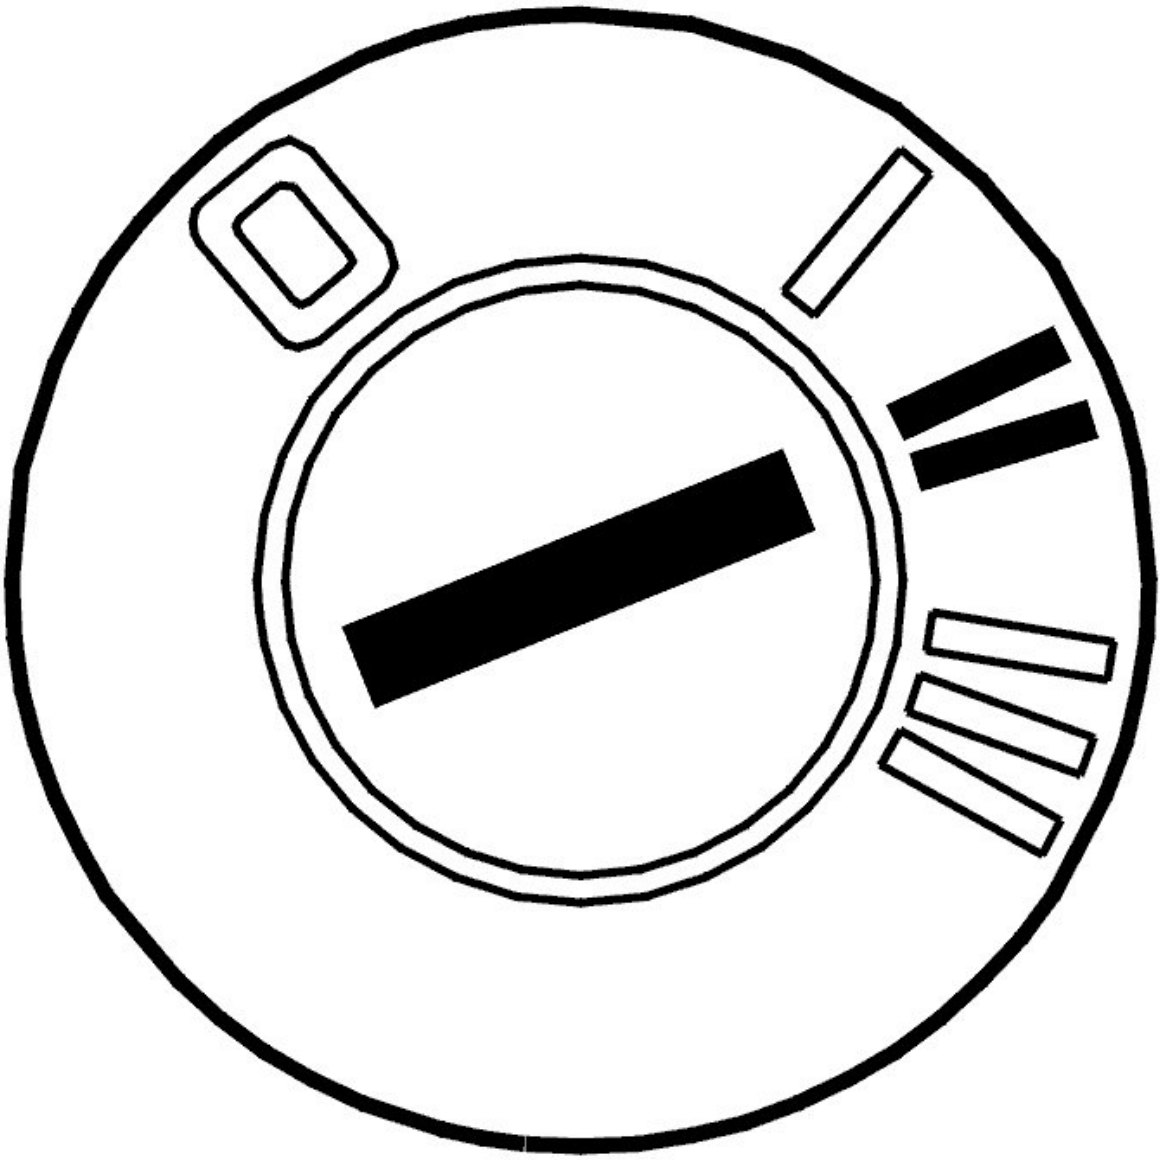
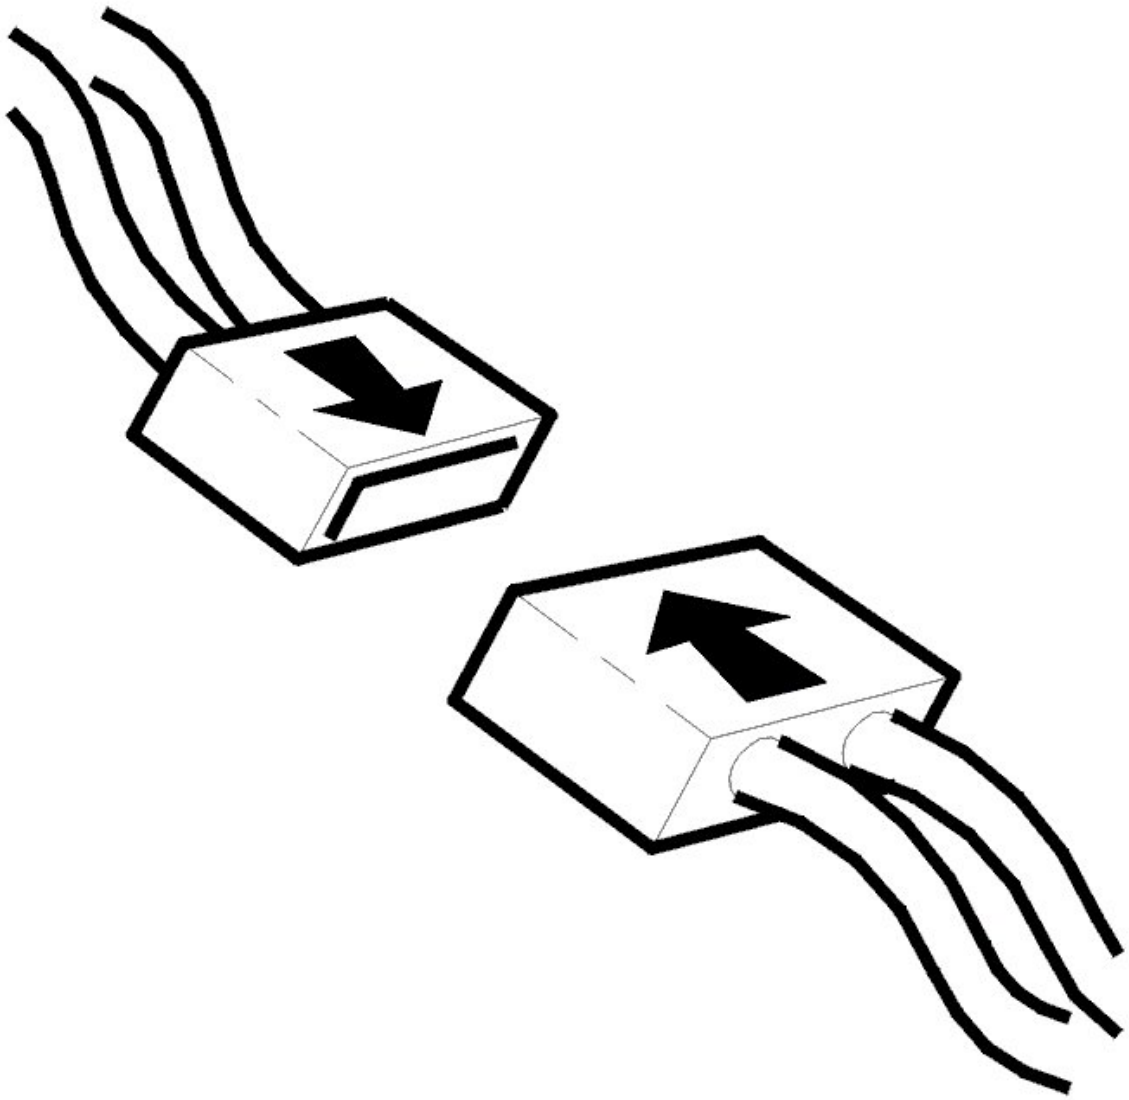
Continue - Adaptation of the throttle unit

Adaptation of the throttle unit

Note! The ignition must be switched on for at least 30 seconds after the basic conditions are met in order for the adaptation to start. It takes approximately 10 seconds to run the adaptation.





- Ignition off
- Reinstall the connectors, components etc.
- Ignition on
- Read off the parameters.

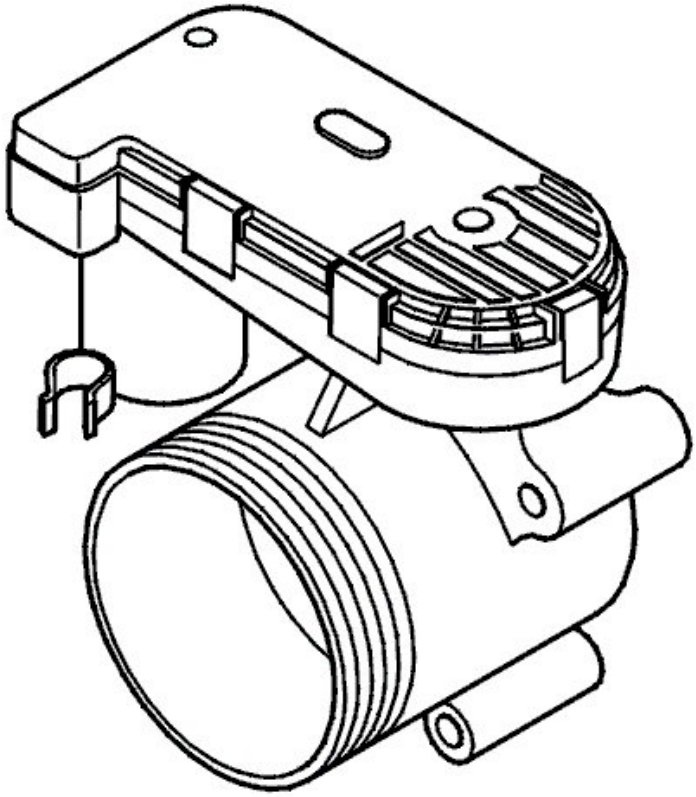
Check that the following basic conditions for adaptation of the throttle unit are met.

1. Ignition on / engine off
2. Battery voltage above 10 V
3. Accelerator pedal (AP) unaffected
4. The vehicle must be stationary (no vehicle speed signal)
5. Engine coolant temperature (ECT) between 5-100°C
6. Intake air temperature (IAT) above 5 °C.

Remedy as necessary.

Check that the adaptation is correctly run after the "Adaptation of the throttle unit running" parameter changes status from "YES" to "NO". When all basic conditions are met, the adaptation must be completed after approximately 40 seconds. When the adaptation has been run correctly, the following information will be displayed:

- Adaptation of the throttle unit: OK
- Adaptation of the throttle unit running: NO.

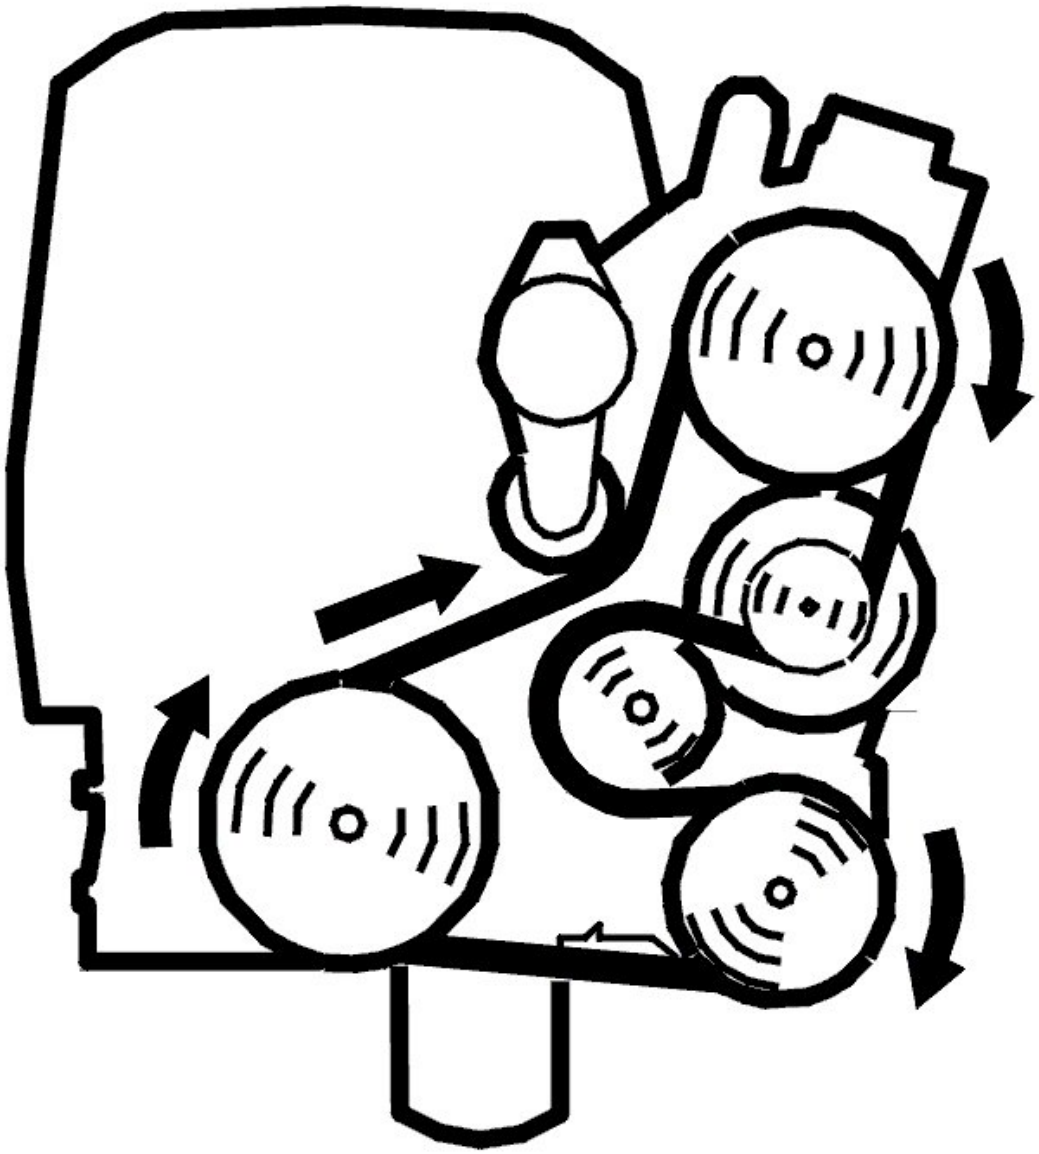


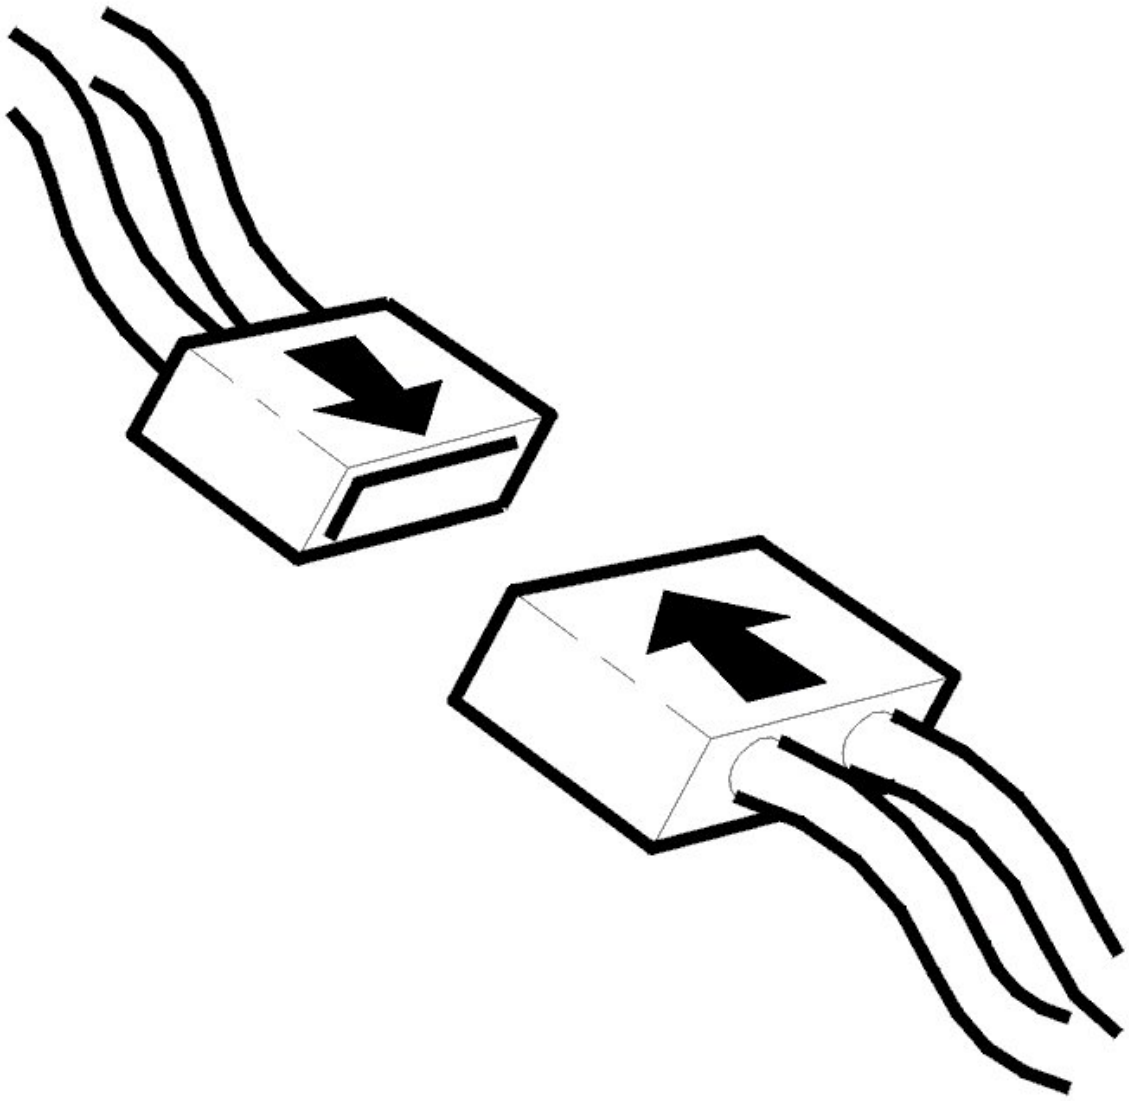
Then select Continue when the adaptation has been completed correctly.

Continue - Verification

Verification

Hint: After carrying out the repair, check that the fault has been remedied.





- Ignition off
- Reconnect the connectors, reinstall components etc.
- Start the engine.

Read off the diagnostic status and fault status for the diagnostic trouble code (DTC) by selecting the relevant diagnostic trouble code (DTC) from the list.
Check the fault status for the diagnostic trouble code (DTC) when the diagnostic is "Complete". If the function is correct, the fault status must be "No fault found" when the diagnostic is complete.

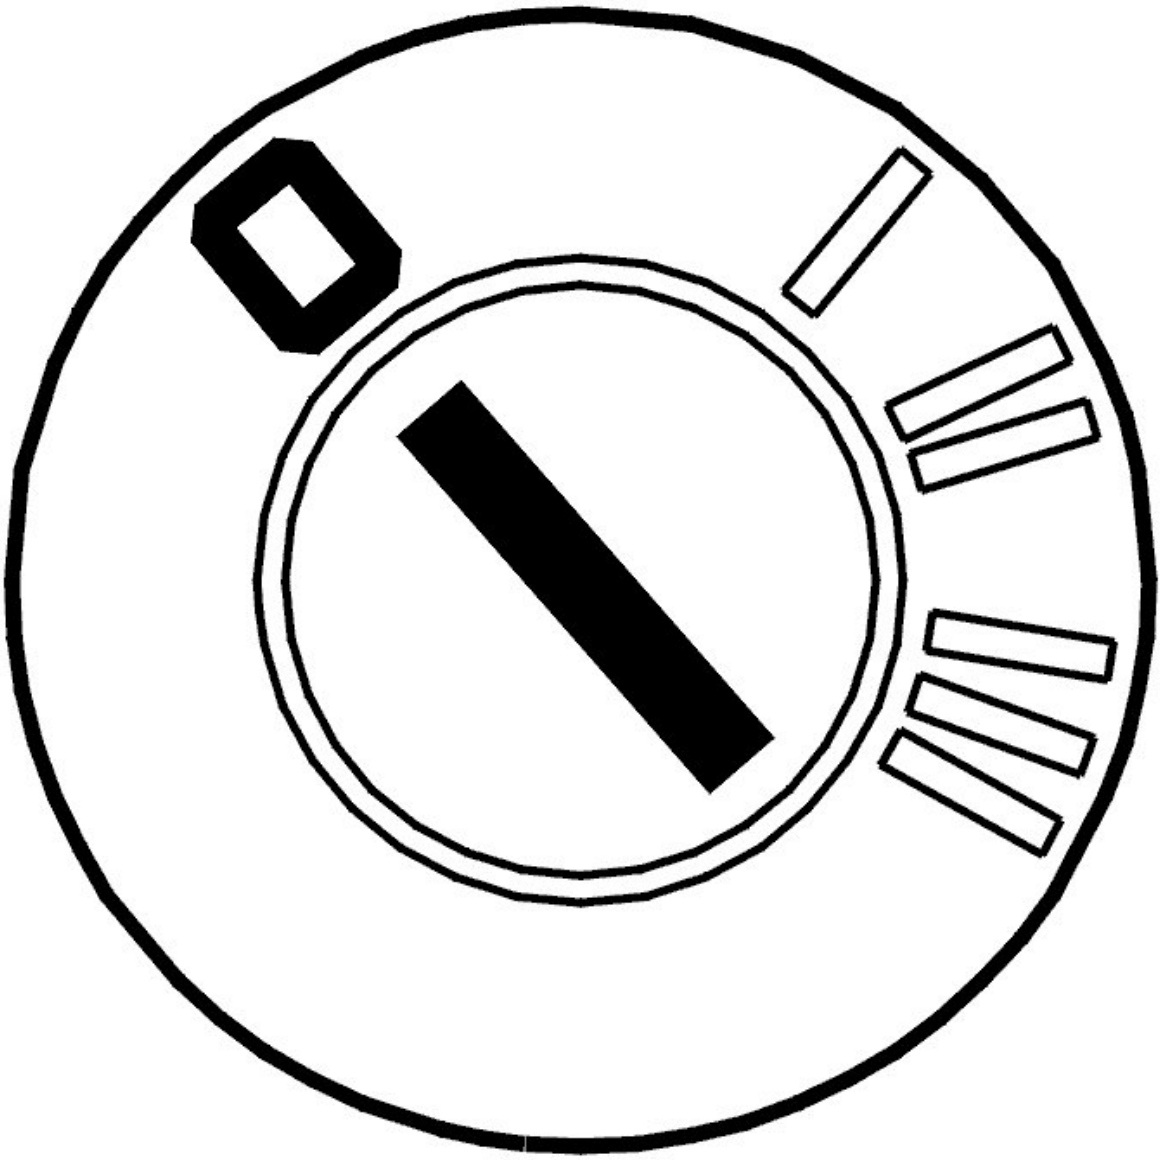
Is the function OK?

Yes - Fault Found

No - Programming the engine control module (ECM)

Programming the engine control module (ECM)

Hint: This diagnostic trouble code (DTC) may be caused by faulty software.



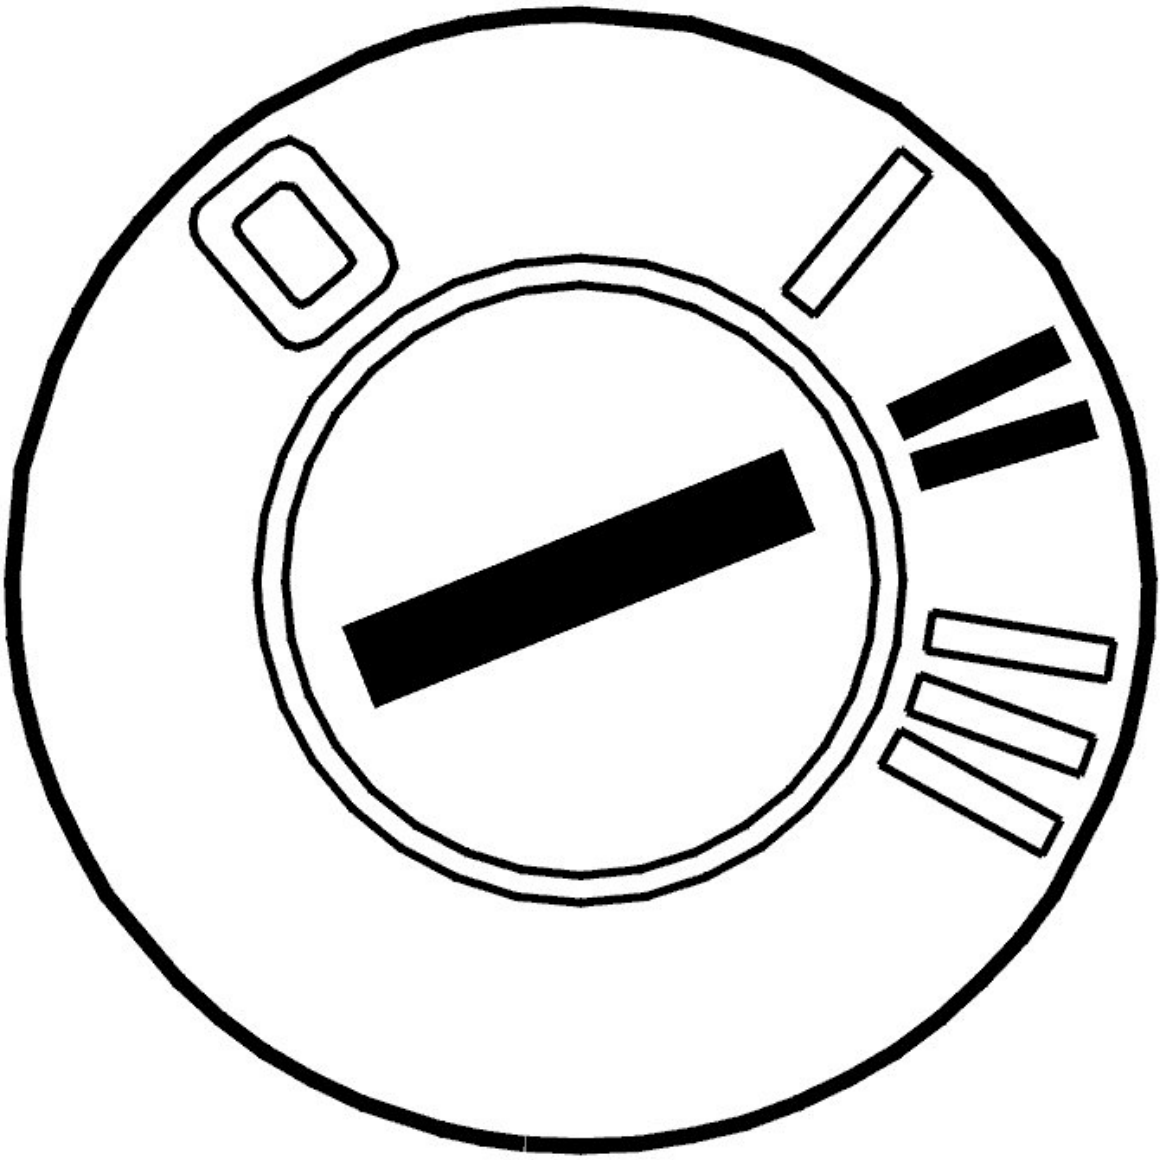
- Ignition off.

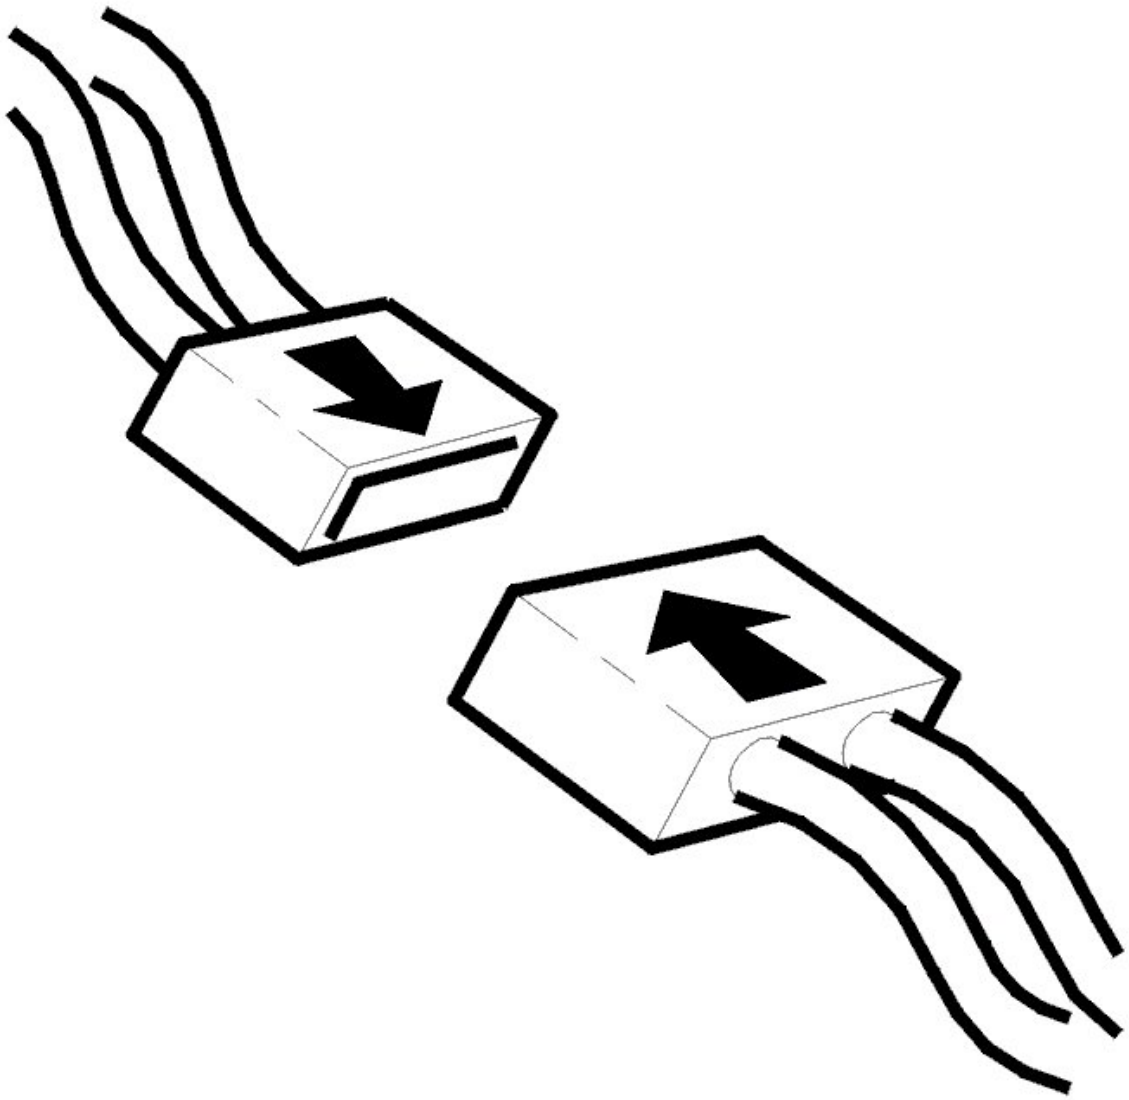
Try downloading new software to the engine control module (ECM). To download new software, see: Engine control module (ECM), replacing
See: Engine Control Module/Service and Repair
Remedy as necessary.

Continue - Adaptation of the throttle unit

Adaptation of the throttle unit

Note! The ignition must be switched on for at least 30 seconds after the basic conditions are met in order for the adaptation to start. It takes approximately 10 seconds to run the adaptation.





- Ignition off
- Reinstall the connectors, components etc.
- Ignition on
- Read off the parameters.

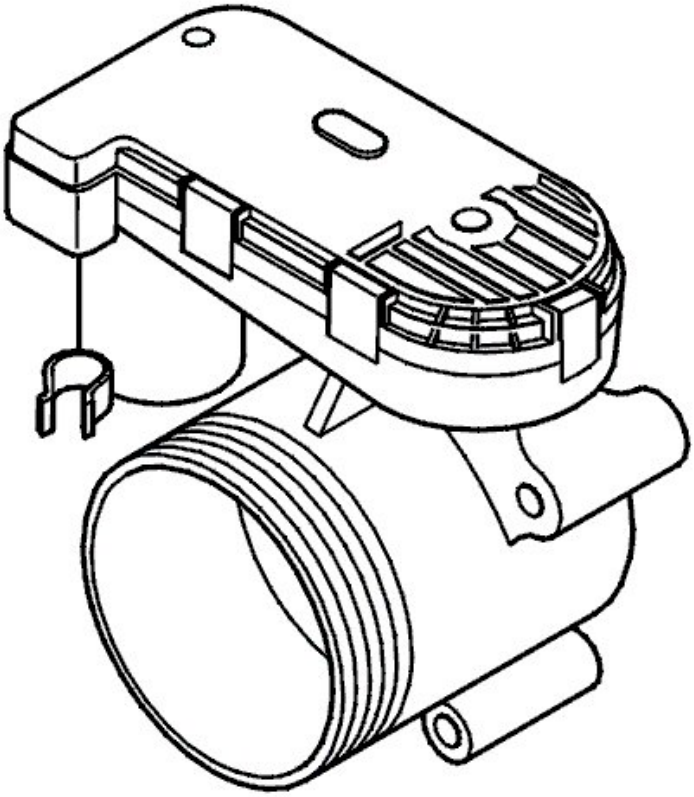
Check that the following basic conditions for adaptation of the throttle unit are met.

1. Ignition on / engine off
2. Battery voltage above 10 V
3. Accelerator pedal (AP) unaffected
4. The vehicle must be stationary (no vehicle speed signal)
5. Engine coolant temperature (ECT) between 5-100°C
6. Intake air temperature (IAT) above 5 °C.

Remedy as necessary.

Check that the adaptation is correctly run after the "Adaptation of the throttle unit running" parameter changes status from "YES" to "NO". When all basic conditions are met, the adaptation must be completed after approximately 40 seconds. When the adaptation has been run correctly, the following information will be displayed:

- Adaptation of the throttle unit: OK
- Adaptation of the throttle unit running: NO.



Then select Continue when the adaptation has been completed correctly.

Continue - Verification

Verification

Diagnostic Trouble Code (DTC) Information

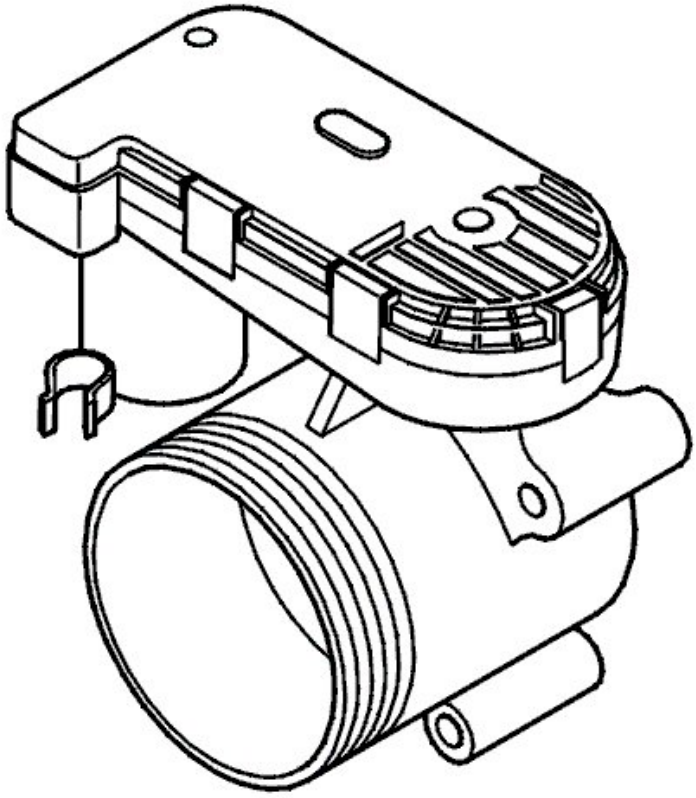
Diagnostic trouble code (DTC) information ECM-92B0

Condition



The diagnostic trouble code (DTC) is stored if the engine control module (ECM) fails to carry out its first adaptation of the electronic throttle unit. This is because the programmed parameter for the stop position in the throttle position (TP) sensor has been exceeded. This adaptation is normally run during manufacture of the vehicle. However the electronic throttle unit must be adapted again if the software, the engine control module (ECM) or the throttle unit is replaced. If other diagnostic trouble codes (DTCs) are stored, these must be remedied first. These may have caused the adaptation to fail.

Substitute value

- The engine control module (ECM) uses nominal values for the throttle unit parameters
- The engine control module (ECM) shuts down the supply to the damper motor for the electronic throttle unit. The throttle will set itself to the return position.

Possible source

- The throttle is sticking or is blocked (e.g. oil film, dust)
- Contact resistance or oxidation in the terminals between the engine control module (ECM) and the electronic throttle unit
- Damaged throttle unit.

Fault symptom[s]

- Malfunction indicator lamp (MIL) lit
- Poor performance.

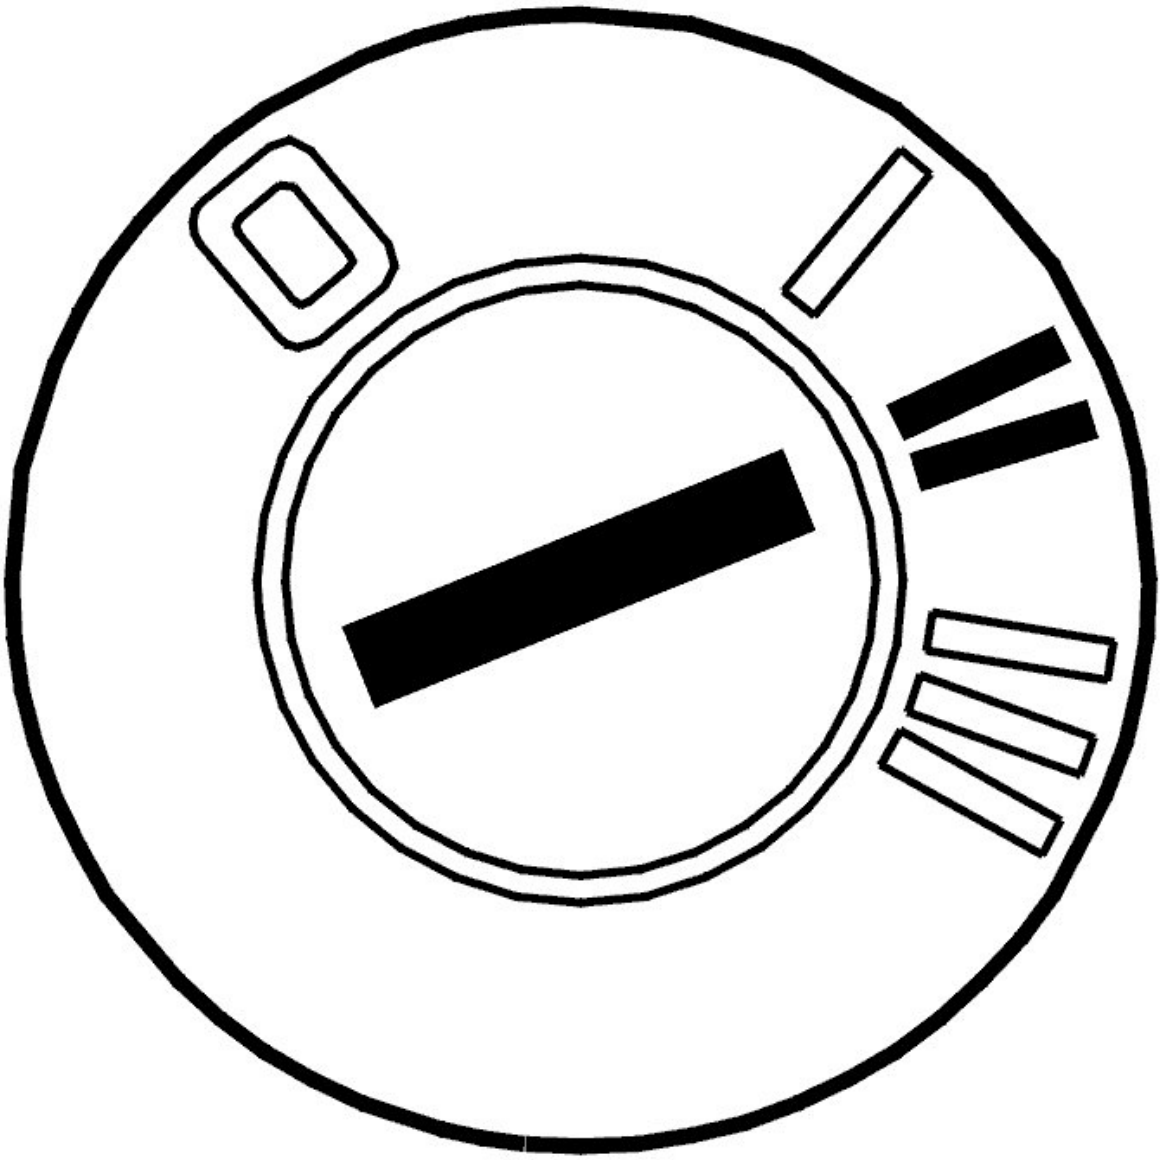
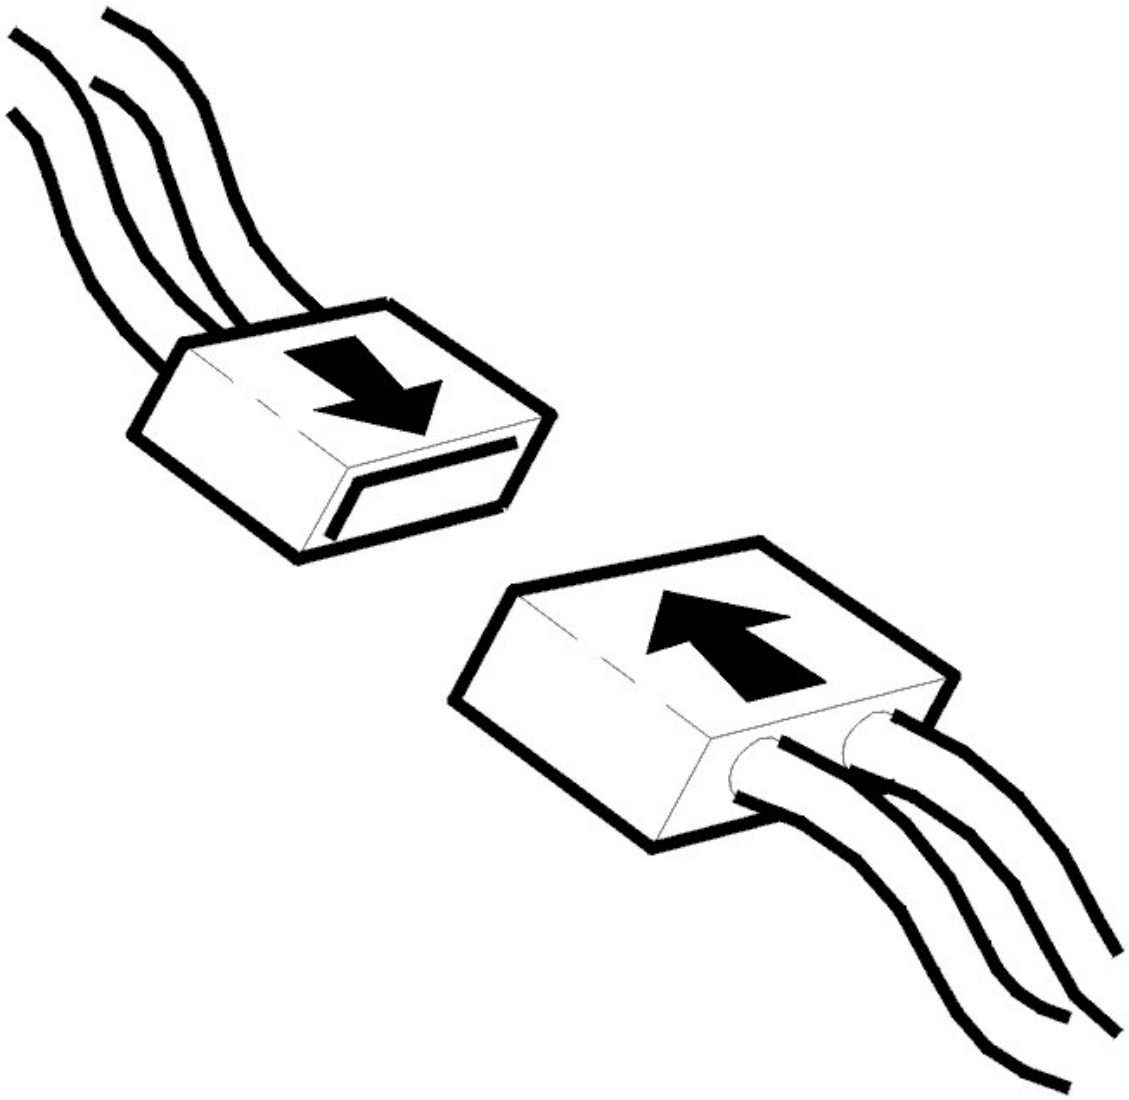
Verification

Hint: After carrying out the repair, check that the fault has been remedied.

Note! The ignition must be switched on for at least 30 seconds after the basic conditions are met in order for the adaptation to start. It takes approximately 10 seconds to run the adaptation.





- Ignition off
- Reinstall the connectors, components etc.
- Ignition on
- Read off the parameters.

Check that the following basic conditions for adaptation of the throttle unit are met.

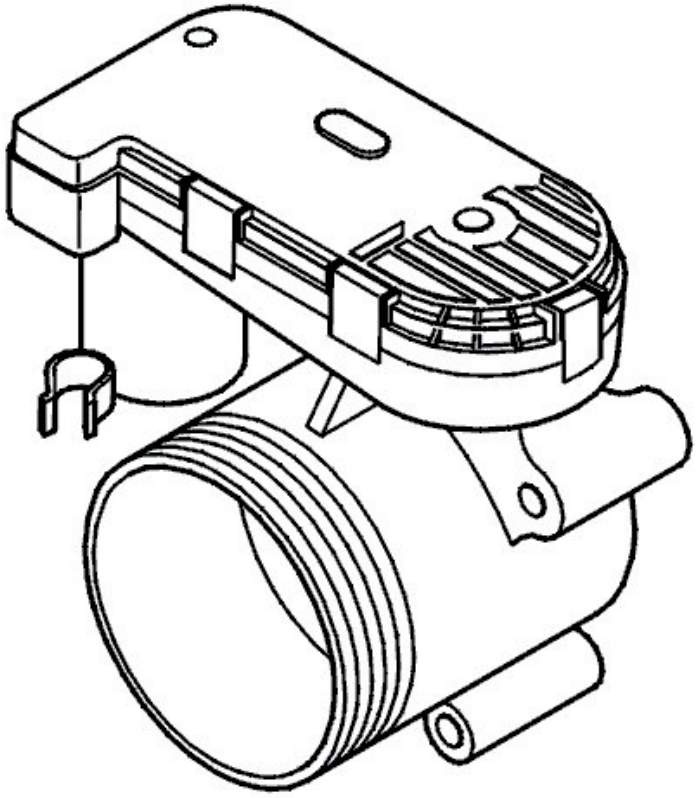
1. Ignition on / engine off
2. Battery voltage above 10 V
3. Accelerator pedal (AP) unaffected
4. The car must be stationary (no vehicle speed signal)
5. Engine coolant temperature (ECT) between 5-100 °C
6. Intake air temperature (IAT) above 5 °C.

Remedy as necessary.

Check that the adaptation is correctly run after the "Adaptation of the throttle unit running" parameter changes status from "YES" to "NO". When all basic conditions are met, the adaptation must be completed after approximately 40 seconds. When the adaptation is completed correctly, the following information will be displayed:

- Adaptation of the throttle unit: OK
- Adaptation of the throttle unit running: NO.

The fault has been remedied if the adaptation has been completed correctly.



Is the adaptation OK?

Diagnostic Trouble Code (DTC) Information

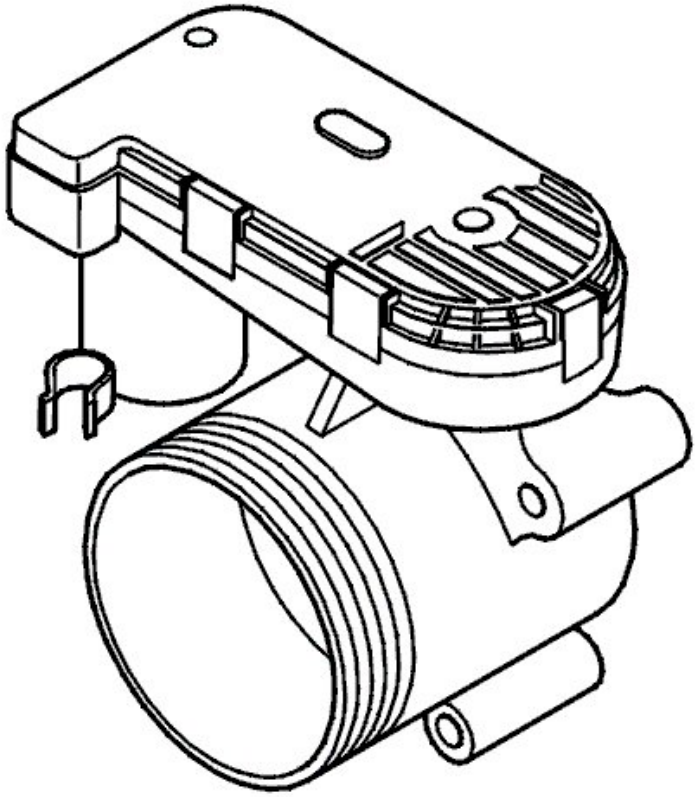
Diagnostic trouble code (DTC) information ECM-92D0

Condition



The diagnostic trouble code (DTC) is stored if the ignition has been left on for 30 seconds and the engine control module (ECM) has been unable to adapt the electronic throttle unit. This is because the programmed parameter for the stop position in the throttle position (TP) sensor has been exceeded. Adaptation is usually carried out to ensure that the throttle unit parameters are within the programmed values that are stored in the engine control module (ECM). If other diagnostic trouble codes (DTCs) are stored, these must be remedied first. These may have caused the adaptation to fail.

Substitute value
- The engine control module (ECM) uses parameters from previous successful adaptations
- The engine control module (ECM) shuts down the supply to the damper motor for the electronic throttle unit. The throttle will set itself to the return position.

Possible source
- The throttle is sticking or is blocked (e.g. oil film, dust)
- Contact resistance or oxidation in the terminals between the engine control module (ECM) and the electronic throttle unit
- Damaged throttle unit.

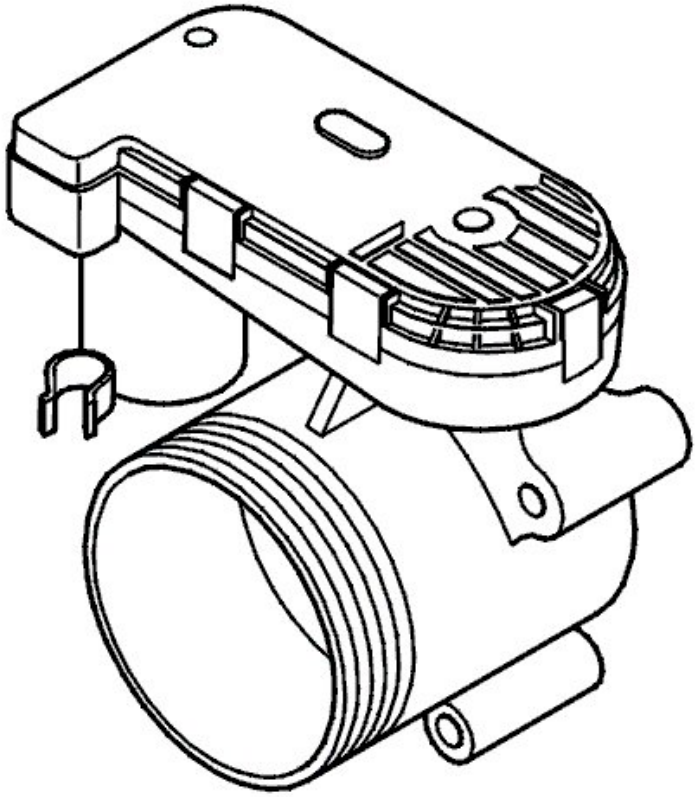
Fault symptom[s]
- Poor performance.

Faulty Signal

Faulty signal

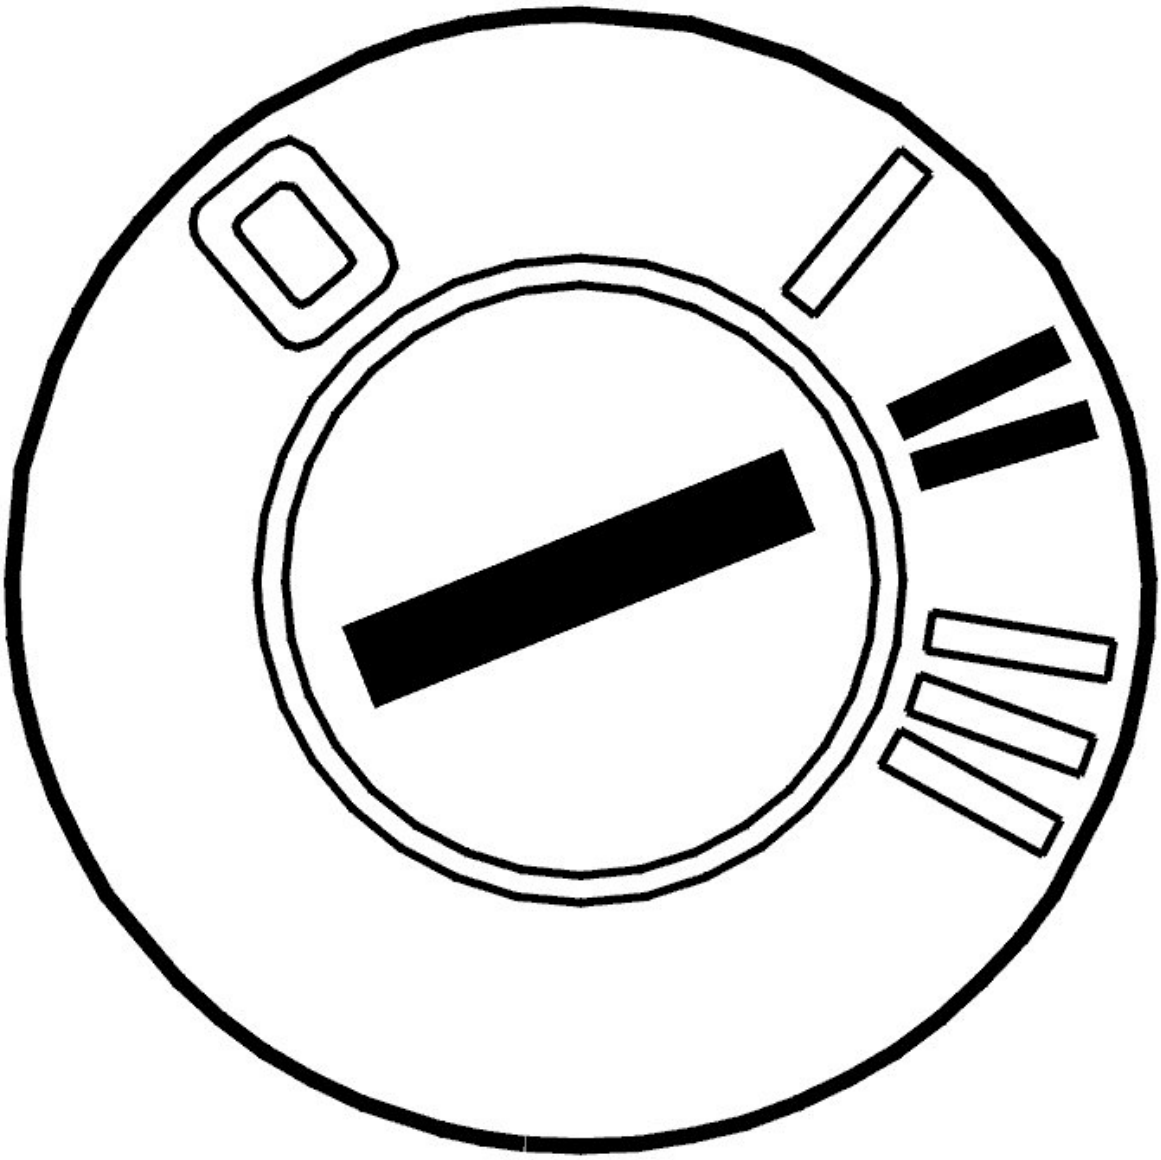
Fault-tracing information

Caution! The male and female pins on the electronic throttle unit connectors are gold plated. Great care must be taken when measuring. Damage to the gold plating can result in operating difficulties.



Continue - Checking diagnostic trouble codes (DTCs)

Checking diagnostic trouble codes (DTCs)



- Ignition on
- Read off diagnostic trouble codes (DTCs).

Check to see if any other diagnostic trouble codes (DTCs) are stored. If other diagnostic trouble codes (DTCs) are stored, they may mean that it is not possible to run the adaptation of the engine control module (ECM).

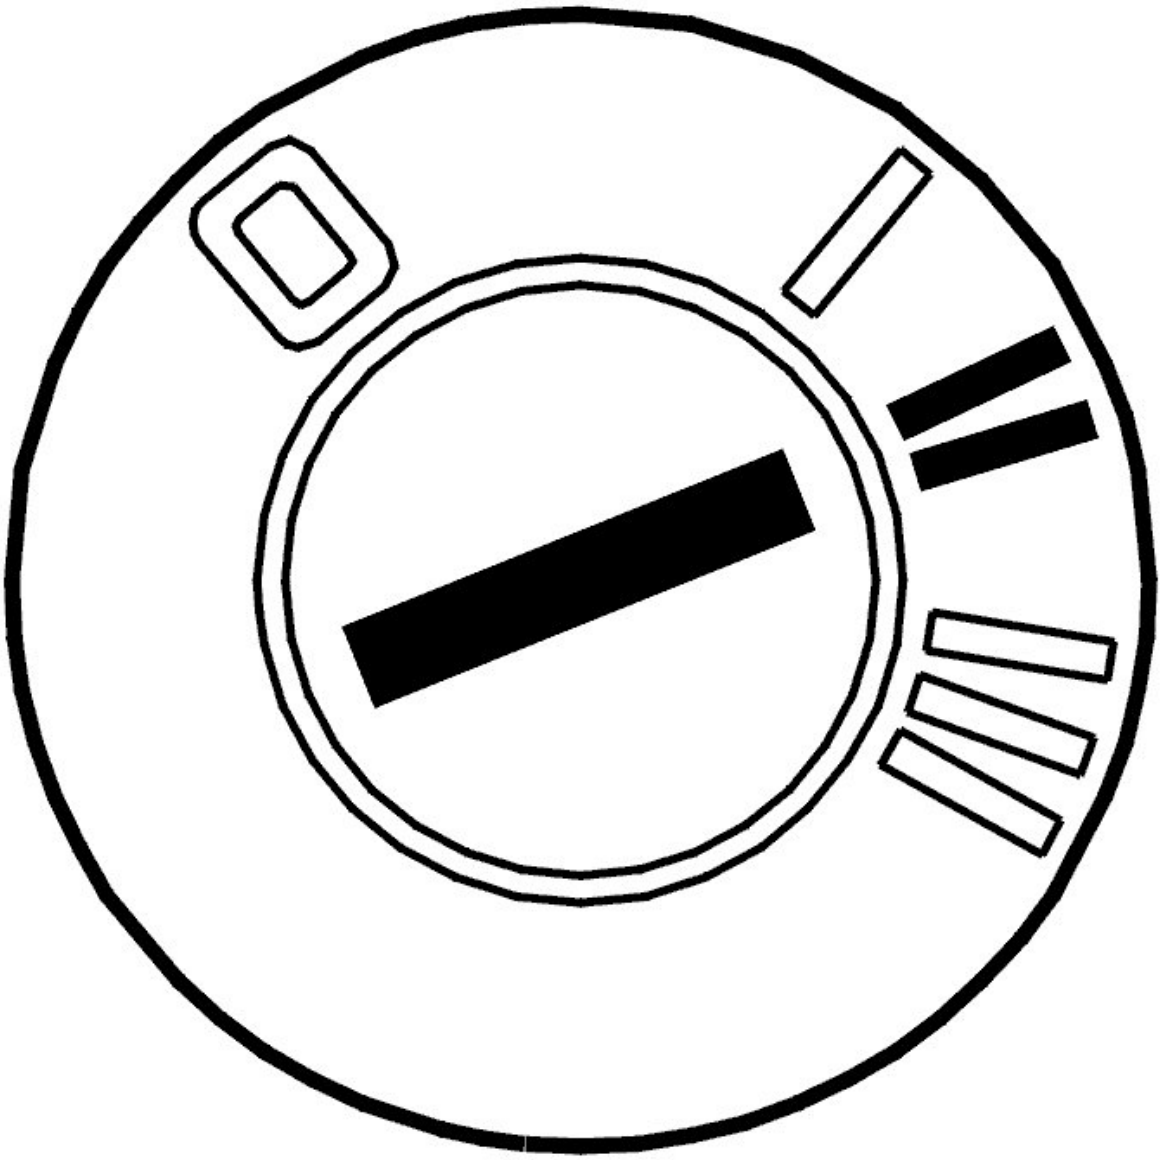
Are any other diagnostic trouble codes (DTCs) stored?

Yes - Fault-tracing information

No - Checking the status

Checking the status

Note! The ignition must be switched on for at least 30 seconds after the basic conditions are met in order for the adaptation to start. It takes approximately 10 seconds to run the adaptation.



- Ignition off

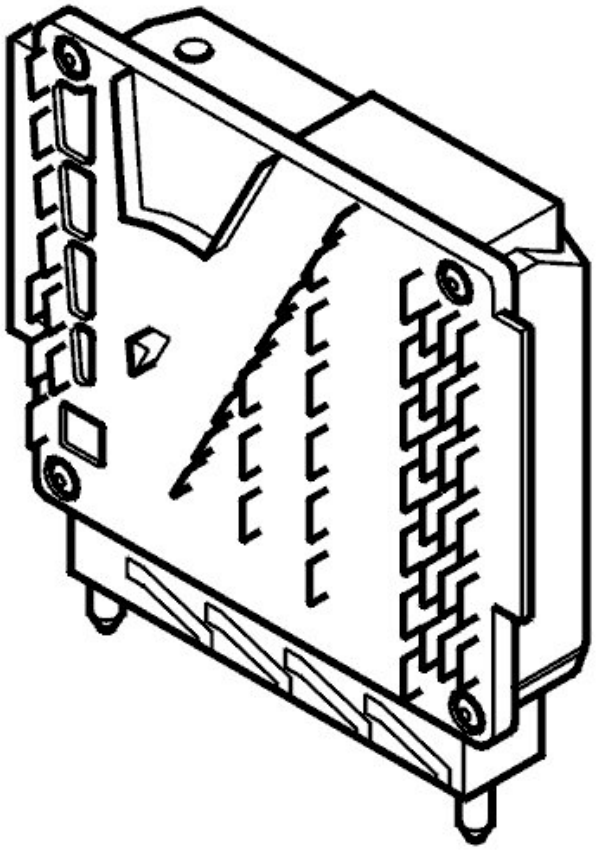
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information ECM-92E0

Condition



The diagnostic trouble code (DTC) is stored if the engine control module (ECM), when attempting to adapt the electronic throttle unit, registers an internal fault in the integrated amplifier for the signal from potentiometer 1 in throttle position sensor (circuit 1) in the electronic throttle unit.

Substitute value

The engine control module (ECM) does not use the signal from potentiometer 1 for the throttle position (TP) sensor (circuit 1) in the electronic throttle unit.

Possible source
- Damaged engine control module (ECM).

Fault symptom[s]
- None.

Internal Fault

Internal fault

Replacing the component

The engine control module (ECM) has registered an internal fault.
If the fault is intermittent, it has been registered previously but is no longer present. Intermittent faults can be caused by interference at start up of the engine control module (ECM) or may be a different type of fault which occurs on different occasions. The fault is evaluated depending on how it occurs. Replace the engine control module (ECM) if the fault recurs.
Replace the engine control module (ECM) in the event of a permanent fault.
Engine control module (ECM), replacing See: Engine Control Module/Service and Repair
Remedy as necessary.

Diagnostic Trouble Code (DTC) Information

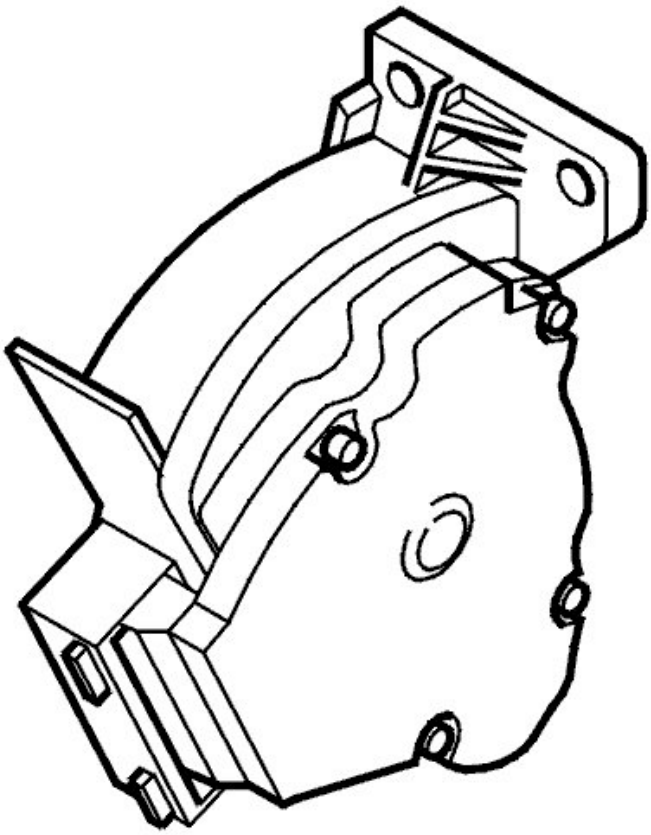
Diagnostic trouble code (DTC) information ECM-9400

Condition



The diagnostic trouble code (DTC) is stored if the engine control module (ECM) registers a fault in the analog signal from the accelerator pedal (AP) position sensor.
The diagnostic trouble code (DTC) can be diagnosed when the ignition is switched on.

Substitute value
- The accelerator pedal (AP) is disabled at the same time as the brake pedal is pressed.

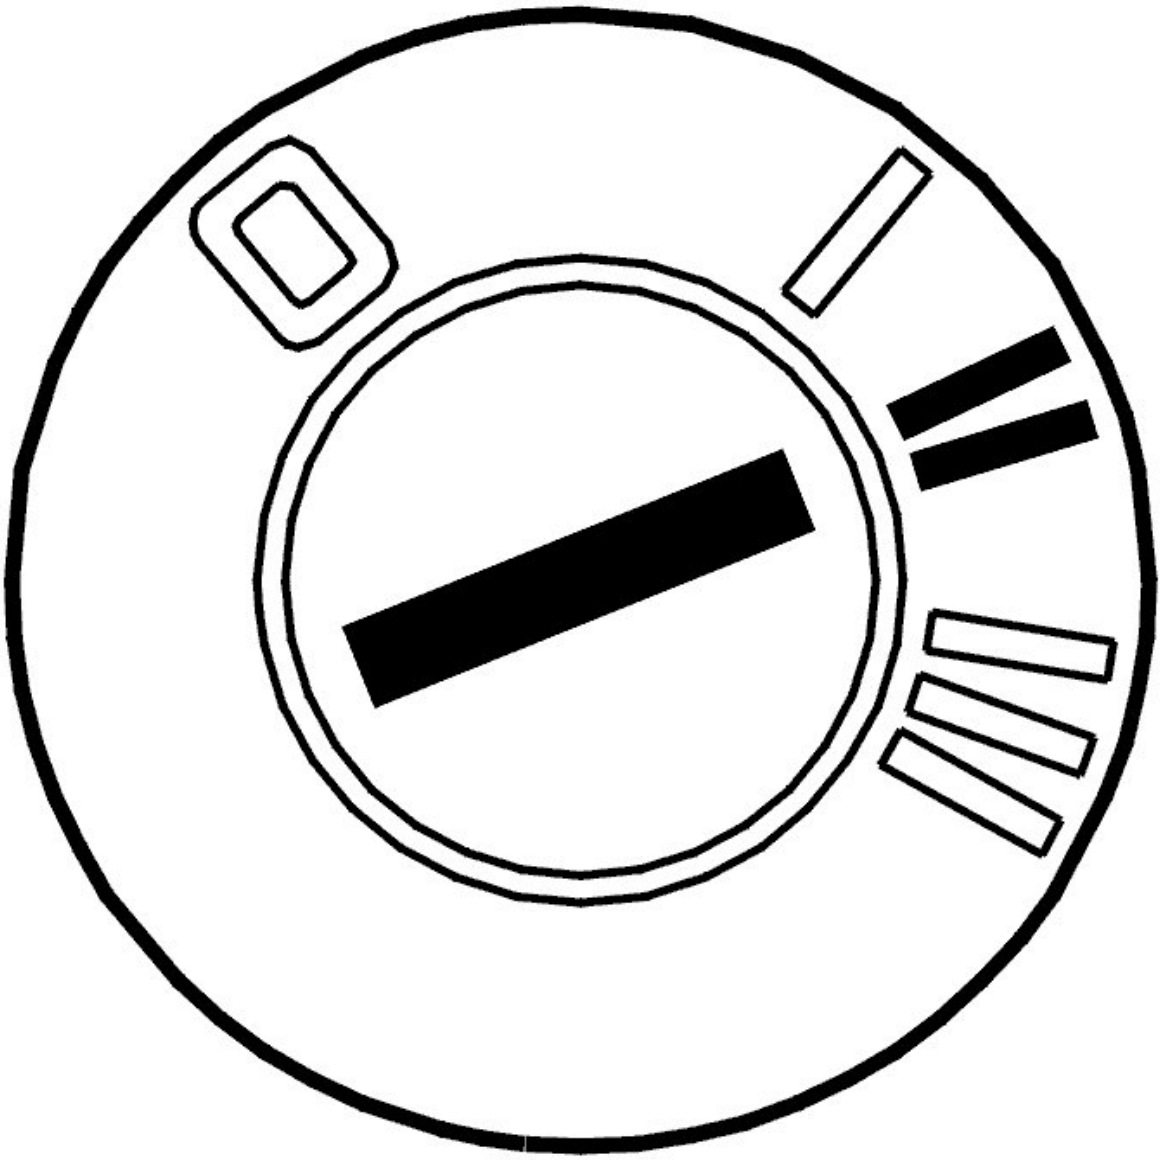
Possible source
- Open-circuit in the power supply (12 V) for the accelerator pedal (AP) position sensor
- Water in the connectors.
- Damaged accelerator pedal (AP) position sensor.

Fault symptom[s]
- Poor accelerator pedal (AP) response.
- Message in information display

Faulty Signal

Faulty signal

Checking the status

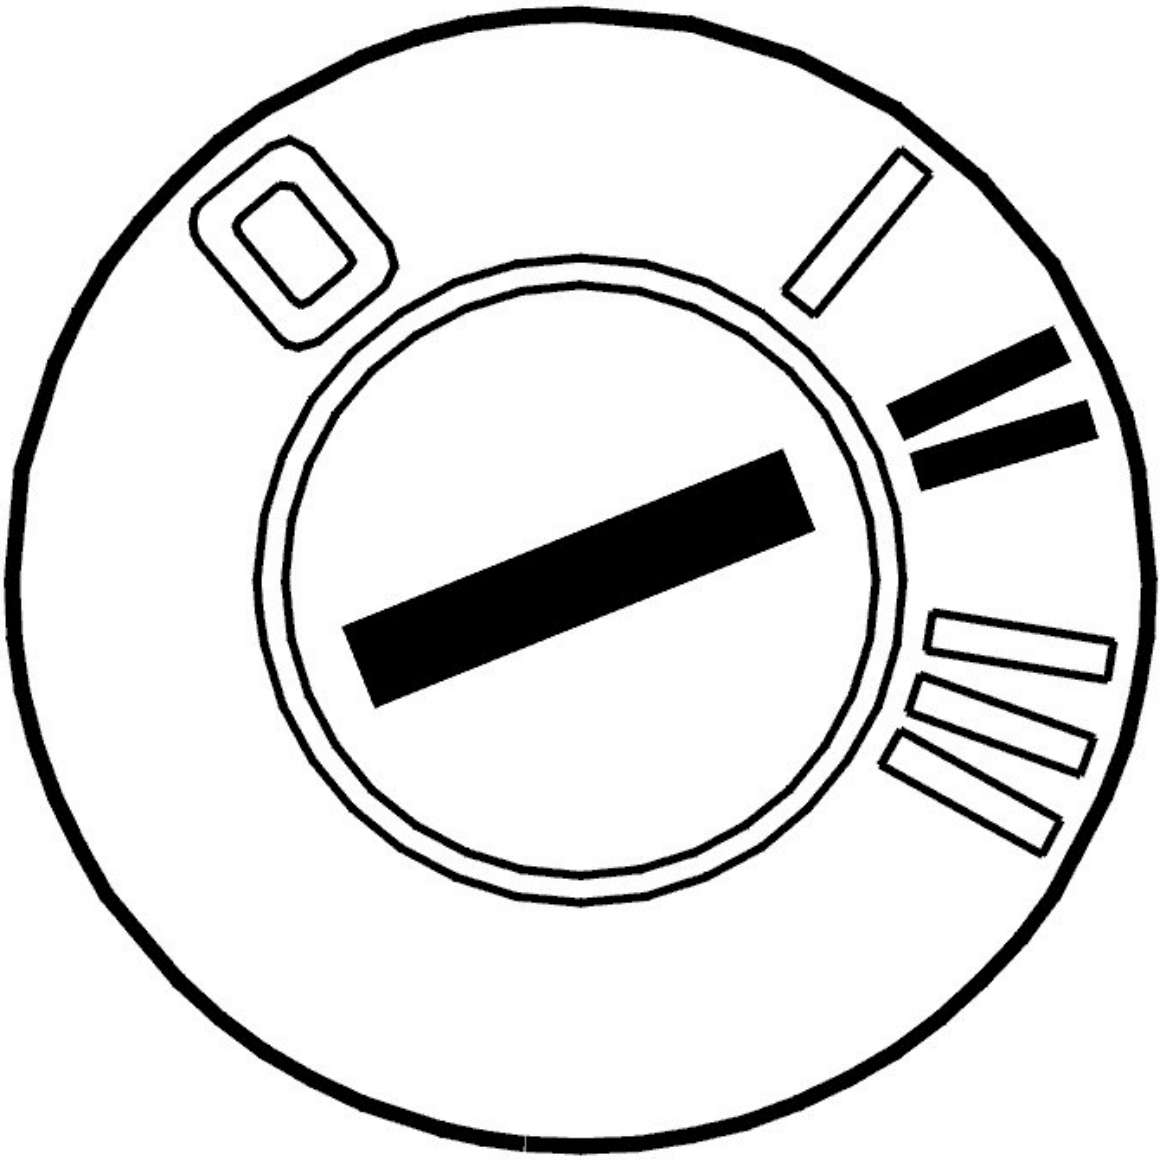


- Ignition on
- Read off the movement of the accelerator pedal by carefully depressing and releasing the accelerator pedal (AP).

Check that the value changes with accelerator pedal movement. The value must be approximately 0.4 V when the accelerator pedal (AP) is unaffected and approximately 4 V when the accelerator pedal (AP) is fully depressed.
The fault is intermittent at the moment if the values are OK.

Continue - Checking the power supply

Checking the power supply



- Ignition on.

Check the connectors and terminals for water penetration.
Check the power supply (12 V) to the accelerator pedal (AP) position sensor between accelerator pedal (AP) position sensor terminals #1 (wiring side) and #3 (wiring side).
Check that the power supply is approximately 12 V with the ignition on.
Remedy as necessary.

Continue - Verification

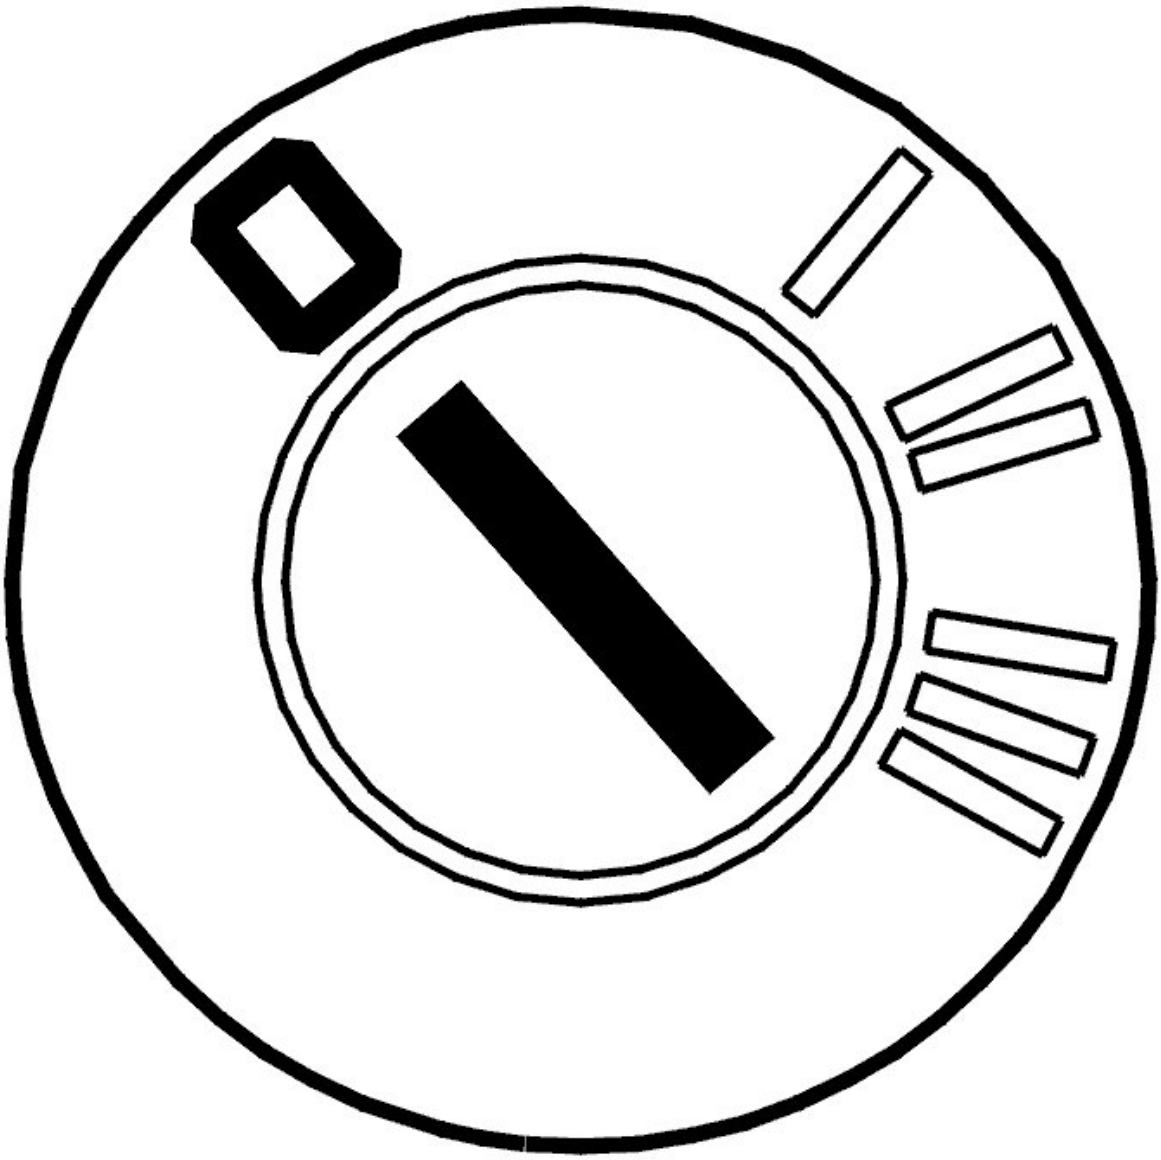
Checking components and wiring



- Ignition off
- Check the accelerator pedal (AP) position sensor connector. Check for contact resistance and oxidation.

Check the power supply cable (12 V) between accelerator pedal (AP) position sensor terminal #1 (wiring side) and the relevant fuse for the circuit. Check for a short-circuit to ground. Check for an open-circuit. Check that the fuse for the circuit has not blown.
Check the ground lead for power supply (12 V) between accelerator pedal (AP) position sensor terminal #3 (wiring side) and the relevant ground terminal. Check for contact resistance and oxidation. Check for an open-circuit.

Hint: With the ignition on, the power supply to the accelerator pedal (AP) position sensor must be approximately 12 V measured between accelerator pedal (AP) position sensor terminals #1 (wiring side) and #3 (wiring side).

Remedy as necessary.

Other information:

- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

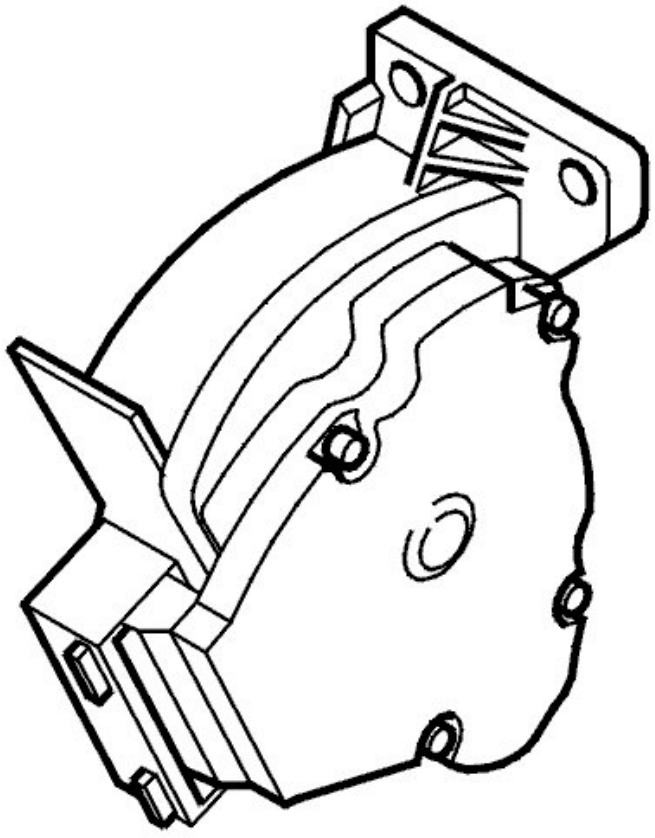
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information ECM-941D

Condition



The diagnostic trouble code (DTC) is stored if the engine control module (ECM) registers a fault in the PWM-signal from the accelerator pedal (AP) position sensor.
The diagnostic trouble code (DTC) can be diagnosed when the ignition is switched on.

Substitute value

- The accelerator pedal (AP) is disabled at the same time as the brake pedal is pressed.

Possible source

- Contact resistance or oxidation in the terminals between the engine control module (ECM) and the accelerator pedal (AP) position sensor

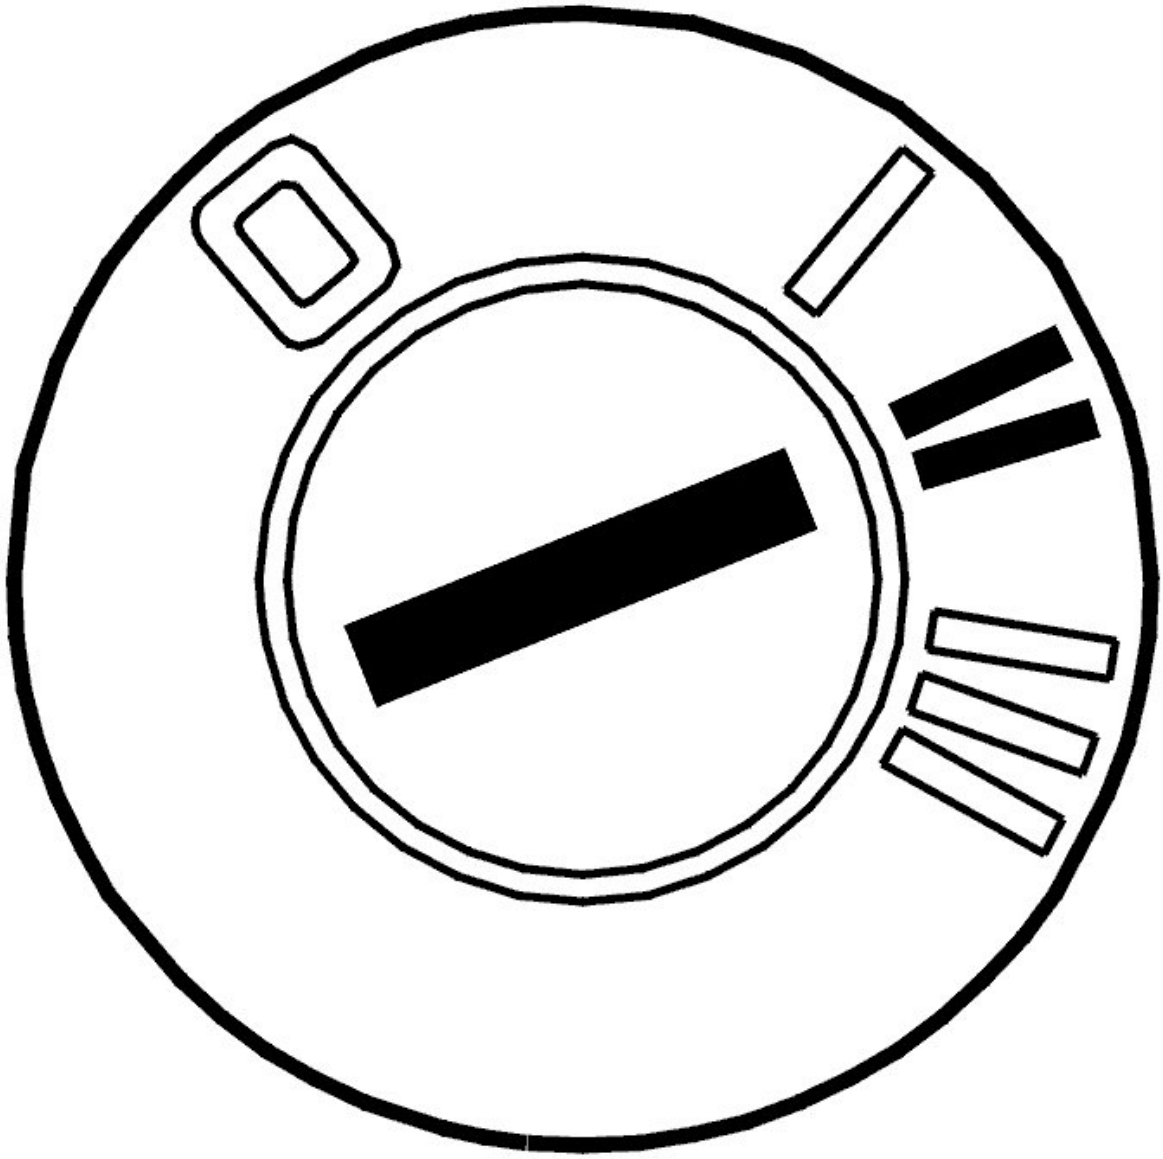
- Open-circuit or short-circuit to ground in the signal cable
- Open-circuit in the power supply (12 V) for the accelerator pedal (AP) position sensor
- Damaged accelerator pedal (AP) position sensor.

Fault symptom[s]
- Poor accelerator pedal (AP) response.

Signal Too Low

Signal too low

Checking the status



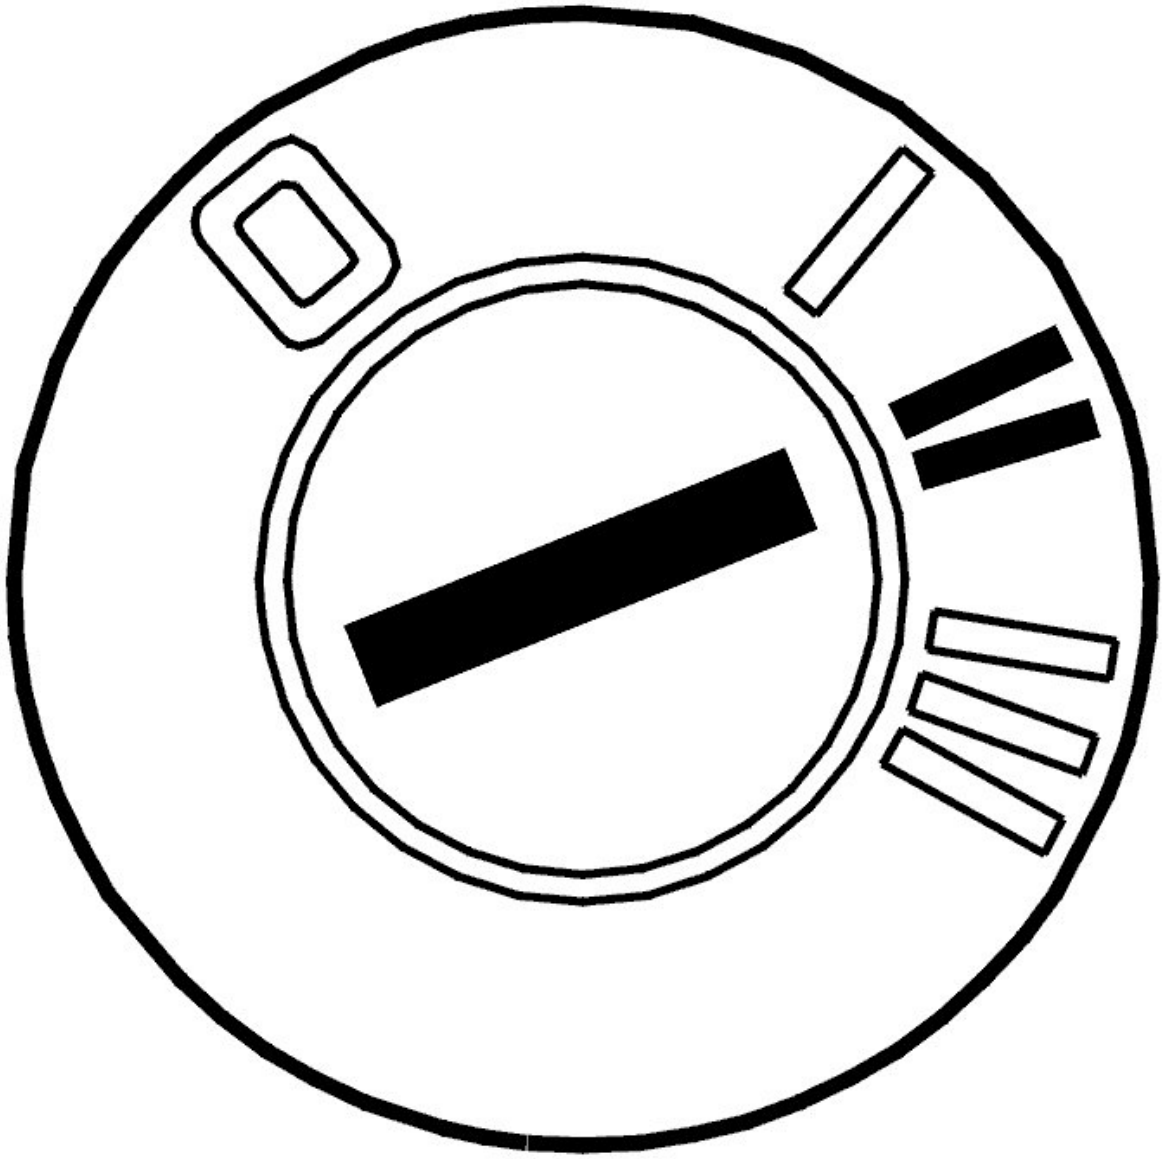
- Start the engine
- Ignition off
- Ignition on
- Read off the movement of the accelerator pedal by carefully depressing and releasing the accelerator pedal (AP).

Check that the value changes with accelerator pedal movement. The value must be between approximately 0.4 V when the accelerator pedal (AP) is unaffected and approximately 4 V when the accelerator pedal (AP) is fully depressed.
The fault is intermittent at the moment if the values are OK.

Continue - Checking the power supply

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

Checking the power supply



- Ignition on.

Check the power supply (12 V) to the accelerator pedal (AP) position sensor between accelerator pedal (AP) position sensor terminals #1 (wiring side) and #3 (wiring side).
Check that the power supply is approximately 12 V with the ignition on.

Other information:

- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals

Diagnostic Trouble Code (DTC) Information

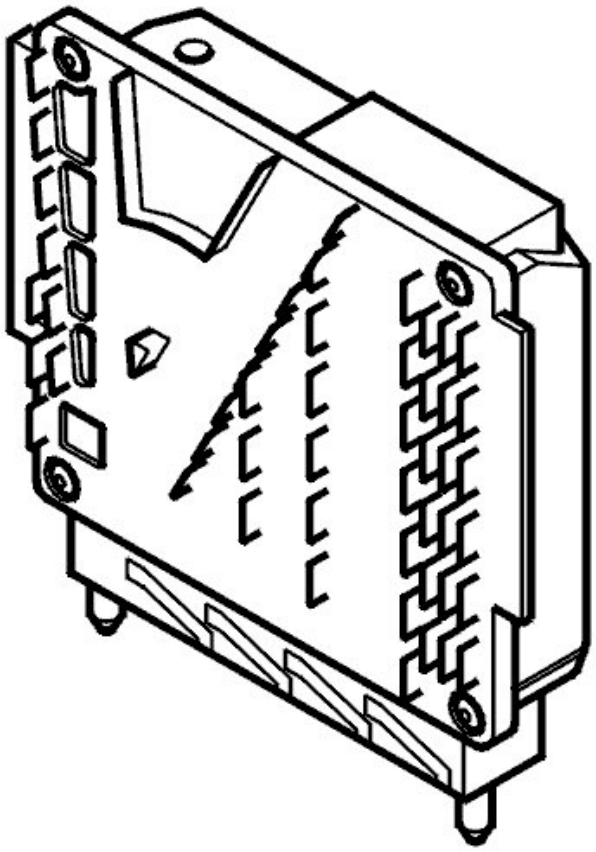
Diagnostic trouble code (DTC) information ECM-9850

Condition



The diagnostic trouble code (DTC) is stored if the engine control module (ECM) registers an internal fault in one of the internal monitoring functions in the engine control module (ECM). This diagnostic trouble code (DTC) is normally always stored with one of the other diagnostic trouble codes (DTCs) which affect the internal monitoring functions.
The diagnostic trouble code (DTC) is diagnosed at ignition on or with the engine running.

Substitute value

None.

Possible source
- One of the diagnostic trouble codes (DTCs) which affect the internal monitoring functions is stored in the engine control module (ECM)
- Damaged engine control module (ECM).

Fault symptom[s]
- Driving/Poor performance/lacks power
- Idling/Uneven idle

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information ECM-A12B

Condition

A fault message is transmitted to the engine control module (ECM) and the diagnostic trouble code (DTC) is stored if a fault is detected in the brake control module (BCM). Diagnostic trouble codes (DTCs) for the vehicle speed sensor (VSS) signal are also stored in the brake control module (BCM).

Substitute value

- The speed signal from the brake control module (BCM) is set at 0 km/h.

Possible source
- Contact resistance in the control area network (CAN) terminals
- Open-circuit in one or both CAN cables
- Short-circuit to ground, voltage or each other in one or both signal cables
- Damaged brake control module (BCM)
- Damaged engine control module (ECM).

Fault symptom[s]
- Malfunction indicator lamp (MIL) lit.

Fault-Tracing Information

Fault-tracing information

Information

The diagnostic trouble code (DTC) indicates that the primary fault is in another unit. The fault-tracing is carried out from the primary diagnostic trouble code.
For further information on this diagnostic trouble code, see Diagnostic trouble code (DTC) information.

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information ECM-A12C

Condition

A fault message is transmitted to the engine control module (ECM) and the diagnostic trouble code (DTC) is stored if a fault is detected in the brake control module (BCM). Diagnostic trouble codes (DTCs) for the vehicle speed sensor (VSS) signal are also stored in the brake control module (BCM).

Substitute value
- The speed signal from the brake control module (BCM) is set at 0 km/h.

Possible source
- Faulty speed signal to the brake control module (BCM).

Fault symptom[s]
- Malfunction indicator lamp (MIL) lit.

Fault-Tracing Information

Fault-tracing information

Information

The diagnostic trouble code (DTC) indicates that the primary fault is in another unit. The fault-tracing is carried out from the primary diagnostic trouble code.
For further information on this diagnostic trouble code, see Diagnostic trouble code (DTC) information.

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information ECM-A130

Condition

The control modules transmit and receive information via a standardized serial communication method - CAN (Control Area Network). The diagnostic trouble code (DTC) is stored if the engine control module (ECM) registers serious interference (CAN communication blocked).

Note! In the event of system communication problems, it is not possible to communicate with the engine control module (ECM). Therefore it will only be possible to read off the diagnostic trouble code (DTC) if the fault is intermittent.

Substitute value
- The engine control module (ECM) shuts itself off "bus-off".

Hint: The engine control module (ECM) will then be shut off until the supply voltage is interrupted (15-, 30-, X supply). When the power supply is switched on, the engine control module (ECM) will make a new attempt to communicate.

Possible source
- Contact resistance or oxidation in the terminals
- Open-circuit in the control area network (CAN) wiring
- Short-circuit between the control area network (CAN) wiring
- Internal fault in the engine control module (ECM)
- Internal fault in another control module in the same part of the control area network (CAN).

Fault symptom[s]
- General warning lamp lit
- The cruise control does not function at all
- The engine judders under acceleration
- The engine judders heavily after engine braking
- Uneven idle.

Faulty Communication

Faulty communication

General information

In order to check the control area network (CAN) cables, the resistance in the network must be measured. The resistance between the two controller area network (CAN) wiring, with the network connected 60 ohms. The resistance can differ depending on the configuration of the car. Permitted values are 55-65 ohms. This applies to both the high speed side network and the low speed side network.

Hint: Use the applicable wiring diagram to provide support when taking readings. Take a copy of the data communication side for each model. Note which diagnostic trouble codes (DTCs) are stored in each control module. This facilitates fault-tracing considerably.

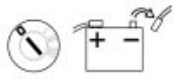
Check if the diagnostic trouble codes (DTCs) for failed communication are stored in the central electronic module (CEM). If this is the case, first fault-trace according to these diagnostic trouble codes (DTCs).

Other information
- For general information about fault-tracing the control area network (CAN), see

Continue - Checking the resistance of the control area network (CAN) cables

---

Checking the resistance of the control area network (CAN) cables



- Disconnect the battery negative lead. The power to the network must be cut when taking resistance readings. The reading may otherwise be incorrect.

Note! Also read: Battery, disconnecting See: Starting and Charging/Battery/Service and Repair/Procedures/Battery, Disconnecting

- Connect the adapter wiring to the central electronic module (CEM).

Hint: Where a breakout box cannot be used, take readings from the rear of the affected connectors if possible. This prevents terminal pins and socket housings being damaged.

When taking readings on the low speed network
- When taking readings on the low speed network, the adapter wiring should be connected to the central electronic module (CEM) and the readings taken from there. The readings can also be taken in the connector for the power seat module (PSM). The advantage of using the adapter wiring connected to the central electronic module (CEM) is that all control modules can be connected to the network when taking readings and there is access to both the high speed and the low speed networks.

This resistance reading only measures main arteries in the low speed network, not the junctions for the road traffic information module (RTI), accessory electronic module (AEM), power seat module (PSM), phone module (PHM), audio module (AUM), driver's door module (DDM) and passenger door module (PDM). See the applicable wiring diagram, Data communication.

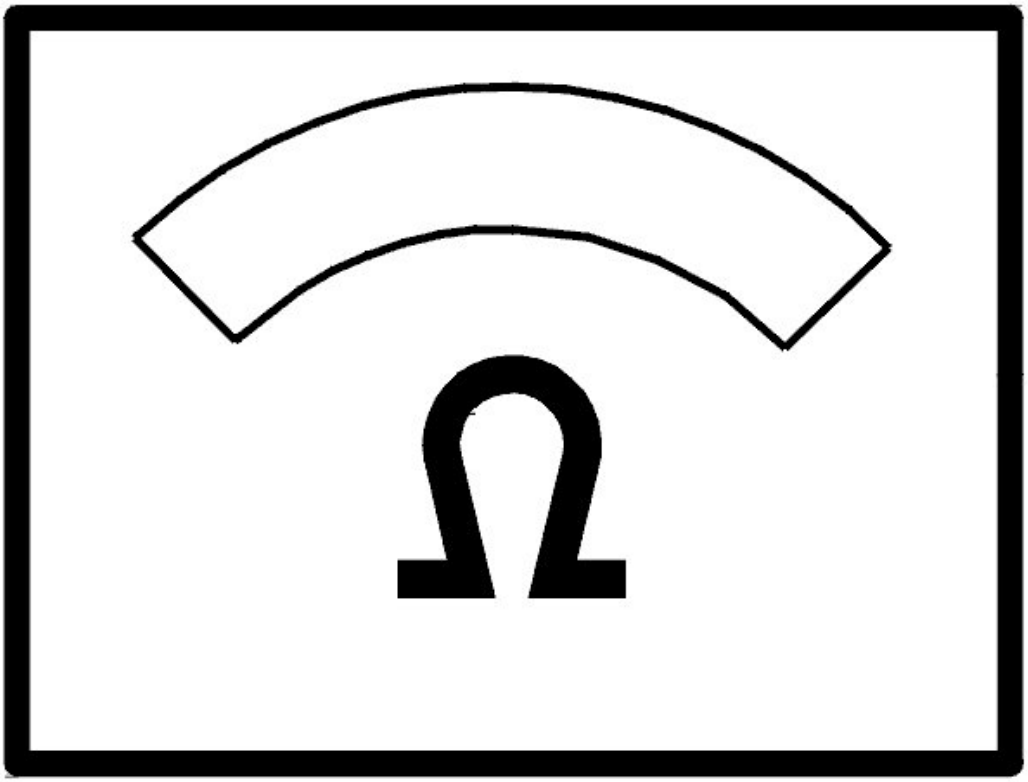
When taking readings on the high speed network

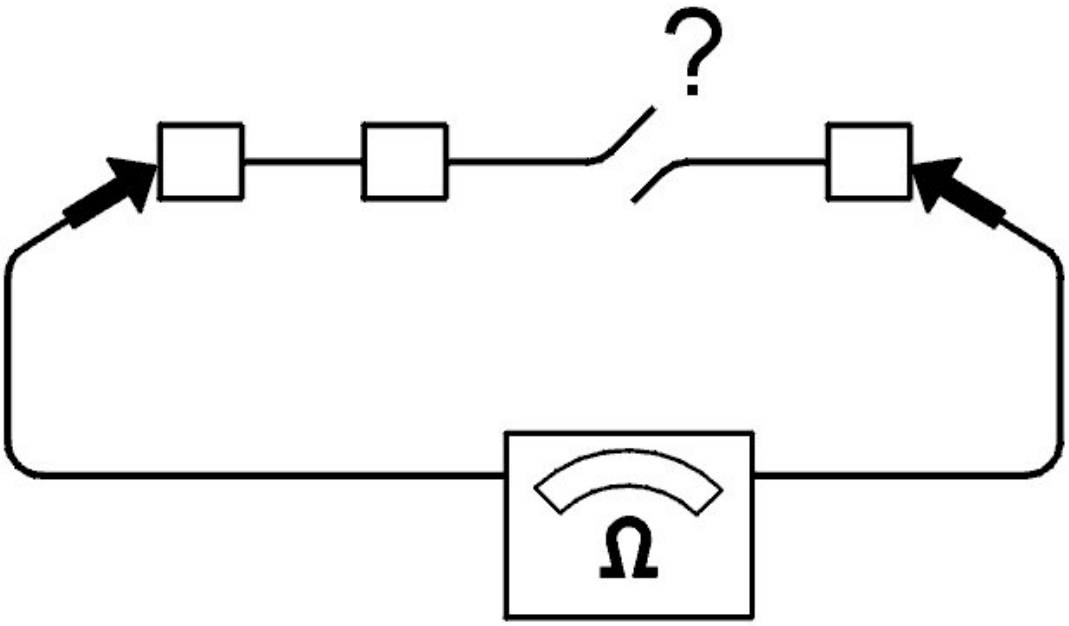
- When taking readings on the high speed network, the readings should be taken at the engine control module (ECM) using adapter wiring. The engine control module (ECM) must be connected. This resistance reading only takes readings from the main arteries in the high speed network. See the applicable wiring diagram, Data communication.

Connect the ohmmeter to the terminals for CAN-L and CAN-H on the relevant network. Work the connectors and twist the cable harness. The resistance must be approximately 60 ohms. Permitted values are 55-65 ohms.

Other information

- Connecting the breakout box See: Body and Frame/Body Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box/Connecting the Breakout Box, Central Electronic Module (CEM)
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals





Is the value OK?

Yes - Checking a short-circuit in CAN cables

No - Identifying fault causes in the CAN network

Checking a short-circuit in CAN cables

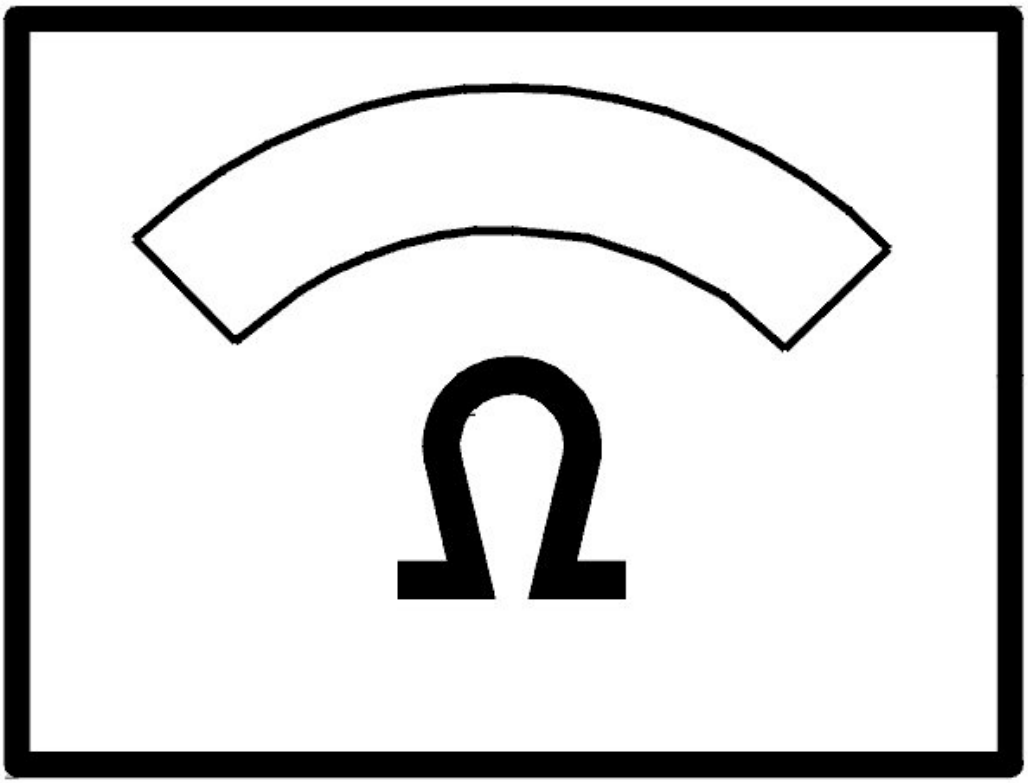
Connect an ohmmeter between the relevant CAN cable (CAN-L and CAN-H) and the power supply, and between the CAN cable and ground. Twist the connectors and turn the cable harness to different positions at each reading to determine any intermittent short-circuits.

Take the following readings:

- The resistance between CAN-L and ground
- The resistance between CAN-L and voltage
- The resistance between CAN-H and ground
- The resistance between CAN-H and voltage.

The resistance must be infinite or very high in all cases (greater than 1 M Ohms).

Hint: The reading can be taken from the same connector if the CAN cables, power supply and ground are exposed. If possible, take readings on the rear of the connector to prevent damage to the terminals in the connector. If this is not possible, use the adapter wiring or loose terminal pins to obtain a good contact.

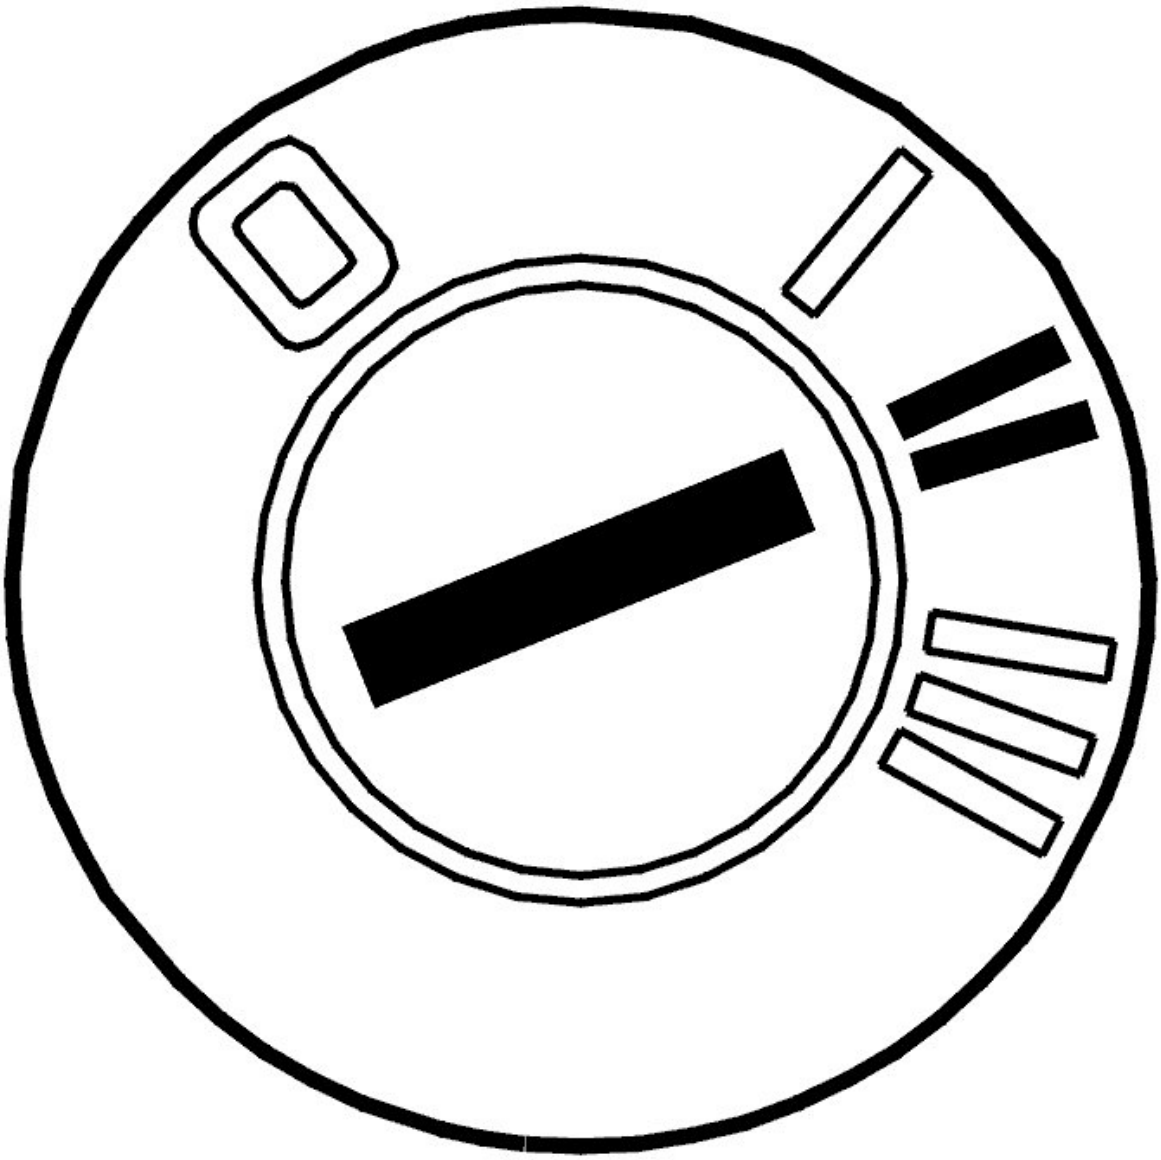


Was a fault detected?

Yes - Identifying fault causes in the CAN network

No - Checking the traffic load on the CAN cables

Checking the traffic load on the CAN cables



- Connect the battery
- Ignition on

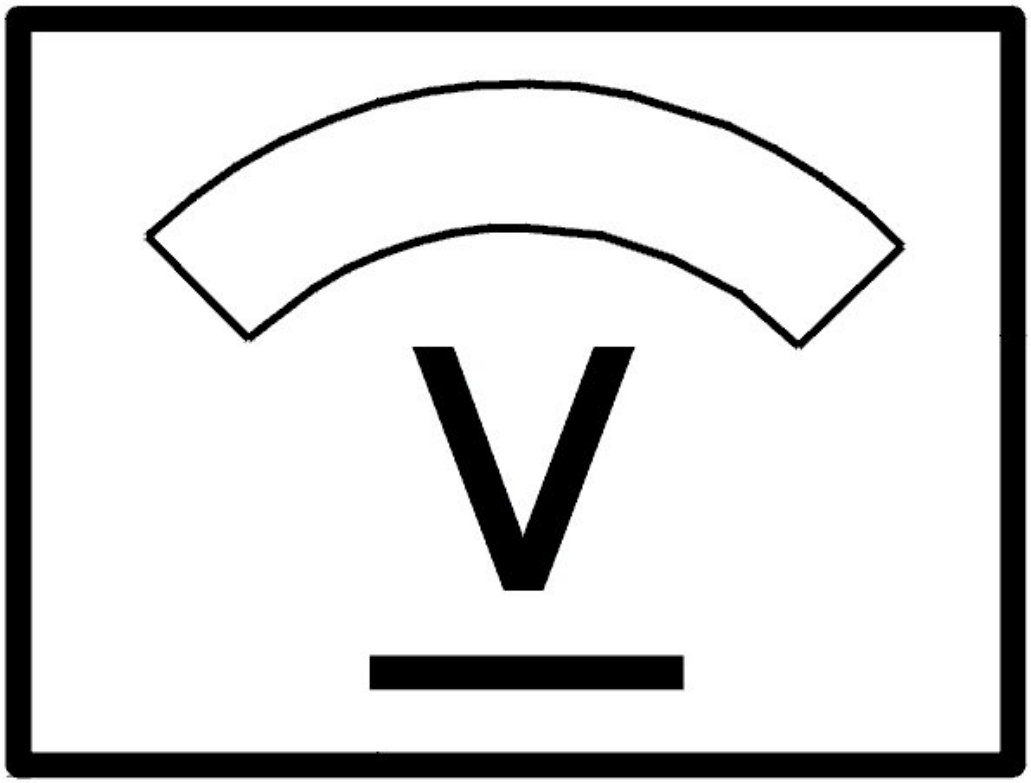
Also read: Battery, disconnecting See: Starting and Charging/Battery/Service and Repair/Procedures/Battery, Disconnecting

Faults in the CAN network may be due to a control module sending faulty messages that disrupt "normal" communication. When messages are sent incorrectly, this results in a considerable increase in the amount of traffic on the CAN network. Check the load by measuring the average voltage value on the CAN cables in relation to ground.

Connect a voltmeter between CAN-L and ground. The voltage must be approximately 2.3 V.

Then connect a voltmeter between CAN-H and ground. The voltage must be approximately 2.8 V.

Hint: If possible measure from the rear of the affected connectors so that they are not damaged.



Is the value OK?

Yes - Fault-tracing without result

No - Identifying a control module in the CAN network

Identifying fault causes in the CAN network

- Disconnect a control module that disconnects the CAN network (a control module that has four terminals to the CAN network).

Hint: For the low speed network, suitable places for disconnecting the network are at the steering wheel module (SWM), the driver information module (DIM) or the climate control module (CCM).

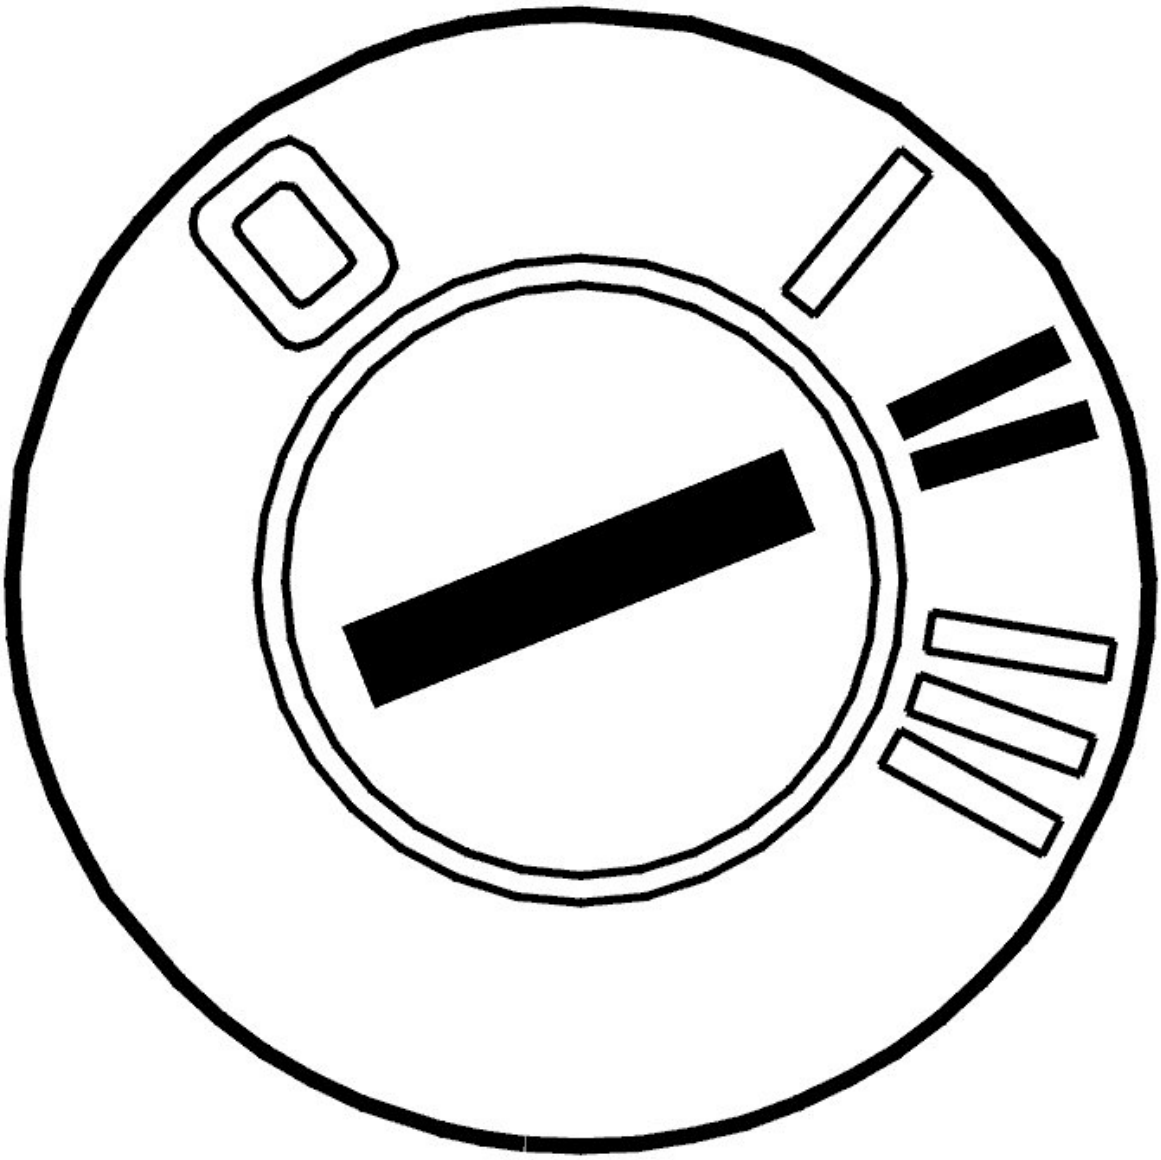
In the event of a short-circuit between one of the CAN cables and voltage or ground, the fault can be located by disconnecting a control module that disconnects the CAN network. Readings can then be taken to determine on which side of the disconnected control module the fault is located. Connect an ohmmeter between the CAN cable and supply voltage or ground. Take readings at both ends of the CAN network where the network is disconnected. Twist and bend the cable harness to locate any intermittent short-circuits. The resistance must be infinite or very high (greater than 1Mohms).
If a fault can be localized in one direction, disconnect the network at a point further down on the CAN network in the direction in which the fault was discovered and repeat the reading. In this way, try to identify where in the network the fault might be located.

Hint: A short-circuit between the CAN cables and supply voltage or ground may be in either the wiring or in a control module.

Rectify the wiring as necessary. Replace the control module if the fault has been localized to a control module.

Continue - Verification

Identifying a control module in the CAN network



- Connect the battery

Also read: Battery, disconnecting See: Starting and Charging/Battery/Service and Repair/Procedures/Battery, Disconnecting

- Ignition on

If the load on the CAN network is too high, this may be due to a control module sending faulty messages on the CAN network (known as a disruptive control module). The fault may also be due to an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The faults can occur without a diagnostic trouble code (DTC) being stored by the control modules. The voltage can be measured between the CAN cables in order to check the load on the CAN network. Connect a voltmeter between the CAN cables. If the communication on the network is correct, the average voltage value should be approximately 0.5 V (0.4 V to 0.6 V). If there is a fault in the communication, the voltage reading will be approximately 0.7 V or higher.
In order to identify from which control module the faulty communication is being transmitted, cut the supply voltage to one control module at a time and check the voltage in the CAN cables again. The easiest way to cut the supply voltage is to remove a fuse. Repeat until the voltage between the CAN cables drops to approximately 0.5 V.

Hint: When the probable faulty control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the fault appears and disappears.

Note! Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.

The control module that is communicating incorrectly must be replaced. Remedy as necessary.

Note! Following a fault involving "disruptive" control modules, other modules may remain in "Limp-Home mode" even after switching the ignition off and on a number of times. To remedy this, disconnect and reconnect the battery negative terminal to restore the control modules to normal function.

Continue - Verification

Fault-tracing without result

Information

Fault-tracing information

Verification shows that the fault is no longer present. The diagnostic trouble code (DTC) was probably caused by an intermittent fault.
Fault-tracing for this diagnostic trouble code (DTC) is not followed by a verification.
You can view the information again or exit fault-tracing for this diagnostic trouble code (DTC).

Do you want to view information again?

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information ECM-E000

Condition

The control modules transmit and receive information via a standardized serial communication method - CAN (Control Area Network). The diagnostic trouble code (DTC) is stored if the engine control module (ECM) registers serious interference (CAN communication blocked).

Note! In the event of system communication problems, it is not possible to communicate with the engine control module (ECM). Therefore it will only be possible to read off the diagnostic trouble code (DTC) if the fault is intermittent.

Substitute value
- The engine control module (ECM) shuts itself off "bus-off".

Hint: The engine control module (ECM) will then be shut off until the supply voltage is interrupted (15-, 30-, X supply). When the power supply is switched on, the engine control module (ECM) will make a new attempt to communicate.

Possible source
- Contact resistance or oxidation in the terminals
- Open-circuit in the control area network (CAN) wiring
- Short-circuit between the control area network (CAN) wiring
- Internal fault in the engine control module (ECM)
- Internal fault in another control module in the same part of the control area network (CAN).

Fault symptom[s]
- General warning lamp lit
- The cruise control does not function at all
- The engine judders under acceleration
- The engine judders heavily after engine braking
- Uneven idle.

General Information

General Information

HINT: For general information about fault-tracing the control area network (CAN), see the linked document below.

NOTE: When selecting the vehicle profile, the correct vehicle must be identified. Use the "Retrieve VIN" button. The fault-tracing may fail if this is not done.

In order to check the control area network (CAN) cables, the resistance in the network must be measured. When the network is connected, the resistance between the two CAN cables must be **60 ohms** in the high speed network. Generally the permitted values **55-65 ohms**.

NOTE: Resistance will only be **60 ohms** if the main artery of the CAN network is whole and the network is connected. If the main artery of the CAN network is split somewhere and a reading is taken between the CAN cables, resistance will be **120 ohms**.

If diagnostic trouble codes (DTCs) for communication faults can be read off from a control module, the fault is probably intermittent.

Intermittent fault in the voltage supply to a control module on the CAN network results in the Central electronic module (CEM) storing a diagnostic trouble code (DTC) for an open-circuit in communication with the control module where the voltage supply does not work. There will probably not be a diagnostic trouble code (DTC) in the control module where the open-circuit in the voltage supply occurred as the control module cannot store a diagnostic trouble code (DTC) when it is not supplied with power.

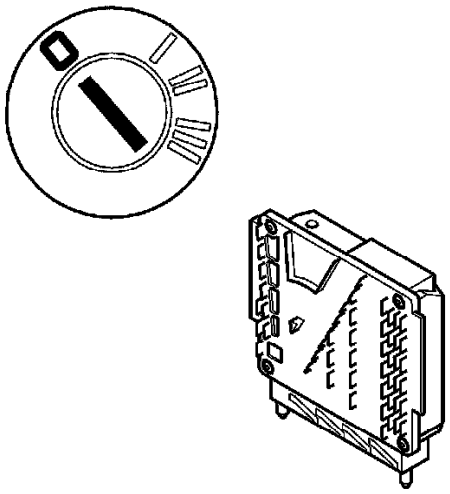
CAUTION: During this fault-tracing use the wiring diagram to provide support when taking readings.

Other Information
- **General information about fault-tracing in the CAN network**

Continue: Refer to Taking Reading on Cables In the CAN Network (HS-CAN). See: Diagnostic Trouble Code Tests and Associated Procedures/Manufacturer Code Charts/ECM Codes (Engine Control Module)/ECM-E000/Signal Missing/Taking Reading on Cables In the CAN Network (HS-CAN)

Taking Reading on Cables In the CAN Network (HS-CAN)

Taking Reading On Cables In The CAN Network (HS-CAN)



- Ignition off
- Disconnect the battery negative lead
- Connect the breakout box to the engine control module (ECM).

HINT: Use the Wiring diagrams to provide support when taking readings.

Take resistance readings across the following terminals. Various readings must be taken due to the structure of the network. Twist the cable harness and work the connectors at accessible points along the cable harness in order to check whether the resistance changes during each measurement. This method can be used to detect intermittent short-circuits or open-circuits.

NOTE: The following resistance readings only measure the main arteries in the high speed network, not the junctions that exist for some control modules. See the Wiring diagrams for the relevant car model. An open-circuit in one artery cannot be detected by this reading. However a short-circuit in an artery can be detected.

Measure the resistance between control module terminals #B1(#1) and #B13 (#13). The resistance must be approximately **60 ohms**. The permitted values are **55-65 ohms**.

HINT: Resistance will only be **60 ohms** if the main artery of the CAN network is whole and the network is connected. If the main artery of the CAN network is split somewhere and a reading is taken between the CAN cables, resistance will be **120 ohms**.

Also measure the resistance between each terminal and supply voltage and ground. The resistance must be infinite or very high (higher than **1 M ohm**).

HINT: If a fault is found, try to disconnect the junction with the fault at a point further forward. Disconnect any connector/control module immediately before the measurement point and take the reading again. Try to locate the fault in this way.

Remedy the cables as necessary.

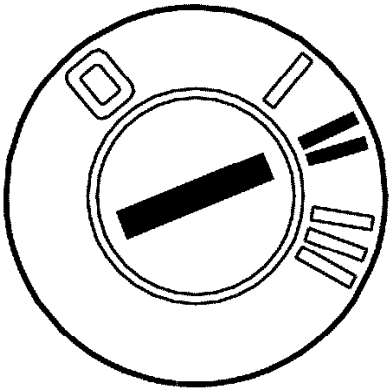
Other Information
- **Battery, disconnecting**
- See Checking Wiring and Terminals under Related Tests, Information and Procedures

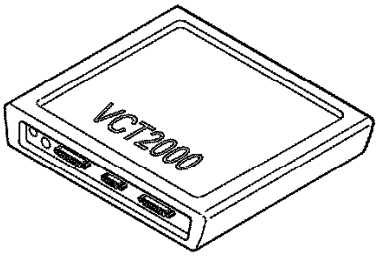
Was a fault detected?

YES: Refer to Reading Off DTCs From All Systems Before Erasing. See: Diagnostic Trouble Code Tests and Associated Procedures/Manufacturer Code Charts/ECM Codes (Engine Control Module)/ECM-E000/Signal Missing/Reading Off DTCs From All Systems Before Erasing
NO: Refer to Checking the Traffic Load on the CAN Cables. See: Diagnostic Trouble Code Tests and Associated Procedures/Manufacturer Code Charts/ECM Codes (Engine Control Module)/ECM-E000/Signal Missing/Checking the Traffic Load on the CAN Cables

Reading Off DTCs From All Systems Before Erasing

Reading Off Diagnostic Trouble Codes (DTCs) From All Systems Before Erasing





CAUTION: This function erases all diagnostic trouble codes (DTCs) in all the systems in the car. The procedure begins with the reading off and display of diagnostic trouble codes (DTCs). The diagnostic trouble codes (DTCs) can then be erased.

NOTE: When erasing diagnostic trouble codes (DTCs) in all systems, alarm causes are also erased.

- Check that the transmission and engine type have been selected
- Ignition on.

NOTE: The engine must not be running.

Click on the VCT2000 symbol to read off the diagnostic trouble codes (DTCs).

After the read off, it will be possible to access the function for erasing diagnostic trouble codes (DTCs).

HINT: The read off may take up to **1 minute**.

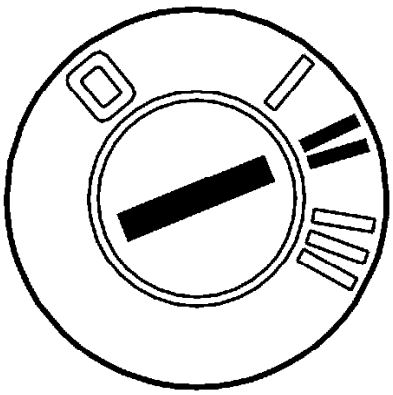
NOTE: Always fault-trace any stored diagnostic trouble codes (DTCs) via the VIDA symptom input before diagnostic trouble codes (DTCs) are erased.

Select "Continue" from the tool on the left to continue erasing diagnostic trouble codes (DTCs).

To cancel the function, select Cancel in the tool on the left.

Checking the Traffic Load on the CAN Cables

Checking The Traffic Load On The CAN Cables



- Connect the battery
- Ignition on.

Faults in the CAN network may be due to a control module sending faulty messages that disrupt normal communication. When messages are sent

incorrectly, this results in a considerable increase in the amount of traffic on the CAN network. Check the load by measuring the average voltage value on the CAN cables in relation to ground.

For further information, see the wiring diagram.

Check as follows:
- Connect a voltmeter between CAN-L and ground. The voltage should be approx: **1,8-2,2V**
- Connect a voltmeter between CAN-H and ground. The voltage should be approx: **2,8-3,2V**

Other Information
- **Battery, disconnecting**

Is the value OK?

YES: Refer to Fault-Tracing Information. See: Diagnostic Trouble Code Tests and Associated Procedures/Manufacturer Code Charts/ECM Codes (Engine Control Module)/ECM-E000/Signal Missing/Fault-Tracing Information
NO: Refer to Identifying A Control Module In the CAN Network. See: Diagnostic Trouble Code Tests and Associated Procedures/Manufacturer Code Charts/ECM Codes (Engine Control Module)/ECM-E000/Signal Missing/Identifying A Control Module In the CAN Network

NO: Refer to Diagnostic Trouble Code Descriptions. See: Diagnostic Trouble Code Descriptions

Identifying A Control Module In the CAN Network

Identifying A Control Module In The CAN Network
If the load on the CAN network is too high, this may be due to a control module sending faulty messages on the CAN network (known as a disruptive control module). The fault may also be due to an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The faults can occur without a diagnostic trouble code (DTC) being stored by the control modules. The voltage can be measured between the CAN cables in order to check the load on the CAN network.

NOTE: It is not necessarily the control module(s) that stored the diagnostic trouble code (DTC) that is communicating faultily. Faulty messages can come from any control module in the same section of the CAN network. However, faulty communication in one network cannot affect the communication on the other network. In other words, faulty communication on the LS-CAN cannot disrupt communication on the HS-CAN and vice versa.

Check communication/load on CAN-net by measuring voltage between #B1 (#1) and # B13 (#13). The average value of the voltage must be approximately **0.6-1.4 V**. In the event of a communication fault the voltage is significantly higher than the above specified values.

In order to identify which control module has faulty communication, cut the power supply to one control module at a time. Check the voltage in the CAN cables again. The easiest way to cut the power supply is to remove the fuse(s) for the relevant control module. Repeat until the voltage between the CAN wiring drops to the normal level.

NOTE: When connecting and disconnecting individual control modules, other diagnostic trouble codes (DTCs) may be stored in certain control modules.

HINT: When the suspected control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the fault appears and disappears. Switch off the ignition between each check.

NOTE: Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.

A control module that is communicating incorrectly must be replaced. See Repairing and installing/Removing, replacing and installing.

NOTE: Following a fault involving control modules that disrupt communication, other control modules may remain in Limp-Home mode (i.e. they work but with limited functionality) even after switching the ignition off and on a number of times. To remedy this, disconnect and reconnect the battery negative terminal to restore the control modules to normal function.

Continue: Refer to Reading Off DTCs From All Systems Before Erasing. See: Diagnostic Trouble Code Tests and Associated Procedures/Manufacturer Code Charts/ECM Codes (Engine Control Module)/ECM-E000/Signal Missing/Reading Off DTCs From All Systems Before Erasing

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information ECM-E003

Condition

The engine control module (ECM) compares its configuration ID with the signal configuration transmitted by the central electronic module (CEM) on the control area network (CAN). If the configuration IDs do not correspond the fault code is stored. The diagnostic trouble code (DTC) is also stored if the communication between the engine control module (ECM) and the central electronic module (CEM) is interrupted.

Note! In the event of an open-circuit in both the control area network (CAN) cables, it is not possible to communicate with the engine control module (ECM). Therefore it will only be possible to read off the diagnostic trouble code (DTC) if this type of fault is intermittent. When the diagnostic trouble code (DTC) is stored, the engine control module (ECM) responds to the diagnostic commands. However normal control area network (CAN) communication "Expulsion mode" does not work.

Substitute value
- None.

Possible source
- Incorrect CAN configuration ID (present engine control module (ECM) is not intended for the vehicle, for example a used control module with other software/hardware)
- Open-circuit in the control area network (CAN) wiring between the engine control module (ECM) and the central electrical module (CEM).

Fault symptom[s]
- General warning lamp lit
- The cruise control does not function at all
- The engine judders under acceleration
- The engine judders heavily after engine braking
- Uneven idle.

General Information

General Information

HINT: For general information about fault-tracing the control area network (CAN), see the linked document below.

NOTE: When selecting the vehicle profile, the correct vehicle must be identified. Use the "Retrieve VIN" button. The fault-tracing may fail if this is not done.

In order to check the control area network (CAN) cables, the resistance in the network must be measured. When the network is connected, the resistance between the two CAN cables must be **60 ohms** in the high speed network. Generally the permitted values **55-65 ohms**.

NOTE: Resistance will only be **60 ohms** if the main artery of the CAN network is whole and the network is connected. If the main artery of the CAN network is split somewhere and a reading is taken between the CAN cables, resistance will be **120 ohms**.

If diagnostic trouble codes (DTCs) for communication faults can be read off from a control module, the fault is probably intermittent.

Intermittent fault in the voltage supply to a control module on the CAN network results in the Central electronic module (CEM) storing a diagnostic trouble code (DTC) for an open-circuit in communication with the control module where the voltage supply does not work. There will probably not be a diagnostic trouble code (DTC) in the control module where the open-circuit in the voltage supply occurred as the control module cannot store a diagnostic trouble code (DTC) when it is not supplied with power.

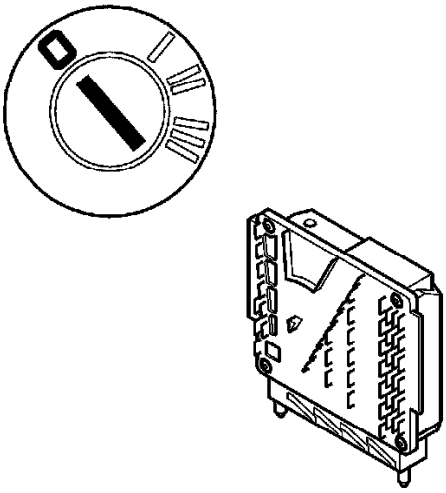
CAUTION: During this fault-tracing use the wiring diagram to provide support when taking readings.

Other Information
- **General information about fault-tracing in the CAN network**

Continue: Refer to Taking Reading on Cables In the Can Network (HS-CAN). See: Diagnostic Trouble Code Tests and Associated Procedures/Manufacturer Code Charts/ECM Codes (Engine Control Module)/ECM-E003/Signal Missing/Taking Reading on Cables In the CAN Network (HS-CAN)

Taking Reading on Cables In the CAN Network (HS-CAN)

Taking Reading On Cables In The CAN Network (HS-CAN)



- Ignition off
- Disconnect the battery negative lead
- Connect the breakout box to the engine control module (ECM).

HINT: Use the Wiring diagrams to provide support when taking readings.

Take resistance readings across the following terminals. Various readings must be taken due to the structure of the network. Twist the cable harness and work the connectors at accessible points along the cable harness in order to check whether the resistance changes during each measurement. This method can be used to detect intermittent short-circuits or open-circuits.

NOTE: The following resistance readings only measure the main arteries in the high speed network, not the junctions that exist for some control modules. See the Wiring diagrams for the relevant car model. An open-circuit in one artery cannot be detected by this reading. However a short-circuit in an artery can be detected.

Measure the resistance between control module terminals #B1(#1) and #B13 (#13). The resistance must be approximately **60 ohms**. The permitted values are **55-65 ohms**.

HINT: Resistance will only be **60 ohms** if the main artery of the CAN network is whole and the network is connected. If the main artery of the CAN network is split somewhere and a reading is taken between the CAN cables, resistance will be **120 ohms**.

Also measure the resistance between each terminal and supply voltage and ground. The resistance must be infinite or very high (higher than **1 MOhm**).

HINT: If a fault is found, try to disconnect the junction with the fault at a point further forward. Disconnect any connector/control module immediately before the measurement point and take the reading again. Try to locate the fault in this way.

Remedy the cables as necessary.

Other Information

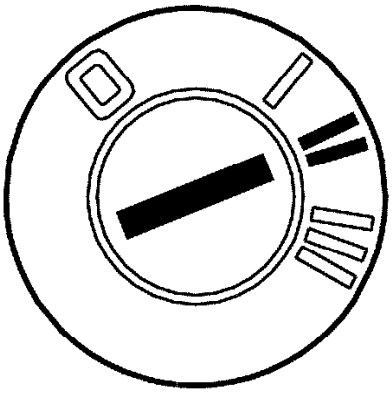
- **Battery, disconnecting**
- See Checking Wiring and Terminals under Related Tests, Information and Procedures

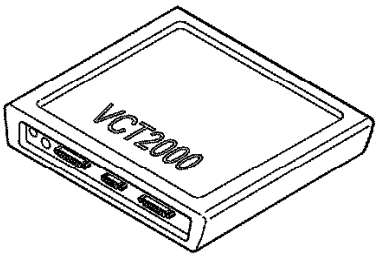
Was a fault detected?

YES: Refer to Reading Off DTCs From All Systems Before Erasing. See: Diagnostic Trouble Code Tests and Associated Procedures/Manufacturer Code Charts/ECM Codes (Engine Control Module)/ECM-E003/Signal Missing/Reading Off DTCs From All Systems Before Erasing
NO: Refer to Checking the Traffic Load on the CAN Cables. See: Diagnostic Trouble Code Tests and Associated Procedures/Manufacturer Code Charts/ECM Codes (Engine Control Module)/ECM-E003/Signal Missing/Checking the Traffic Load on the CAN Cables

Reading Off DTCs From All Systems Before Erasing

Reading Off Diagnostic Trouble Codes (DTCs) From All Systems Before Erasing





CAUTION: This function erases all diagnostic trouble codes (DTCs) in all the systems in the car. The procedure begins with the reading off and display of diagnostic trouble codes (DTCs). The diagnostic trouble codes (DTCs) can then be erased.

NOTE: When erasing diagnostic trouble codes (DTCs) in all systems, alarm causes are also erased.

- Check that the transmission and engine type have been selected
- Ignition on.

NOTE: The engine must not be running.

Click on the VCT2000 symbol to read off the diagnostic trouble codes (DTCs).

After the read off, it will be possible to access the function for erasing diagnostic trouble codes (DTCs).

HINT: The read off may take up to **1 minute**.

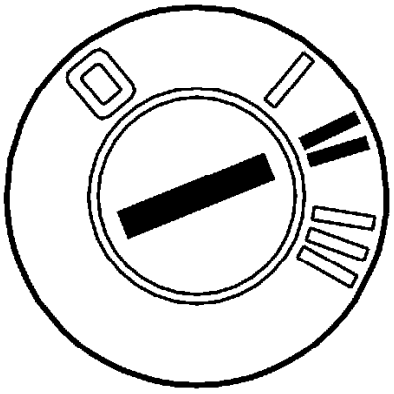
NOTE: Always fault-trace any stored diagnostic trouble codes (DTCs) via the VIDA symptom input before diagnostic trouble codes (DTCs) are erased.

Select "Continue" from the tool on the left to continue erasing diagnostic trouble codes (DTCs).

To cancel the function, select Cancel in the tool on the left.

Checking the Traffic Load on the CAN Cables

Checking The Traffic Load On The CAN Cables



- Connect the battery
- Ignition on.

Faults in the CAN network may be due to a control module sending faulty messages that disrupt normal communication. When messages are sent incorrectly, this results in a considerable increase in the amount of traffic on the CAN network. Check the load by measuring the average voltage value on the CAN cables in relation to ground.

For further information, see the wiring diagram.

Check as follows:
- Connect a voltmeter between CAN-L and ground. The voltage should be approx: **1,8-2,2V**
- Connect a voltmeter between CAN-H and ground. The voltage should be approx: **2,8-3,2V**

Other Information
- **Battery, disconnecting**

Is the value OK?

YES: Refer to Fault-Tracing Information. See: Diagnostic Trouble Code Tests and Associated Procedures/Manufacturer Code Charts/ECM Codes (Engine Control Module)/ECM-E000/Signal Missing/Fault-Tracing Information
NO: Refer to Identifying A Control Module In the CAN Network. See: Diagnostic Trouble Code Tests and Associated Procedures/Manufacturer Code Charts/ECM Codes (Engine Control Module)/ECM-E000/Signal Missing/Identifying A Control Module In the CAN Network

Fault-Tracing Information

Fault-tracing Information
Verification shows that the fault is no longer present. The diagnostic trouble code (DTC) was probably caused by an intermittent fault.

Fault-tracing for this diagnostic trouble code (DTC) is not followed by a verification.

You can view the information again or exit fault-tracing for this diagnostic trouble code (DTC).

Do you want to view information again?

YES: Refer to General Information. See: Diagnostic Trouble Code Tests and Associated Procedures/Manufacturer Code Charts/ECM Codes (Engine Control Module)/ECM-E000/Signal Missing/General Information
NO: Refer to Diagnostic Trouble Code Descriptions. See: Diagnostic Trouble Code Descriptions

Identifying A Control Module In the CAN Network

Identifying A Control Module In The CAN Network
If the load on the CAN network is too high, this may be due to a control module sending faulty messages on the CAN network (known as a disruptive control module). The fault may also be due to an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The faults can occur without a diagnostic trouble code (DTC) being stored by the control modules. The voltage can be measured between the CAN cables in order to check the load on the CAN network.

NOTE: It is not necessarily the control module(s) that stored the diagnostic trouble code (DTC) that is communicating faultily. Faulty messages can come from any control module in the same section of the CAN network. However, faulty communication in one network cannot affect the communication on the other network. In other words, faulty communication on the LS-CAN cannot disrupt communication on the HS-CAN and vice versa.

Check communication/load on CAN-net by measuring voltage between #B1 (#1) and # B13 (#13). The average value of the voltage must be approximately **0.6-1.4 V**. In the event of a communication fault the voltage is significantly higher than the above specified values.

In order to identify which control module has faulty communication, cut the power supply to one control module at a time. Check the voltage in the CAN cables again. The easiest way to cut the power supply is to remove the fuse(s) for the relevant control module. Repeat until the voltage between the CAN wiring drops to the normal level.

NOTE: When connecting and disconnecting individual control modules, other diagnostic trouble codes (DTCs) may be stored in certain control modules.

HINT: When the suspected control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the fault appears and disappears. Switch off the ignition between each check.

NOTE: Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.

A control module that is communicating incorrectly must be replaced. See Repairing and installing/Removing, replacing and installing.

NOTE: Following a fault involving control modules that disrupt communication, other control modules may remain in Limp-Home mode (i.e. they work but with limited functionality) even after switching the ignition off and on a number of times. ECM-XXXX

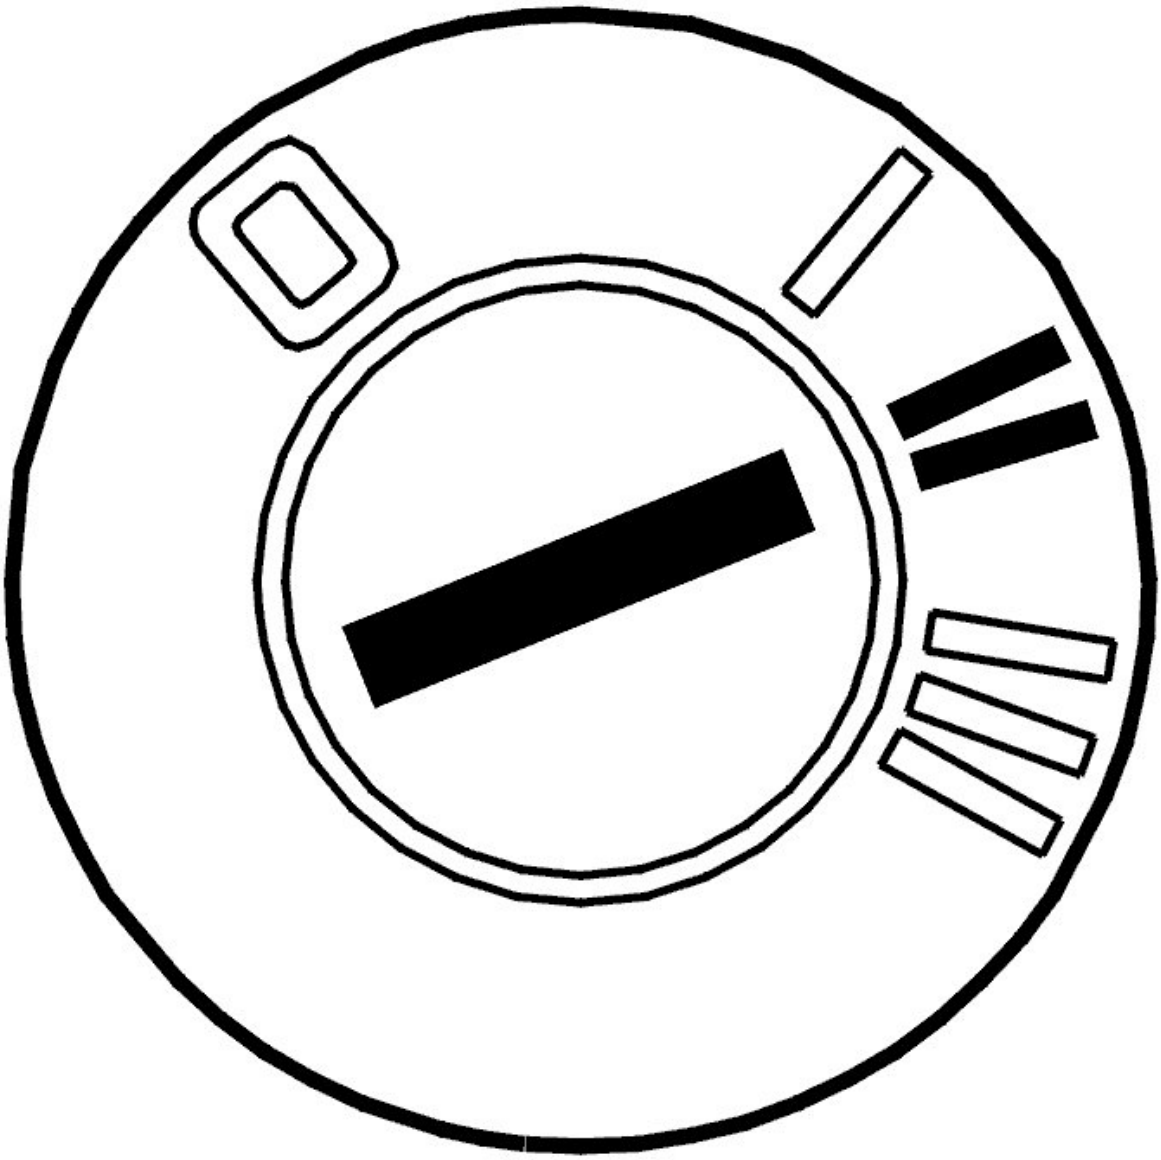
Unknown diagnostic trouble code (DTC) for the current control module version

Reading off diagnostic trouble codes (DTCs)



- Ignition on.

Read off the diagnostic trouble code (DTC) that is stored in the car.
Make a note of the code. Report the code to VIDA customer support.

Continue - DONE

PDM-E001

Diagnostic trouble code (DTC) information PDM-E001

Condition

The control modules transmit and receive information via a standardized serial communication method - CAN (Controller Area Network). The diagnostic trouble code (DTC) is stored if the control module registers serious interference (CAN communication blocked).

Note! In the event of system communication problems, it is not possible to communicate with the control module. Therefore it will only be possible to read off the fault if it is intermittent.

Substitute value
- The control module shuts itself off ("bus-off").

  Hint: The control module will remain shut off until the power supply is broken (15, 30, X). When the power supply is connected the control module will make a new attempt to communicate.

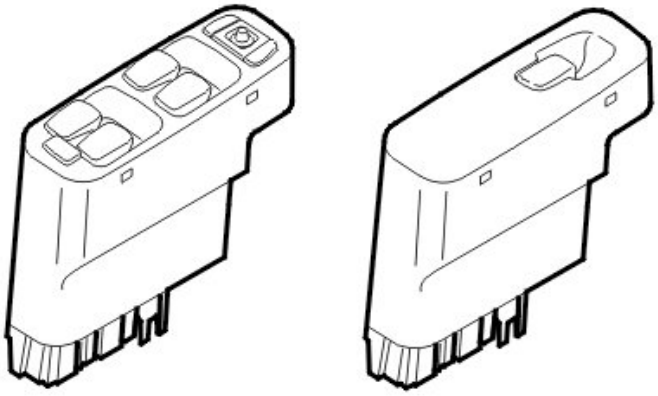
Possible source
- Short-circuit between the control area network (CAN) wiring
- Open-circuit in the control area network (CAN) wiring
- Internal fault in the control module
- Internal fault in another control module in the same part of the control area network (CAN).

Fault symptom[s]
- The switch panel for the driver's door does not work
- Automatic window closure does not function
- Cannot be controlled with the remote control.

PDM-E003

Diagnostic trouble code (DTC) information PDM-E003

Condition



The control module compares its configuration ID with the signal configuration transmitted on the control area network (CAN) by the central electronic module (CEM). If the configuration IDs do not correspond the fault code is stored. The diagnostic trouble code (DTC) is also stored if the communication between the control module and the central electronic module (CEM) is interrupted.

Note! In the event of open-circuit in both the control area network (CAN) cables, it is not possible to communicate with the control module. Therefore it will only be possible to read off the diagnostic trouble code (DTC) if this type of fault is intermittent. When the diagnostic trouble code (DTC) is stored, the control module responds to the diagnostic command, however normal control area network (CAN) communication does not work. ("Expulsion mode")

Substitute value
- None.

Possible source
- Faulty control area network (CAN) configuration ID. (The node is not intended for this car, for example a used control module with different software/hardware.)
- Open-circuit in the control area network (CAN) wiring between the control module and the central electrical module (CEM).

Fault symptom[s]
- The switch panel for the passenger door does not work
- Automatic window closure does not function
- Cannot be controlled with the remote control.

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code information

Condition

If the passenger door module (PDM) registers that the central locking button is depressed for more than 60 seconds, error code PDM-001D is set.

Substitute value
- Nothing.

Possible source
- Button depressed for more than 60 seconds.
- Defective central locking button.

Fault symptom[s]
- Cannot be operated from central-locking switch.

Diagnostic Trouble Code (DTC) Information

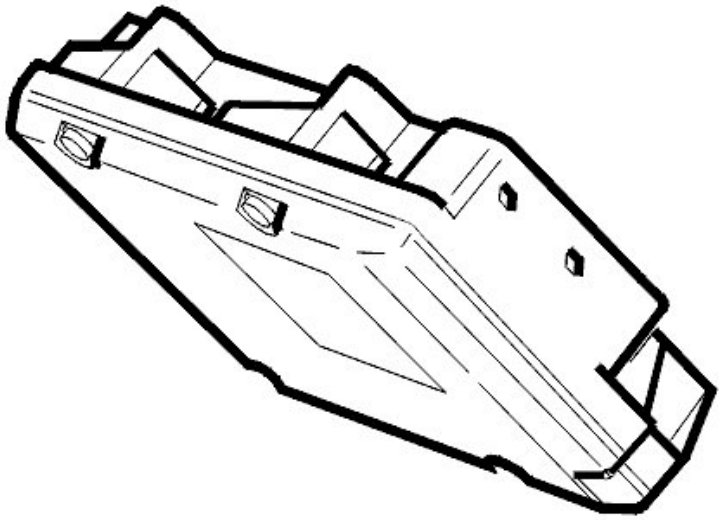
Diagnostic trouble code (DTC) information PSM-E001

Condition



The control modules transmit and receive information via a standardized serial communication method - CAN (Controller Area Network). The diagnostic trouble code (DTC) is stored if the control module registers serious interference (CAN communication blocked).

Note! In the event of system communication problems, it is not possible to communicate with the control module. Therefore it will only be possible to read off the fault if it is intermittent.

Substitute value

- The control module shuts itself off ("bus-off")

  Hint: The control module will remain shut off until the power supply is broken (15, 30, X). When the power supply is connected the control module will make a new attempt to communicate.

Possible source

- Short-circuit between Control area network (CAN) wiring
- Open-circuit in the control area network (CAN) wiring
- Internal fault in the control module
- Internal fault in another control module in the same part of the Control area network (CAN).

Fault symptom[s]

- Power seat with memory function does not operate at all
- Automatic seat/door mirror operation does not function.

Faulty Communication

Faulty communication

General information

In order to check the control area network (CAN) cables, the resistance in the network must be measured. The resistance between the two controller area network (CAN) wiring, with the network connected 60 ohms. The resistance can differ depending on the configuration of the car. Permitted values are 55-65 ohms. This applies to both the high speed side network and the low speed side network.

Hint: Use the applicable wiring diagram to provide support when taking readings. Take a copy of the data communication side for each model. Note which diagnostic trouble codes (DTCs) are stored in each control module. This facilitates fault-tracing considerably.

Check if the diagnostic trouble codes (DTCs) for failed communication are stored in the central electronic module (CEM). If this is the case, first fault-trace according to these diagnostic trouble codes (DTCs).

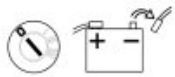
Other information

- For general information about fault-tracing the control area network (CAN), see

Continue - Checking the resistance of the control area network (CAN) cables

---

Checking the resistance of the control area network (CAN) cables



- Disconnect the battery negative lead. The power to the network must be cut when taking resistance readings. The reading may otherwise be incorrect.

Note! Also read: Battery, disconnecting See: Starting and Charging/Battery/Service and Repair/Procedures/Battery, Disconnecting

- Connect the adapter wiring to the central electronic module (CEM).

Hint: Where a breakout box cannot be used, take readings from the rear of the affected connectors if possible. This prevents terminal pins and socket housings being damaged.

When taking readings on the low speed network

- When taking readings on the low speed network, the adapter wiring should be connected to the central electronic module (CEM) and the readings taken from there. The readings can also be taken in the connector for the power seat module (PSM). The advantage of using the adapter wiring connected to the central electronic module (CEM) is that all control modules can be connected to the network when taking readings and there is access to both the high speed and the low speed networks.

This resistance reading only measures main arteries in the low speed network, not the junctions for the road traffic information module (RTI), accessory electronic module (AEM), power seat module (PSM), phone module (PHM), audio module (AUM), driver's door module (DDM) and passenger door module (PDM). See the applicable wiring diagram, Data communication.

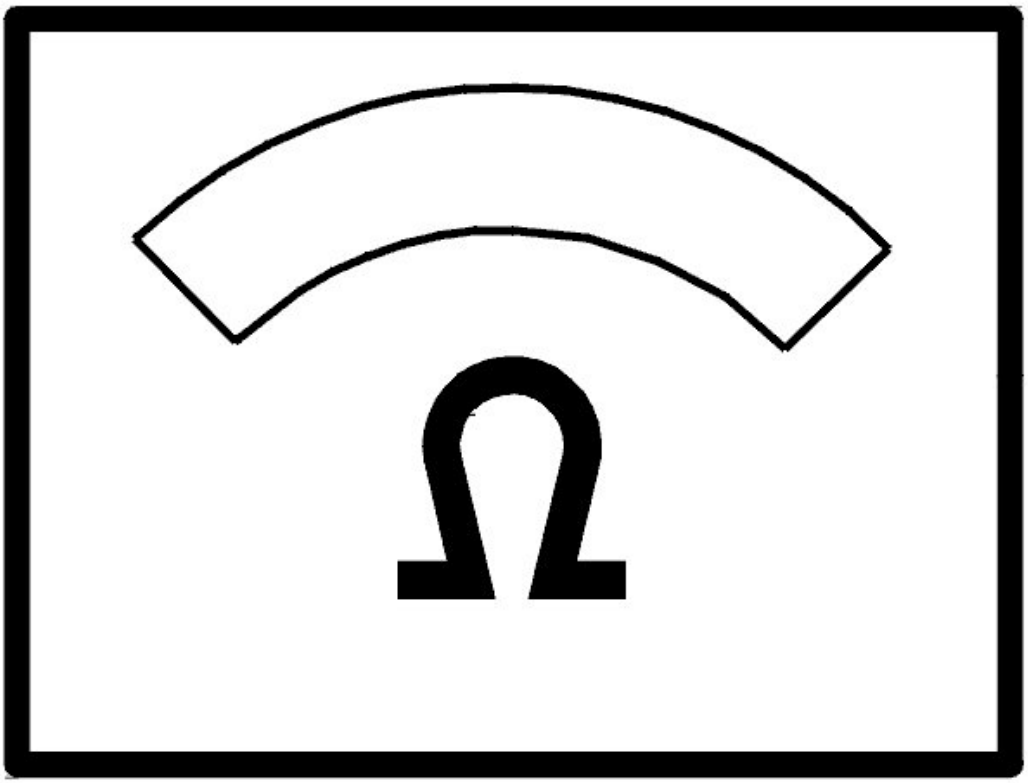
When taking readings on the high speed network

- When taking readings on the high speed network, the readings should be taken at the engine control module (ECM) using adapter wiring. The engine control module (ECM) must be connected. This resistance reading only takes readings from the main arteries in the high speed network. See the applicable wiring diagram, Data communication.

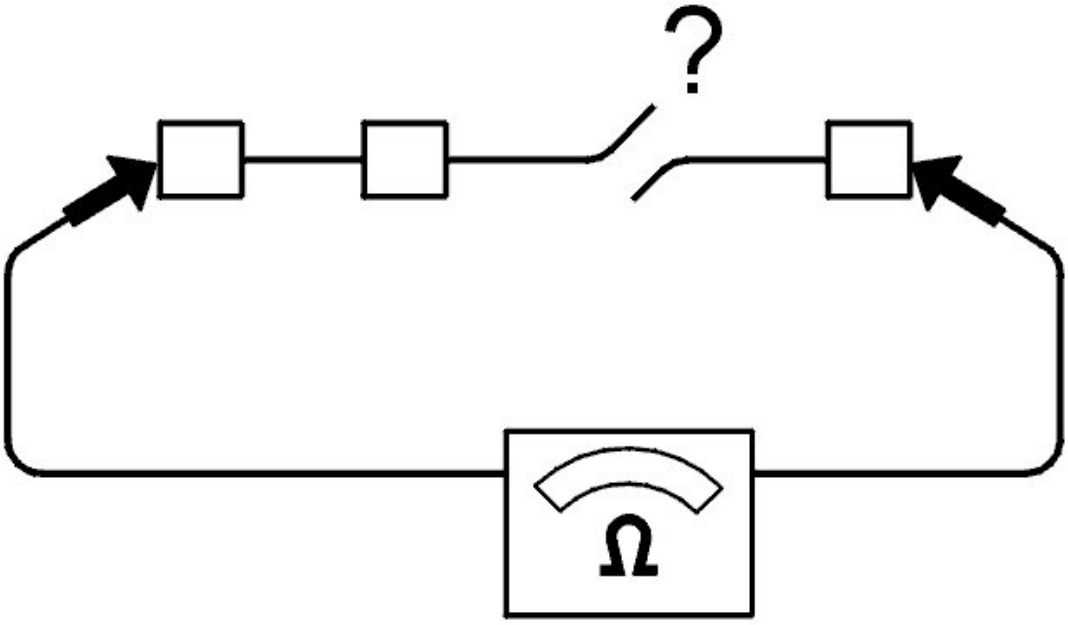
Connect the ohmmeter to the terminals for CAN-L and CAN-H on the relevant network. Work the connectors and twist the cable harness. The resistance must be approximately 60 ohms. Permitted values are 55-65 ohms.

Other information

- Connecting the breakout box See: Body and Frame/Body Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box/Connecting the Breakout Box, Central Electronic Module (CEM)
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals



Ω



?
Ω

Is the value OK?

Yes - Checking a short-circuit in CAN cables

No - Identifying fault causes in the CAN network

Checking a short-circuit in CAN cables

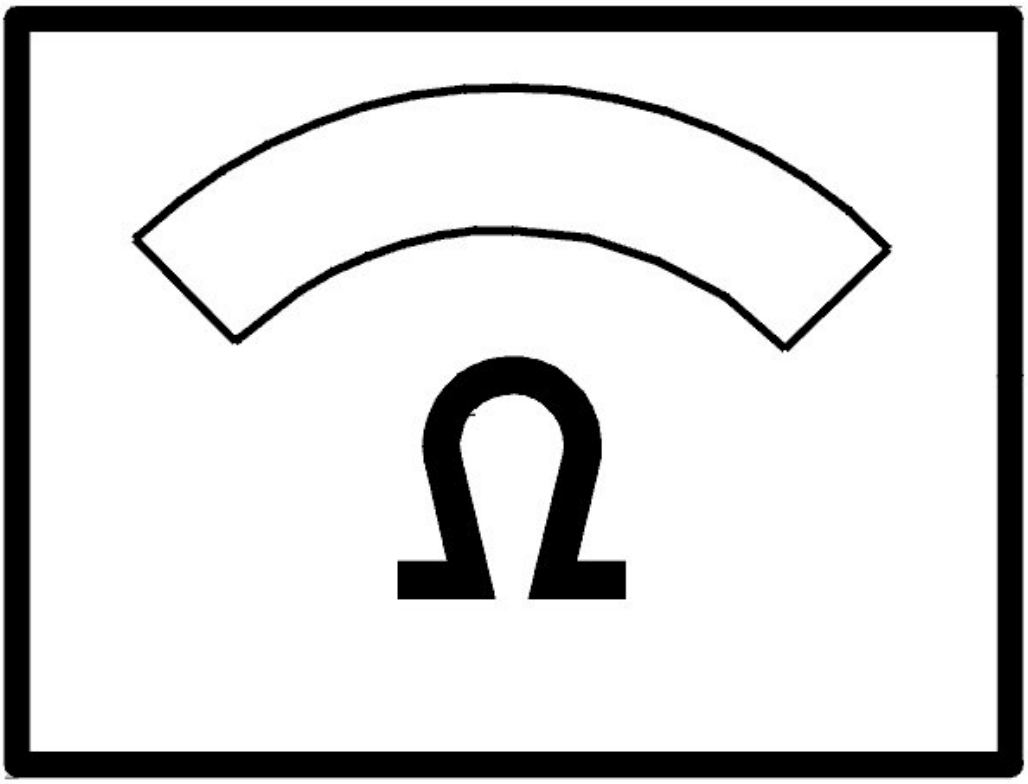
Connect an ohmmeter between the relevant CAN cable (CAN-L and CAN-H) and the power supply, and between the CAN cable and ground. Twist the connectors and turn the cable harness to different positions at each reading to determine any intermittent short-circuits.

Take the following readings:

- The resistance between CAN-L and ground
- The resistance between CAN-L and voltage
- The resistance between CAN-H and ground
- The resistance between CAN-H and voltage.

The resistance must be infinite or very high in all cases (greater than 1 M Ohms).

Hint: The reading can be taken from the same connector if the CAN cables, power supply and ground are exposed. If possible, take readings on the rear of the connector to prevent damage to the terminals in the connector. If this is not possible, use the adapter wiring or loose terminal pins to obtain a good contact.

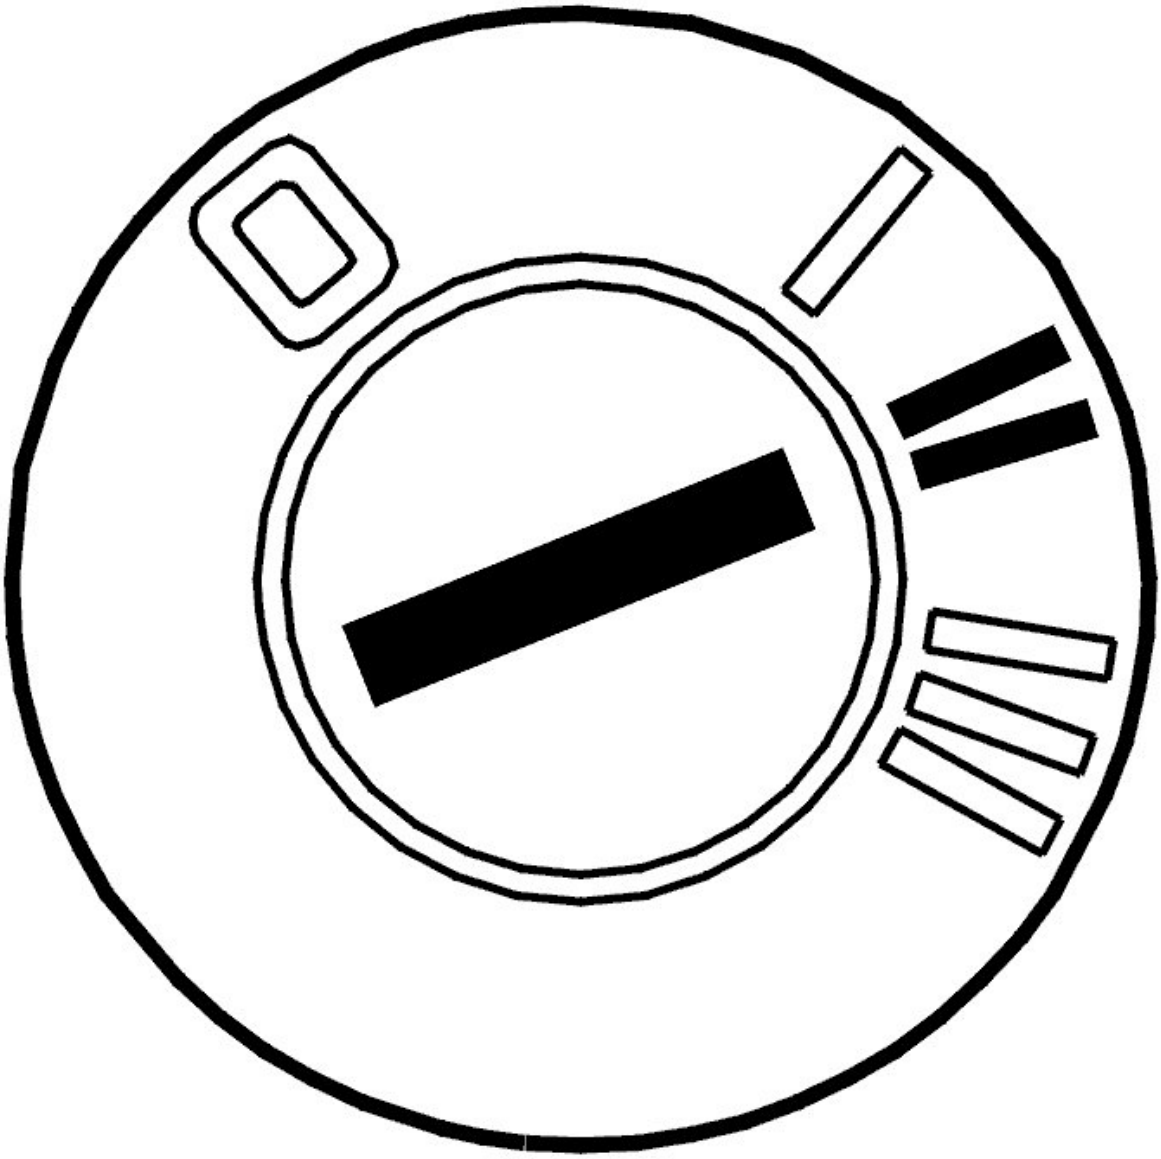


Was a fault detected?

Yes - Identifying fault causes in the CAN network

No - Checking the traffic load on the CAN cables

Checking the traffic load on the CAN cables



- Connect the battery
- Ignition on

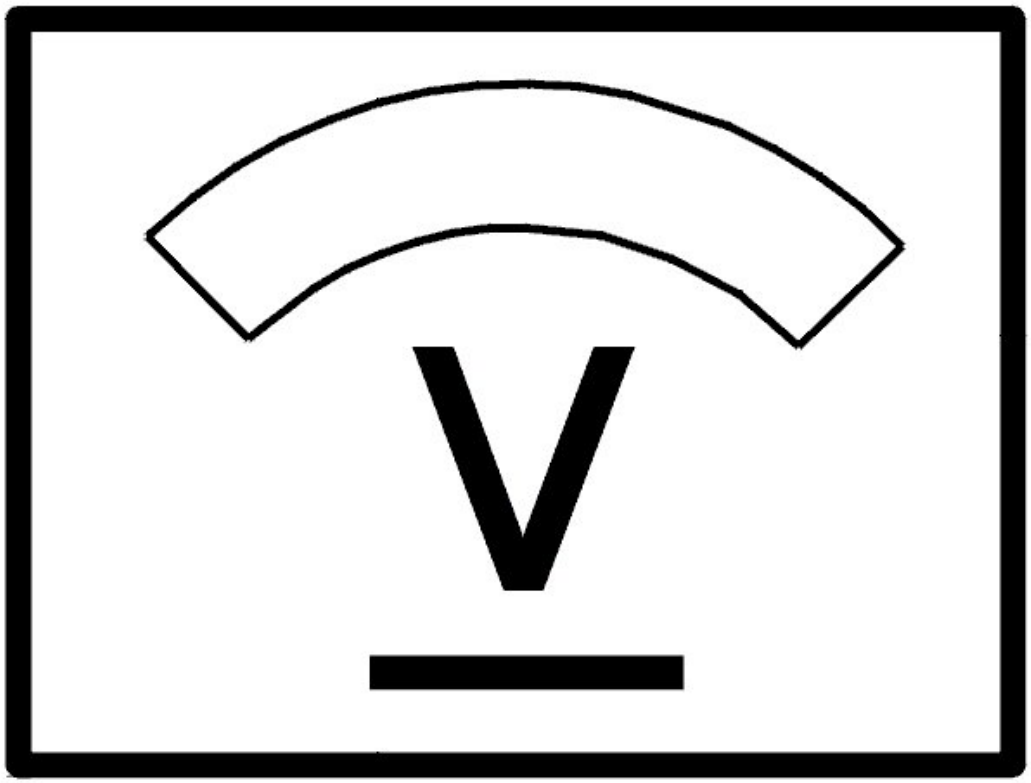
Also read: Battery, disconnecting See: Starting and Charging/Battery/Service and Repair/Procedures/Battery, Disconnecting

Faults in the CAN network may be due to a control module sending faulty messages that disrupt "normal" communication. When messages are sent incorrectly, this results in a considerable increase in the amount of traffic on the CAN network. Check the load by measuring the average voltage value on the CAN cables in relation to ground.

Connect a voltmeter between CAN-L and ground. The voltage must be approximately 2.3 V.

Then connect a voltmeter between CAN-H and ground. The voltage must be approximately 2.8 V.

Hint: If possible measure from the rear of the affected connectors so that they are not damaged.



Is the value OK?

Yes - Fault-tracing without result

No - Identifying a control module in the CAN network

Identifying fault causes in the CAN network

- Disconnect a control module that disconnects the CAN network (a control module that has four terminals to the CAN network).

Hint: For the low speed network, suitable places for disconnecting the network are at the steering wheel module (SWM), the driver information module (DIM) or the climate control module (CCM).

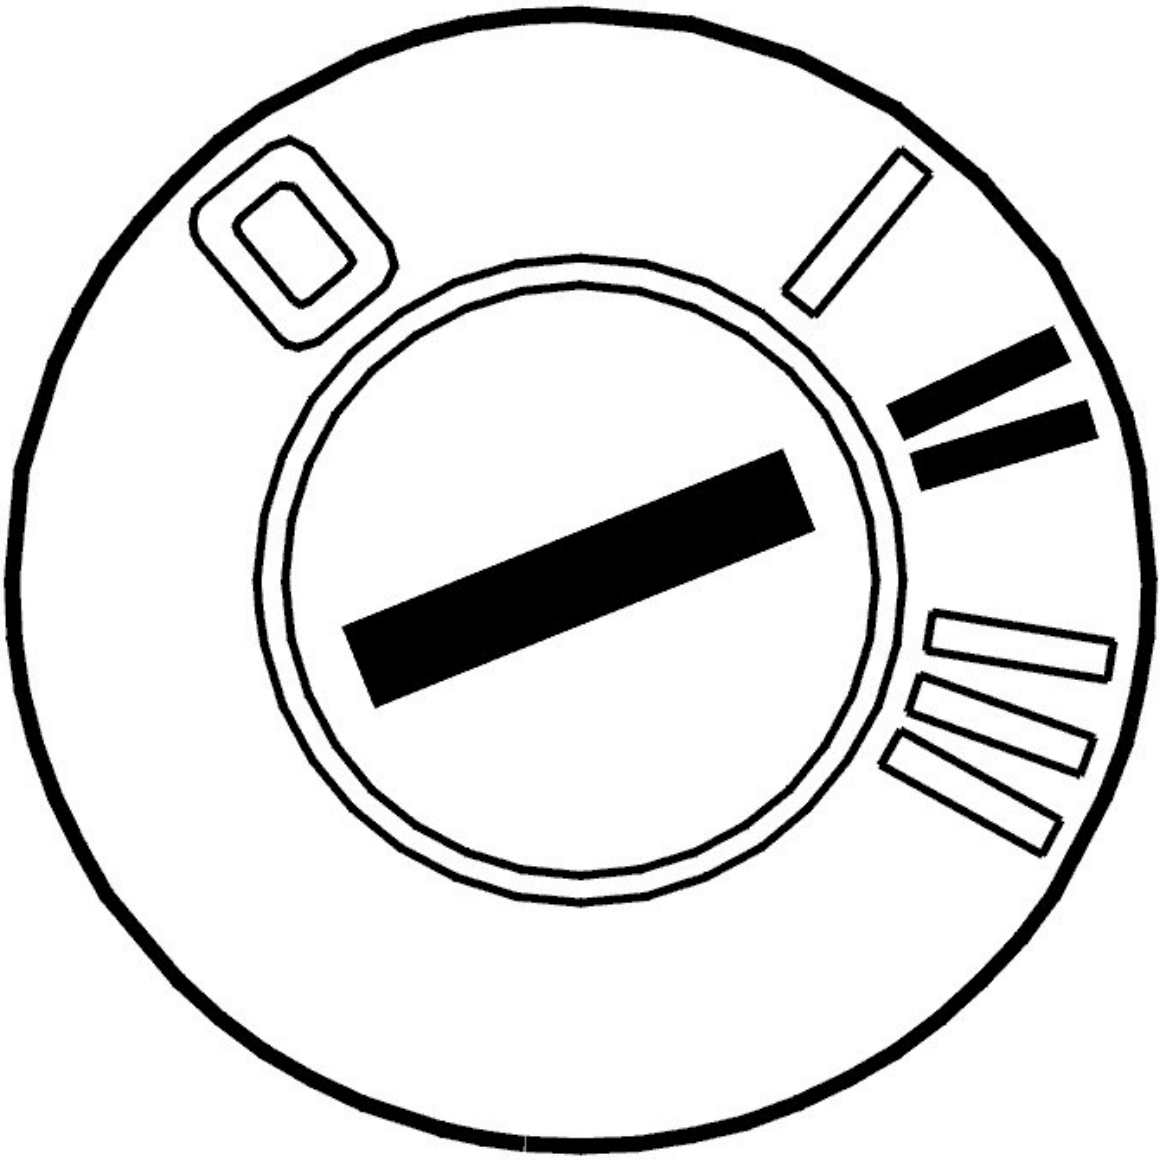
In the event of a short-circuit between one of the CAN cables and voltage or ground, the fault can be located by disconnecting a control module that disconnects the CAN network. Readings can then be taken to determine on which side of the disconnected control module the fault is located. Connect an ohmmeter between the CAN cable and supply voltage or ground. Take readings at both ends of the CAN network where the network is disconnected. Twist and bend the cable harness to locate any intermittent short-circuits. The resistance must be infinite or very high (greater than 1Mohms).
If a fault can be localized in one direction, disconnect the network at a point further down on the CAN network in the direction in which the fault was discovered and repeat the reading. In this way, try to identify where in the network the fault might be located.

Hint: A short-circuit between the CAN cables and supply voltage or ground may be in either the wiring or in a control module.

Rectify the wiring as necessary. Replace the control module if the fault has been localized to a control module.

Continue - Verification

Identifying a control module in the CAN network



- Connect the battery

Also read: Battery, disconnecting See: Starting and Charging/Battery/Service and Repair/Procedures/Battery, Disconnecting

- Ignition on

If the load on the CAN network is too high, this may be due to a control module sending faulty messages on the CAN network (known as a disruptive control module). The fault may also be due to an intermittent short-circuit to supply voltage or ground in one of the CAN cables. This results in the control modules on the CAN network starting to send faulty messages. The faults can occur without a diagnostic trouble code (DTC) being stored by the control modules. The voltage can be measured between the CAN cables in order to check the load on the CAN network. Connect a voltmeter between the CAN cables. If the communication on the network is correct, the average voltage value should be approximately 0.5 V (0.4 V to 0.6 V). If there is a fault in the communication, the voltage reading will be approximately 0.7 V or higher.
In order to identify from which control module the faulty communication is being transmitted, cut the supply voltage to one control module at a time and check the voltage in the CAN cables again. The easiest way to cut the supply voltage is to remove a fuse. Repeat until the voltage between the CAN cables drops to approximately 0.5 V.

Hint: When the probable faulty control module has been identified, connect and disconnect the supply voltage to the control module a number of times to verify that the fault appears and disappears.

Note! Do not cut the power to the central electronic module (CEM) unless it is the last control module left to check.

The control module that is communicating incorrectly must be replaced. Remedy as necessary.

Note! Following a fault involving "disruptive" control modules, other modules may remain in "Limp-Home mode" even after switching the ignition off and on a number of times. To remedy this, disconnect and reconnect the battery negative terminal to restore the control modules to normal function.

Continue - Verification

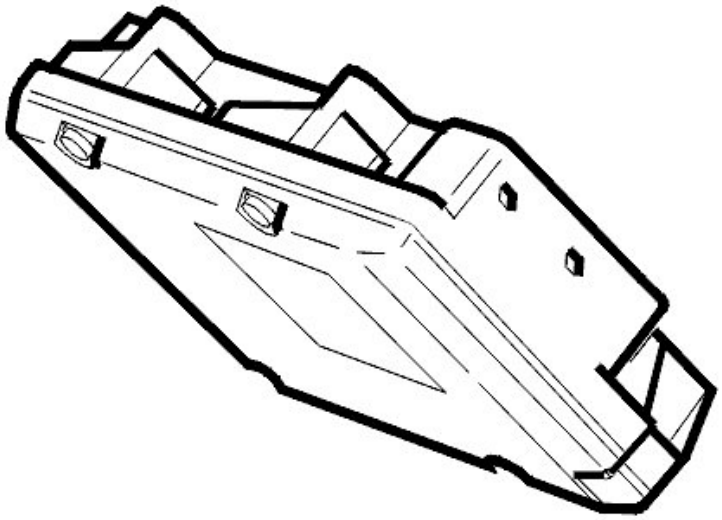
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information PSM-E003

Condition



The control module compares its configuration ID with the signal configuration transmitted on the control area network (CAN) by the central electronic module (CEM). If the configuration IDs do not correspond the fault code is stored. The diagnostic trouble code (DTC) is also stored if the communication between the control module and the central electronic module (CEM) is interrupted.

Note! In the event of open-circuit in both the control area network (CAN) cables, it is not possible to communicate with the control module. Therefore it will only be possible to read off the diagnostic trouble code (DTC) if this type of fault is intermittent. When the diagnostic trouble code (DTC) is stored, the control module responds to the diagnostic command, however normal control area network (CAN) communication does not work. ("Expulsion mode")

Substitute value
- None.

Possible source
- Faulty control area network (CAN) configuration ID. (The node is not intended for this car, for example a used control module with different software/hardware.)
- Open-circuit in the control area network (CAN) wiring between the control module and the central electrical module (CEM).

Fault symptom[s]

- Power seat with memory function does not operate at all
- Automatic seat/door mirror operation does not function.

Faulty Configuration

Faulty configuration

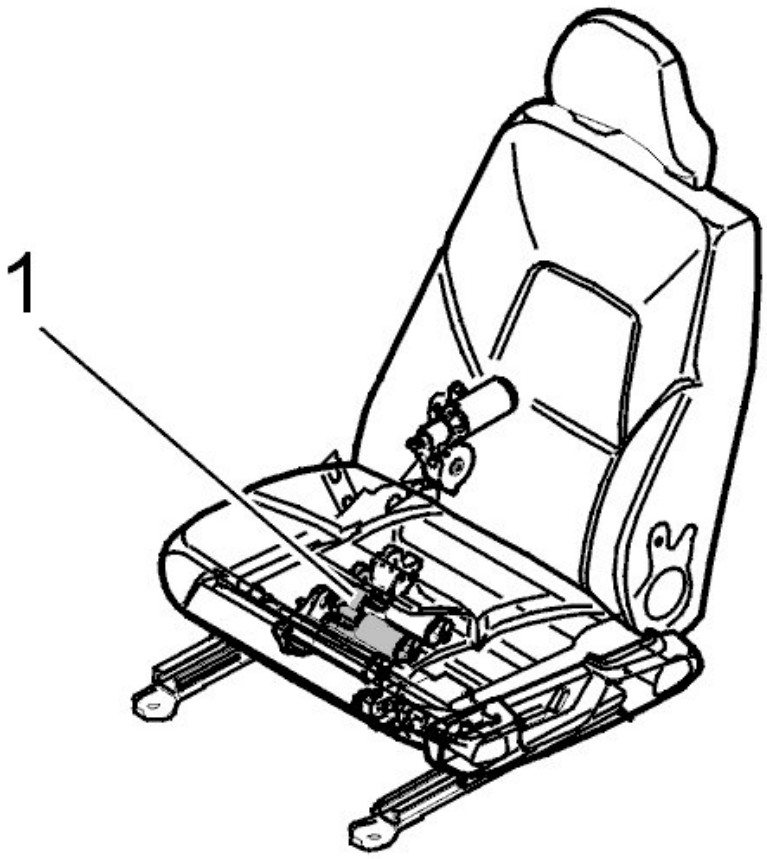
Diagnostic trouble code (DTC) information

Condition



Motor 1 controls the seat front-rear adjustment. Motor 1 must be activated before the diagnostic trouble code (DTC) can be detected. Diagnostic trouble code (DTC) PSM-0001 is stored if no Hall sensor pulse is detected when motor 1 is activated and in operation.

Possible source

- Defective Hall sensor in motor 1.
- Short-circuit to supply voltage or ground in the signal cable.
- Open-circuit in the signal cable to the Hall sensor.

Fault symptom[s]

- Automatic seat control does not function (automatic control of other motors functioning as normal).

Faulty Signal

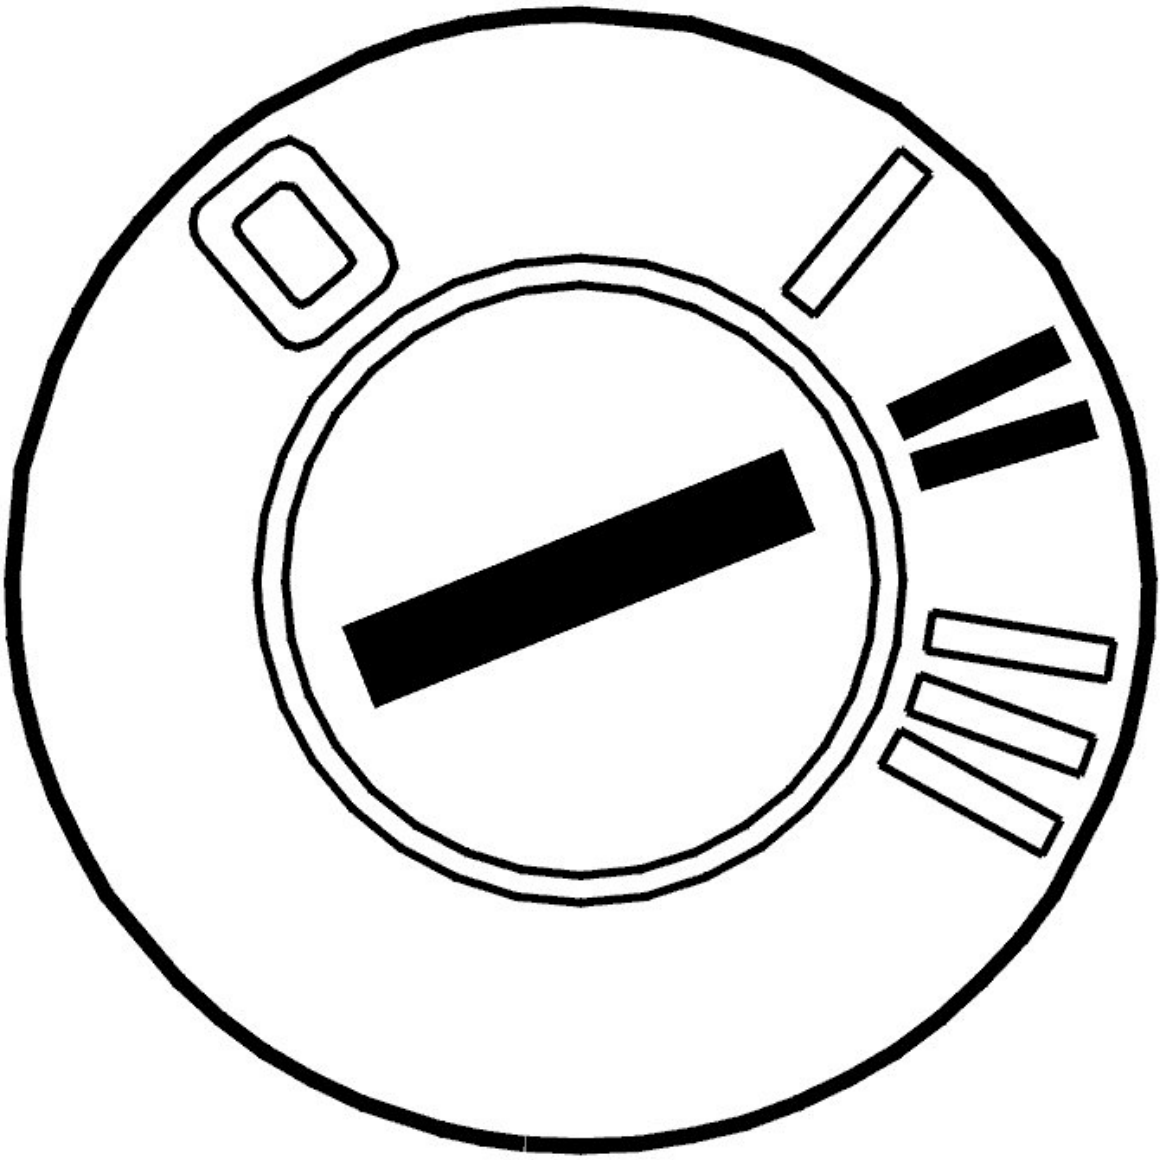
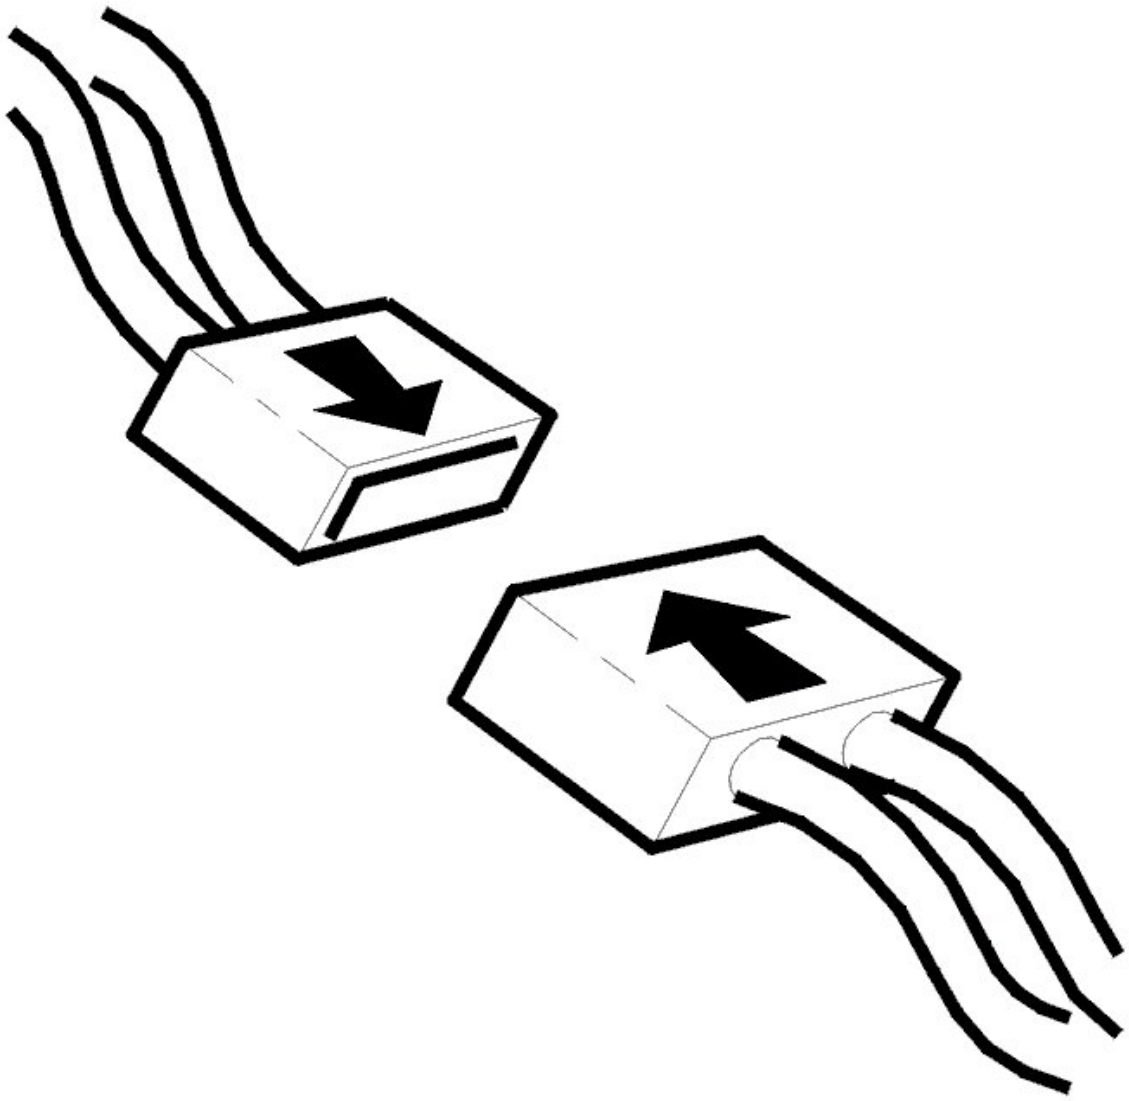
Faulty signal. Permanent fault

Checking the Hall sensor signal

Hint: The motor should be activated when the check is carried out.





- Reconnect components, connectors etc.
- Ignition on.

Read off value.
Check whether the power seat module (PSM) receives the signal from the Hall sensor. Operate the relevant seat motor and check whether the value counts upwards and downwards as the seat is moved in each direction.
The value should count up or down depending on seat operation.

Is the function OK?

Yes - Fault Found

No - Checking wiring and components

Checking wiring and components

Check the cable between the power seat module (PSM) #3E and the Hall sensor, and the cable between the power seat module (PSM) #4E and the Hall sensor for an open-circuit according to Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault , a short-circuit to ground according to Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault and a short-circuit to supply voltage according to Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and

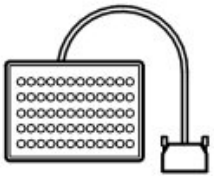
Terminals. Permanent Fault.
Check hall sensor and replace if necessary.

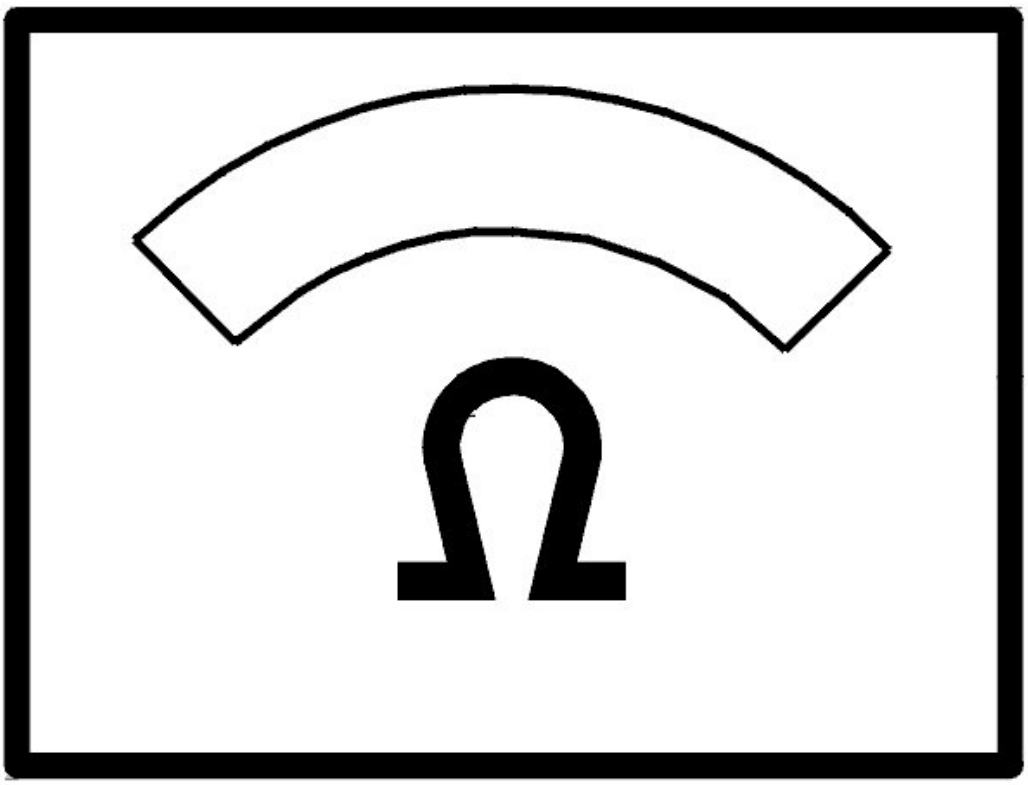
Hint: The sensor should generate a pulsed signal.

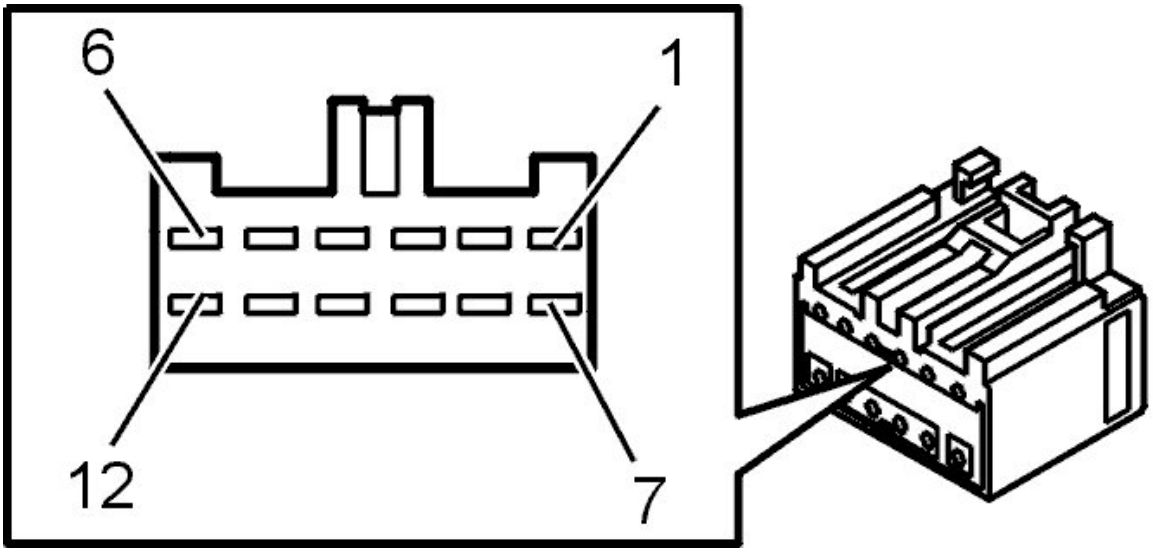
Remedy as necessary.

Other information

- To connect the breakout box, see Connecting the breakout box, power seat module (PSM) See: Body and Frame/Seats/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box, Power Seat Module (PSM).
- For information on signals, refer to Signal specification, Power seat module See: Body and Frame/Seats/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Specification, Power Seat Module (PSM).





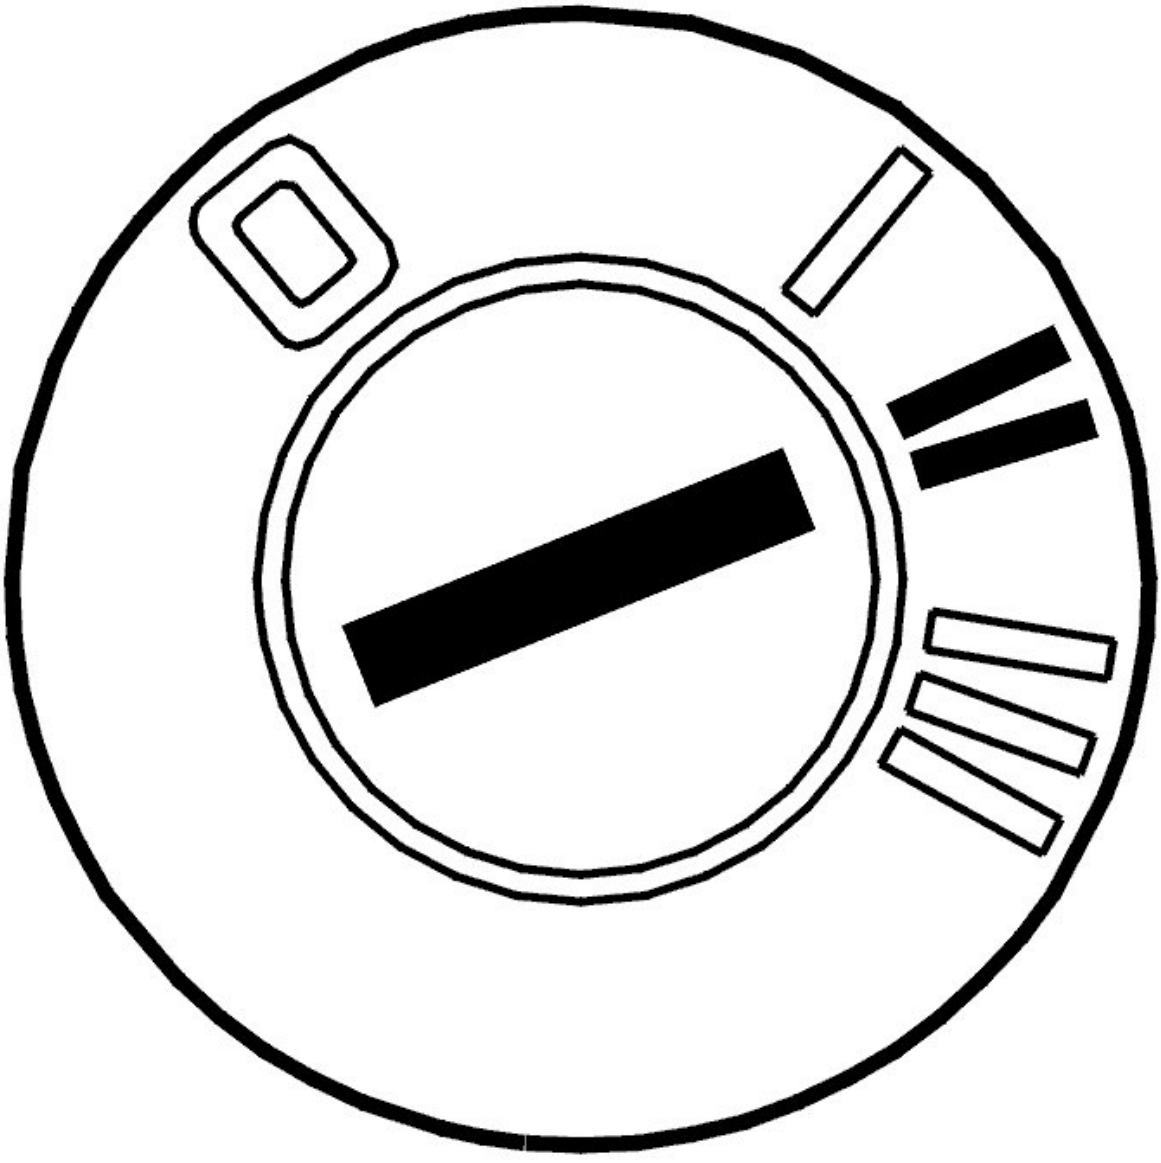


Select Continue

Continue - Verification

Verification

Hint: The motor should be activated when the check is carried out.



- Ignition on.

Read off value.
The Hall sensor must generate a pulsed signal and the power seat module (PSM) should count up or down depending on the movement of the seat.

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition

Motor 2 controls backrest rake. Motor 2 must be activated before the diagnostic trouble code (DTC) can be detected. Diagnostic trouble code (DTC) PSM-0002 is stored if no Hall sensor pulse is detected when motor 2 is activated and in operation.

Possible source

- Defective Hall sensor in motor 2.
- Short-circuit to supply voltage or ground in the signal cable.
- Open-circuit in the signal cable to the Hall sensor.

Fault symptom[s]

- Automatic seat control does not function (automatic control of other motors functioning as normal).

Faulty Signal

Faulty signal. Intermittent fault

Checking cable

Check the power seat module (PSM) and motor connector for contact resistance and oxidation according to Checking wiring and terminals. Intermittent faults See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Intermittent Faults and loose connections according to Checking wiring and terminals. Intermittent faults See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Intermittent Faults.
The Hall sensor is integrated in the motor.
Check the wiring between the power seat module (PSM) and the sensor according to the table below for an intermittent open-circuit according to Checking wiring and terminals. Intermittent faults See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Intermittent Faults , an intermittent short-circuit to ground according to Checking wiring and terminals. Intermittent faults See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Intermittent Faults and an intermittent short-circuit to supply voltage according to Checking wiring and terminals. Intermittent faults See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Intermittent Faults.

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition

Motor 3 must be switched off before the diagnostic trouble code (DTC) can be detected. Diagnostic trouble code (DTC) PSM-003C is stored if the power seat module (PSM) detects Hall sensor pulses when M3 is switched off.

Possible source
- Defective Hall sensor 3.

Fault symptom[s]
- Automatic seat operation does not function.

Faulty Signal

Faulty signal. Intermittent fault

Checking input signal

When the seat is operated there should be a pulsed signal between pins according to the table.

DTC	Component	Terminal	Connector
PSM-003A	Hall sensor 1	#3, #4	E
PSM-003B	Hall sensor 2	#3, #4	D
PSM-003C	Hall sensor 3	#7, #8	E
PSM-003D	Hall sensor 4	#11, #12	E

Other information:

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition

Motor 4 must be switched off before the diagnostic trouble code (DTC) can be detected. Diagnostic trouble code (DTC) PSM-003D is stored if the power seat module (PSM) detects Hall sensor pulses when M4 is switched off.

Possible source
- Defective Hall sensor 4.

Fault symptom[s]
- Automatic seat operation does not function.

Faulty Signal

Faulty signal. Permanent fault

Checking input signal

Read off the value for Hall sensor 4.
The value should not change when the seat is not affected.

Hint: If the value counts up or down there may be a fault in the sensor, an intermittent short-circuit to supply voltage or an internal fault in the power seat module (PSM).

Remedy as necessary.

Other information:
- To access Hall sensor 4, see Height adjustment motor, front See: Body and Frame/Seats/Power Seat Motor/Service and Repair/Removal and Replacement/Front Seat, Driver's Seat/Front Height Adjustment Motor.

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition

Motor 4 controls seat front edge height. Motor 4 must be activated before the diagnostic trouble code (DTC) can be detected. Diagnostic trouble code (DTC) PSM-0004 is stored if no Hall sensor pulse is detected when motor 4 is activated and in operation.

Possible source

- Defective Hall sensor in motor 4.
- Short-circuit to supply voltage or ground in the signal cable.
- Open-circuit in the signal cable to the Hall sensor.

Fault symptom[s]

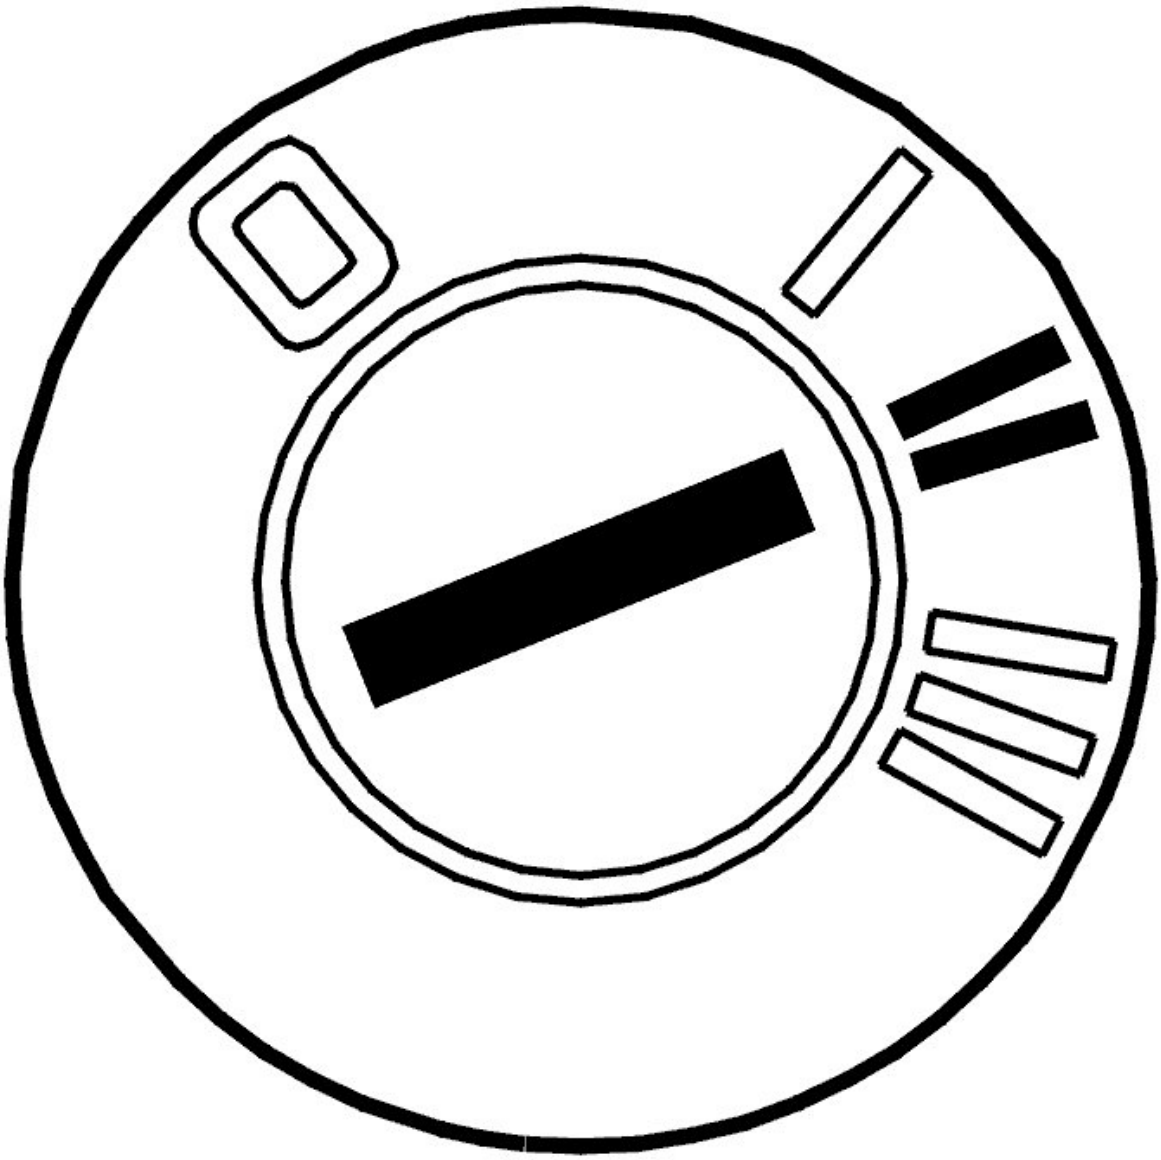
- Automatic seat control does not function (automatic control of other motors functioning as normal).

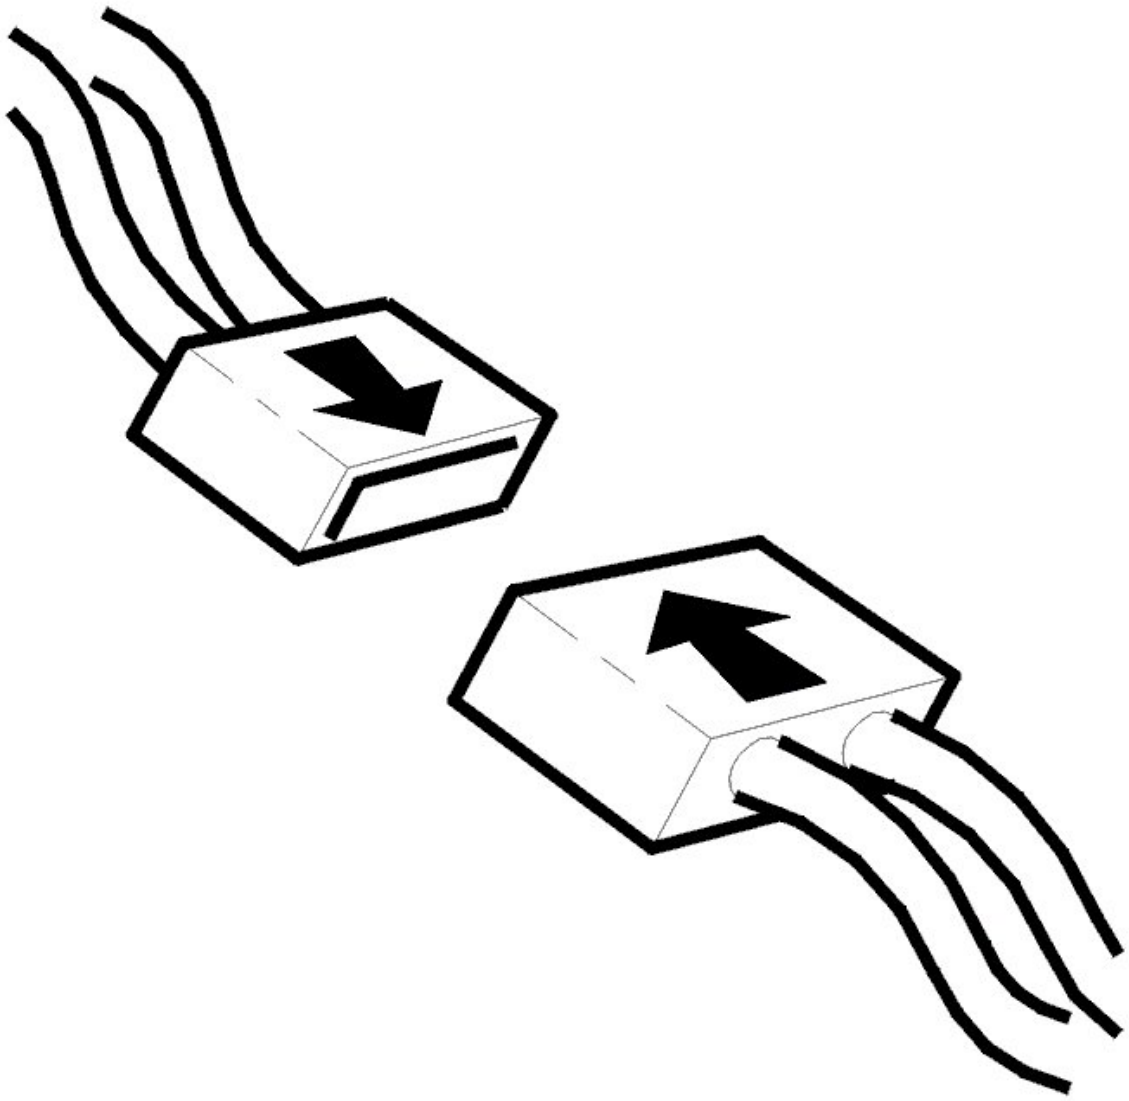
Faulty Signal

Faulty signal. Permanent fault

Checking Hall sensor signal

Hint: The motor should be activated when the check is carried out.





- Reconnect components, connectors etc.
- Ignition on.

Read off value.
Check whether the power seat module (PSM) receives the signal from the Hall sensor. Operate the relevant seat motor and check whether the value counts upwards and downwards as the seat is moved in each direction.
The value should count up or down depending on seat operation.

Is the function OK?

Yes - Fault Found

No - Checking wiring and components

Checking wiring and components

Check the cable between the power seat module (PSM) #3D and the Hall sensor, and the cable between the power seat module (PSM) #4D and the Hall sensor for an open-circuit according to Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault , a short-circuit to ground according to Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault and a short-circuit to supply voltage according to Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and

Terminals. Permanent Fault.
Check hall sensor and replace if necessary.

Hint: The sensor should generate a pulsed signal.

Remedy as necessary.

Other information

- To connect the breakout box, see Connecting the breakout box, power seat module (PSM) See: Body and Frame/Seats/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box, Power Seat Module (PSM).

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition

The M4+ button must be activated before the diagnostic trouble code (DTC) can be detected. Diagnostic trouble code (DTC) PSM-0026 is stored if button M4+ has been activated for longer than 60 seconds.

Possible source
- Button M4+ has jammed in the depressed position.
- Defective control panel.

Fault symptom[s]
- The operation button does not function.

Too Long Time

Too long time. Permanent fault

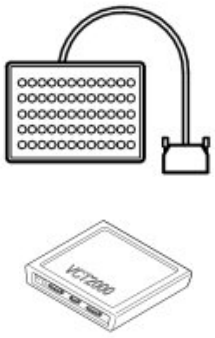
Checking inputs

Check the function of the control panel buttons.

Hint: The value should change when the button is activated.

Replace the control panel if the power seat control module (PSM) does not receive any signal.

Other information:
- To access or replace the control panel, see Side panel, replacing See: Body and Frame/Seats/Service and Repair/Removal and Replacement
- To connect the breakout box, see Connecting the breakout box, power seat module (PSM) See: Body and Frame/Seats/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box, Power Seat Module (PSM)
- For information about signals, see Signal specification, Power seat module See: Body and Frame/Seats/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Specification, Power Seat Module (PSM).



Is the function OK?

Yes - Fault Found

No - No Fault Found

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition

Motor 4 controls the height of the front edge of the seat. Motor 4 must be activated before the diagnostic trouble code (DTC) can be detected. Diagnostic trouble code (DTC) PSM-0036 is stored if motor 4 does not run despite M4+ being activated and the power seat module registering +12 V on the M4+ signal cable.

Possible source

- Open-circuit in signal cable M4+.
- Blown fuse (11C/4).

Fault symptom[s]

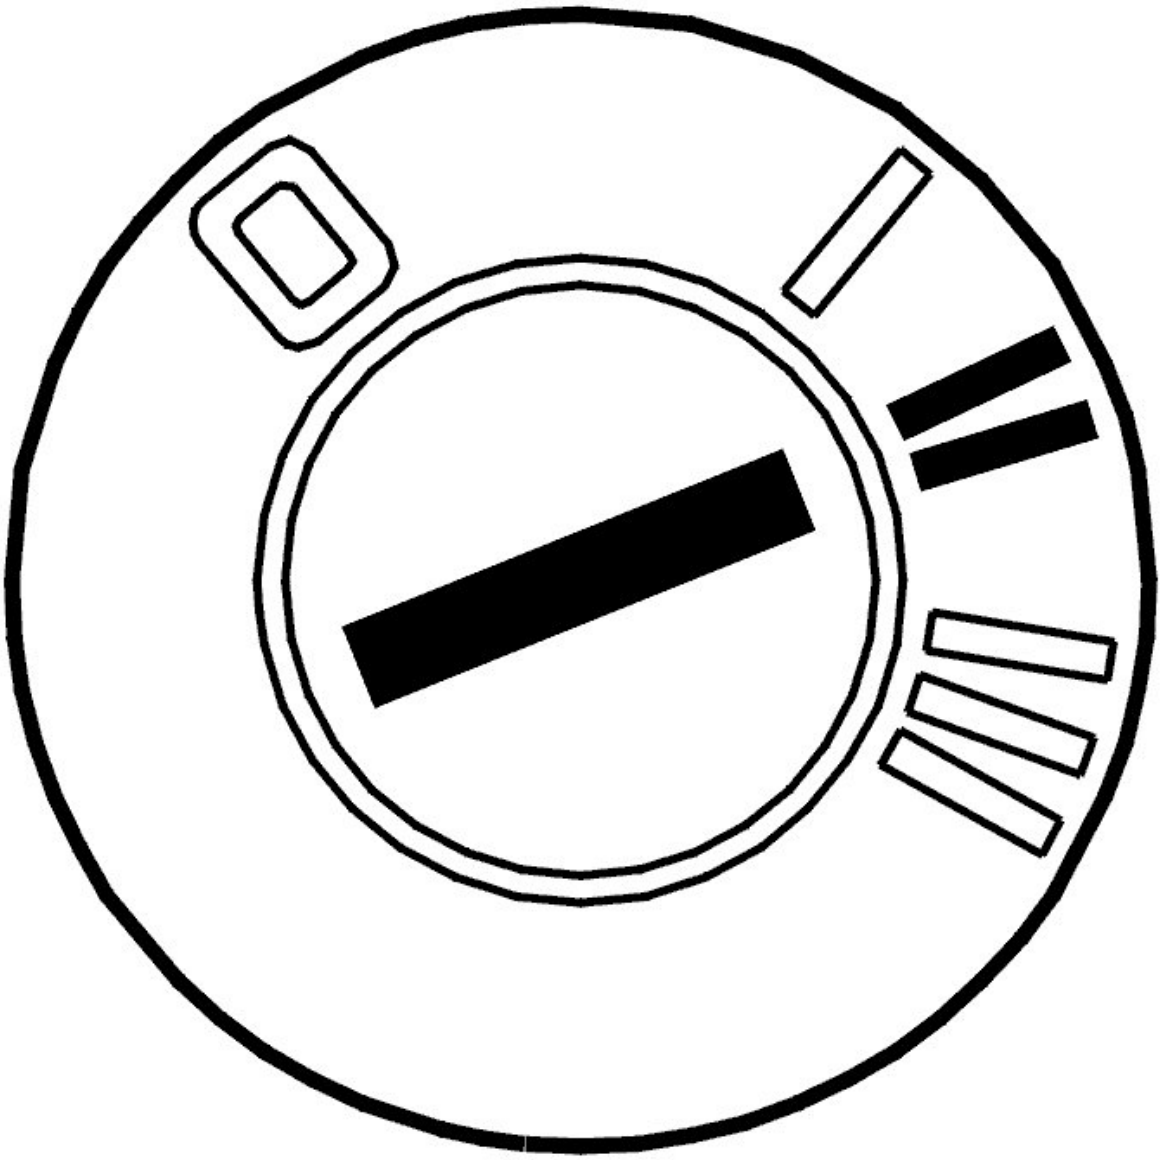
- The height of the front edge of the seat cannot be adjusted.

Signal Missing

Signal missing. Permanent fault

Checking the cable



- Ignition on
- Try to activate the motor.

Hint: The resistance between terminals #9E and #10E must be approximately 0 ohms.

Check the cable between the power seat module (PSM) #9E and the motor. Check for an open-circuit. See Checking wiring and terminals.
Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault.
Remedy as necessary.
If no fault is found try replacing the motor.

Other information:

- To access or replace the motor, see Electric motor cushion, replacing See: Body and Frame/Seats/Power Seat Motor/Service and Repair/Removal and Replacement
- To connect the breakout box, see Connecting the breakout box, power seat module (PSM) See: Body and Frame/Seats/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box, Power Seat Module (PSM)

Diagnostic Trouble Code (DTC) Information

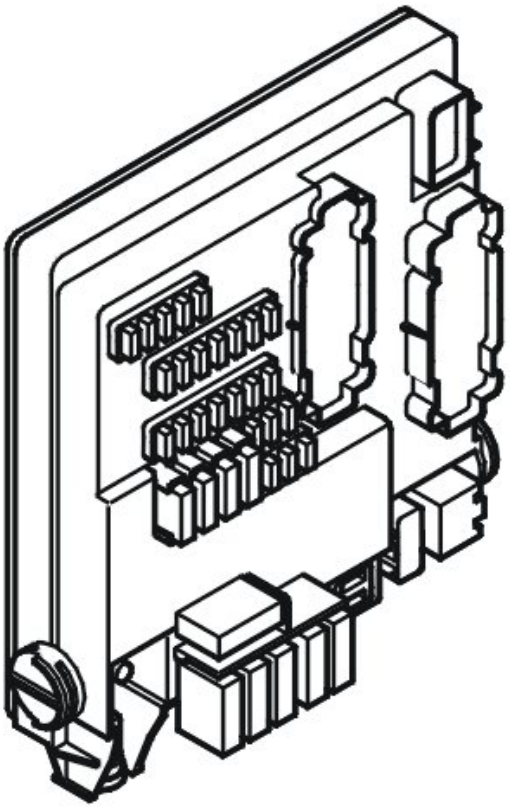
Diagnostic trouble code (DTC) information REM-DD00

Condition



The rear electronic module (REM) transmits and receives information via a standardized serial communication method - LIN (Local Interconnect Network). The diagnostic trouble code (DTC) is stored if the control module registers serious interference (LIN communication blocked) with the parking assistance module (PAM).
The diagnostic trouble code (DTC) can be detected when the ignition is in position II for at least 10 seconds and the battery voltage is > 10.5 volts.
Note! In the event of REM-DDxx diagnostic trouble codes (DTCs), the rear electronic module (REM) must not be replaced as the diagnostic trouble code (DTC) indicates a short-circuit in one or more conductors in the LIN network! The rear electronic module (REM) is the only control module that monitors the voltage level in the LIN wiring. The rear electronic module (REM) is therefore the only control module that can store a diagnostic trouble code (DTC) for a short-circuit to ground or supply voltage in one of the cables. Do not replace the rear electronic module (REM) in the event of a LIN fault unless VIDA fault-tracing has indicated that the rear electronic module (REM) has an internal fault.

Substitute value
- None.

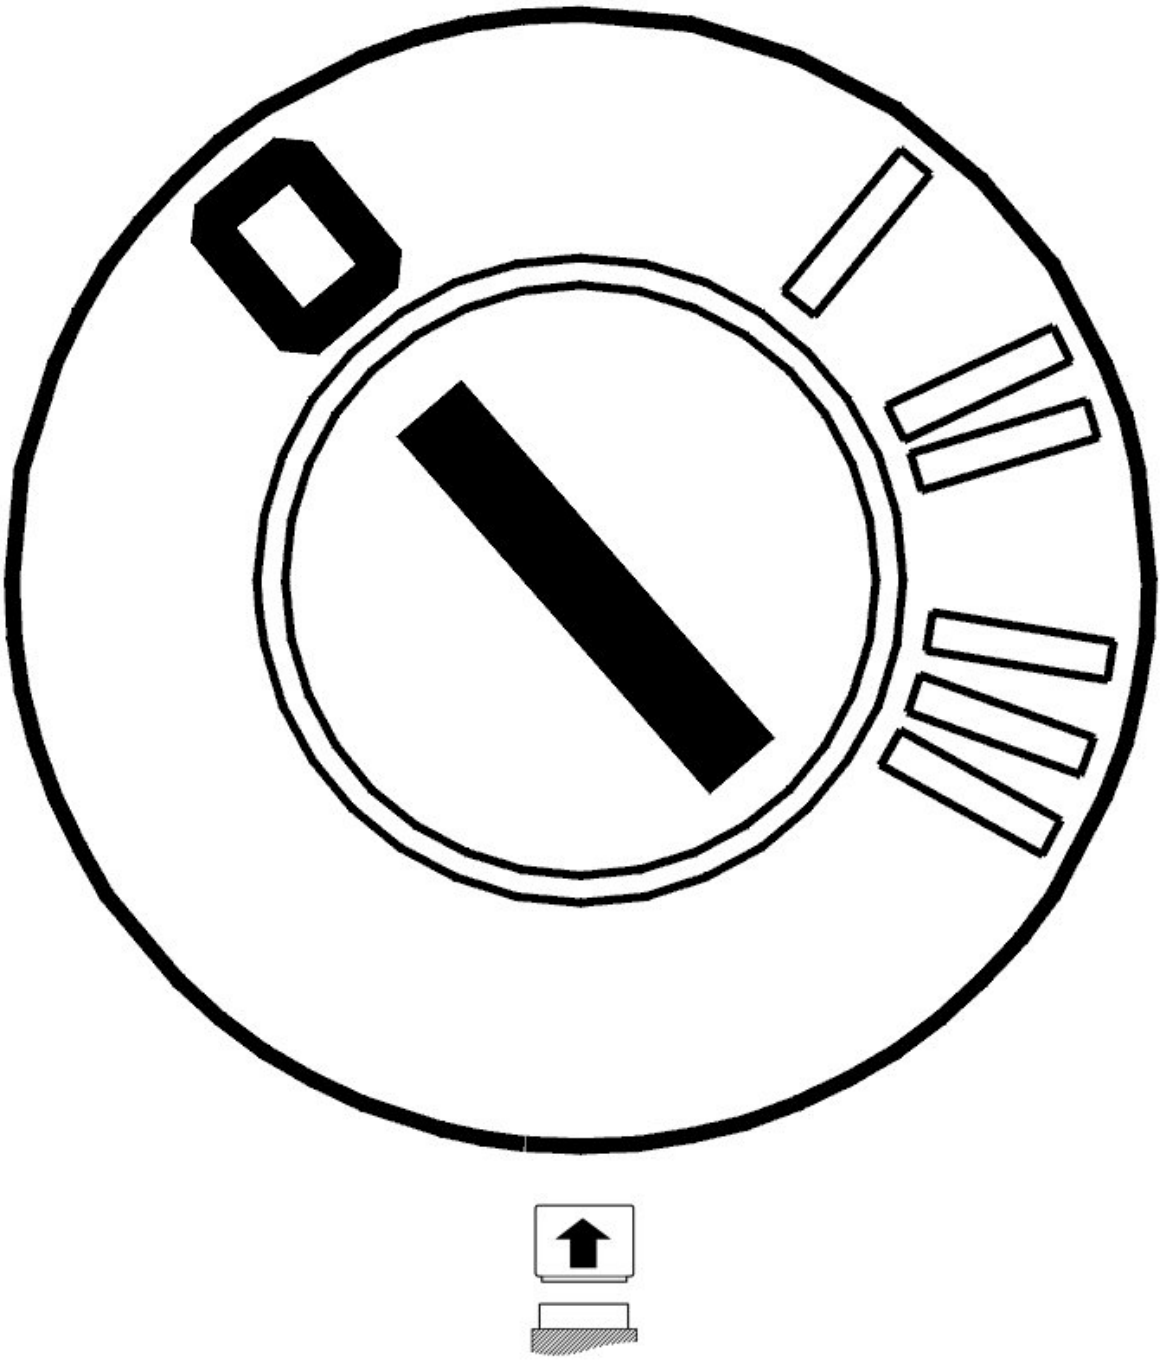
Possible source
- Short-circuit between signal cables
- Open-circuit in one of the signal cables
- Internal fault in another control module in the same part of the network.

Fault symptom[s]
- The parking assistance system does not operate.

Communication Fault

Communication fault

Checking the wiring



- Ignition off
- Disconnect connector D on the rear electronic module (REM).

The diagnostic trouble code (DTC) is stored if there is no communication between the rear electronic module (REM) and the parking assistance module (PAM). This may be due to a fault in the signal cable between the control modules or a defective communication device in one or all of the control modules.
Check the signal cable. Check for an open-circuit. Check for a short-circuit to ground. Check for a short-circuit to supply voltage.
Take readings between:

- Rear electronic module (REM) terminal #D32 (#32) and parking assistance module (PAM) terminal #A12.

Remedy as necessary.

Yes - FAULT-TRACING FAILED

No - Attempt New Test

FAULT-TRACING FAILED - FAULT-TRACING FAILED

Attempt New Test - Checking the wiring

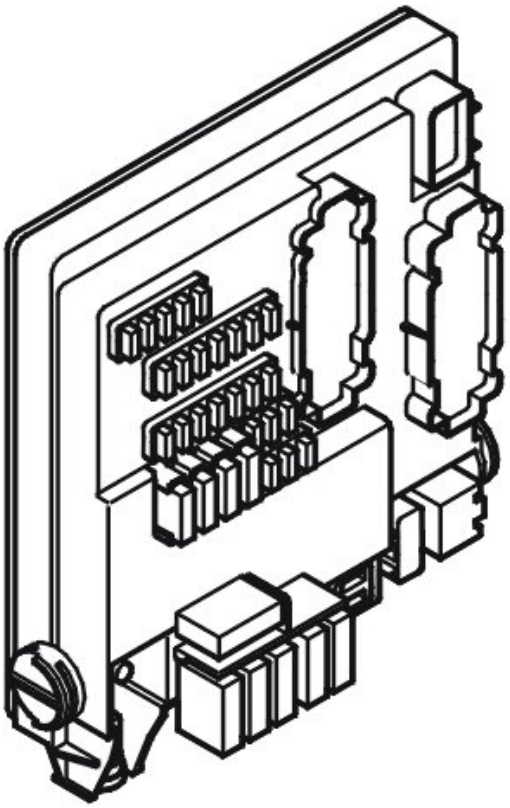
REM-E001

Diagnostic trouble code (DTC) information REM-E001

Condition



The control modules transmit and receive information via a standardized serial communication method - CAN (Control Area Network). The diagnostic trouble code (DTC) is stored if the control module registers serious interference (CAN communication blocked).

Note! In the event of system communication problems, it is not possible to communicate with the control module. Therefore it will only be possible to read off the diagnostic trouble code (DTC) if the fault is intermittent.

Substitute value

- The control module shuts itself off ("bus-off").

  Hint: The control module will remain shut off until the power supply is broken (15, 30, X). When the power supply is connected the control module will make a new attempt to communicate.

Possible source

- Short-circuit between the control area network (CAN) wiring
- Open-circuit in the control area network (CAN) wiring
- Internal fault in the control module
- Internal fault in another control module in the same part of the control area network (CAN).

Fault symptom[s]

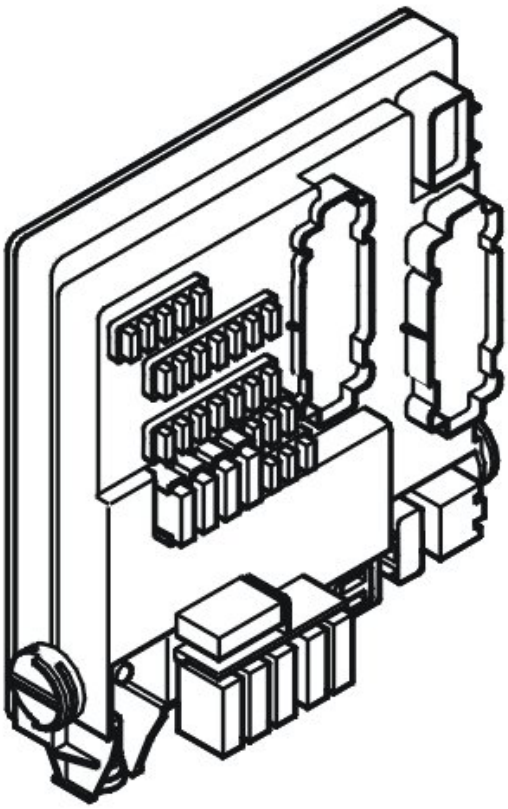
- The central locking system does not function at all

- The fuel gauge indicates zero even though there is fuel in the tank.
- Rear demist does not operate.
- Retractable headrest not operating.
- Does not lock / unlock the fuel tank filler cap.
- The power window mechanism in the rear door does not operate.
- The tail lamps are not working.

REM-E003

Diagnostic trouble code (DTC) information REM-E003

Condition



The control module compares its configuration ID with the signal configuration transmitted on the control area network (CAN) by the central electronic module (CEM). If the configuration IDs do not correspond the fault code is stored. The diagnostic trouble code (DTC) is also stored if the communication between the control module and the central electronic module (CEM) is or has been interrupted.

Note! In the event of an open-circuit in both the control area network (CAN) cables, it is not possible to communicate with the control module. Therefore it will only be possible to read off the diagnostic trouble code (DTC) if this type of fault is intermittent. When the diagnostic trouble code (DTC) is stored, the control module responds to the diagnostic command, however normal control area network (CAN) communication does not work. ("Expulsion mode")

Substitute value
- None.

Possible source
- Incorrect control area network (CAN) configuration ID (the node is not intended for this car - for example a used control module with different software/hardware)
- Open-circuit in the control area network (CAN) wiring between the control module and the central electrical module (CEM).

Fault symptom[s]
- The central locking system does not function at all.
- The fuel gauge indicates zero even though there is fuel in the tank.
- Rear demist does not operate.
- Retractable headrest not operating.
- Does not lock / unlock the fuel tank filler cap.
- The power window mechanism in the rear door does not operate.
- The tail lamps are not working.

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information REM-E010

Condition

The rear electronic module (REM) compares its supply voltage with the information about the supply voltage to the central electronic module (CEM) transmitted on the CAN network.
The diagnostic trouble code (DTC) is stored if the rear electronic module (REM) registers that its own power supply is more than 3V below the power supply to the central electronic module (CEM).
The diagnostic trouble code (DTC) can be diagnosed when the engine is running.

Substitute value
- None.

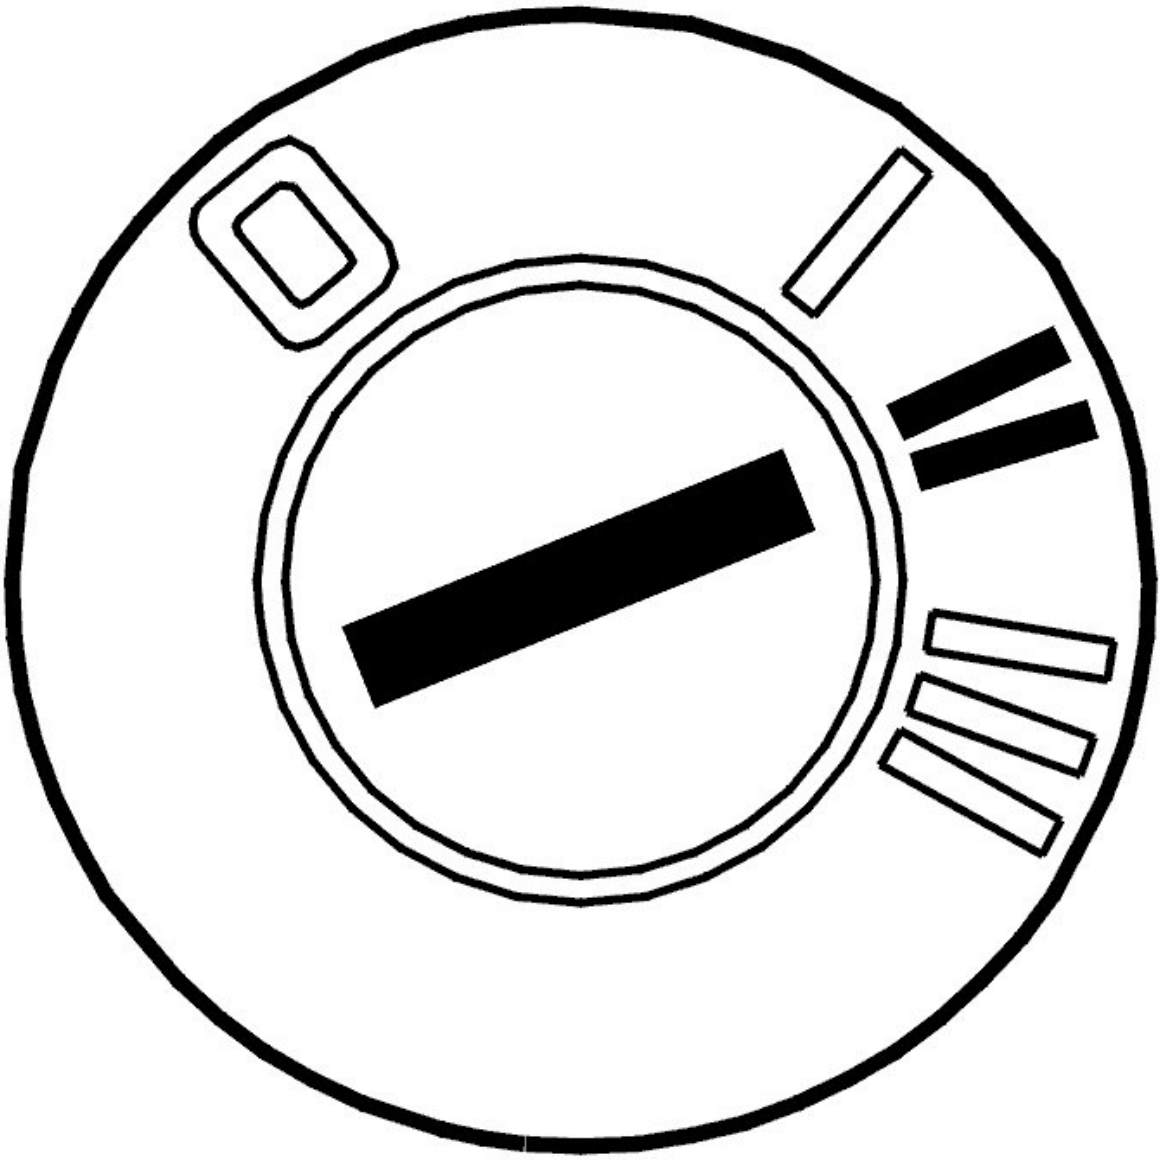
Possible source
- Half-burned fuse for the rear electronic module (REM)
- Damaged power supply cable to the rear electronic module (REM)
- Loose connections in the ground lead for the rear electronic module (REM)
- Contact resistance or oxidation in the terminals.

Fault symptom[s]
- The central locking system does not function at all.
- The fuel gauge indicates zero even though there is fuel in the tank.
- Rear demist does not operate.
- Retractable headrest not operating.
- Does not lock / unlock the fuel tank filler cap.
- The power window mechanism in the rear door does not operate.
- The tail lamps are not working.

Signal Too Low

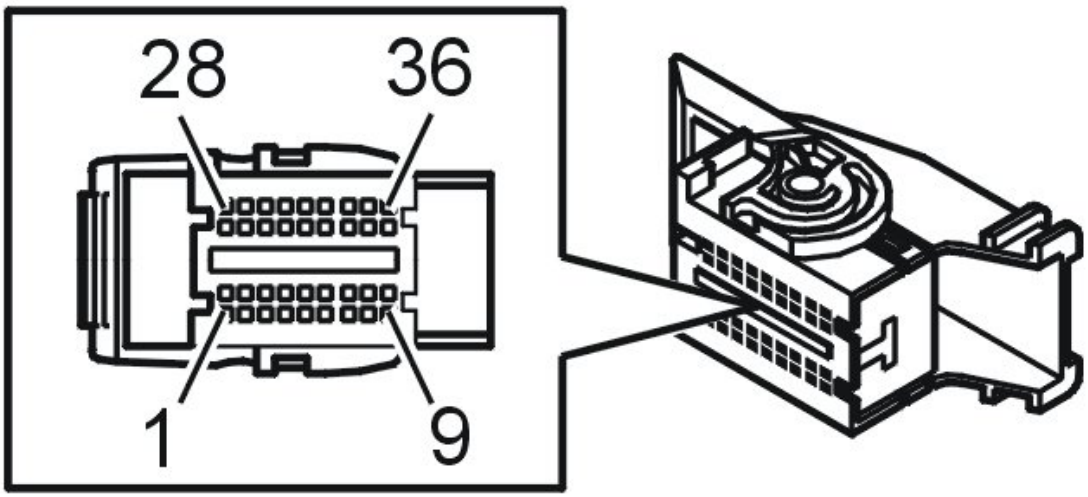
Signal too low

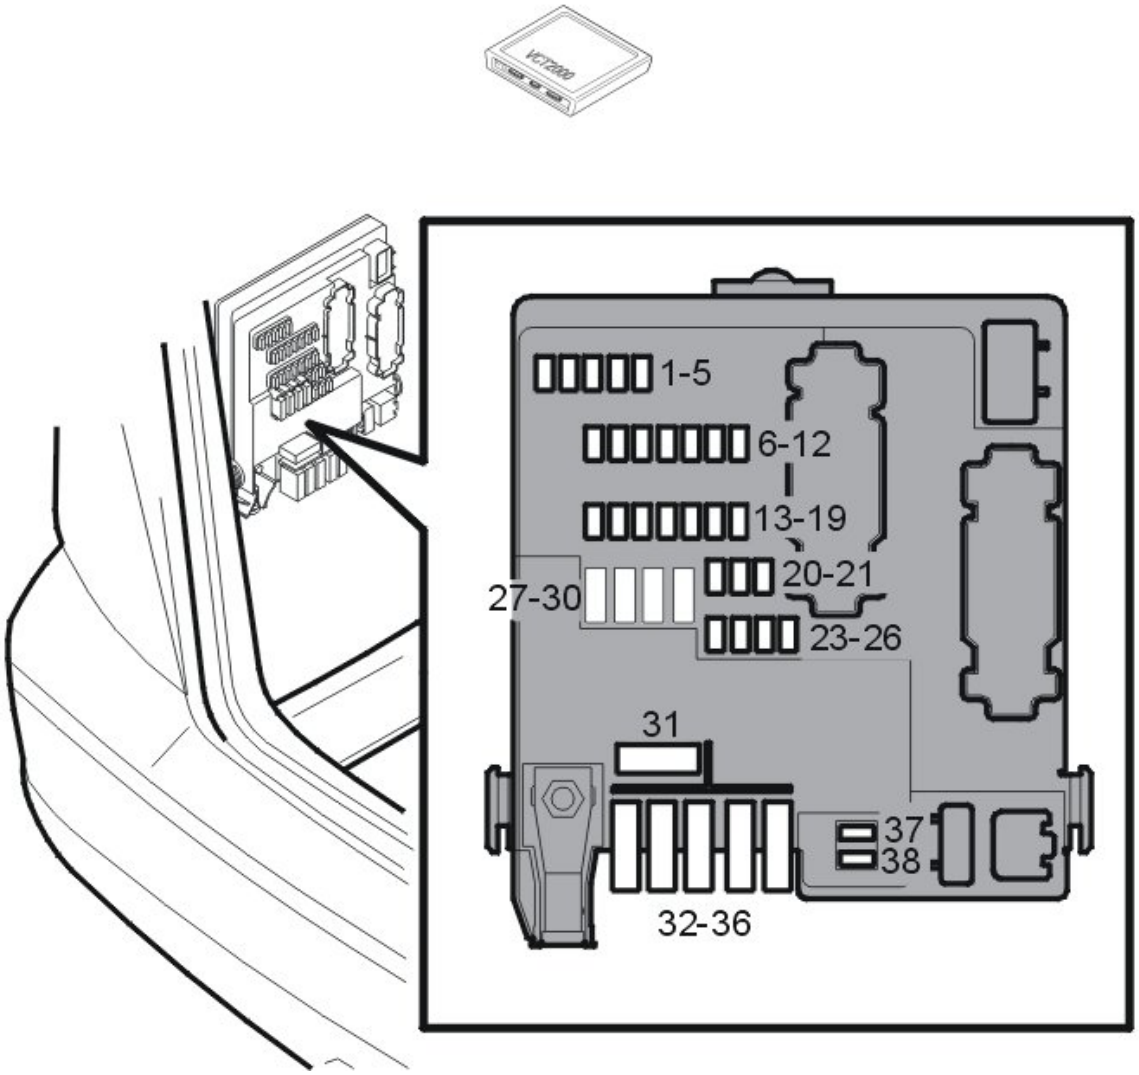
Checking the power supply



- Ignition on
- Read off the power supply for the rear electronic module (REM) and the central electronic module (CEM).

The voltage for the rear electronic module (REM) and the central electronic module (CEM) must be approximately the same.
The fault is permanent if the voltage for the rear electronic module (REM) deviates by more than 3 V from the central electronic module (CEM).
If the voltage is approximately the same, this indicates an intermittent fault, i.e. the fault was present previously but is not active at the moment.





Continue - Checking cable and component

Checking cable and component

Check the connectors for the rear electronic module (REM). Check for contact resistance and oxidation.
Check the terminals for the power supply (30-supply) from the battery to the rear electronic module (REM) (screw terminal). Check for contact resistance and oxidation. Also check the terminals for the fuse to the actual rear electronic module (REM). For information about fuses, see the relevant Wiring Diagram.
Check the ground terminal from the rear electronic module (REM) terminal #12 (#D12) and ground terminal. Check for contact resistance and oxidation.
Remedy as necessary.

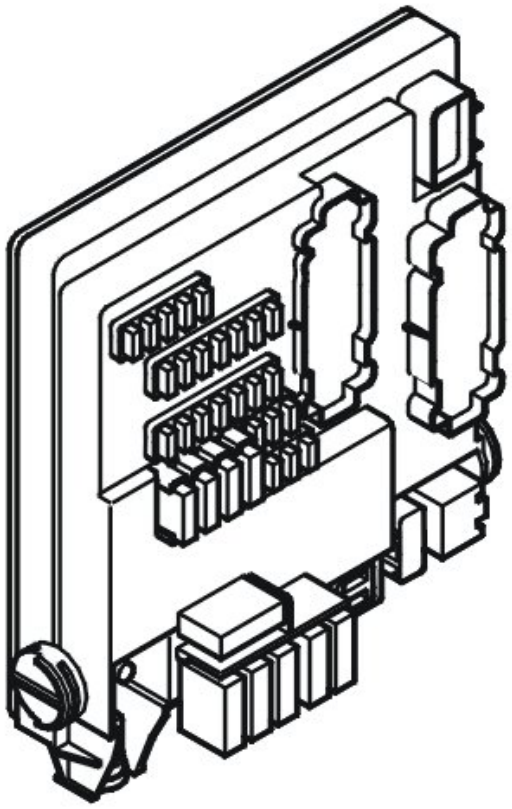
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information REM-1D0A

Condition



The diagnostic trouble code (DTC) is stored if the rear electronic module (REM) registers an internal fault.
The diagnostic trouble code (DTC) can be diagnosed when the ignition is switched on.

Substitute value
- None.

Possible source
- Internal fault in the control module.

Fault symptom[s]
- The fuel gauge does not work

- No locking/unlocking of the tailgate
- Does not lock / unlock the fuel tank filler cap.

Internal Fault

Internal fault

Replacing the component

The rear electronic module (REM) has registered an internal fault.
If the fault is intermittent, it has been registered previously but is no longer present. Intermittent faults can be caused by interference at start up of the rear electronic module (REM) or may be a different type of fault which occurs on different occasions. The fault is evaluated depending on how it occurs. Replace the rear electronic module (REM) if the fault recurs.
Replace the rear electronic module (REM) in the event of a permanent fault.
Remedy as necessary.

Diagnostic Trouble Code (DTC) Information

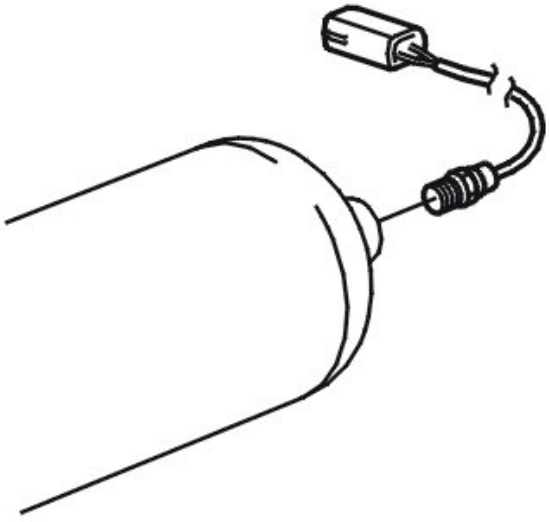
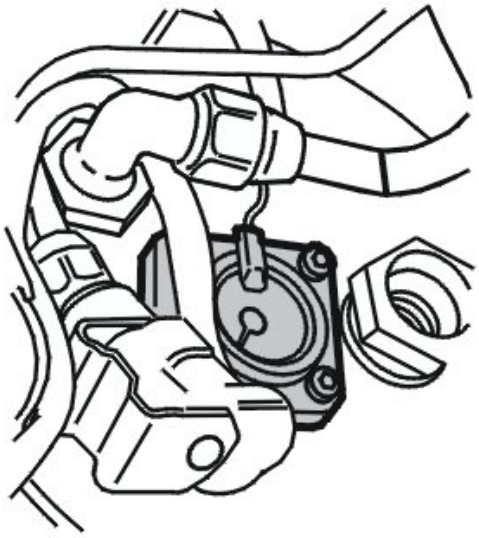
Diagnostic trouble code (DTC) information REM-4A46

Condition





The rear electronic module (REM) checks the signal from the fuel level sensor for gas.
The diagnostic trouble code (DTC) is stored if the rear electronic module (REM) registers that the signal is too low.
The diagnostic trouble code (DTC) can be diagnosed at key position II.

Substitute value
- The fuel level is set to zero.

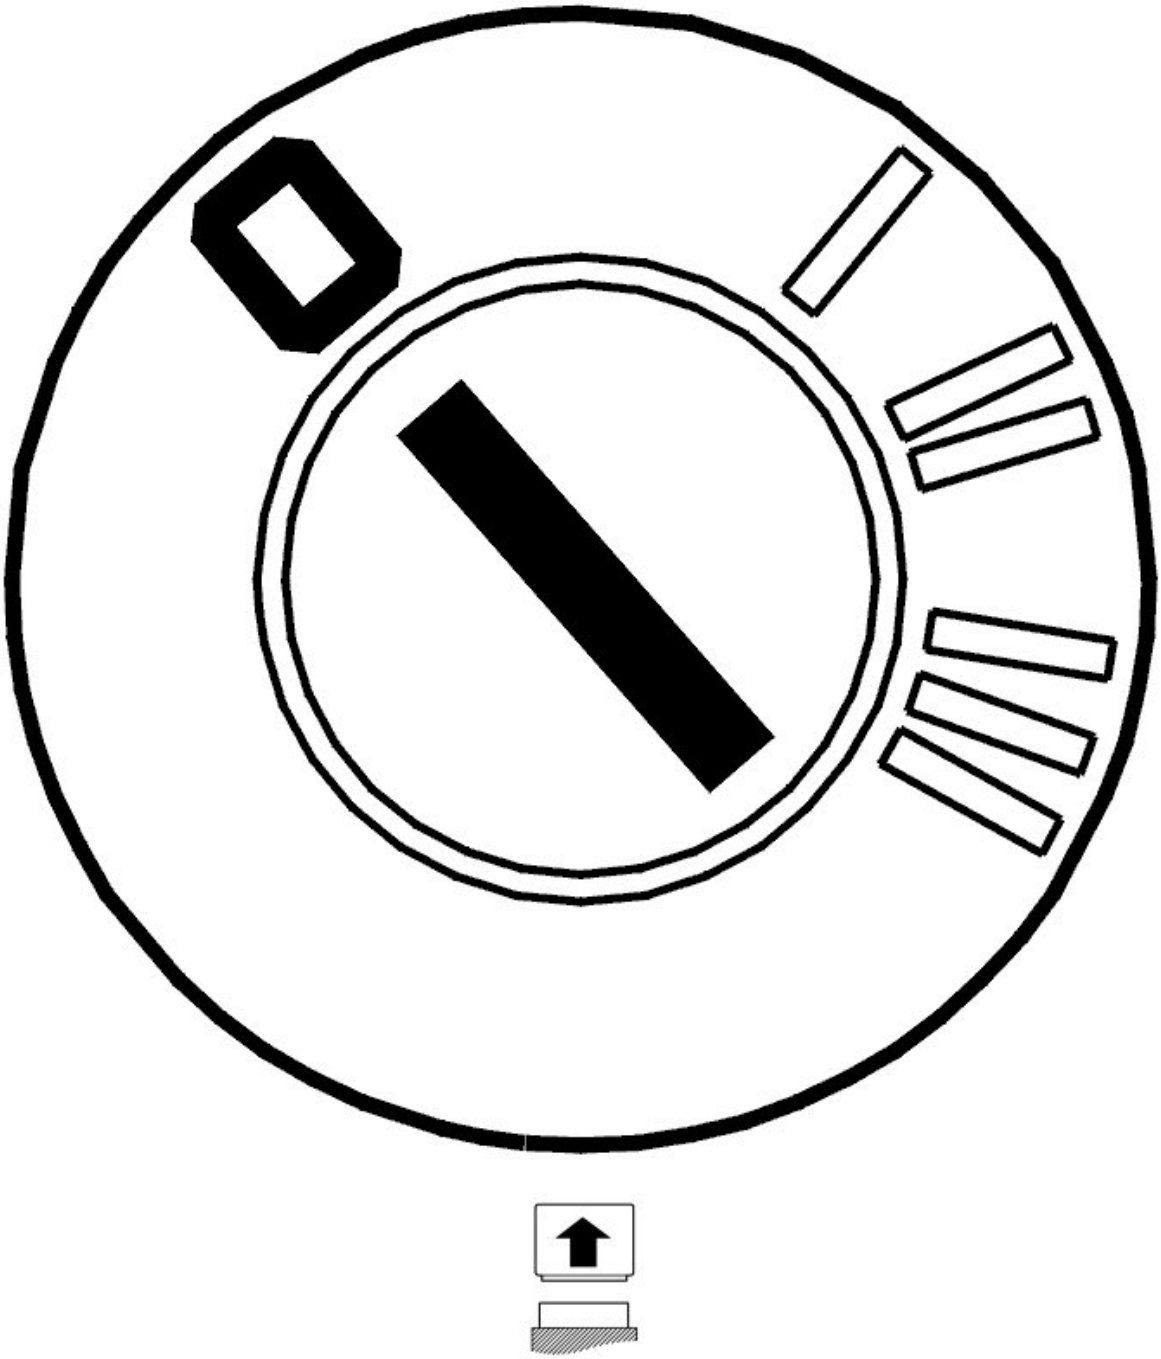
Possible source
- Short-circuit to ground in the signal cable.

Fault symptom[s]
- The trip computer displays an empty fuel tank too early
- The fuel gauge indicates zero even though there is fuel in the tank
- The gas level gauge does not work.

Signal Too Low

Signal too low

Checking the wiring



- Ignition off
- Disconnect connector D on the rear electronic module (REM).

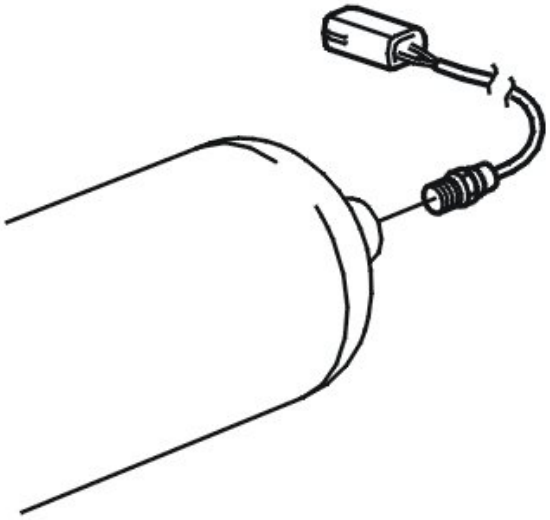
Check the signal cable. Check for an open-circuit. Check for a short-circuit to ground.

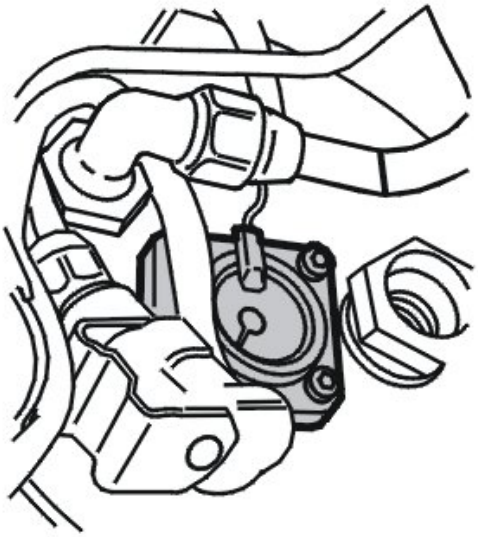
Take readings between:

- Rear electronic module (REM) terminal #D36 (#36) and gas level sensor terminal #1.

Other information

- Connecting the breakout box See: Body and Frame/Body Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box/Connecting Breakout Box, Rear Electronic Module (REM)
- Signal specification See: Body and Frame/Body Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Description / Specification/Signal Specification, Rear Electronic Module (REM)
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals





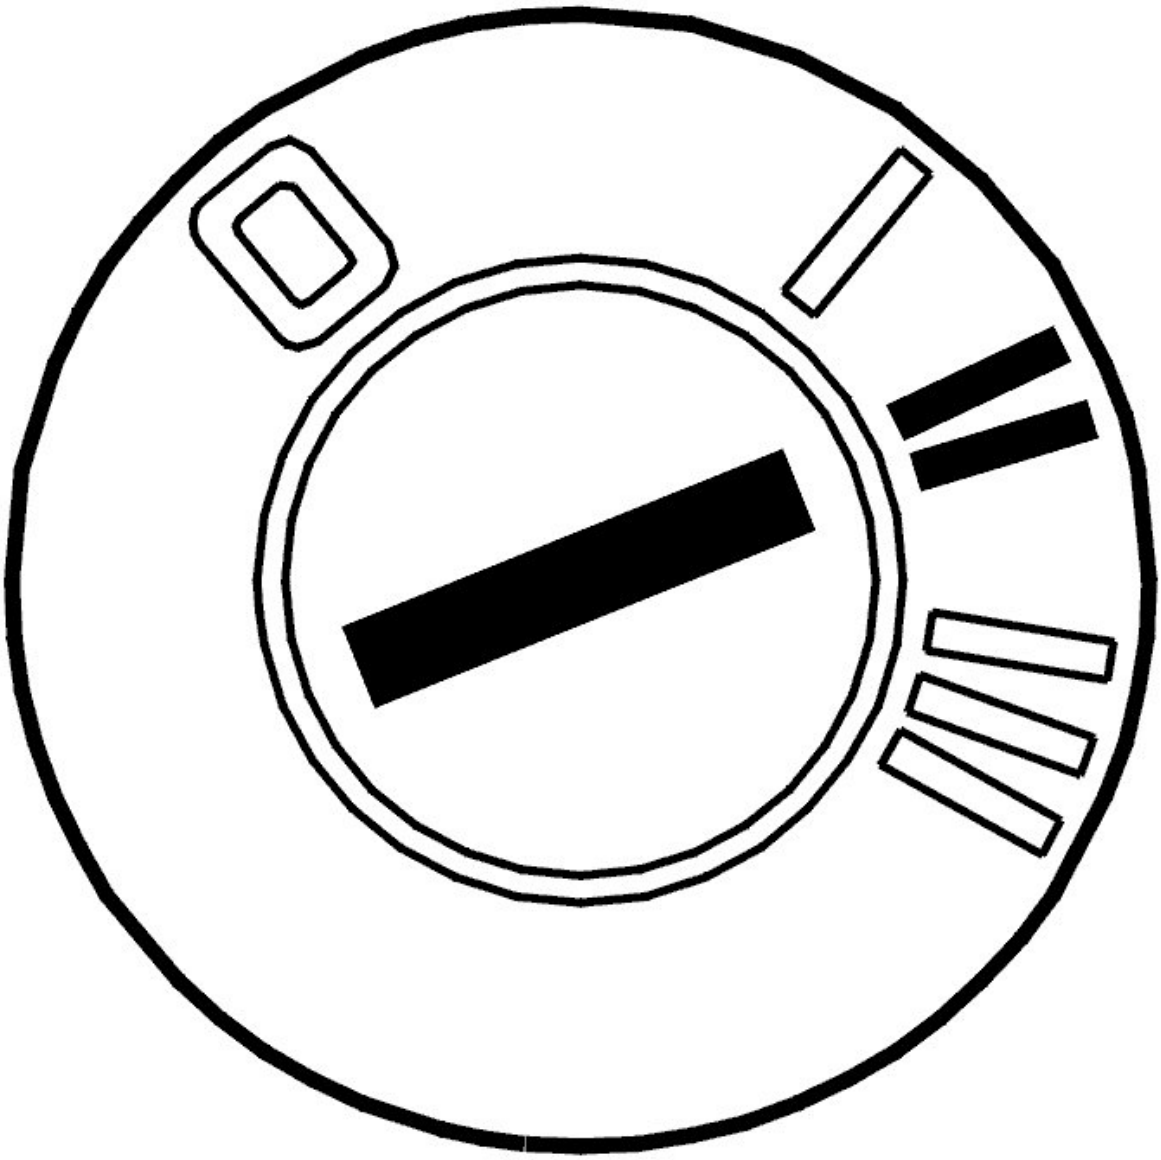
Continue - Verification

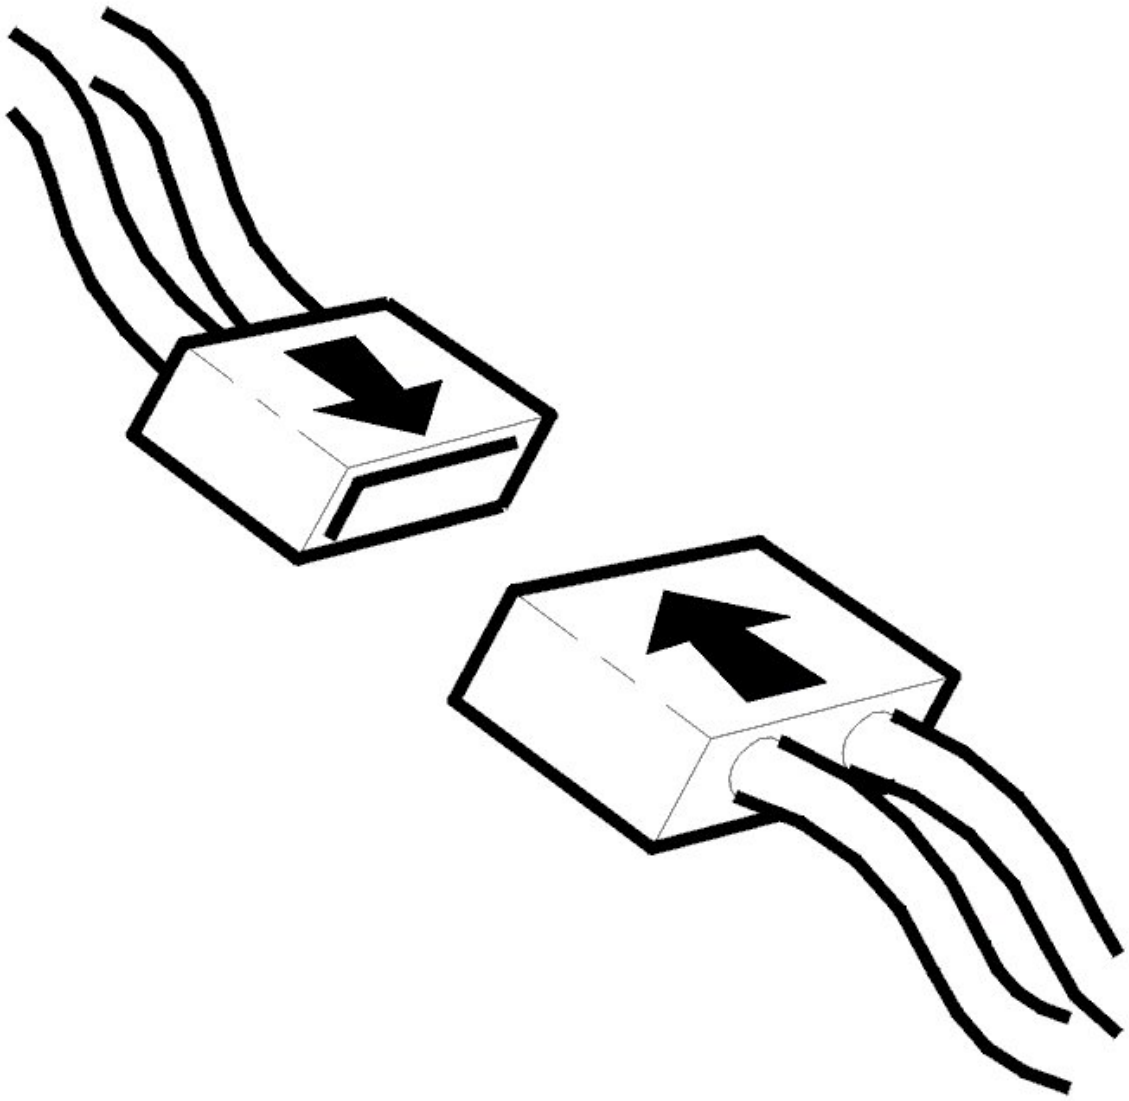
Verification

Verification

Verification

Hint: After carrying out the repair, check that the fault has been remedied.





- Ignition off
- Reinstall the connectors, components etc.
- Ignition on.

Fill up with gas. Check that the level of the fuel gauge changes.

Is the value within its permitted range?

Yes - VERIFIED

No - VERIFICATION FAILED

Diagnostic Trouble Code (DTC) Information

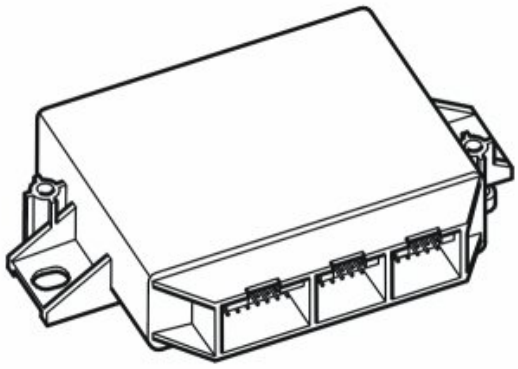
Diagnostic trouble code (DTC) information REM-4F4A

Condition



The rear electronic module (REM) communicates with the parking assistance module (PAM).
The diagnostic trouble code (DTC) is stored if the rear electronic module (REM) receives information from the parking assistance module (PAM) indicating an internal fault.
The diagnostic trouble code (DTC) can be diagnosed at key position II.

Substitute value
- None.

Possible source
- Internal fault in the parking assistance module (PAM).

Fault symptom[s]
- The parking assistance system does not operate
- Message in the display.

Faulty Signal

Faulty signal

Replacing the component

The parking assistance module (PAM) has registered an internal fault.
If the fault is intermittent, it has been registered previously but is no longer present. Intermittent faults can be caused by interference at start up of the parking assistance module (PAM) or may be a different type of fault which occurs on different occasions. The fault is evaluated depending on how it occurs. Replace the parking assistance module (PAM) if the fault recurs.
Replace the parking assistance module (PAM) in the event of a permanent fault.
Remedy as necessary.

Other information
- Parking assistance module (PAM), replacing See: Accessories and Optional Equipment/Collision Avoidance and Parking Assist Systems/Parking Assist Control Module/Service and Repair

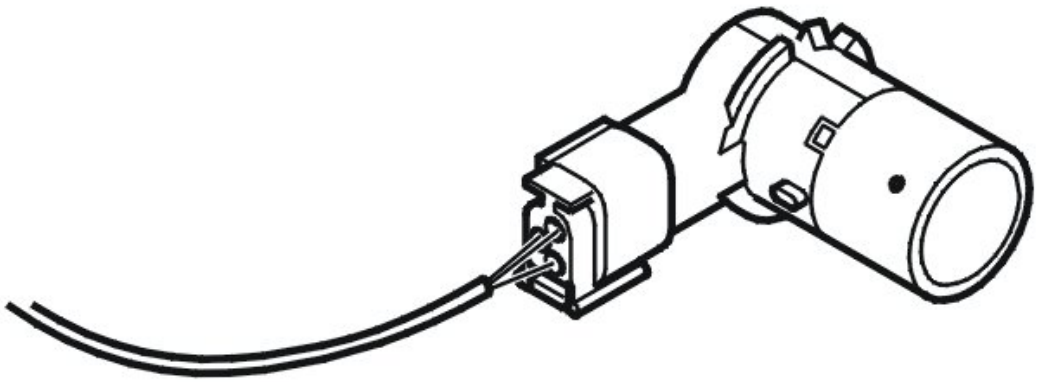
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information REM-4F42

Condition



The rear electronic module (REM) communicates with the parking assistance module (PAM) which checks the signal from parking sensor 1.
The diagnostic trouble code (DTC) is stored if the parking assistance module (PAM) registers a faulty signal from the parking sensor (1).
The diagnostic trouble code (DTC) can be diagnosed at key position II.

Substitute value

- None.

Possible source

- Short-circuit to ground or supply voltage in the signal cable between the parking assistance module (PAM) and parking sensor 1
- Short-circuit to ground in the power supply cable between the parking assistance module (PAM) and parking sensor 1
- Short-circuit to supply voltage in the ground lead between the parking assistance module (PAM) and parking sensor 1.

Fault symptom[s]

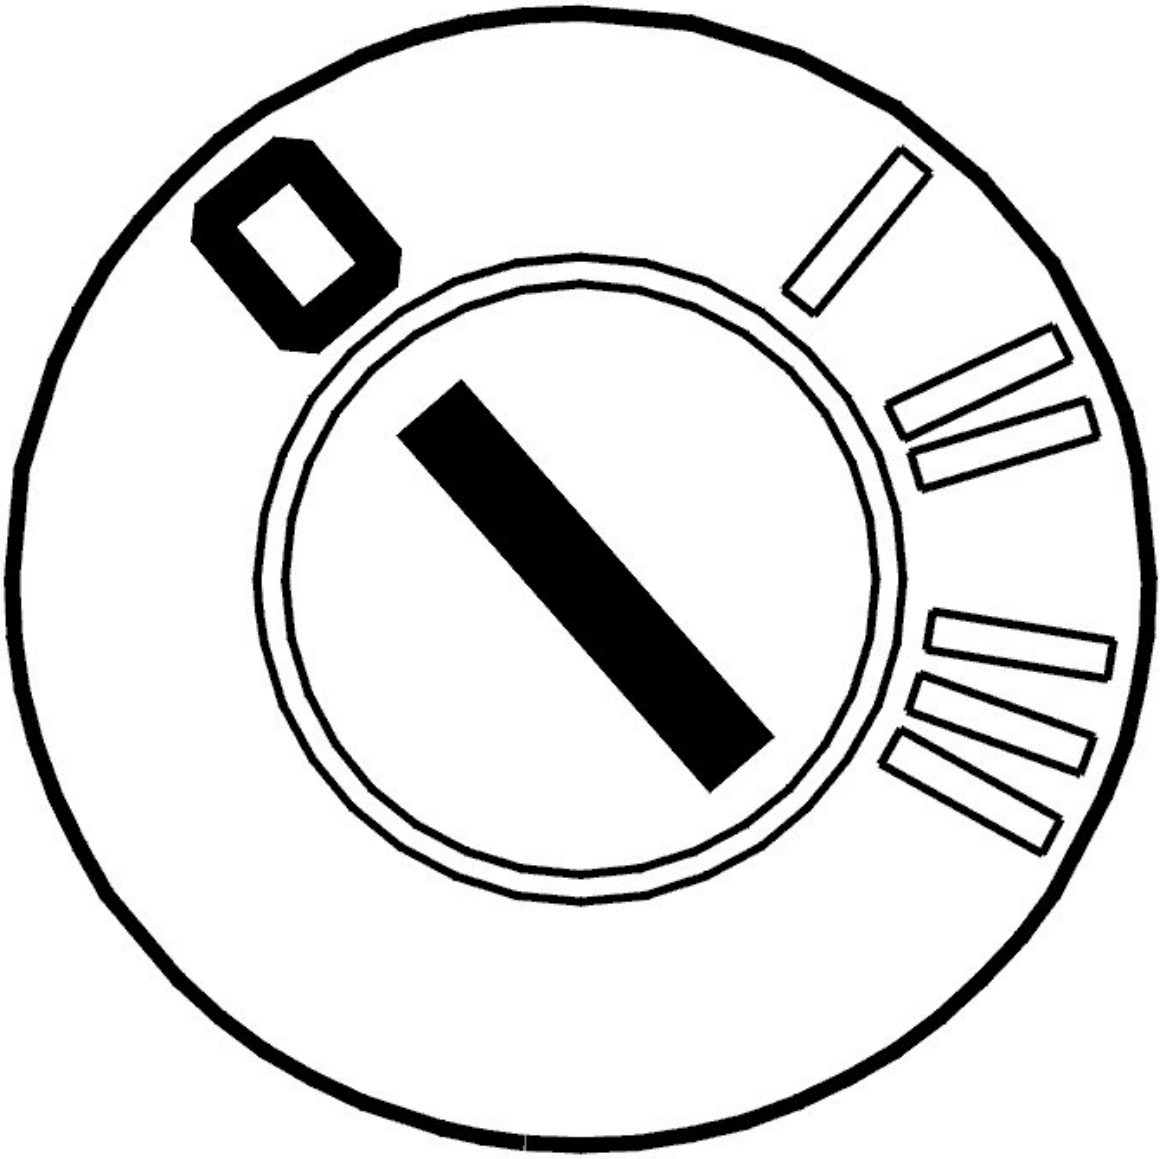
- The parking assistance system does not operate
- Message in the display.

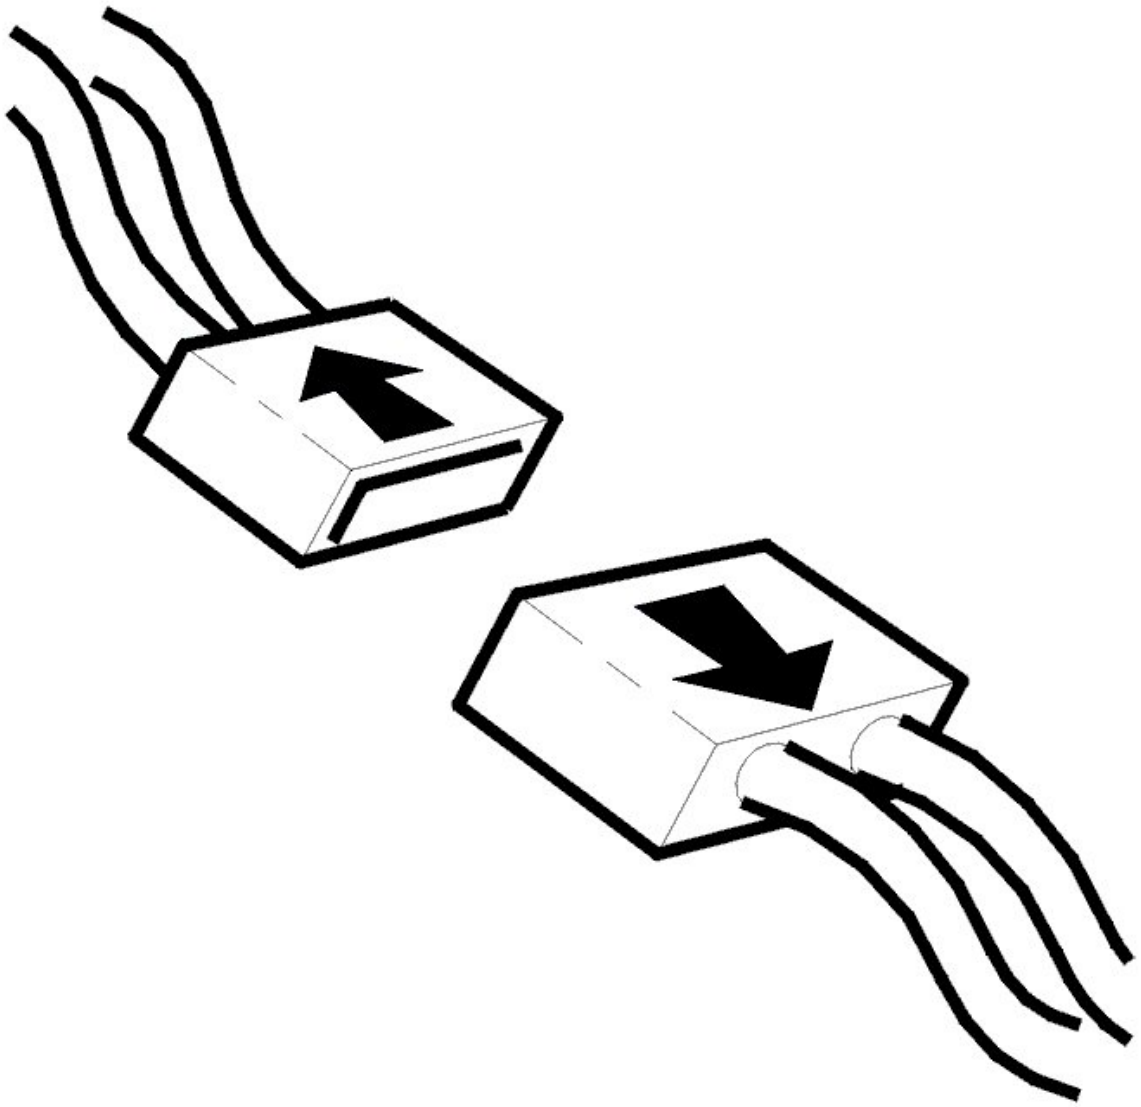
Faulty Signal

Faulty signal

Checking components and wiring

Caution! Do not touch the terminal pins in the parking assistance module (PAM). There is a risk of static discharge. This could damage the parking assistance module (PAM).





- Ignition off.

Check the connectors for the parking sensor 1 (outer left rear) and the parking assistance module (PAM). Check for damage to pins and terminals.
Also check the other connectors that connect the wiring between the parking assistance module (PAM) and the parking sensor.
Check the signal cable between the parking assistance module (PAM) and the parking sensor connector. Check for a short-circuit to supply voltage.
Check for a short-circuit to ground.
Check the cable between:

- Parking assistance module (PAM) terminal #C5 and parking sensor connector terminal #2.

Check the power supply lead between the parking assistance module (PAM) and the parking sensor connector. Check for a short-circuit to ground.
Check the cable between:

- Parking assistance module (PAM) terminal #C6 and parking sensor connector terminal #1.

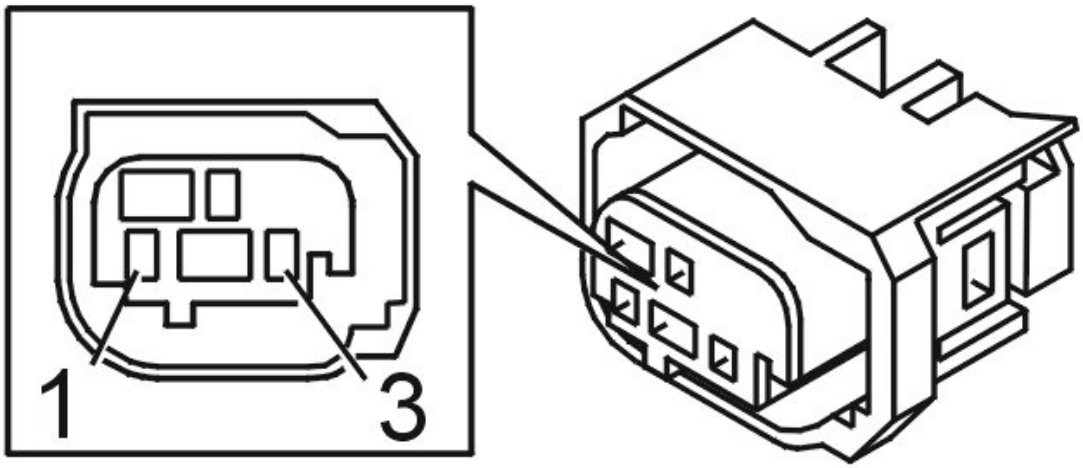
Check the ground lead between the parking assistance module (PAM) and the parking sensor connector. Check for a short-circuit to supply voltage.
Check the cable between:

- Parking assistance module (PAM) terminal #C1 and parking sensor connector terminal #3.

Remedy as necessary.
If no fault is found, replace the parking sensor.

Other information

- Back-up warning sensor, replacing See: Accessories and Optional Equipment/Collision Avoidance and Parking Assist Systems/Parking Assist Distance Sensor/Service and Repair
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals



Select "Continue" when the fault has been remedied.

Diagnostic Trouble Code (DTC) Information

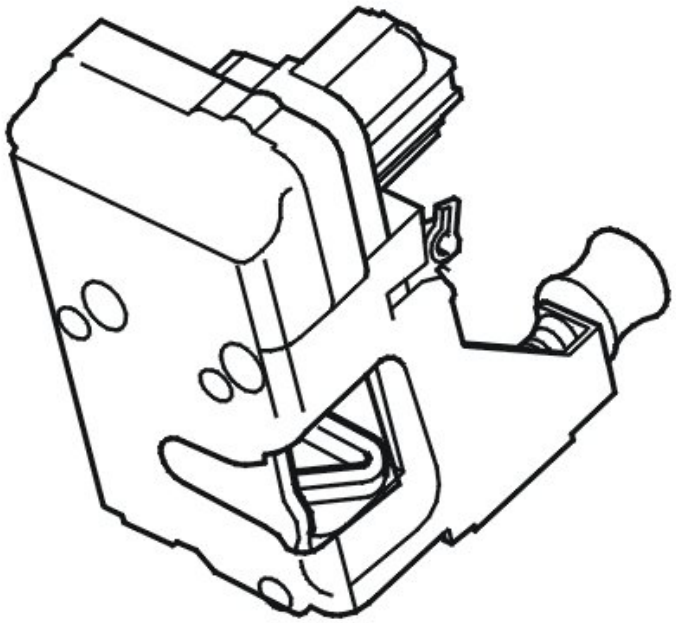
Diagnostic trouble code (DTC) information REM-6A01

Condition



The rear electronic module (REM) controls the lock units in the rear doors via a number of relays.
The rear electronic module (REM) receives an indication from the lock units about whether the central locking motor is in the locked or unlocked position. This information is provided by a switch in each lock unit. The switch must be closed when the lock motor is in the locked position.
The diagnostic trouble code (DTC) is stored if the rear electronic module (REM) detects that the input from the switch in the **left rear door** is still high 15 seconds after the unlock command was given.
The diagnostic trouble code (DTC) can be diagnosed when locking the central locking.

Substitute value
- None.

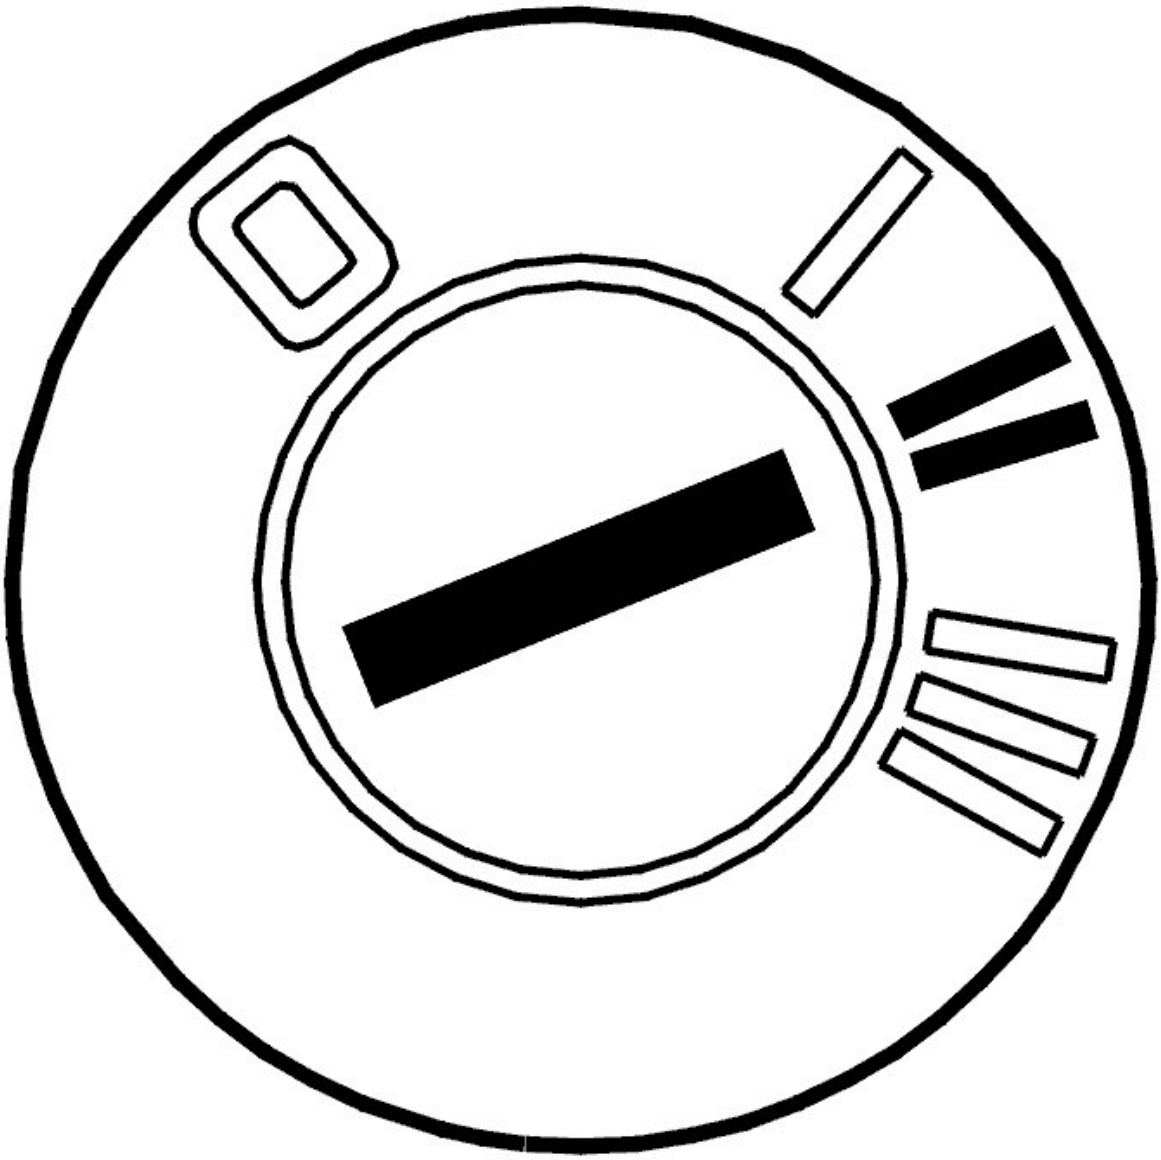
Possible source
- Contact resistance and oxidation in the terminals
- Fault or short-circuit to supply voltage in the switch for indication of the lock motor position
- Open-circuit in the cable from the switch for indication of the lock motor position
- The lock motor is stuck in one position
- Open-circuit in the ground lead/ground terminal for the lock mechanism
- Open-circuit, short-circuit to ground or supply voltage in the control cable to the lock motors
- Open-circuit, short-circuit to ground or supply voltage in the control cable to the lock motors from/to the relay for the child-proof lock
- Open-circuit, short-circuit to ground or supply voltage in the wiring to the relay for the child-proof lock from the power window switch
- Damaged relay for the child-proof lock.

Fault symptom[s]
- Does not lock / unlock a door.

Signal Too High

Signal too high

Checking the signal from the switches in the rear doors

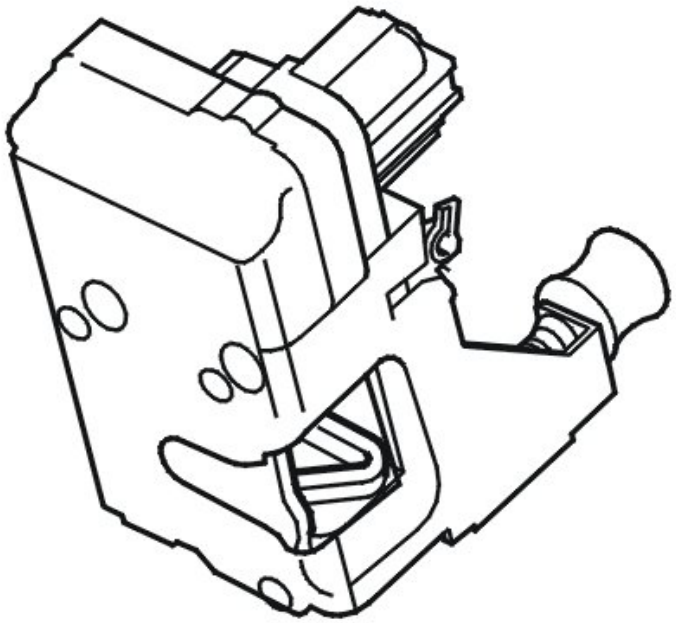


- Ignition on
- Read off the status from the control switch in both rear doors (indicates whether the doors are locked or not).

Lock and unlock the left and right-hand rear doors. The status of each door should change when the door is locked or unlocked.

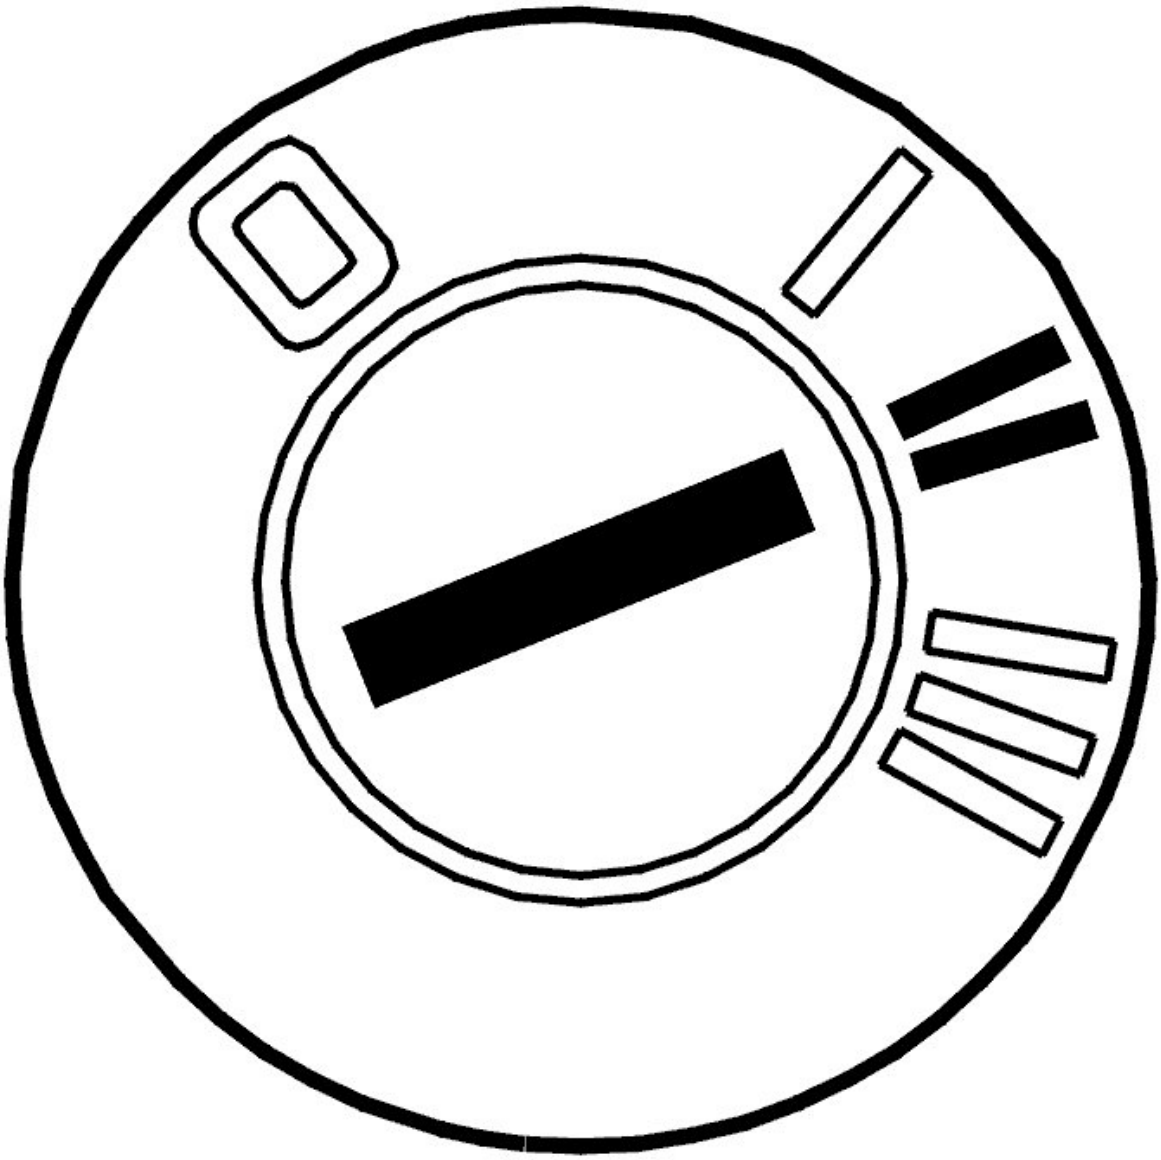
Hint: The doors can also be locked/unlocked using the remote control.

The fault is permanent if the status does not change.
If the status changes, this indicates an intermittent fault, i.e. the fault was present previously but is not active at the moment.



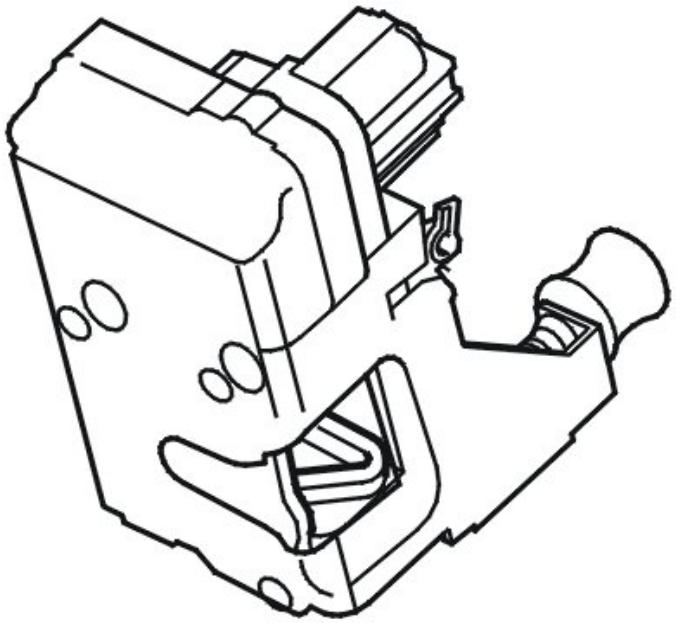
Continue - Checking the function of the lock mechanism

Checking the function of the lock mechanism



- Ignition on

Lock and unlock the left and right-hand rear doors. Check that the door can be opened when it is unlocked and cannot be opened when it is locked.



Is the function OK?

Yes - Checking the signal from the switches in the rear doors

No - Checking cable and component

Checking the signal from the switches in the rear doors

Note! Only fault-trace the circuit of the door displaying the faulty value.

Check the connectors for the lock mechanism and the rear electronic module (REM). Check for contact resistance and oxidation.
Check the switch in the lock mechanism. Check for a short-circuit. Check for an open-circuit. Check by measuring the resistance between terminals #1 and #5 on the connector for the lock mechanism and ground.
Check the resistance between terminals #1 and #5 on the lock mechanism side. The resistance must be infinite or near 0 ohm depending on the position of the switch.

Left rear door

Check the signal cable between rear electronic module (REM) connector terminal #45 (#C5) and terminal #5 on the lock mechanism connector. Check for a short-circuit to supply voltage. Check for an open-circuit. The lock mechanism is jammed if no fault is found in the cable or the switch.

Right rear door

Check the signal cable between rear electronic module (REM) connector terminal #28 (#D28) and terminal #5 on the lock mechanism connector. Check for a short-circuit to supply voltage. Check for an open-circuit. The lock mechanism is jammed if no fault is found in the cable or the switch. Remedy as necessary.

Other information

- Connecting the breakout box See: Body and Frame/Body Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box/Connecting Breakout Box, Rear Electronic Module (REM)

Diagnostic Trouble Code (DTC) Information

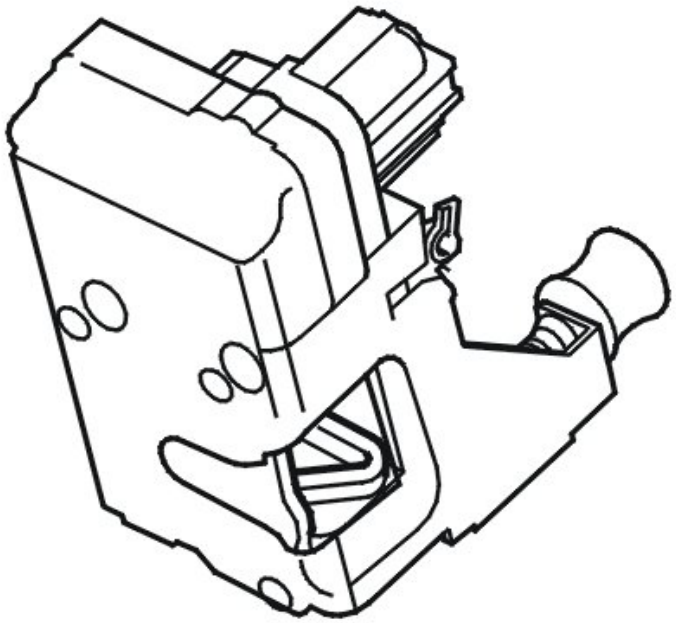
Diagnostic trouble code (DTC) information REM-6A03

Condition



The rear electronic module (REM) uses a number of relays to control the lock units in the rear doors for locking and unlocking.
The rear electronic module (REM) receives an indication from the lock units when the central locking motor is in the locked or unlocked position. This information is supplied by a switch in each lock unit. The switch provides a ground when the lock motor is in the locked position.
The diagnostic trouble code (DTC) is stored if the rear electronic module (REM) detects that the input from the switch in the **left rear door** is still low 15 seconds after the unlock command was given.
The diagnostic trouble code (DTC) can be diagnosed during unlocking by the central locking and when no further lock command has been received within 15 seconds.

Substitute value
- None.

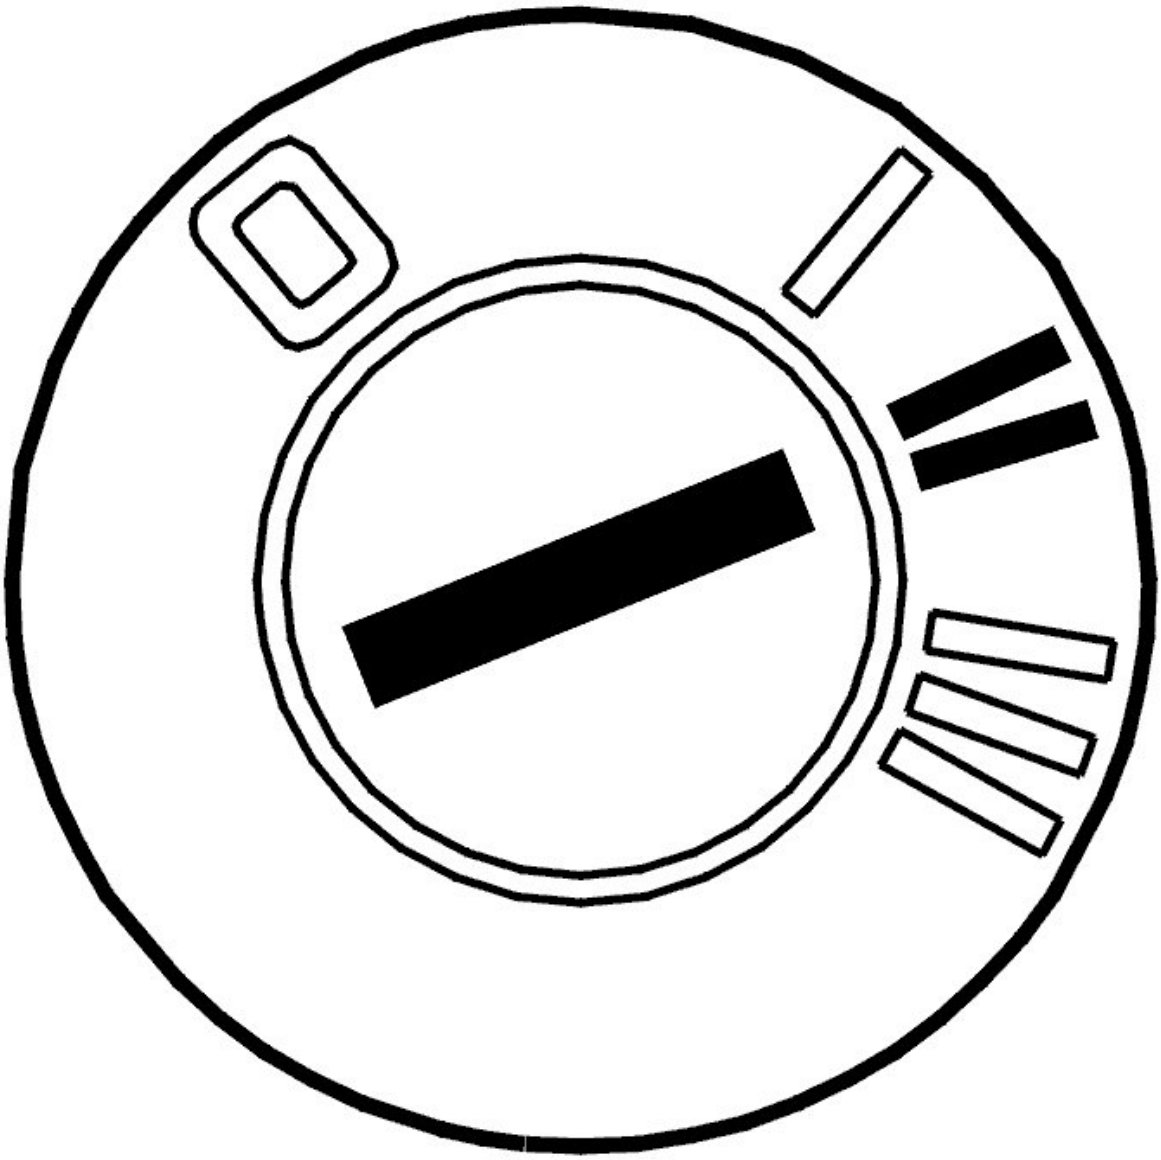
Possible source
- Contact resistance and oxidation in the terminals
- Fault or short-circuit to ground in the switch for indication of the lock motor position
- Short-circuit to ground in the cable from the switch for indication of the lock motor position
- The lock motor is stuck in one position
- Open-circuit in the ground lead/ground terminal for the lock mechanism
- Open-circuit, short-circuit to ground or supply voltage in the control cable to the lock motors
- Open-circuit, short-circuit to ground or supply voltage in the control cable to the lock motors from/to the relay for the child-proof lock
- Open-circuit, short-circuit to ground or supply voltage in the wiring to the relay for the child-proof lock from the power window switch
- Damaged relay for the child-proof lock.

Fault symptom[s]
- Does not lock / unlock a door.

Signal Too Low

Signal too low

Checking the signal from the switches in the rear doors

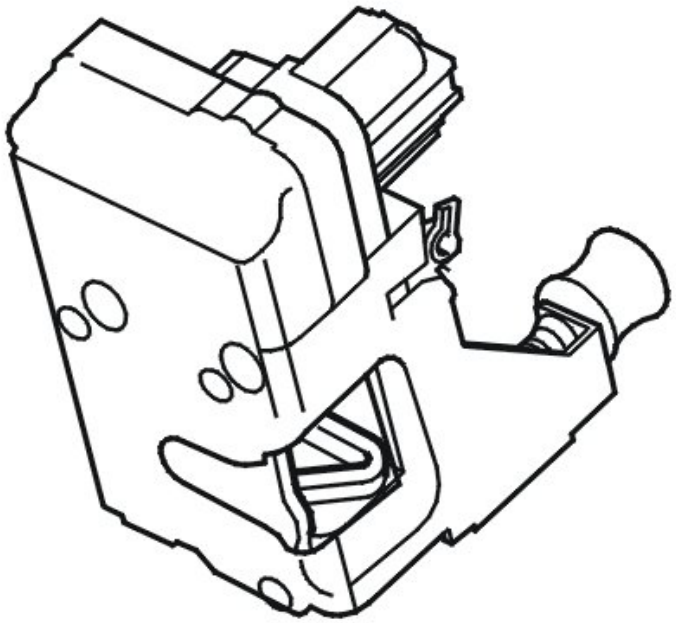


- Ignition on
- Read off the status from the control switch in both rear doors (indicates whether the doors are locked or not).

Lock and unlock the left and right-hand rear doors. The status of each door should change when the door is locked or unlocked.

Hint: The doors can also be locked/unlocked using the remote control.

The fault is permanent if the status does not change.
If the status changes, this indicates an intermittent fault, i.e. the fault was present previously but is not active at the moment.



Continue - Checking the function of the lock mechanism

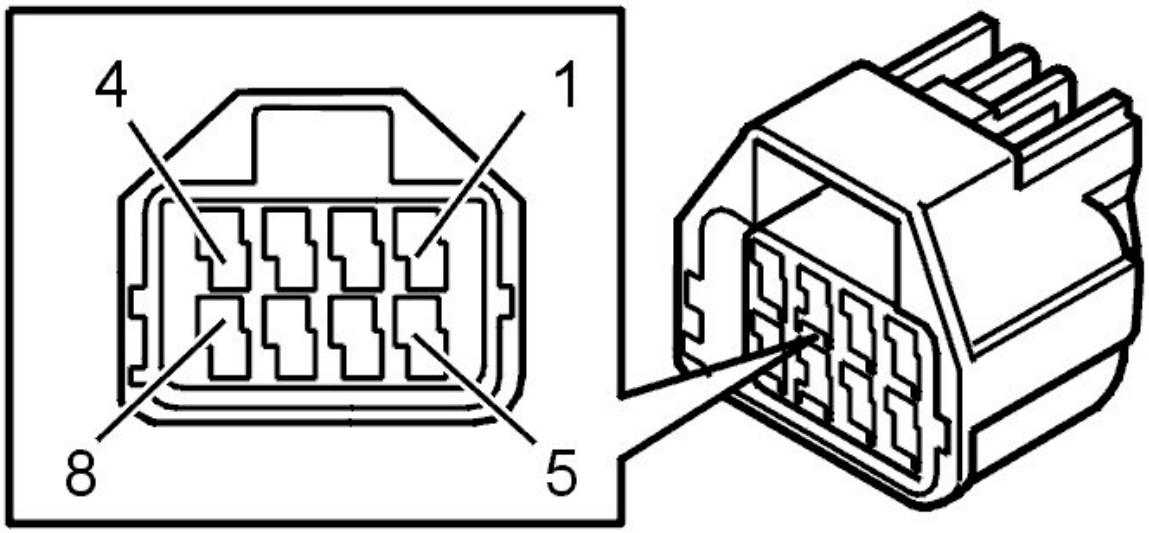
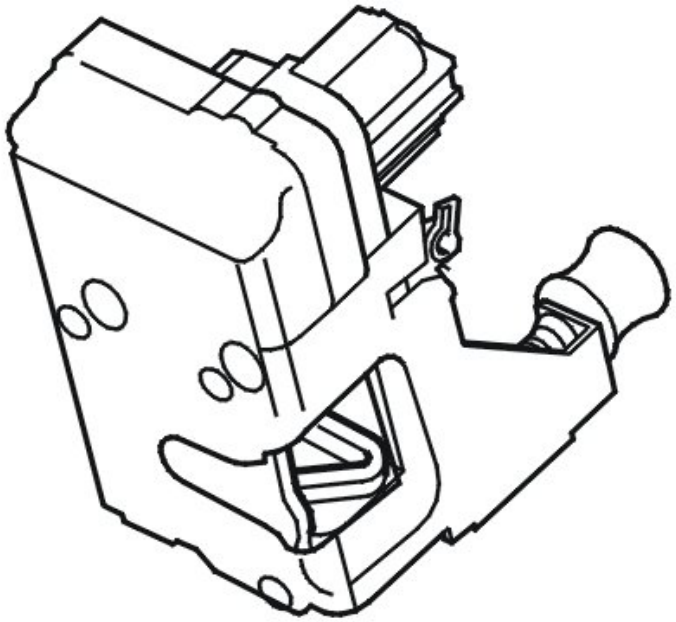
- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals





Continue - Verification

Checking cable and component

Note! Only fault-trace the circuit of the door displaying the faulty value.

Check the connectors for the lock mechanism and the rear electronic module (REM). Check for contact resistance and oxidation.

Left rear door

Check the wiring between the lock mechanism connector terminals #3 and #8 and the relay terminals #2 and #4 for the child lock. Check for an open-circuit. Check for a short-circuit to ground. Check for a short-circuit to supply voltage.

Check the wiring between the lock mechanism connector terminals #3 and #5 and the power window switch. Check for an open-circuit. Check for a short-circuit to ground. Check for a short-circuit to supply voltage.
Check the cable between relay terminal #1 for the child lock and rear electronic module (REM) terminal #27 (#A27). Check for an open-circuit. Check for a short-circuit to ground. Check for a short-circuit to supply voltage.

Hint: Remove the relay for power child locks while checking the lock motors. If the function is OK when the relay is removed it means that there is a fault in the relay or in the circuit for controlling the relay.

Right rear door

Check the wiring between the lock mechanism connector terminals #3 and #8 and the relay terminals #2 and #4 for the child lock. Check for an open-circuit. Check for a short-circuit to ground. Check for a short-circuit to supply voltage.
Check the wiring between the lock mechanism connector terminals #3 and #5 and the power window switch. Check for an open-circuit. Check for a short-circuit to ground. Check for a short-circuit to supply voltage.
Check the cable between relay terminal #1 for the child lock and rear electronic module (REM) terminal #24 (#B24). Check for an open-circuit. Check for a short-circuit to ground. Check for a short-circuit to supply voltage.

Hint: Remove the relay for power child locks while checking the lock motors. If the function is OK when the relay is removed it means that there is a fault in the relay or in the circuit for controlling the relay.

The lock mechanism is jammed if no fault is found in the wiring.
Remedy as necessary.

Diagnostic Trouble Code (DTC) Information

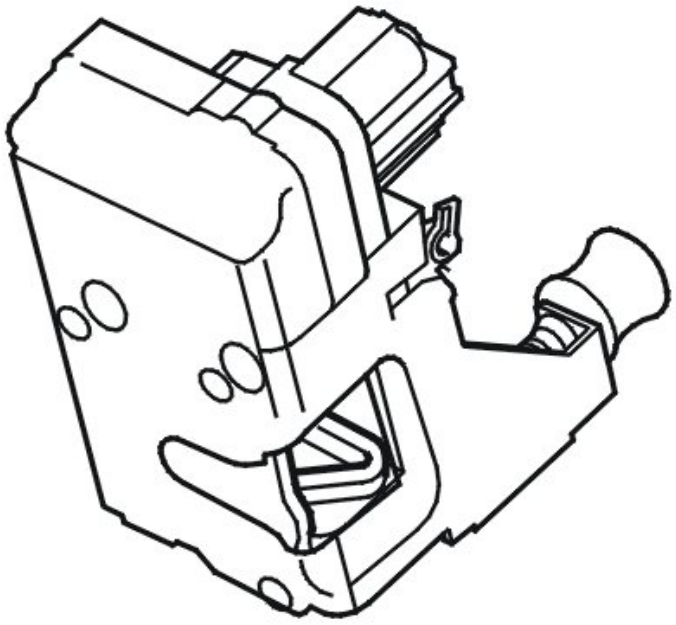
Diagnostic trouble code (DTC) information REM-6A10

Condition



The rear electrical module (REM) checks if the doors are open or closed using the switches in the lock units. The switches provide a ground to the rear electronic module (REM) when the doors are shut.
The rear electronic module (REM) checks the status of the switches by powering them for a short period ("polling").
The diagnostic trouble code (DTC) is stored if the rear electronic module (REM) receives a high signal from the**driver's door**switch when the control module has not polled that switch. This is seen as a short-circuit to supply voltage in the switch or the cable to the switch.

Substitute value
- None.

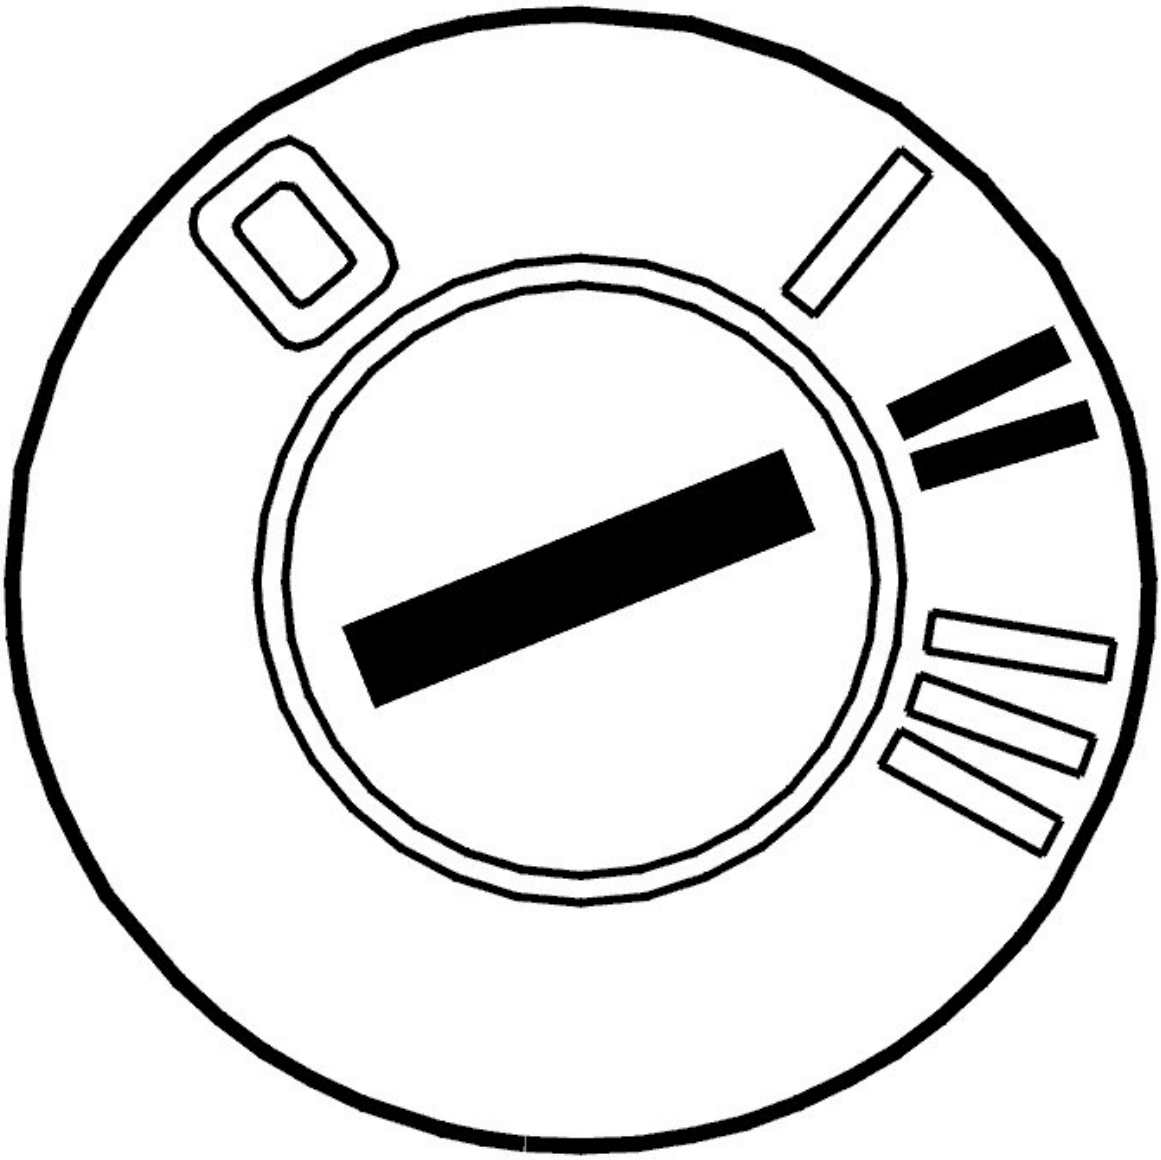
Possible source
- Short-circuit to supply voltage in the switch for indicating a closed door.

Fault symptom[s]
- General warning lamp lit.
- Message in the display.
- Does not alarm the door.

Signal Too High

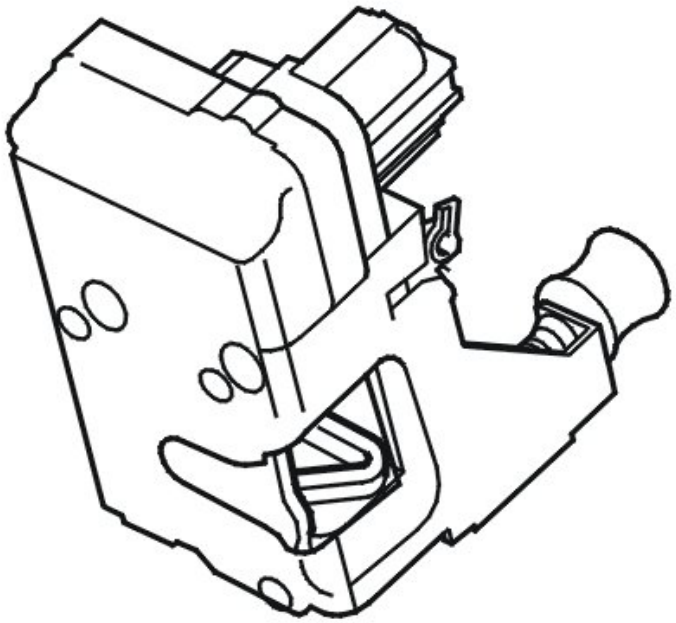
Signal too high

Checking the signal from the switch in the front door



- Ignition on
- Read off the status from the control switch in both front doors (indicates whether the doors are open or closed).

Open and close the left and right-hand front door. The status for each door must change when the door is opened/closed.
The fault is permanent if the status does not change.
If the status changes, this indicates an intermittent fault, i.e. the fault was present previously but is not active at the moment.



Continue - Checking cable and component

Checking cable and component

Note! Only fault-trace the circuit of the door displaying the faulty value.

Left front door

Check the signal cable between rear electronic module (REM) connector terminal #52 (#C12) and terminal #3 on the lock mechanism connector. Check for a short-circuit to supply voltage. Check for an open-circuit.

Right front door

Check the signal cable between rear electronic module (REM) connector terminal #29 (#D29) and terminal #3 on the lock mechanism connector. Check for a short-circuit to supply voltage. Check for an open-circuit.
Remedy as necessary.

Diagnostic Trouble Code (DTC) Information

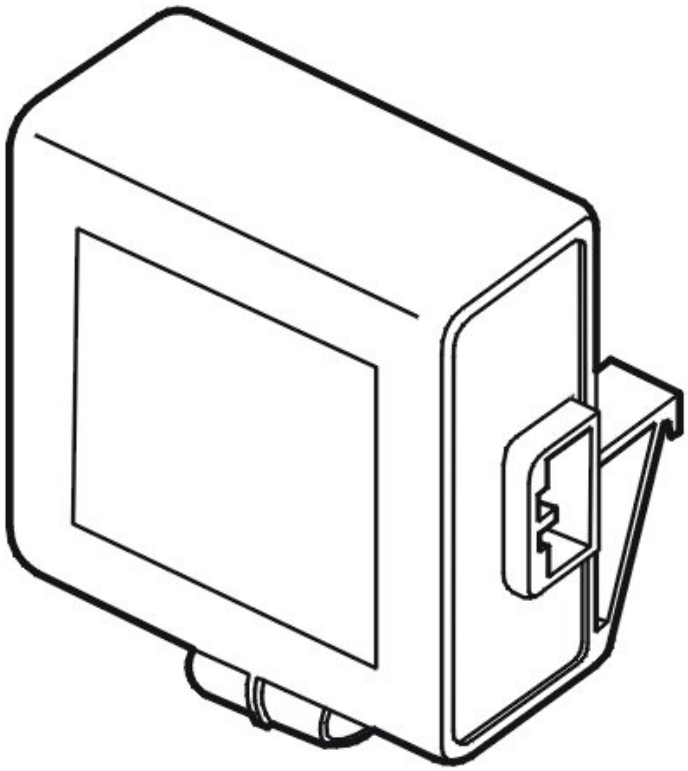
Diagnostic trouble code (DTC) information REM-6C16

Condition



The rear electronic module (REM) receives signals from the inclination sensor module (ISM) when the alarm is activated. Before the rear electronic module (REM) accepts signals from the inclination sensor module (ISM) a communication test is carried out after the alarm is activated.
The diagnostic trouble code (DTC) is stored if the rear electronic module (REM) receives information from the inclination sensor module (ISM) indicating an internal fault.
The diagnostic trouble code (DTC) can be diagnosed when the rear electronic module (REM) is in alert mode.

Substitute value
- None.

Possible source
- Contact resistance or oxidation in the connectors

- Open-circuit in the communication cable to the inclination sensor module (ISM)
- Open-circuit in the power supply to the inclination sensor module (ISM)
- Open-circuit in the ground cable to the inclination sensor module (ISM)
- Internal fault in the inclination sensor module (ISM).

Fault symptom[s]
- Does not alarm the sensor.

Internal Fault

Internal fault

Checking cable and component

Check connector D for the rear electronic module (REM) and the connector for the inclination sensor module (ISM). Check for contact resistance and oxidation.
Check the power cable between rear electronic module (REM) connector terminal #31 (#D31) and inclination sensor module (ISM) connector terminal #1. Check for an open-circuit.
Check the communication cable between rear electronic module (REM) connector terminal #26 (#D26) and inclination sensor module (ISM) connector terminal #2. Check for an open-circuit.
Check the cable between inclination sensor module (ISM) connector terminal #5 and the ground terminal. Check for open-circuit.
Try a new inclination sensor module (ISM) if no fault is found.
Remedy as necessary.

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information REM-6C17

Condition

When the alarm is activated, the central electronic module (CEM) checks the glass breakage loops in the rear side windows at regular intervals. A diagnostic trouble code (DTC) is stored if the control module detects an open-circuit in any of the glass breakage loops.
The diagnostic trouble code (DTC) can be diagnosed when the alarm is activated.

Substitute value
- The alarm sounds.

Possible source
- Open-circuit in one of the glass breakage loops in the rear side windows
- Contact resistance in the terminals.

Fault symptom[s]
- Text window and warning symbol/Text message
- Alarm/False alarm
- Alarm/Other alarm problems

Signal Missing

Signal missing

Checking cable and component
- Disconnect connector C from the rear electronic module (REM).

Hint: The signal loop runs from rear electronic module (REM) terminal #48 (#C8) to the glass breakage loop in the right-hand rear window, to the glass breakage loop in the left-hand rear window and then to the ground terminal.

Check connector C for the rear electronic module (REM) and the terminals for the glass breakage loop. Check for contact resistance and oxidation.
Check the glass breakage loop and the intermediate cable between rear electronic module (REM) terminal #48 (#C8) and the ground terminal. Check for an open-circuit.
Remedy as necessary.

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information REM-6C18

Condition

When the alarm is activated, the central electronic module (CEM) checks the glass breakage loops in the rear side windows at regular intervals. The diagnostic trouble code (DTC) is stored if the control module registers a short-circuit to supply voltage in any of the glass breakage loops.
The diagnostic trouble code (DTC) can be diagnosed when the alarm is activated.

Substitute value
- The alarm sounds.

Possible source
- Short-circuit to supply voltage in one of the glass breakage loops in the rear side windows.

Fault symptom[s]
- False alarm.

Signal Too High

Signal too high

Checking cable and component
- Disconnect connector C from the rear electronic module (REM).

Hint: The signal loop runs from rear electronic module (REM) terminal #48 (#C8) to the glass breakage loop in the right-hand rear window, to the glass breakage loop in the left-hand rear window and then to the ground terminal.

Check the glass breakage loop and the intermediate cable between rear electronic module (REM) terminal #48 (#C8) and the ground terminal.
Check for a short-circuit to supply voltage.
Remedy as necessary.

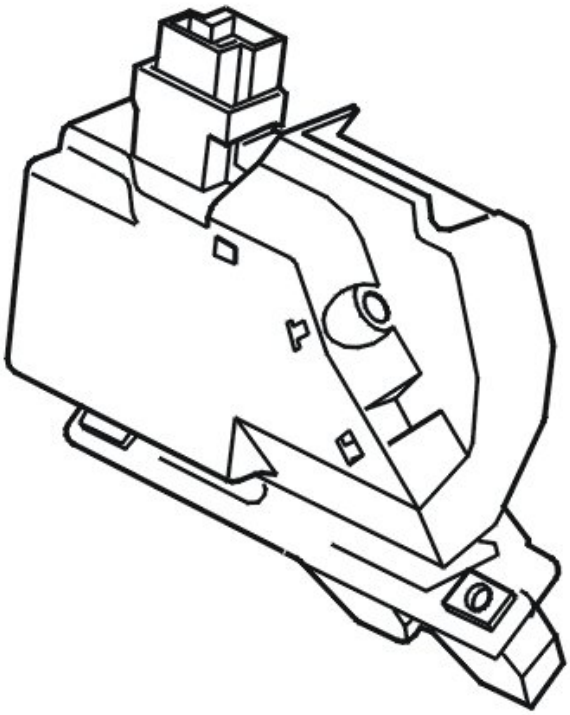
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information REM-6F51

Condition



The rear electronic module (REM) is grounded when a switch on the tailgate is pushed in.
The diagnostic trouble code (DTC) is stored if the rear electronic module (REM) registers that the switch on the tailgate has been activated for more than 20 seconds.

Substitute value
- None.

Possible source
- The switch for the tailgate has stuck in the activated position
- Short-circuit to ground in the cable for the tailgate switch.

Fault symptom[s]

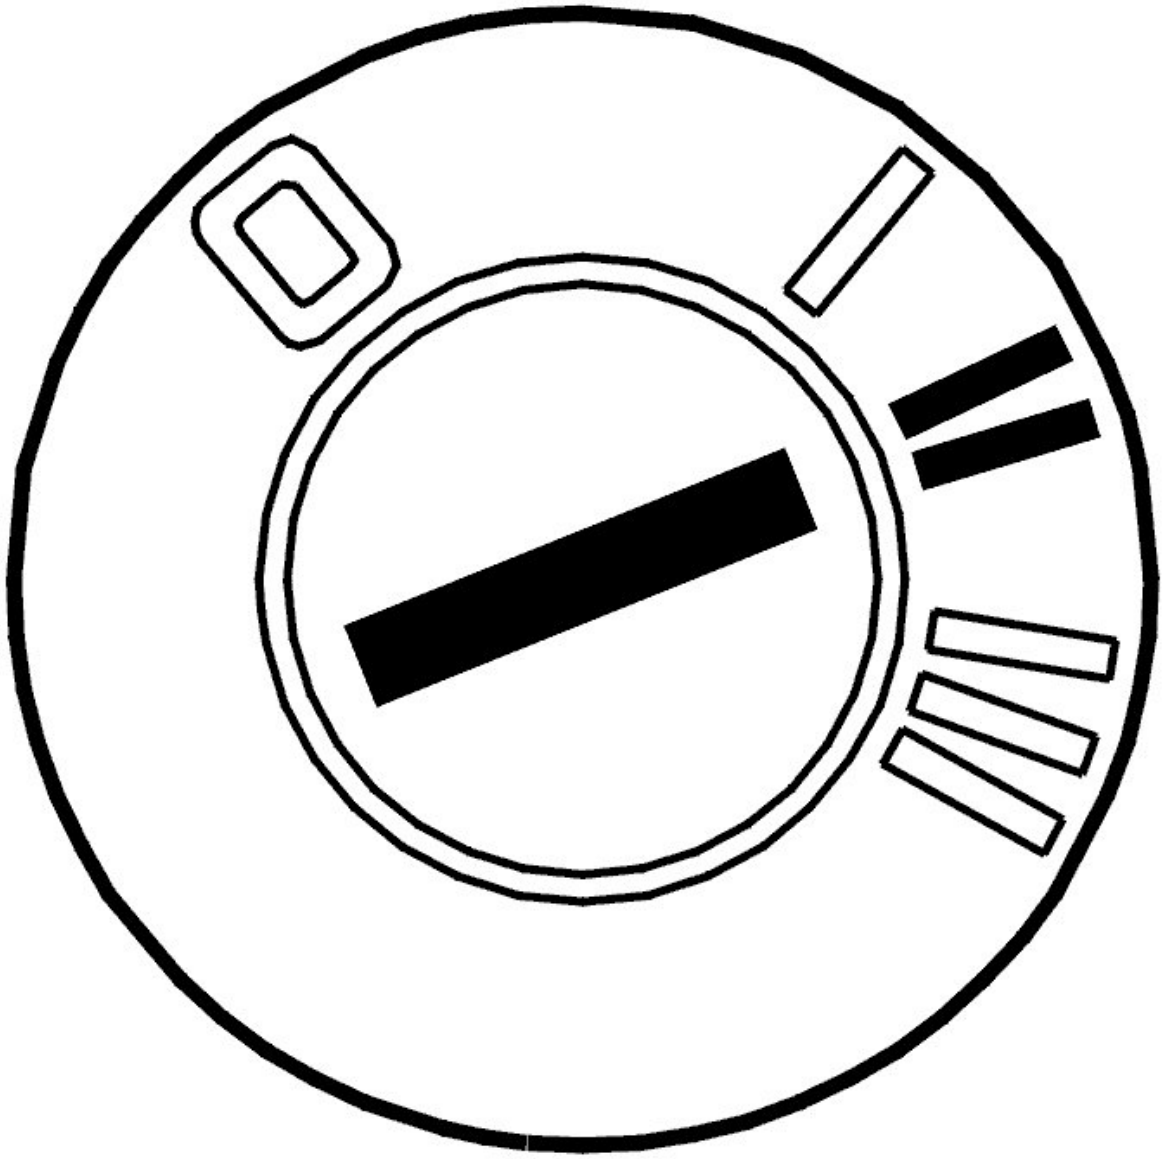
- No locking/unlocking of the tailgate.

Signal Too Low

Signal too low

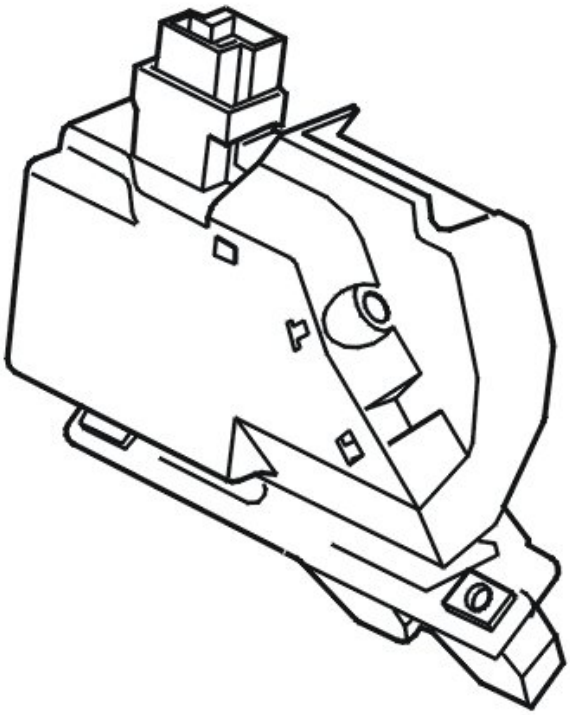
Checking the signal from the trunk lid handle

Note! Only applies to 4-door cars.



- Ignition on
- Read off the status from the trunk lid handle. Open and close the trunk lid using the handle.

The status should alternate as the handle is affected.
The fault is permanent if the status does not change.
If the status changes, this indicates an intermittent fault, i.e. the fault was present previously but is not active at the moment.



Continue - Checking cable and component

Checking cable and component

Disconnect the connector from the lamp housing for the license plate lighting. Check that the button has not stuck in the pressed in position. Check that there is not a short-circuit in the contact breaker for the switch by taking a reading between terminal #1 and ground.
Check the resistance between terminals #1 and #3 on the switch. The resistance must be infinite or near 0 ohm depending on the position of the switch.
Check the signal cable between terminal #43 (#F3) on the connector for the rear electronic module (REM) and terminal #1 on the connector for the lamp housing for the license plate lighting. Check for a short-circuit to ground.
Remedy as necessary.

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information REM-8B01

Condition

The rear electronic module (REM) powers the right-hand parking lamp directly via an output.
The diagnostic trouble code (DTC) is stored if the rear electronic module (REM) registers that the signal at the output is too low.
The diagnostic trouble code (DTC) can be diagnosed at key position II.

Substitute value
- None.

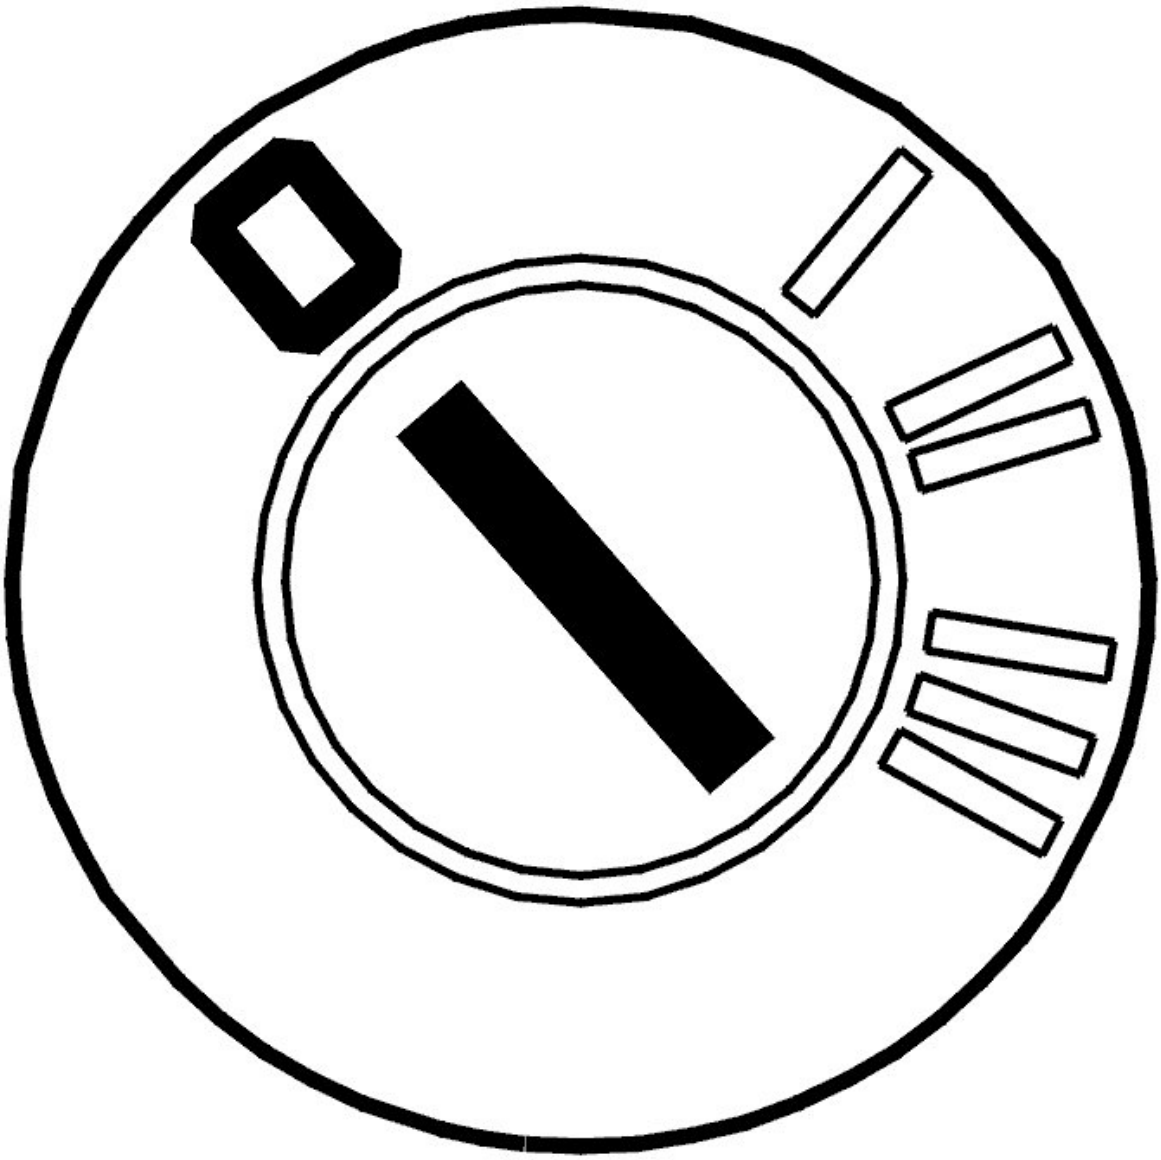
Possible source
- Short-circuit to ground in the signal cable.

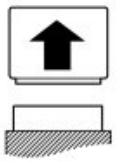
Fault symptom[s]
- The parking lamps do not operate.

Signal Too Low

Signal too low

Checking the wiring





- Ignition off
- Disconnect connector D on the rear electronic module (REM).

Check the signal cable. Check for a short-circuit to ground.

For the S60

Take readings between:

- Rear electronic module (REM) terminal #D5 (#5) and terminal #B1 on the connector for the rear left-hand lamp housing
- Terminal #B1 on the connector for the rear left-hand lamp housing and terminal #B3 on the connector for the rear right-hand lamp housing.

For S80

Take readings between:

- Rear electronic module (REM) terminal #D5 (#5) and terminal #4 on the connector for the rear right-hand lamp housing.

For the V70

Take readings between:

- Rear electronic module (REM) terminal #D5 (#5) and terminal #A1 on the connector for the rear left-hand lamp housing
- Terminal #A1 on the connector for the rear left-hand lamp housing and terminal #A5 on the connector for the rear right-hand lamp housing.

Possible source
- Short-circuit to supply voltage in the signal cable
- High brake light not installed/damaged.

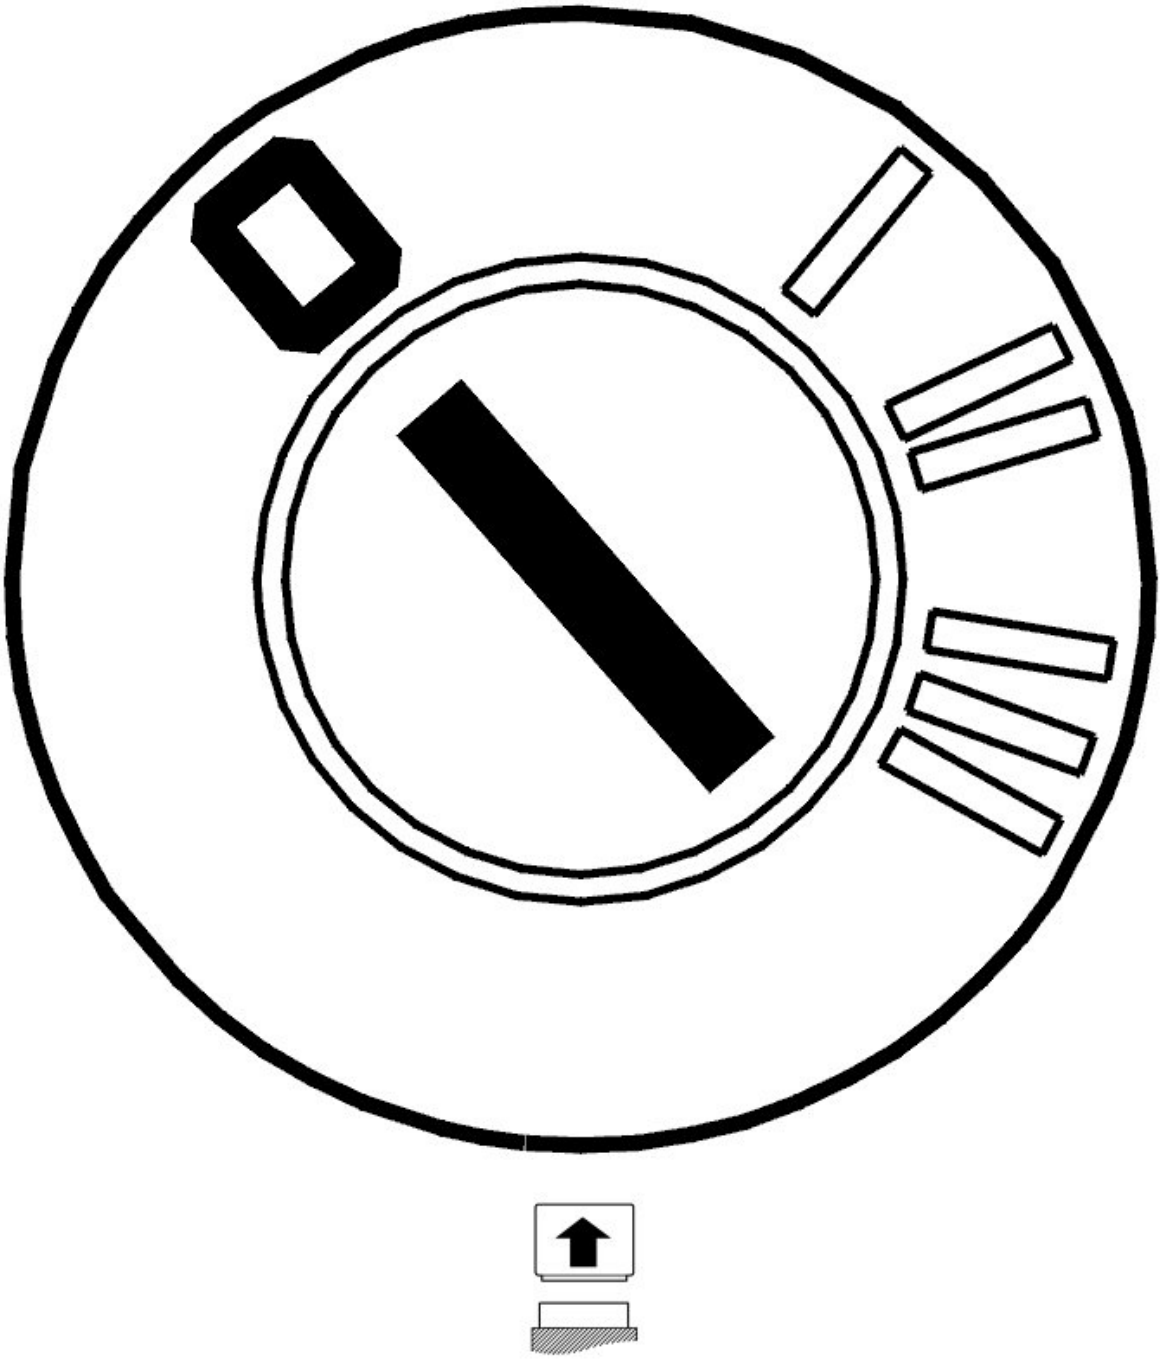
Fault symptom[s]
- The stop lamp lights constantly.

- Message in display

Signal Too High

Signal too high

Checking the wiring



- Ignition off
- Disconnect connectors A and F on the rear electronic module (REM).

Check the signal cable. Check for an open-circuit. Check for a short-circuit to supply voltage.

For the S80 and S60

Take readings between:

- Rear electronic module (REM) terminal #A6 (#6) and terminal #1 on the connector for the high level stop lamp.

For the V70, XC70 and XC90

Take readings between:

- Rear electronic module (REM) terminal #F4 (#44) and terminal #1 on the connector for the high level stop lamp.

Remedy as necessary.

Fault-tracing information

The fault should have been detected and remedied. As this is not the case fault-tracing has failed.
Exit fault-tracing for this diagnostic trouble code (DTC) or make another attempt.

Do you want to exit fault-tracing?

Yes - FAULT-TRACING FAILED

No - Attempt New Test

FAULT-TRACING FAILED - FAULT-TRACING FAILED

Attempt New Test - Replacing the component

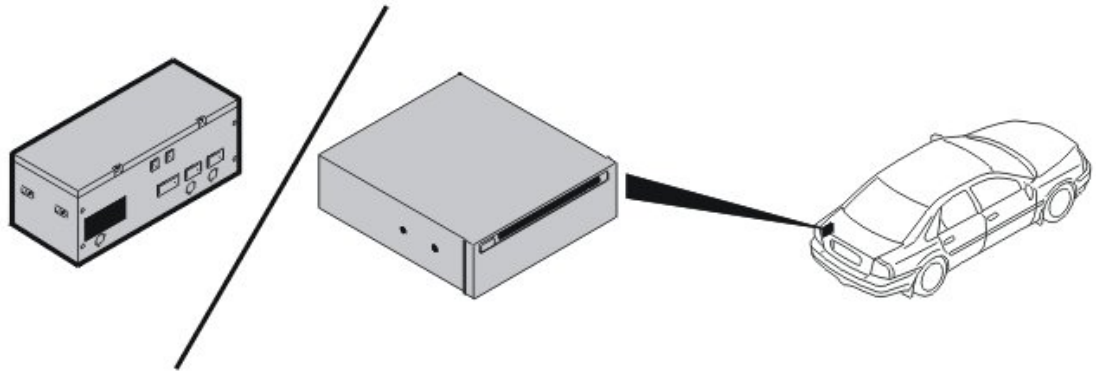
RTI-E001

Diagnostic trouble code (DTC) information RTI-E001

Condition



The control modules transmit and receive information via a standardized serial communication method - CAN (Controller Area Network). The diagnostic trouble code (DTC) is stored if the control module registers serious interference (CAN communication blocked).

Note! In the event of system communication problems, it is not possible to communicate with the control module. Therefore it will only be possible to read off the fault if it is intermittent.

Substitute value
- The control module shuts itself off ("bus-off").

  Hint: The control module will remain shut off until the power supply is broken (15, 30, X). When the power supply is connected the control module will make a new attempt to communicate.

Possible source
- Short-circuit between Control area network (CAN) wiring
- Open-circuit in the control area network (CAN) wiring
- Internal fault in the control module
- Internal fault in another control module in the same part of the Control area network (CAN).

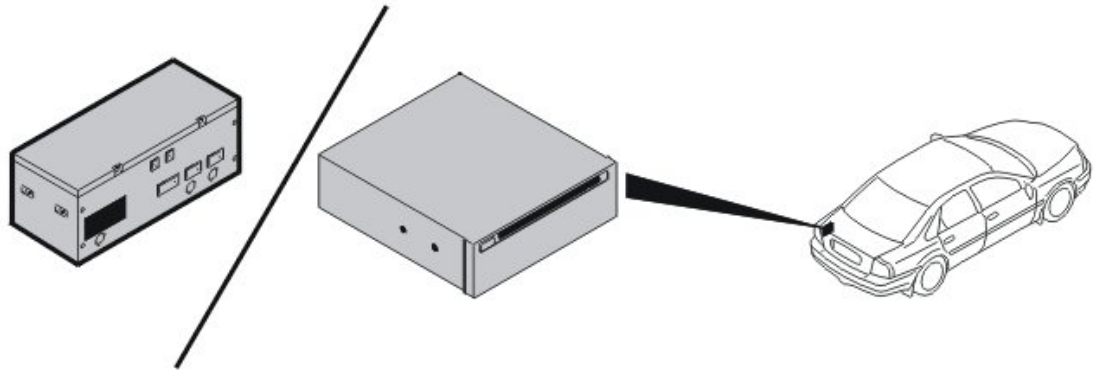
Fault symptom[s]
- The display for the road traffic information module (RTI) does not function
- The display does not deploy
- The car's position on the map is incorrect
- The RTI rheostat function does not function
- The buttons on the steering wheel are not working

- Traffic information is not displayed or updated.

RTI-E003

Diagnostic trouble code (DTC) information RTI-E003

Condition



The control module compares its configuration ID with the signal configuration transmitted on the control area network (CAN) by the central electronic module (CEM). If the configuration IDs do not correspond the fault code is stored. The diagnostic trouble code (DTC) is also stored if the communication between the control module and the central electronic module (CEM) is interrupted.

Note! In the event of open-circuit in both the control area network (CAN) cables, it is not possible to communicate with the control module. Therefore it will only be possible to read off the diagnostic trouble code (DTC) if this type of fault is intermittent. When the diagnostic trouble code (DTC) is stored, the control module responds to the diagnostic command, however normal control area network (CAN) communication does not work. ("Expulsion mode")

Substitute value
- None.

Possible source
- Faulty control area network (CAN) configuration ID. (The node is not intended for this car, for example a used control module with different software/hardware.)
- Open-circuit in the control area network (CAN) wiring between the control module and the central electrical module (CEM).

Fault symptom[s]
- The display for the road traffic information module (RTI) does not function
- The display does not deploy
- The car's position on the map is incorrect
- The RTI rheostat function does not function
- The buttons on the steering wheel are not working
- Traffic information is not displayed or updated.

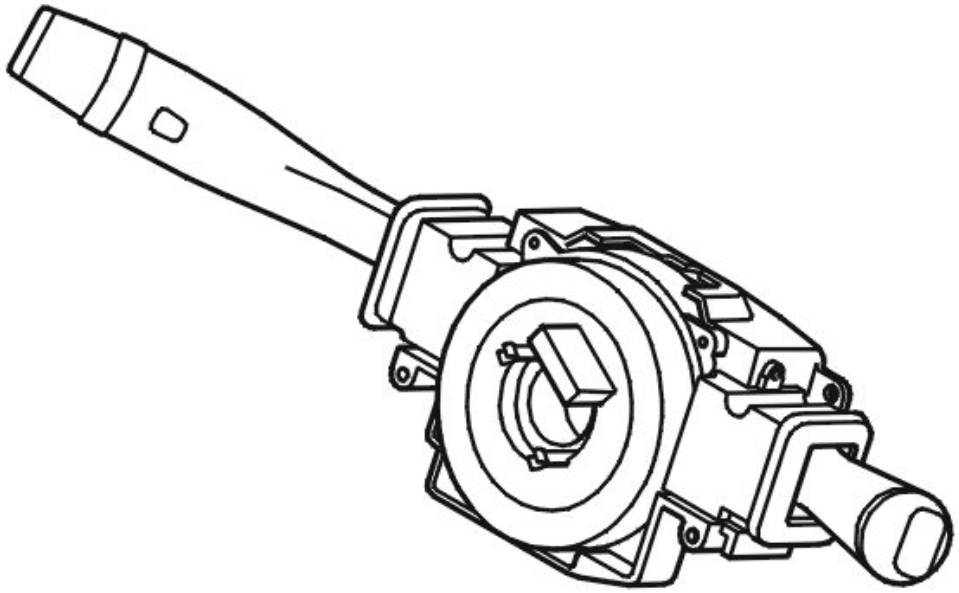
Continue - DONE

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information SAS-000A

Condition



The Steering wheel angle sensor module (SAS) is located in the lever module together with the steering wheel module (SWM) and is supplied with power by it.
The steering wheel angle sensor is installed on the underside of the contact reel and together they create a replaceable unit. A code wheel is mounted inside the steering wheel angle sensor which follows the movements of the steering wheel. 9 x optical digital sensors and 2 x analog photo diodes read off the code wheel. These signals are compared and must create a specific pattern. The diagnostic trouble code (DTC) is stored if the signal pattern created does not correspond.
The diagnostic trouble code (DTC) can be diagnosed when the ignition is switched on and the steering wheel angle sensor is initiated. Initiation is carried out when the steering wheel is turned more than 4.5° in any direction.

Substitute value
- The stability function is blocked.

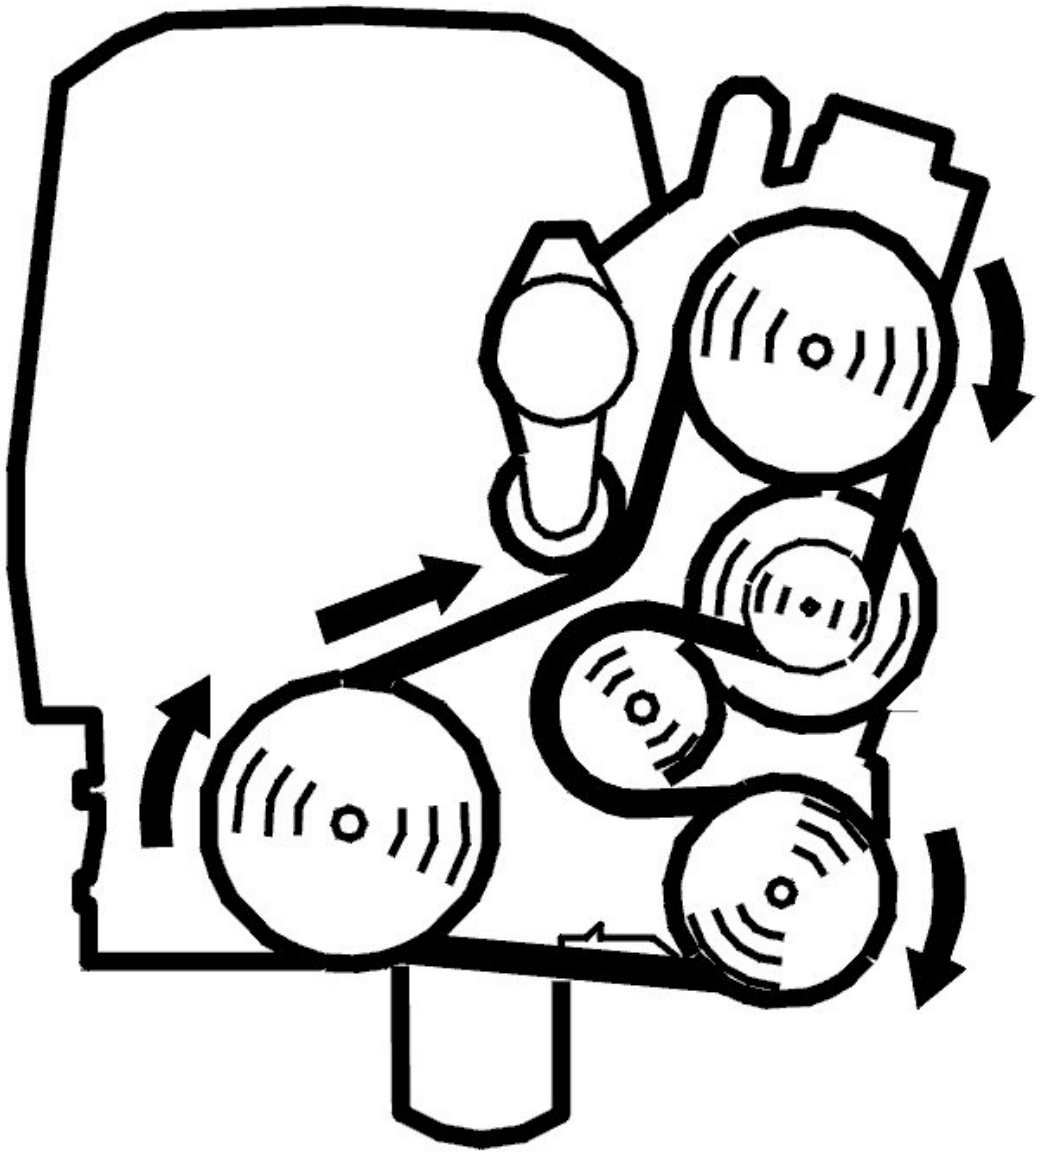
Possible source
- Internal fault in the steering wheel angle sensor.

Fault symptom[s]
- Anti-spin warning lamp lit.
- General warning lamp lit.
- The stability control system does not function.

Internal Fault

Internal fault

Checking the status



- Ignition off
- Wait approximately 10 seconds
- Engine running.
- First turn the steering wheel max. to the right, then max. to the left.
- Click on the VCT2000 symbol to read off the diagnostic trouble code (DTC) counter.

The counters are used to determine the problem's status. For general information about the counters, see: Counters, description See: Steering and Suspension/Suspension/Suspension Control (Automatic - Electronic Level)/Testing and Inspection/Scan Tool Testing and Procedures/Vehicle Communication Information, Suspension Module (SUM)/Counters, Description

Counter 1 counts the number of operating cycles without a fault since the fault was last validated.

If **counter 1** is the same as 0, this means that the fault has been detected in this operating cycle (permanent fault). Replace contact reel/steering wheel angle sensor.

If **counter 1** is over 0, this indicates that the problem has not been detected in this driving cycle (intermittent problem). The problem has existed earlier but is not active right now. Then check **counter 4**. **Counter 4**indicates number of driving cycles **with problem** since the problem was validated for the first time.

- If the number of incorrect driving cycles is high, this indicates an intermittent recurring problem. Replace contact reel/steering wheel angle sensor.
- If the number of incorrect driving cycles is low, this indicates an intermittent temporary problem. No action.

Hint: Counter 3 indicates number of driving cycles since **first time** that the problem occurred. If the value for **counter 3** is divided by the value for **counter 4**, the intensity of the problem is obtained. The higher the value, the higher the problem intensity. A high problem intensity indicates that the malfunction recurs often.

Note! Replace the steering wheel module (SWM) if the fault recurs after replacing the contact reel/steering wheel angle sensor.

Remedy as necessary.

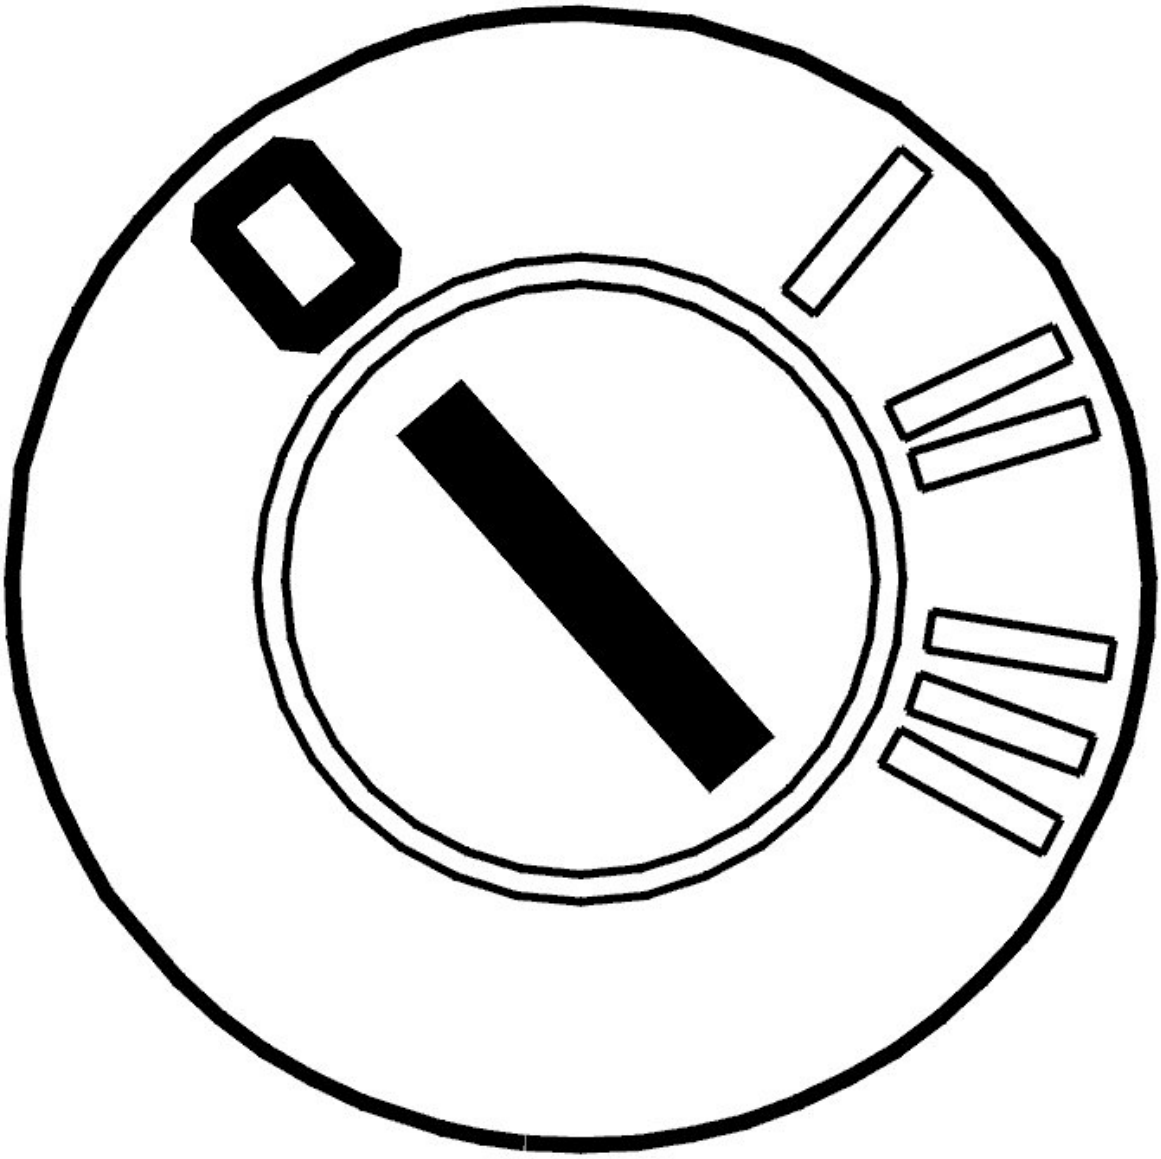
Checking the installation of the steering wheel angle sensor

Note! The diagnostic trouble code (DTC) indicates that the steering wheel angle sensor is incorrectly installed. When installing contact reel/steering wheel angle sensor it is important that the unit is installed correctly. If the unit is installed with the revolving center section one revolution out, internal components may be twisted and broken at full lock. If this is suspected, replace the contact reel.



- Ignition off
- Set the front wheels to the straight ahead position
- Remove the steering wheel
- Ignition on
- Turn the steering wheel more than 5° in any direction to initialize the steering wheel angle sensor module (SAS)
- Click on the VCT2000 symbol to read off the steering wheel angle.

Check that the steering wheel angle is 0° when the front wheels are pointing straight ahead. Set the wheels to the straight ahead position. Lock the steering wheel lock. Then adjust the contact reel so that the yellow marking can be seen in the window of the contact reel when the locking screw for the contact reel is in the correct position.

Note! The diagnostic trouble code (DTC) for the steering wheel buttons is stored in the central electronic module (CEM) if the ignition key is turned to position II when the steering wheel is removed.

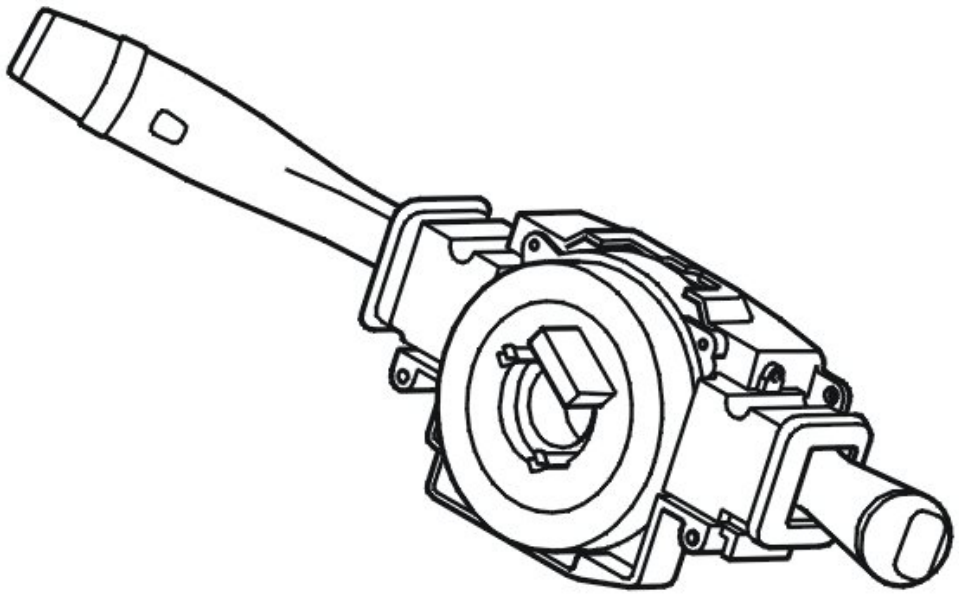
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information SAS-0004

Condition



Steering wheel angle sensor module (SAS) is located inside, and is supplied with power by, the steering wheel module (SWM). Only the steering wheel angle sensor module (SAS) communicates on the controller area network (CAN).
The diagnostic trouble code (DTC) is stored if the steering wheel angle sensor module (SAS) registers that the steering wheel angle speed exceeds 1433 °/second.
The diagnostic trouble code (DTC) can be diagnosed when the ignition is switched on and the steering wheel angle sensor is initiated. Initiation is carried out when the steering wheel is turned more than 4.5° in any direction.

Substitute value
- The stability function is blocked.

Possible source
- The wheel has been pressed against something (the edge of a sidewalk for example)
- Internal fault in the control module.

Fault symptom[s]
- Anti-spin warning lamp lit.
- General warning lamp lit.

- The stability control system does not function.

Signal Outside Its Permitted Range

Signal outside its permitted range

Information

The diagnostic trouble code (DTC) indicates that the steering wheel has been turned at a speed in excess of 1400°/s. The probable cause of the diagnostic trouble code (DTC) is that the driver has driven into the edge of a sidewalk or hit a stone, causing the angle speed of the steering wheel and the wheels to change drastically.
Check that front suspension alignment has not changed and that the wheels are not damaged.
Remedy as necessary.

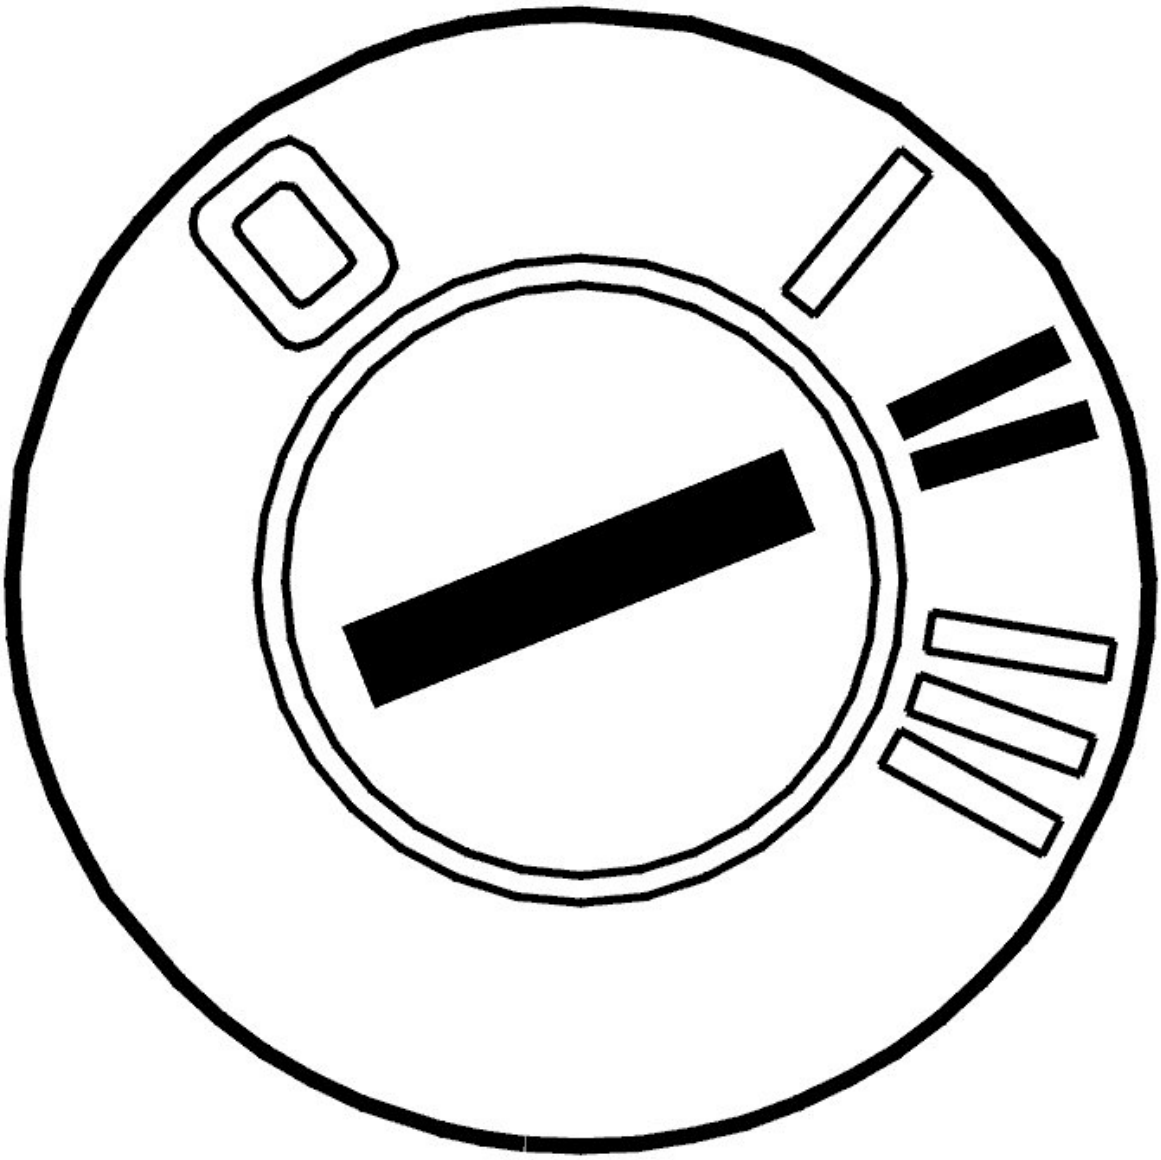
Internal fault

Checking the status



- Ignition off
- Wait approximately 10 seconds
- Engine running.
- First turn the steering wheel max. to the right, then max. to the left. Then set the steering wheel to the straight-ahead position.
- Click on the VCT2000 symbol to read off the diagnostic trouble code (DTC) counter.

The counters are used to determine the problem's status. For general information about the counters, see: Counters, description See: Steering and Suspension/Suspension/Suspension Control (Automatic - Electronic Level)/Testing and Inspection/Scan Tool Testing and Procedures/Vehicle Communication Information, Suspension Module (SUM)/Counters, Description Counters 5, 6 and 7 are not used during this check.
Counter 1 counts the number of operating cycles without a fault since the fault was last validated.
If **counter 1** is the same as 0, this means that the fault has been detected in this operating cycle (permanent fault). Replace the Steering wheel module (SWM).
If **counter 1** is over 0, this indicates that the problem has not been detected in this driving cycle (intermittent problem). The problem has existed earlier but is not active right now. The digit indicates number of driving cycles since the diagnostic trouble code was generated. Then check **counter 4**. **Counter 4**indicates number of driving cycles **with problem** since the problem was validated for the first time.

- If the number of incorrect driving cycles is high, this indicates an intermittent recurring problem. Replace the Steering wheel module (SWM).
- If the number of incorrect driving cycles is low, this indicates an intermittent temporary problem. No action.

Note! Counter 3 indicates number of driving cycles since first time that the problem occurred. If the value for counter 3 is divided by the value for counter 4, the intensity of the problem is obtained. The higher the value, the higher the problem intensity. A high problem intensity indicates that the malfunction recurs often.

Note! Replace the steering wheel module (SWM) if the fault recurs.

Remedy as necessary.

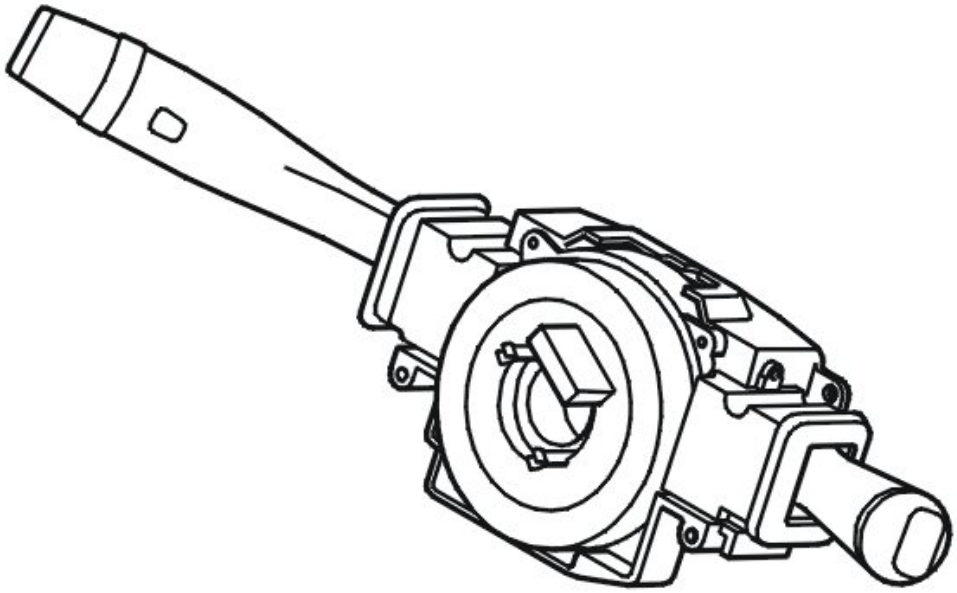
Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition



The Steering wheel angle sensor module (SAS) is located in the lever module together with the steering wheel module (SWM) and is supplied with power by it.
The steering wheel angle sensor is installed on the underside of the contact reel and together they create a replaceable unit. A code wheel is mounted inside the steering wheel angle sensor which follows the movements of the steering wheel. 9 x optical digital sensors and 2 x analog photo diodes read off the code wheel. These signals are compared and must create a specific pattern. The diagnostic trouble code (DTC) is stored if the signal pattern created does not correspond.
Diagnostic trouble code (DTC) SAS-0005 or SAS-0006 is stored (depending on the fault) if the steering wheel angle sensor module (SAS) registers an internal fault in the software.
The diagnostic trouble code (DTC) can be diagnosed when the ignition is switched on and the steering wheel angle sensor is initiated. Initiation is carried out when the steering wheel is turned more than 4.5° in any direction.

Substitute value
- The stability function is blocked.

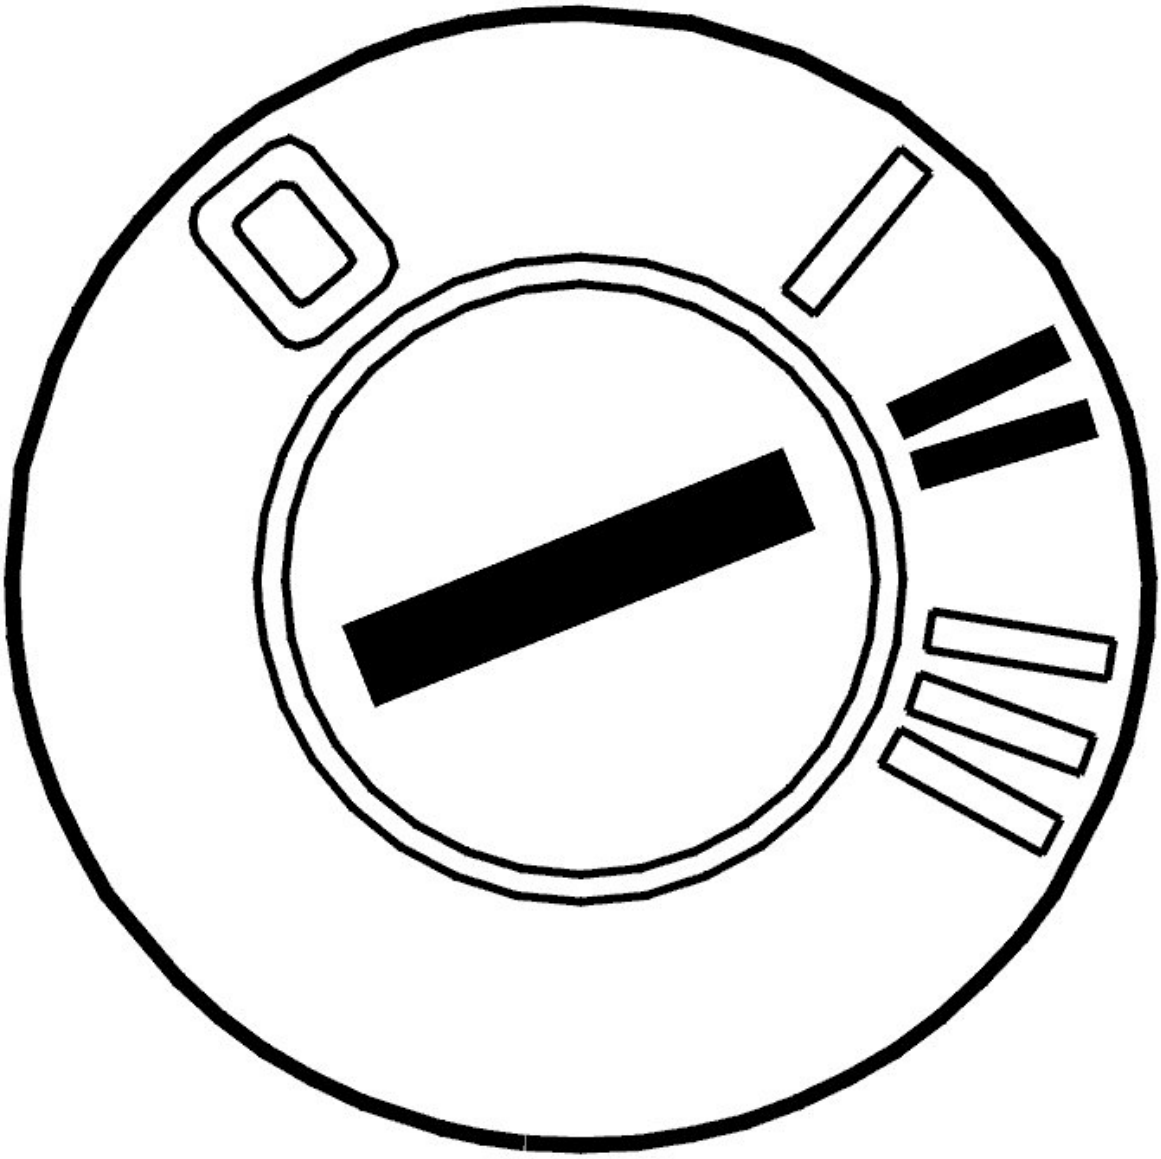
Possible source
- Internal fault in the steering wheel angle sensor module (SAS).

Fault symptom[s]
- Anti-spin warning lamp lit.
- General warning lamp lit.
- The stability control system does not function.

Internal Fault

Internal fault

Checking the status



- Ignition off
- Wait approximately 10 seconds
- Engine running.
- First turn the steering wheel max. to the right, then max. to the left. Then set the steering wheel to the straight-ahead position.
- Click on the VCT2000 symbol to read off the diagnostic trouble code (DTC) counter.

The counters are used to determine the problem's status. For general information about the counters, see: Counters, description See: Steering and Suspension/Suspension/Suspension Control (Automatic - Electronic Level)/Testing and Inspection/Scan Tool Testing and Procedures/Vehicle Communication Information, Suspension Module (SUM)/Counters, Description Counters 5, 6 and 7 are not used during this check.
Counter 1 counts the number of operating cycles without a fault since the fault was last validated.
If **counter 1** is the same as 0, this means that the fault has been detected in this operating cycle (permanent fault). Replace the Steering wheel module (SWM).
If **counter 1** is over 0, this indicates that the problem has not been detected in this driving cycle (intermittent problem). The problem has existed earlier but is not active right now. The digit indicates number of driving cycles since the diagnostic trouble code was generated. Then check **counter 4**. **Counter 4**indicates number of driving cycles **with problem** since the problem was validated for the first time.

- First turn the steering wheel max. to the right, then max. to the left. Then set the steering wheel to the straight-ahead position.
- Click on the VCT2000 symbol to read off the diagnostic trouble code (DTC) counter.

The counters are used to determine the problem's status. For general information about the counters, see: Counters, description See: Steering and Suspension/Suspension/Suspension Control (Automatic - Electronic Level)/Testing and Inspection/Scan Tool Testing and Procedures/Vehicle Communication Information, Suspension Module (SUM)/Counters, Description Counters 5, 6 and 7 are not used during this check.
Counter 1 counts the number of operating cycles without a fault since the fault was last validated.
If **counter 1** is the same as 0, this means that the fault has been detected in this operating cycle (permanent fault). Replace the Steering wheel module (SWM).
If **counter 1** is over 0, this indicates that the problem has not been detected in this driving cycle (intermittent problem). The problem has existed earlier but is not active right now. The digit indicates number of driving cycles since the diagnostic trouble code was generated. Then check **counter 4**. **Counter 4**indicates number of driving cycles **with problem** since the problem was validated for the first time.

- If the number of incorrect driving cycles is high, this indicates an intermittent recurring problem. Replace the Steering wheel module (SWM).
- If the number of incorrect driving cycles is low, this indicates an intermittent temporary problem. No action.

Note! Counter 3 indicates number of driving cycles since first time that the problem occurred. If the value for counter 3 is divided by the value for counter 4, the intensity of the problem is obtained. The higher the value, the higher the problem intensity. A high problem intensity indicates that the malfunction recurs often.

Note! Replace the steering wheel module (SWM) if the fault recurs.

Remedy as necessary.

Other information

- Steering wheel angle sensor module (SAS) is integrated in the steering wheel module (SWM). To replace the control module, see Steering wheel module (SWM), replacing See: Relays and Modules/Relays and Modules - Steering and Suspension/Relays and Modules - Steering/Steering Column Control Module/Service and Repair

Continue - DONE

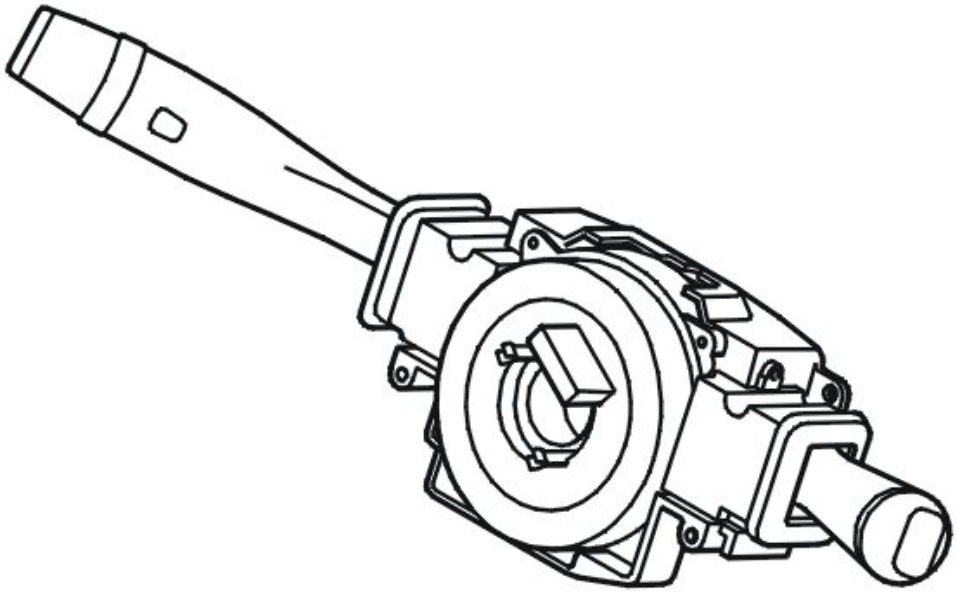
SAS-E000

Diagnostic trouble code (DTC) information SAS-E000

Condition



The control modules transmit and receive information via a standardized serial communication method, CAN (Control Area Network). The diagnostic trouble code (DTC) is stored if the control module registers serious interference on the high speed network (CAN communication blocked).
Steering wheel angle sensor module (SAS) is located inside, and is supplied with power by, the steering wheel module (SWM). Only the steering wheel angle sensor module (SAS) communicates on the controller area network (CAN).

Note! In the event of system communication problems, it is not possible to communicate with the control module. Therefore it will only be possible to read off the diagnostic trouble code (DTC) if the fault is intermittent.

Substitute value
- The control module shuts itself off ("bus-off").

Possible source
- Short-circuit between the control area network (CAN) wiring
- Open-circuit in the control area network (CAN) wiring
- Internal fault in the control module
- Internal fault in another control module in the same part of the control area network (CAN).

Fault symptom[s]
- None.

SAS-E003

Diagnostic trouble code (DTC) information SAS-E003

Condition

Steering wheel angle sensor module (SAS) is located inside, and is supplied with power by, the steering wheel module (SWM). Only the steering wheel angle sensor module (SAS) communicates on the controller area network (CAN).
The control module compares its configuration ID with the signal configuration transmitted on the control area network (CAN) by the central electronic module (CEM). If the configuration IDs do not correspond the fault code is stored. The diagnostic trouble code (DTC) is also stored if the communication between the steering wheel angle sensor module (SAS) and the central electronic module (CEM) is interrupted.

Note! In the event of an open-circuit in both the control area network (CAN) cables, it is not possible to communicate with the control module. Therefore it will only be possible to read off the diagnostic trouble code (DTC) if this type of fault is intermittent. When the diagnostic trouble code (DTC) is stored, the control module responds to the diagnostic commands. However, normal control area network (CAN) communication does not work ("Expulsion mode").

Substitute value
- None.

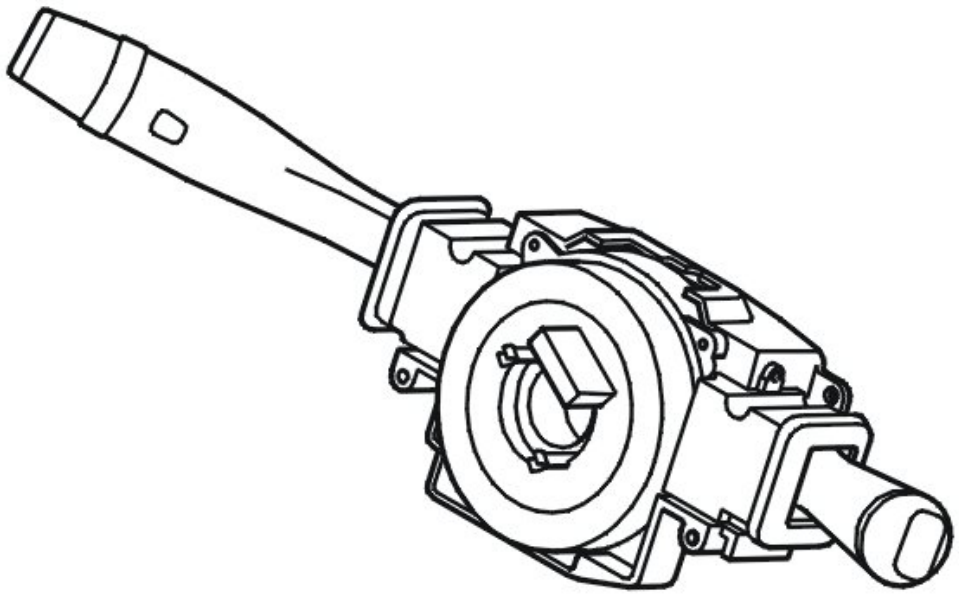
Possible source
- Incorrect CAN configuration ID (the control module is not intended for this vehicle, for example it is a used control module with different software/hardware)
- Open-circuit in the control area network (CAN) wiring between the control module and the central electrical module (CEM)
- Incorrect version of software.

Fault symptom[s]
- None.

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information SAS-E010

Condition



The Steering wheel angle sensor module (SAS) is located in the lever module together with the steering wheel module (SWM) and is supplied with power by it.
The steering wheel angle sensor module (SAS) compares the voltage with the central electronic module (CEM).
Diagnostic trouble code (DTC) is stored if the steering wheel angle sensor module (SAS) registers that the voltage when compared to the voltage signal from the central electronic module (CEM) is lower than 2 V for 10 seconds.

The diagnostic trouble code (DTC) can be diagnosed when the ignition is switched on and the steering wheel angle sensor is initiated. Initiation is carried out when the steering wheel is turned more than 4.5° in any direction.

Substitute value
- The stability function is blocked.

Possible source
- Contact resistance or oxidation in the connectors of the steering wheel module (SWM)
- Internal fault in the steering wheel angle sensor module (SAS).

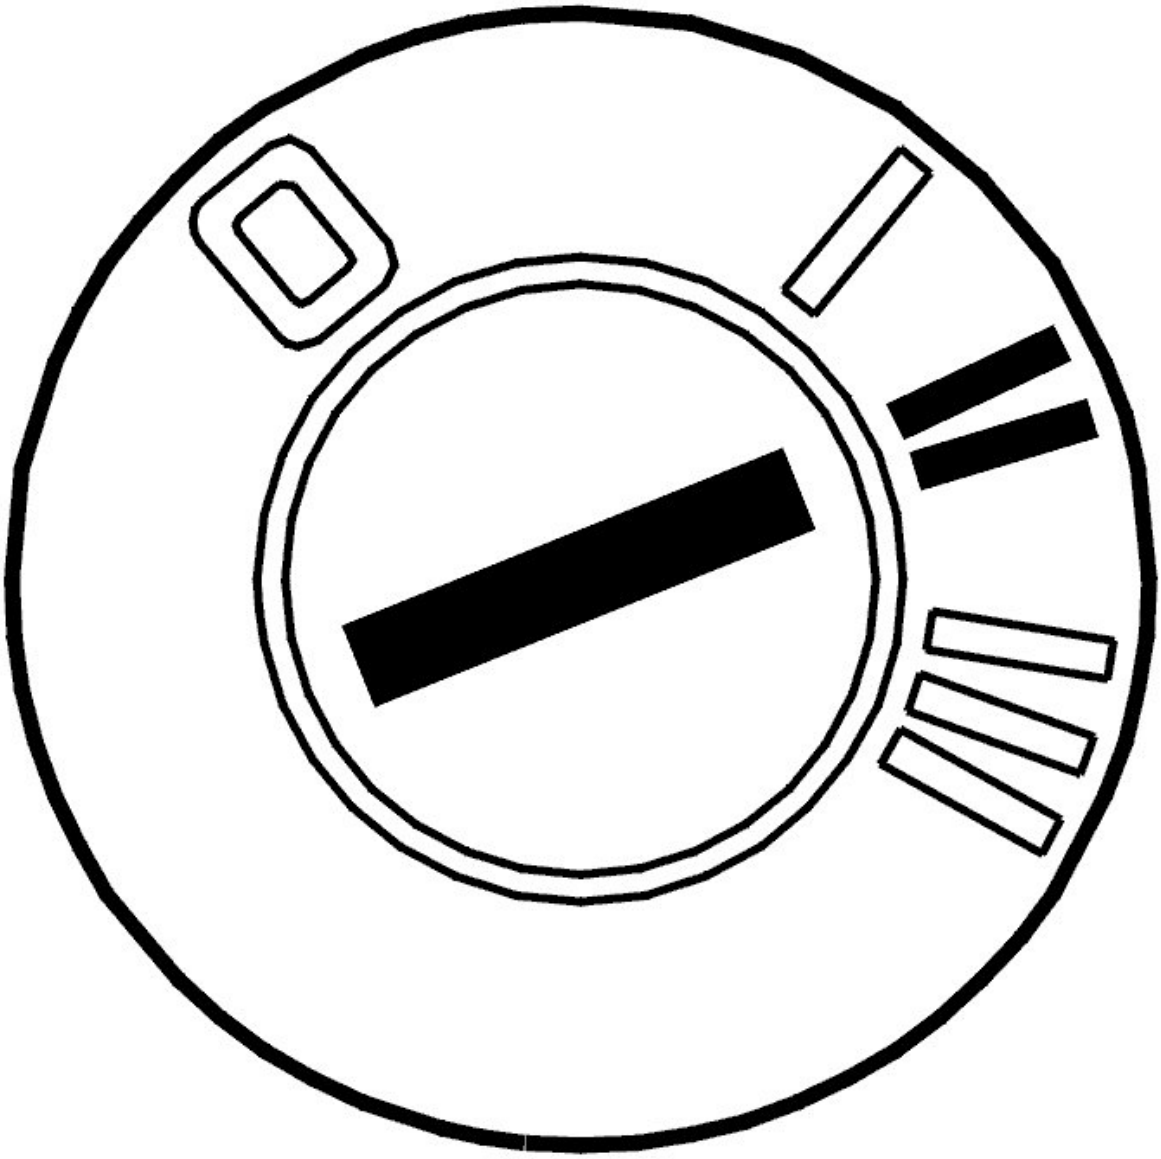
Fault symptom[s]
- Anti-spin warning lamp lit.
- General warning lamp lit.
- The stability control system does not function.

Voltage Too Low

Voltage too low

Checking the power supply

Note! Steering wheel angle sensor module (SAS) is located inside, and is supplied with power by, the steering wheel module (SWM).



- Ignition on
- Read off the power supply for the steering wheel angle sensor module (SAS) and the central electronic module (CEM).

The voltage for the steering wheel angle sensor module (SAS) and the central electronic module (CEM) must be approximately the same.
The fault is permanent if the voltage for the steering wheel angle sensor module (SAS) deviates by more than 2.0 V from the central electronic module (CEM).
If the voltage is approximately the same, this indicates an intermittent fault, i.e. the fault was present previously but is not active at the moment.

Continue - Checking wiring and terminals

Checking wiring and terminals

Check the connector for the steering wheel module (SWM). Check for contact resistance and oxidation.
Check the power supply cable (15i-supply) between the fuse in the integrated relay/fusebox in the cargo compartment and steering wheel module (SWM) terminal #A8 (#8). Check for contact resistance. Check for oxidation. For information about the circuit, see the relevant Wiring Diagram.

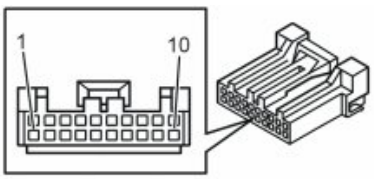
Hint: With the ignition on the voltmeter should indicate battery voltage.

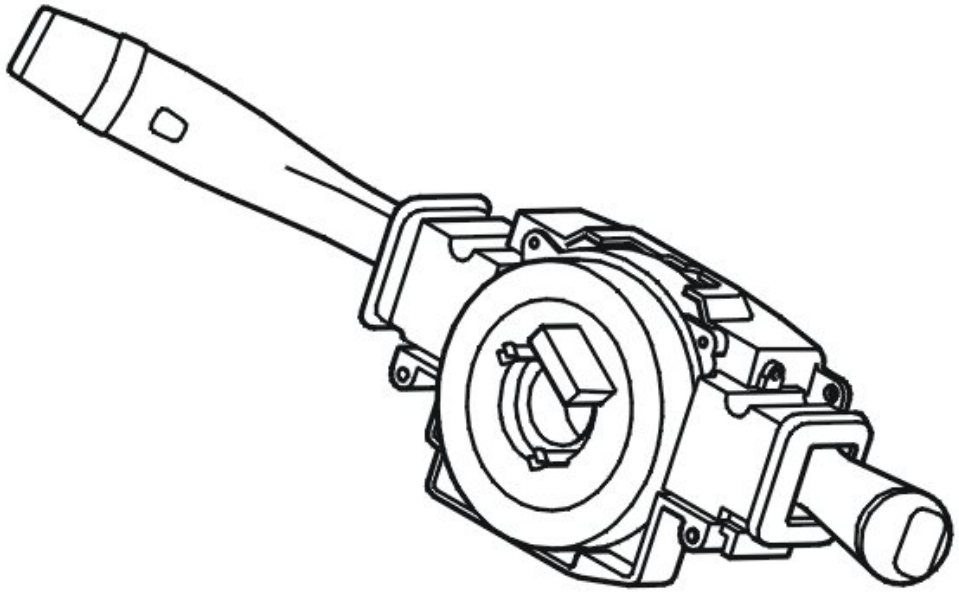
Check the ground lead between steering wheel module (SWM) terminal #A2 (#2) and the ground terminal. Check for contact resistance. Check for oxidation. For information about the circuit, see the relevant Wiring Diagram.
Remedy as necessary.

Other information

- Connecting the breakout box See: Brakes and Traction Control/Antilock Brakes / Traction Control Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box/Connecting the Breakout Box, Steering Wheel Angle Sensor Module (SAS)

- Checking wiring and terminals See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring And Terminals
- Steering wheel angle sensor module (SAS) is integrated in the steering wheel module (SWM). To replace the control module, see Steering wheel module (SWM), replacing See: Relays and Modules/Relays and Modules - Steering and Suspension/Relays and Modules - Steering/Steering Column Control Module/Service and Repair.

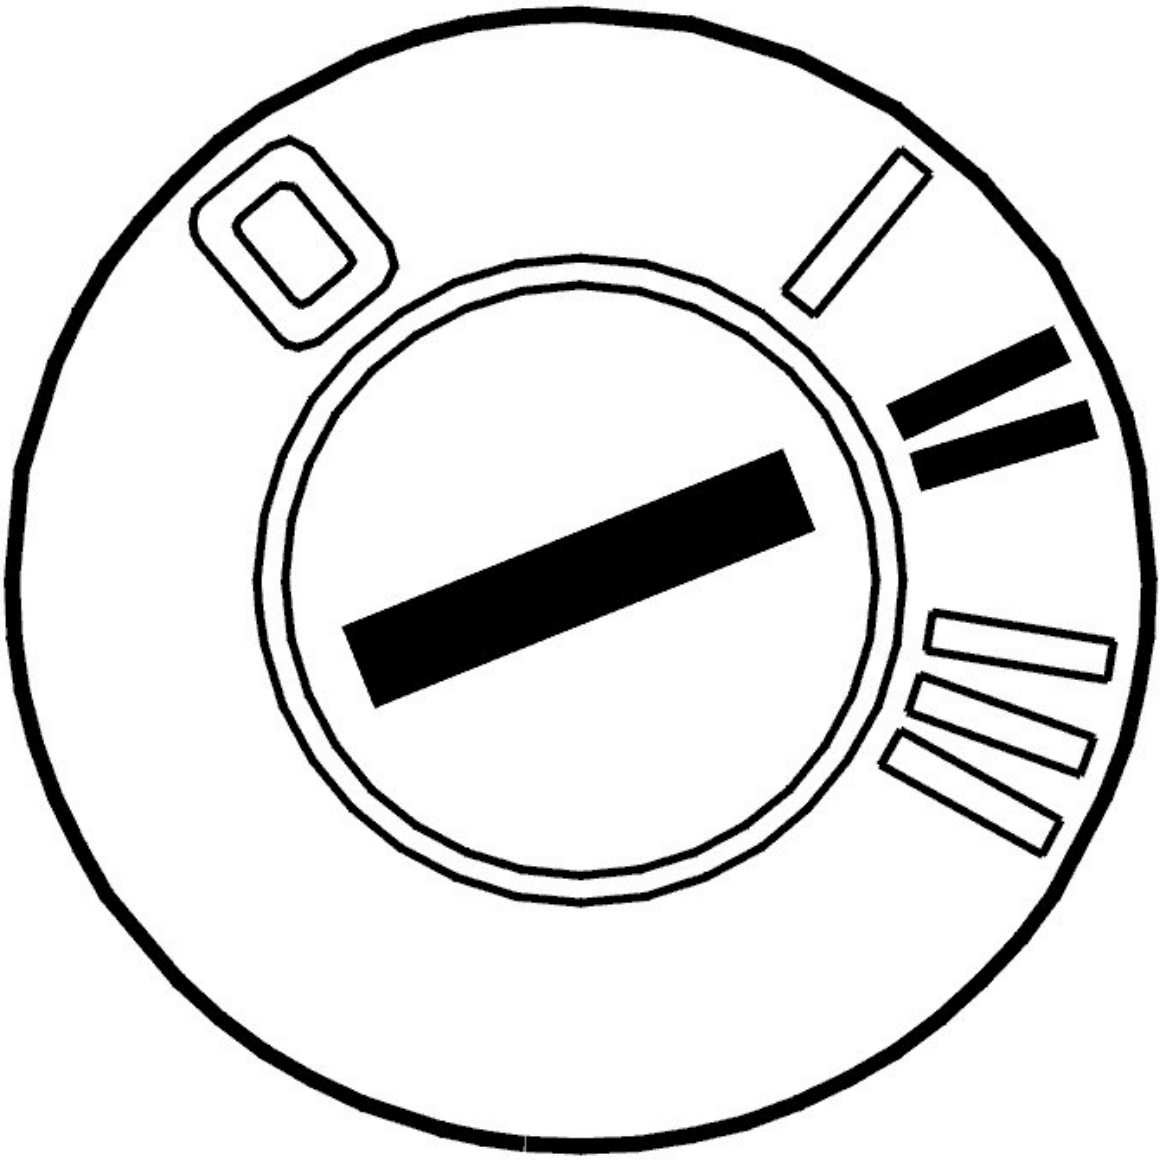


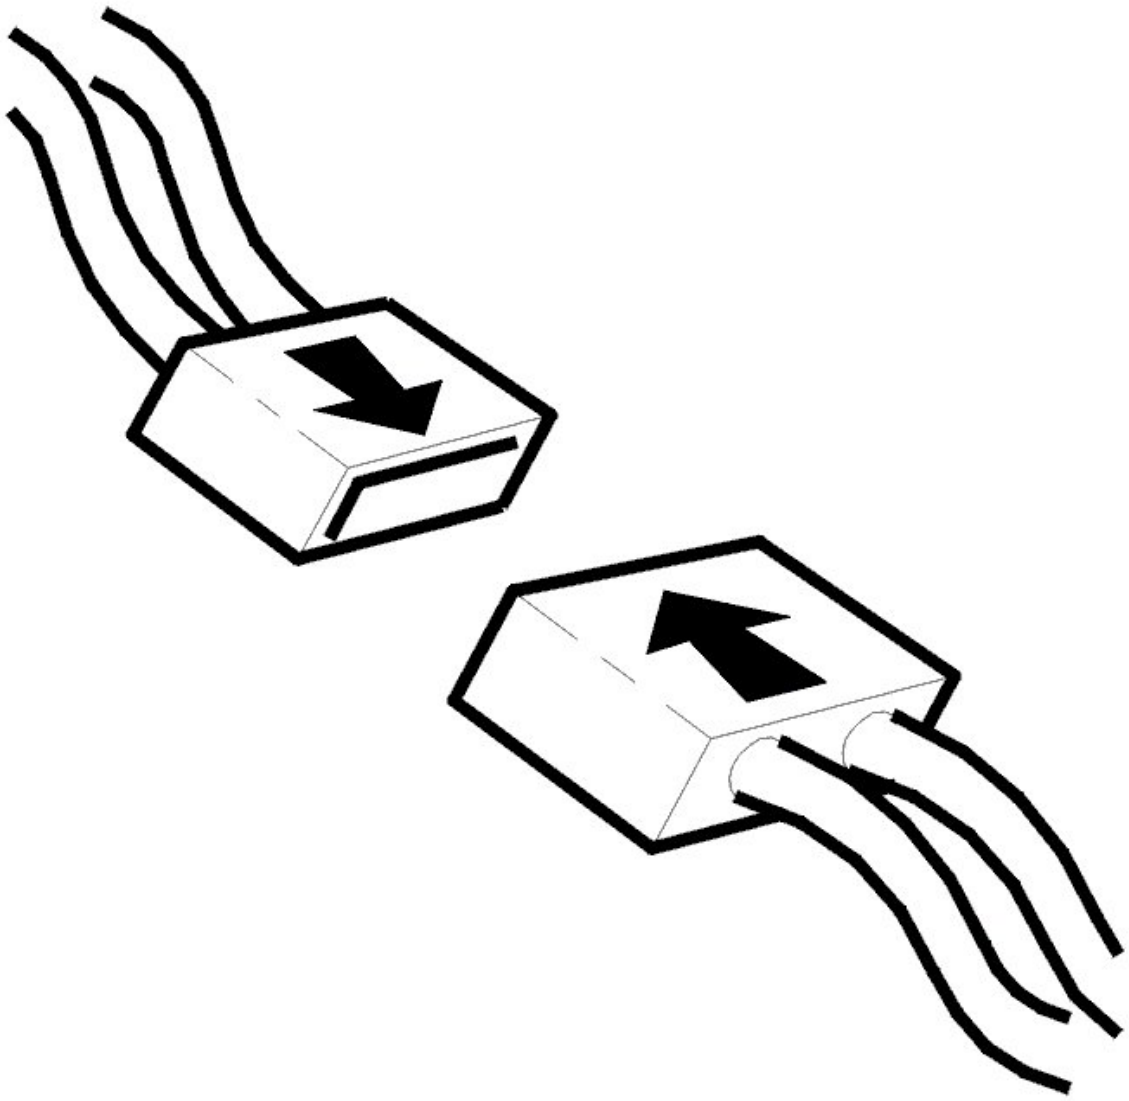


Continue - Verification

Verification

Hint: After carrying out the repair, check that the fault has been remedied.





- Ignition off
- Reconnect the connectors, reinstall components etc.
- Ignition on
- Read off the power supply for the steering wheel angle sensor module (SAS) and the central electronic module (CEM).

Check that the voltage is approximately battery voltage.

Is the voltage OK?

Yes - VERIFIED

No - Fault-tracing information

Fault-tracing information

Diagnostic Trouble Code (DTC) Information

SRS-0010 Diagnostic trouble code information

Condition

If the control unit registers that the voltage in the circuit is high for more than 10 seconds, diagnostic trouble code SRS-0010 is displayed.

Substitute value
- Nothing.

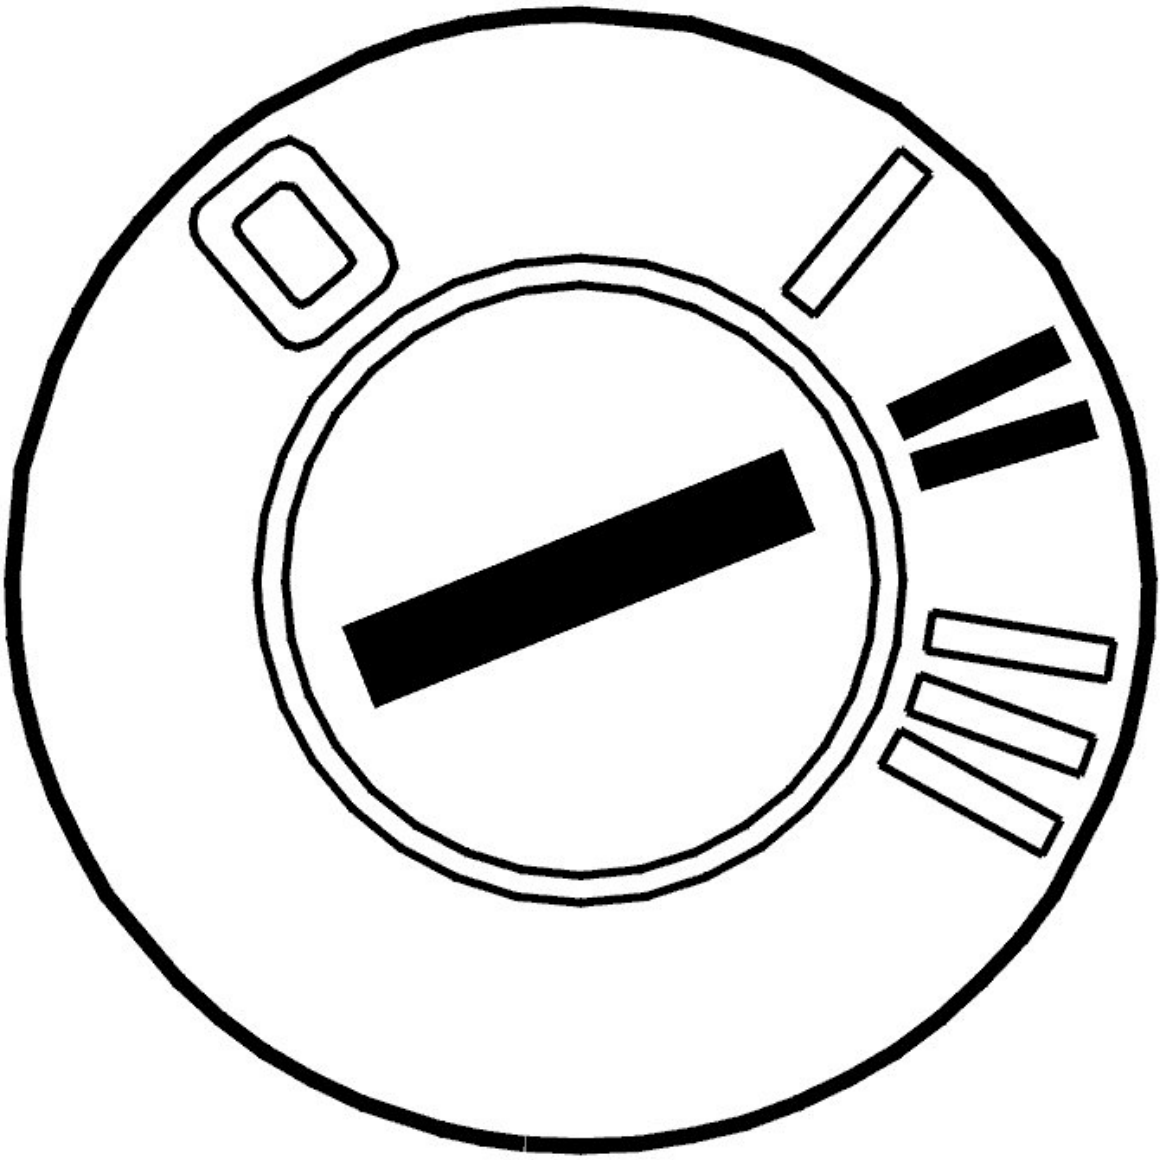
Possible source
- Short circuit to voltage supply in igniter wire or connectors between the air bag and the supplemental restraint system (SRS) control unit
- Short circuit to voltage supply in air bag
- Short circuit to voltage supply in contact reel.

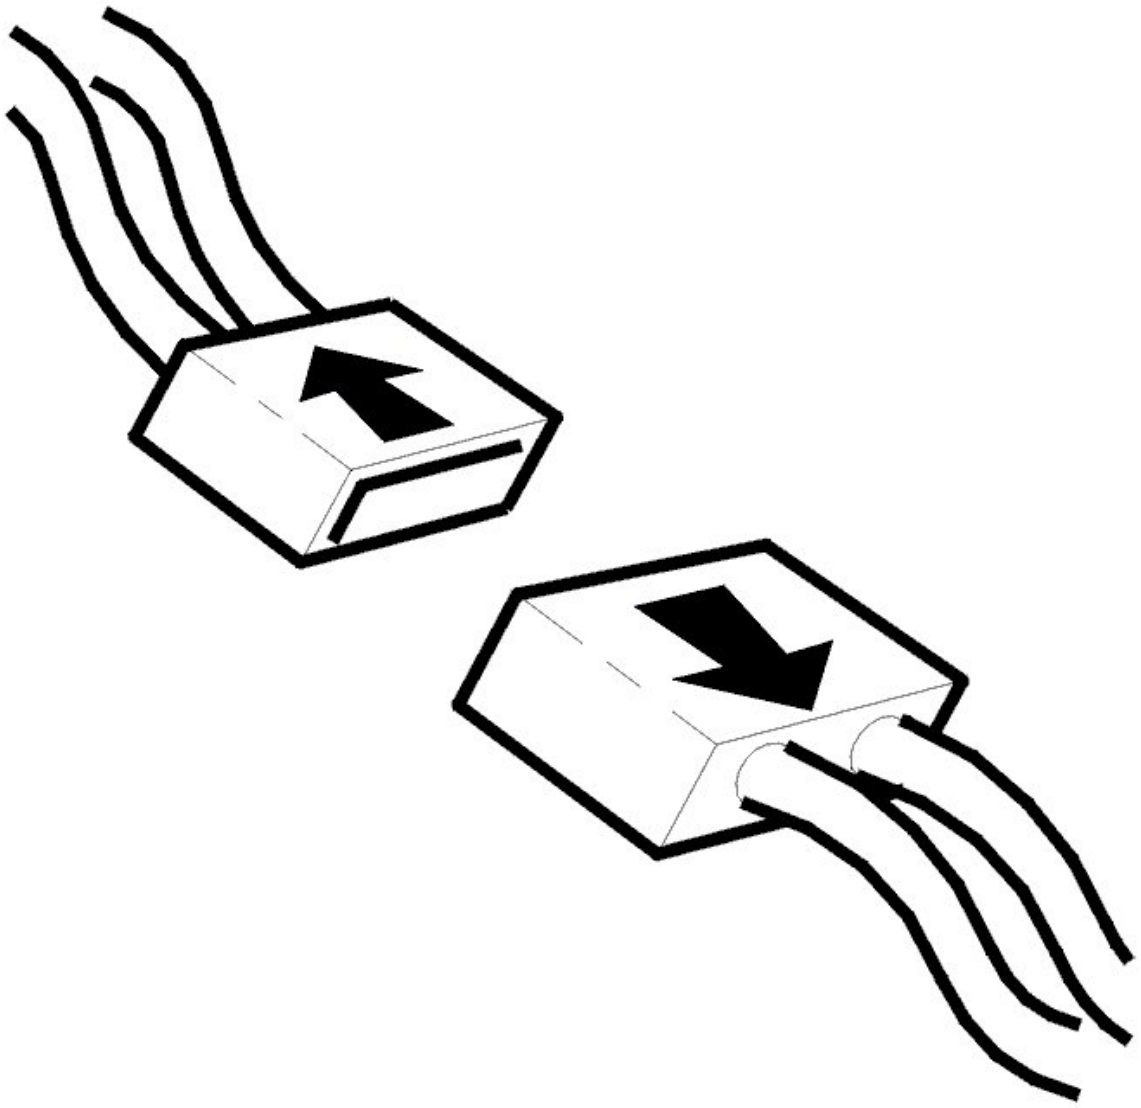
Fault symptom[s]
- SRS warning lamp on.

Signal Too High

Signal too high. Permanent fault

Checking the component





- Ignition off
- Disconnect the (green) connector from the airbag on the driver's side
- Connect special tool 951 1506 Test dummy See: Tools and Equipment/951 1506 Test Dummy to the airbag connector (green) on the driver's side

Warning! Under no circumstances use an ohmmeter or other live measuring instrument to take readings on a disconnected, non-deployed, pyrotechnical airbag. This could deploy the airbag!

Note! The special tool must be checked and fault-free. If the tool is defective, the diagnosis readings will be incorrect. This will make fault-tracing harder.

- Switch on the ignition. Wait 10 seconds.

Read off diagnostic trouble codes (DTCs).
Try a new airbag on the driver's side if the diagnostic trouble code (DTC) changes status from a permanent to an intermittent fault.

Other information:

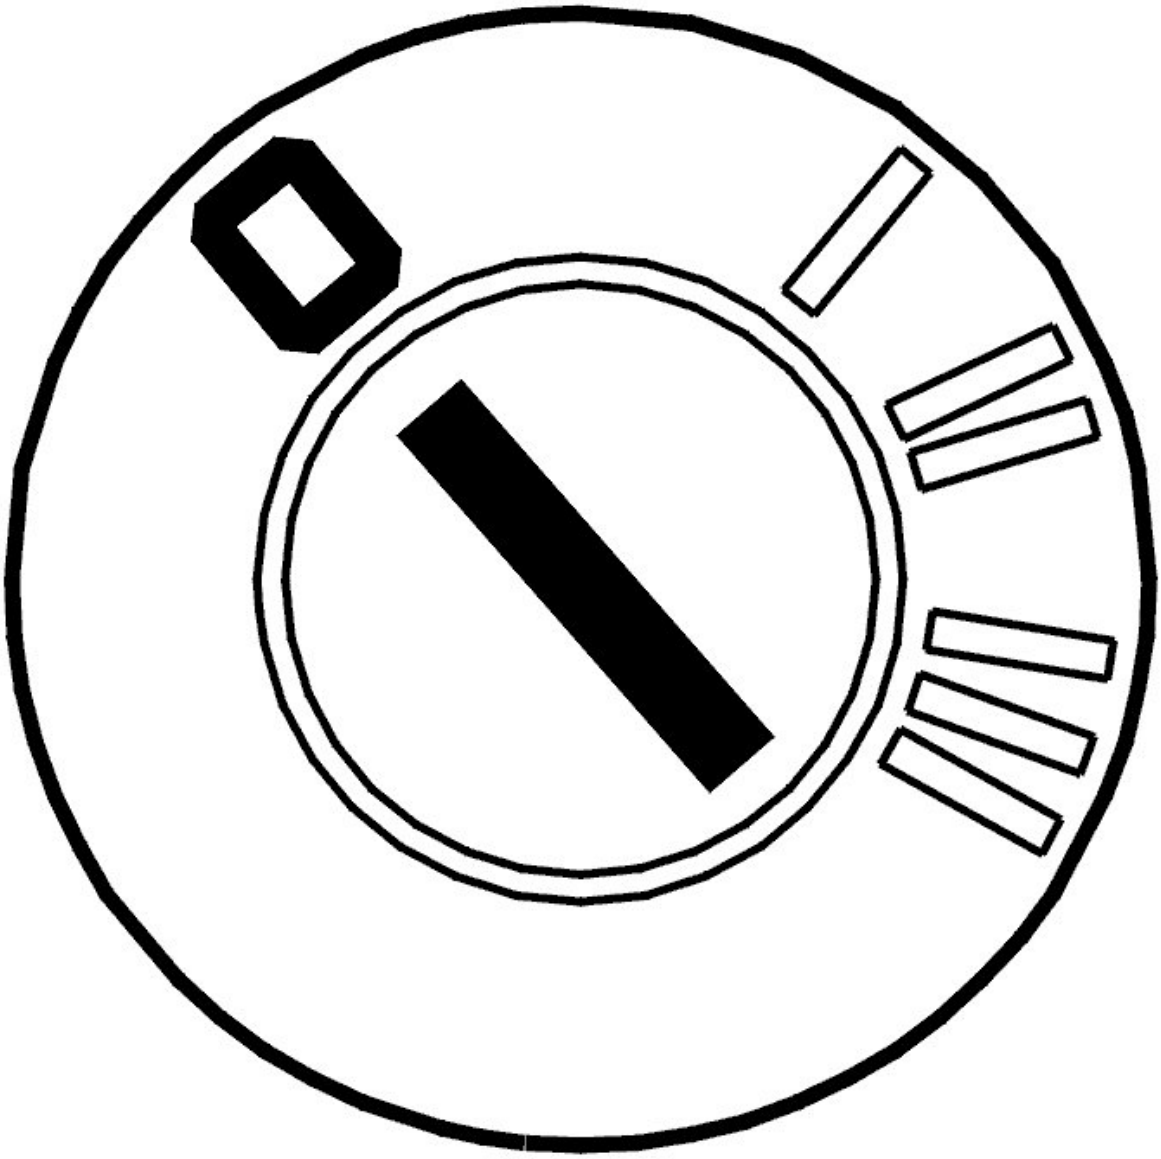
- To access and replace the airbag on the driver's side, see Airbag driver's side (SRS), replacing See: Restraint Systems/Air Bag Systems/Air Bag/Service and Repair/Airbag Driver's Side (SRS), Replacing
- To check the special tool, see Calibration See: Restraint Systems/Service and Repair/Calibrating the Special Tool.

Does the status of the diagnostic trouble code (DTC) change?

Yes - Verification

No - Checking components and wiring

Checking components and wiring



- Ignition off
- Disconnect special tool 951 1506 Test dummy See: Tools and Equipment/951 1506 Test Dummy from the airbag connector (green) on the driver's side.

Warning! Under no circumstances use an ohmmeter or other live measuring instrument to take readings on a disconnected, non-deployed, pyrotechnical airbag. This could deploy the airbag!

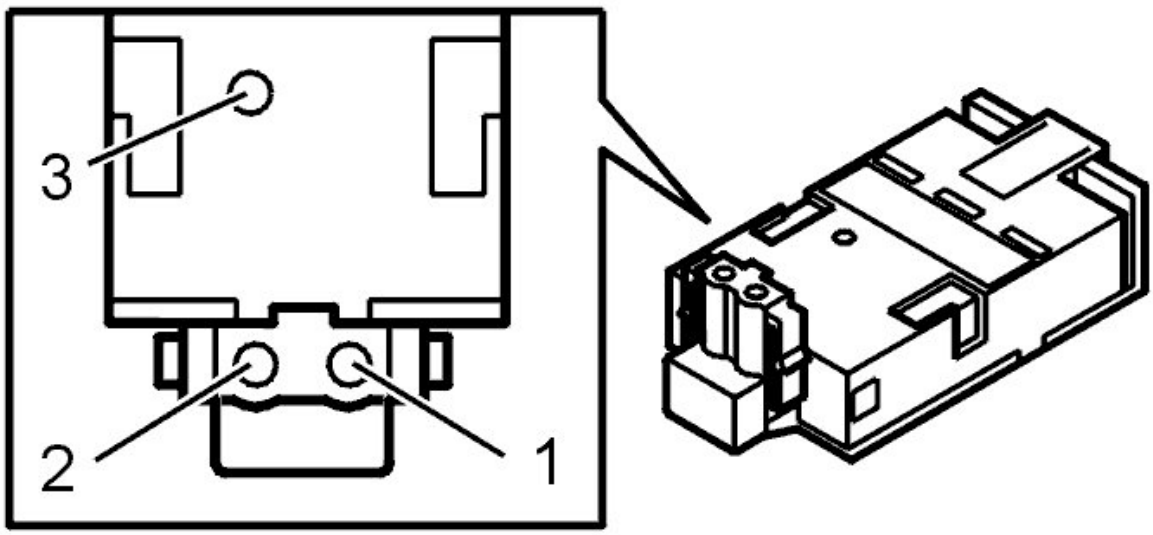
Caution! Do not touch the terminal pins in the SRS control module. There is a risk of static discharge. This could damage the SRS control module.

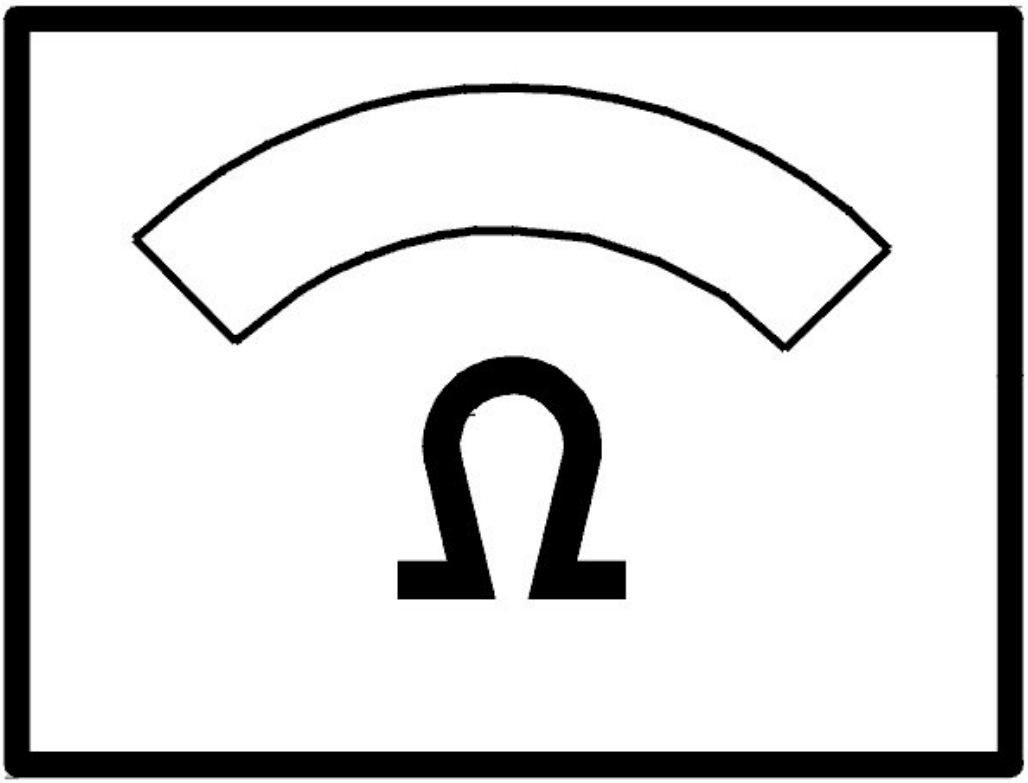
Check the cable between SRS control module terminals #8B (36) and #7B (35) and driver's airbag connector (green) terminals #1 and #3 for a short-circuit to supply voltage according to Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault.
Check the contact reel wiring: Disconnect the contact reel connector. Connect an ohmmeter between terminals #1 and #2 (driver's airbag side) and the disconnected battery positive terminal. The ohmmeter should read infinite resistance. Take the readings again while turning the steering slowly to full lock in each direction. The ohmmeter should read infinite resistance for all steering wheel positions.
Remedy as necessary.

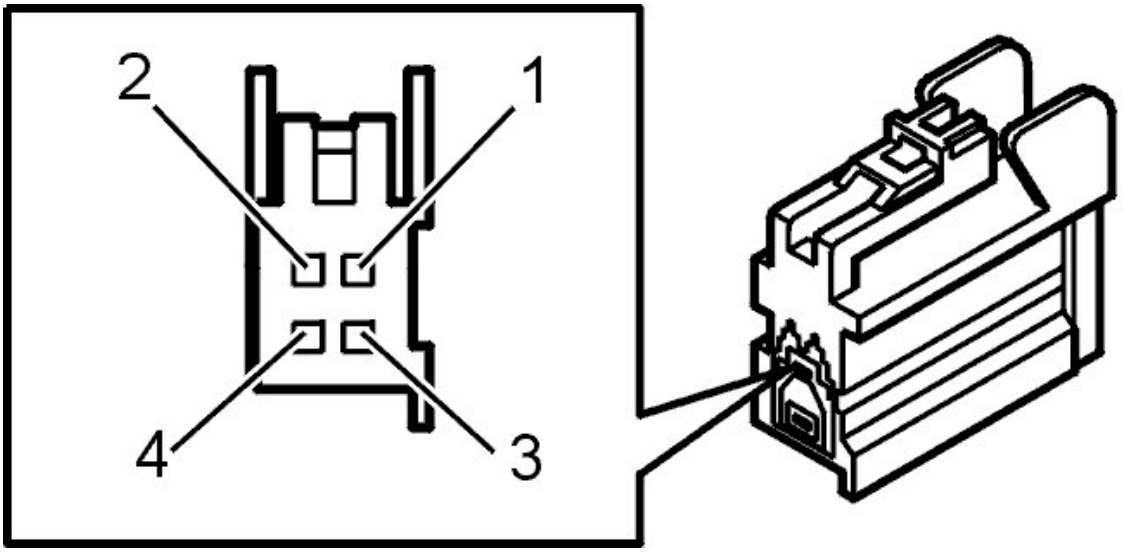
Other information:

- To access and replace the SRS control module and connector, see Control module SRS (supplemental restraint system), replacing See: Relays and Modules/Relays and Modules - Restraint Systems/Air Bag Control Module/Service and Repair
- To access and replace the driver's airbag connector, see Airbag driver's side (SRS), replacing See: Restraint Systems/Air Bag Systems/Air Bag/Service and Repair/Airbag Driver's Side (SRS), Replacing

- To access and replace the contact reel, see Contact reel / steering wheel angle sensor, replacing See: Restraint Systems/Air Bag Systems/Clockspring Assembly / Spiral Cable/Service and Repair/Removal and Replacement/Contact Reel / Steering Wheel Angle Sensor, Replacing
- To connect the breakout box, see Connecting the breakout box See: Restraint Systems/Air Bag Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box, Supplemental Restraint System Module (SRS)
- With the ignition off and the connectors for the contact reel and the SRS control module disconnected, the resistance between terminals #1 and #2 on the contact reel connector (SRS control module side) and the removed battery positive pole should be infinite
- For information about removing the battery cables, see Battery, disconnecting See: Starting and Charging/Battery/Service and Repair/Procedures/Battery, Disconnecting
- For information about the repair of SRS wiring, see Cable harness SRS system, repair See: Restraint Systems/Air Bag Systems/Air Bag/Air Bag Harness/Service and Repair/Procedures
- For other values, see Signal specification See: Restraint Systems/Air Bag Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Specification, Supplemental Restraint System Module (SRS).







Select "Continue" when the fault has been remedied.

Diagnostic Trouble Code (DTC) Information

SRS-0012 Diagnostic trouble code information

Condition

If the control unit registers that the capacitance in the circuit is too high for more than 10 seconds, diagnostic trouble code SRS-0012 is displayed.

Substitute value
- Nothing.

Possible source
- Capacitance too high or short circuit in built-in capacitor in igniter wire connector.

Fault symptom[s]
- SRS warning lamp on.

Capacitance Too High

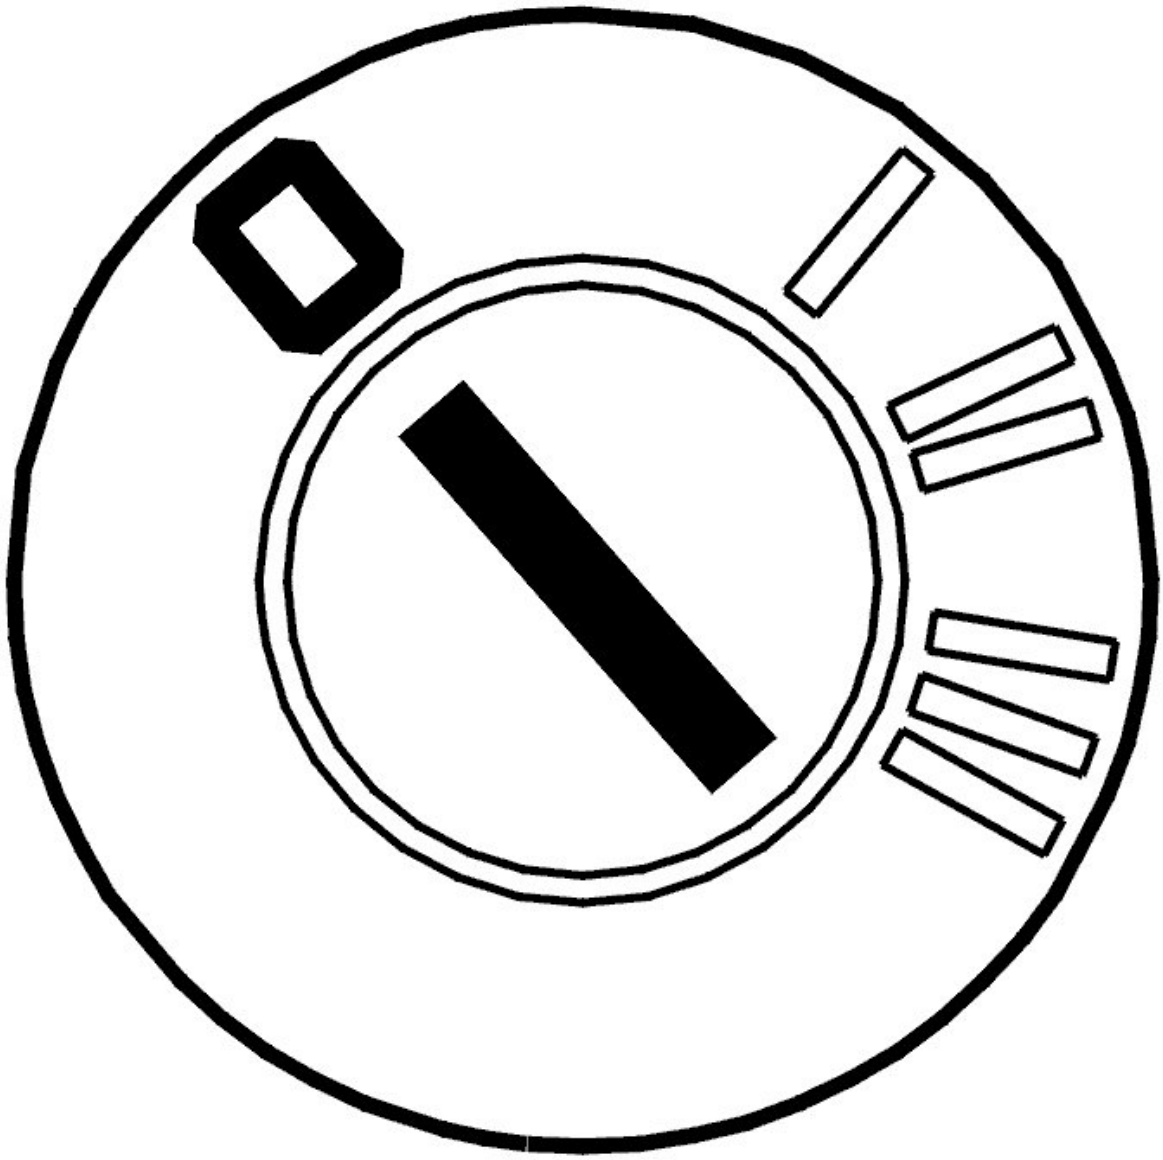
Capacitance too high. Intermittent fault

Intermittent fault



- Ignition off.

Warning! Under no circumstances use an ohmmeter or other live measuring instrument to take readings on a disconnected, non-deployed, pyrotechnical airbag. This could deploy the airbag!

Caution! Do not touch the terminal pins in the SRS control module. There is a risk of static discharge. This could damage the SRS control module.

Check the connectors for:
- the driver's airbag
- the contact reel
- the SRS control module.

check for contact resistance and oxidation. See Checking wiring and terminals. Intermittent faults See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Intermittent Faults. Check for loose connections. See Checking wiring and terminals. Intermittent faults See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Intermittent Faults.
Check the cable between SRS control module terminals #8B (36) and #7B (35) and driver's airbag connector (green) terminals #1 and #3 for an intermittent short-circuit to ground according to Checking wiring and terminals. Intermittent faults See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Intermittent Faults.
Connect special tool951 1506 Test dummy See: Tools and Equipment/951 1506 Test Dummy to the airbag connector (green) on the driver's side.

Check the contact reel wiring: Disconnect the contact reel connector. Connect an ohmmeter between terminals #1 and #2 (driver's airbag side). The ohmmeter should read infinite resistance. Take the readings again while turning the steering slowly to full lock in each direction. The ohmmeter should read infinite resistance.
Remedy as necessary.

Other information:

- To access and replace the SRS control module and connector, see Control module SRS (supplemental restraint system), replacing See: Relays and Modules/Relays and Modules - Restraint Systems/Air Bag Control Module/Service and Repair
- To access the connector for the driver's airbag, see Airbag driver's side (SRS), replacing See: Restraint Systems/Air Bag Systems/Air Bag/Service and Repair/Airbag Driver's Side (SRS), Replacing
- To access and replace the contact reel, see Contact reel / steering wheel angle sensor, replacing See: Restraint Systems/Air Bag Systems/Clockspring Assembly / Spiral Cable/Service and Repair/Removal and Replacement/Contact Reel / Steering Wheel Angle Sensor, Replacing
- To connect the breakout box, see Connecting the breakout box See: Restraint Systems/Air Bag Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box, Supplemental Restraint System Module (SRS)
- With the ignition off and the contact reel connector disconnected, the resistance between terminals #1 and #2 on the contact reel connector (SRS control module side) should be approximately 22 kohms.
- With the ignition off and the connectors for the contact reel and the control module disconnected, the resistance between the terminals #1 and #2 on the contact reel connector (SRS control module side) should be infinite
- For information about the repair of SRS wiring, see Cable harness SRS system, repair See: Restraint Systems/Air Bag Systems/Air Bag/Air Bag Harness/Service and Repair/Procedures
- For other values, see Signal specification See: Restraint Systems/Air Bag Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Specification, Supplemental Restraint System Module (SRS).

Diagnostic Trouble Code (DTC) Information

SRS-0013 Diagnostic trouble code information

Condition

If the control unit registers that the capacitance in the circuit is too low for more than 10 seconds, diagnostic trouble code SRS-0013 is displayed.

Substitute value
- Nothing.

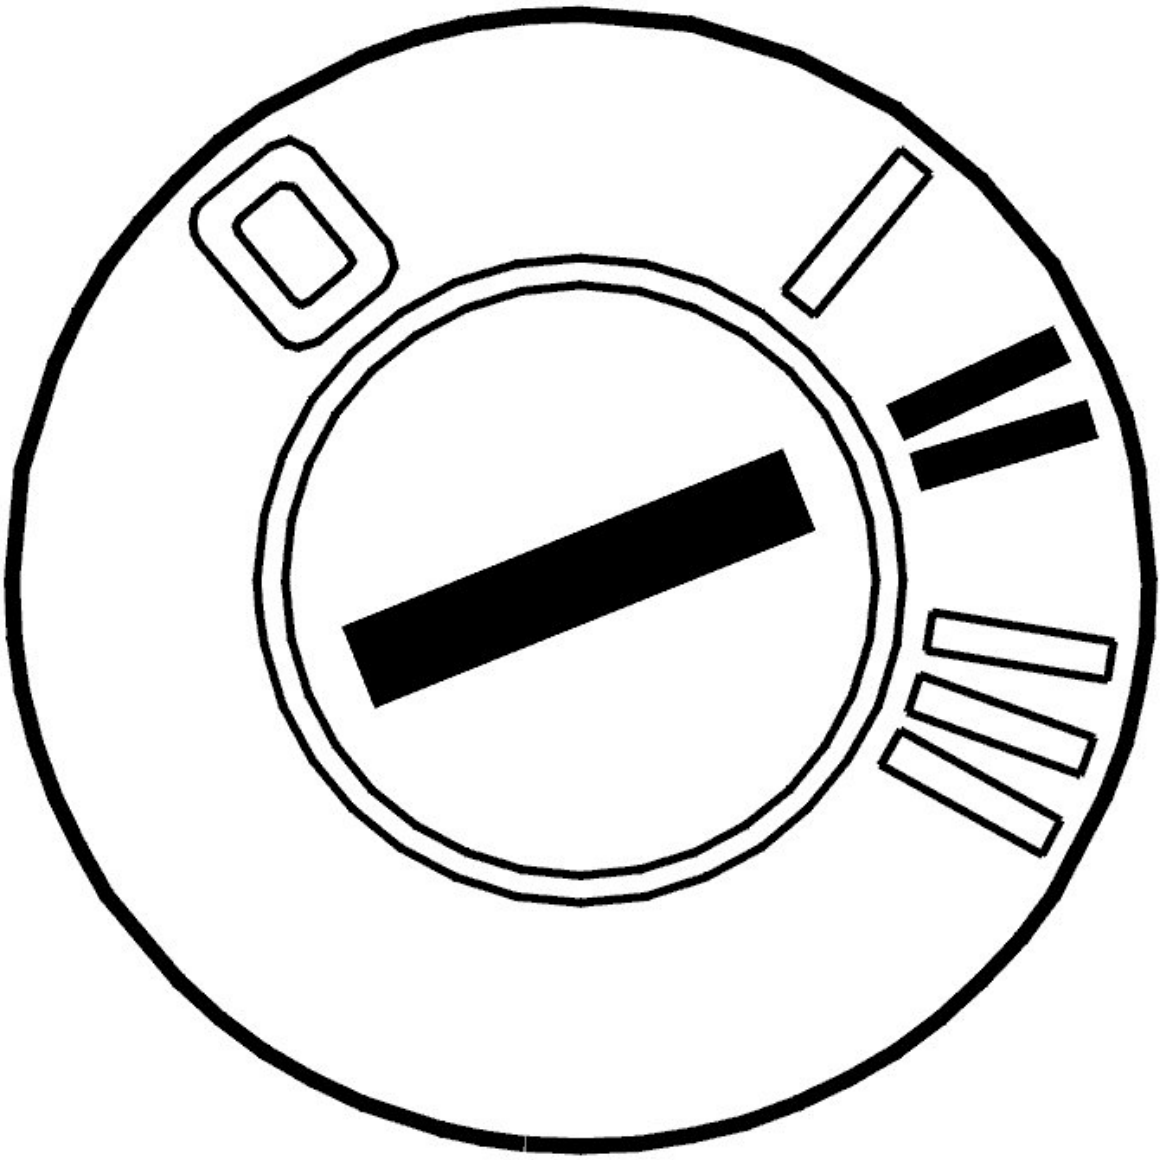
Possible source
- Capacitance too low or open circuit in in-built capacitor in igniter wire connector.

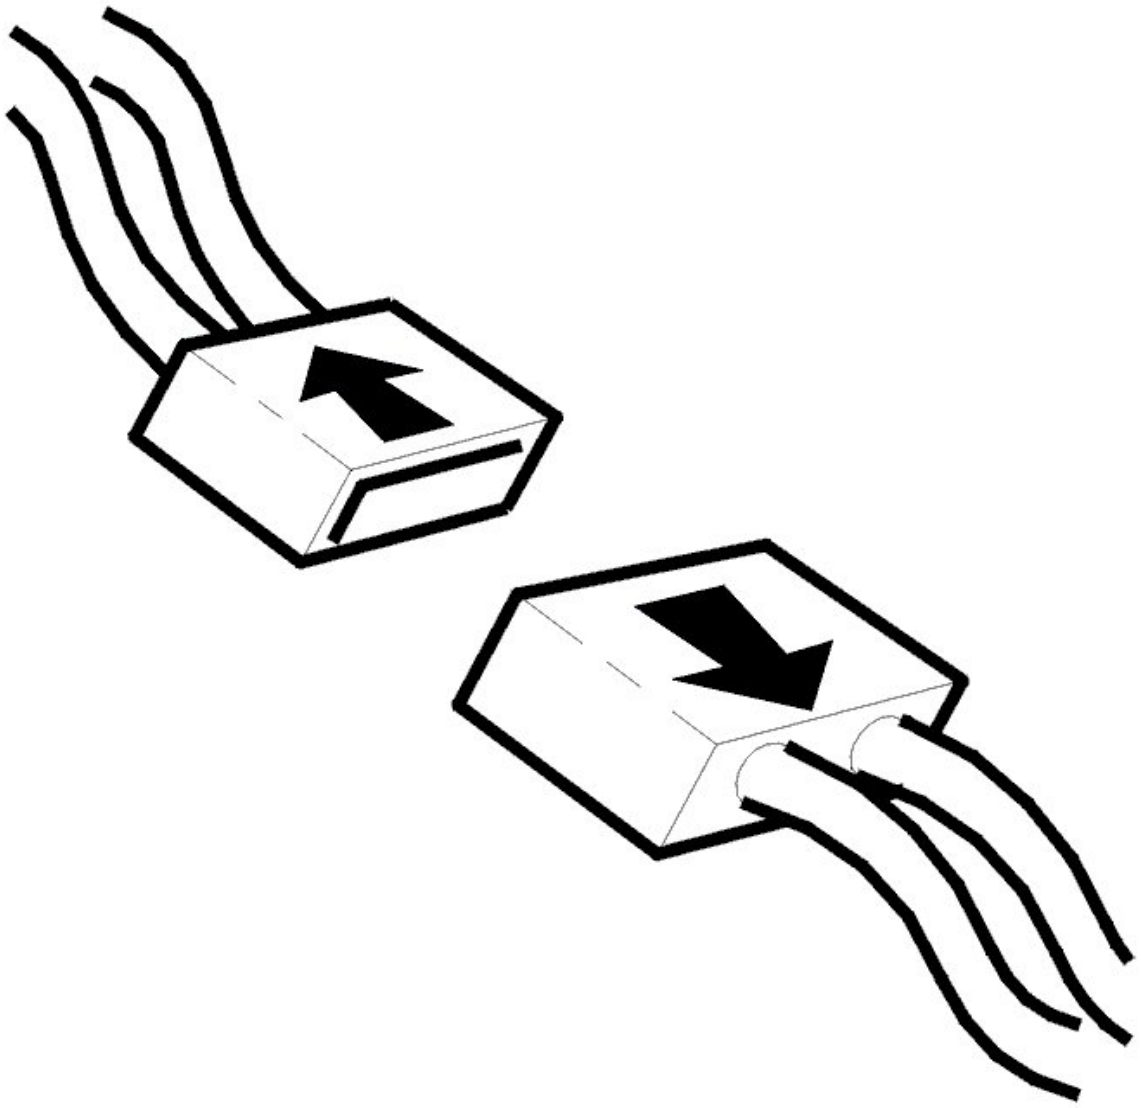
Fault symptom[s]
- SRS warning lamp on.

Capacitance Too Low

Capacitance too low. Permanent fault

Checking the component





- Ignition off
- Disconnect the (green) connector from the airbag on the driver's side
- Connect special tool951 1506 Test dummy See: Tools and Equipment/951 1506 Test Dummy to the airbag connector (green) on the driver's side

Warning! Under no circumstances use an ohmmeter or other live measuring instrument to take readings on a disconnected, non-deployed, pyrotechnical airbag. This could deploy the airbag!

Note! The special tool must be checked and fault-free. If the tool is defective, the diagnosis readings will be incorrect. This will make fault-tracing harder.

- Switch on the ignition. Wait 10 seconds.

Read off diagnostic trouble codes (DTCs).
Try a new airbag on the driver's side if the diagnostic trouble code (DTC) changes status from a permanent to an intermittent fault.

Other information:

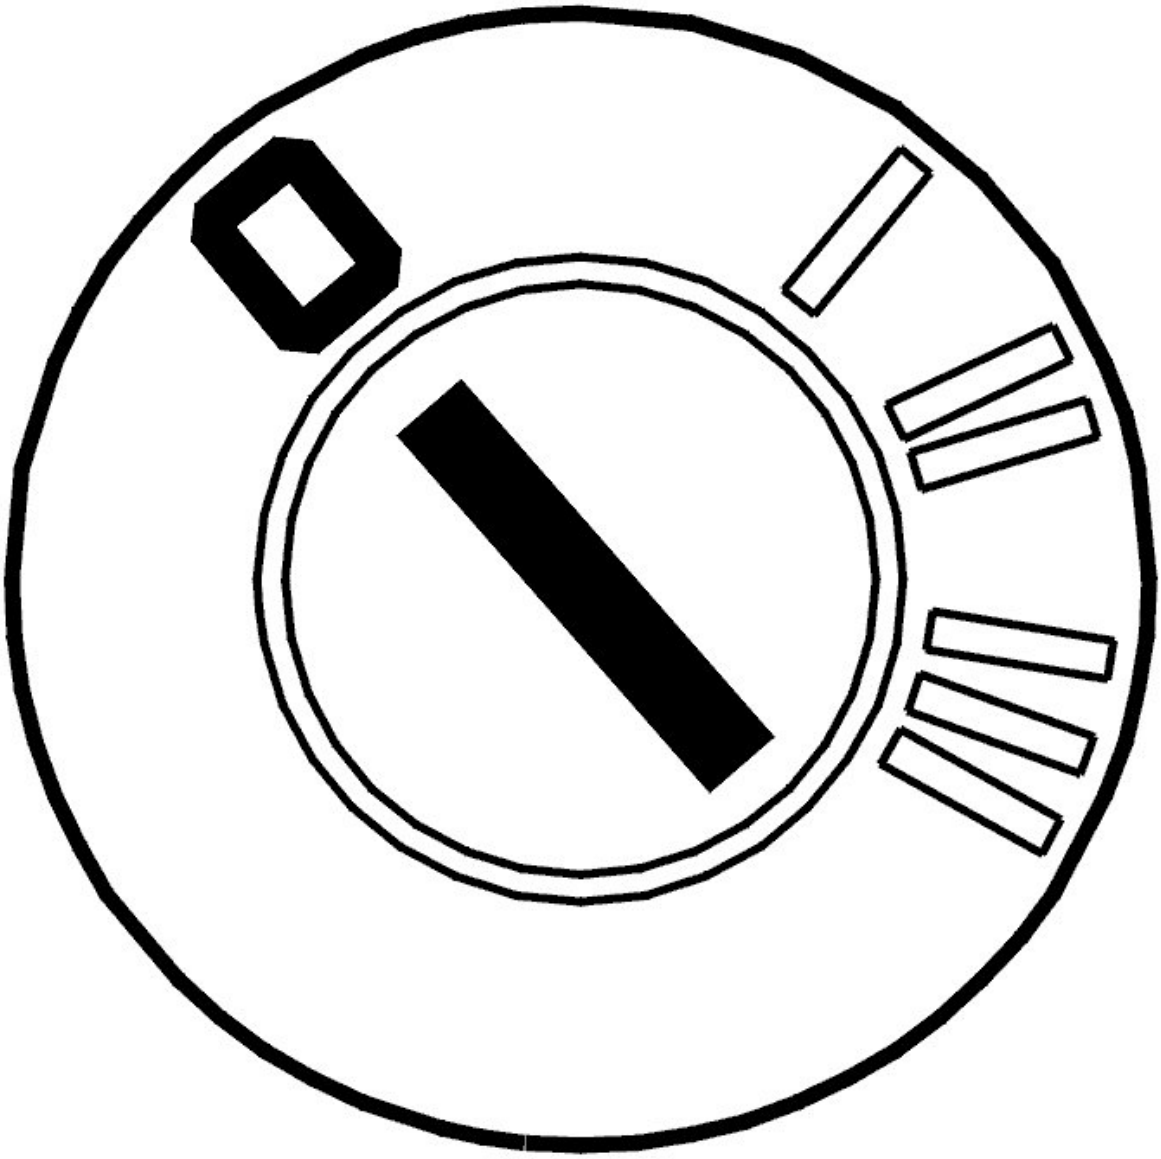
- To access and replace the airbag on the driver's side, see Airbag driver's side (SRS), replacing See: Restraint Systems/Air Bag Systems/Air Bag/Service and Repair/Airbag Driver's Side (SRS), Replacing
- To check the special tool, see Calibration See: Restraint Systems/Service and Repair/Calibrating the Special Tool.

Does the status of the diagnostic trouble code (DTC) change?

Yes - Verification

No - Checking components and wiring

Checking components and wiring



- Ignition off
- Disconnect special tool951 1506 Test dummy See: Tools and Equipment/951 1506 Test Dummy from the airbag connector (green) on the driver's side.

Warning! Under no circumstances use an ohmmeter or other live measuring instrument to take readings on a disconnected, non-deployed, pyrotechnical airbag. This could deploy the airbag!

Caution! Do not touch the terminal pins in the SRS control module. There is a risk of static discharge. This could damage the SRS control module.

Disconnect the connector from:
- the SRS control module
- the contact reel.

Check the cable terminals in the female and male sections of the connector. The cable terminals must not be damaged or pressed back.
Check the cable between SRS control module terminals #8B (36) and #7B (35) and driver's airbag connector (green) terminals #1 and #3 for an open-circuit according to Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault.

Hint: Check the integrated capacitor in the igniter connector: Measure the resistance.
With the ignition off, connect the test instrument probes between terminals #1 and #3 on the driver's airbag connector (green). The ohmmeter reading should rise rapidly to infinity.
Reverse the position of the ohmmeter positive and negative test probes. Connect them to the connector as in the previous measurement. The ohmmeter reading should drop rapidly to approximately 0 ohms and then increase to infinity.

Disconnect the connector from the contact reel. Check the contact reel wiring by connecting an ohmmeter between terminals #1 and #2 (driver's airbag side) and driver's airbag connector terminals #1 and #3. The ohmmeter should read approximately 0 ohms. Take the readings again while turning the steering slowly to full lock in each direction. The ohmmeter should read approximately 0 ohms for all positions for the steering wheel. Remedy as necessary.

Caution! Do not touch the terminal pins in the SRS control module. There is a risk of static discharge. This could damage the SRS control module.

Check the connectors for:
- the driver's airbag
- the contact reel
- the SRS control module.

check for contact resistance and oxidation. See Checking wiring and terminals. Intermittent faults See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Intermittent Faults. Check for loose connections. See Checking wiring and terminals. Intermittent faults See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Intermittent Faults.
Check the cable between SRS control module terminals #8B (36) and #7B (35) and driver's airbag connector (green) terminals #1 and #3 for an intermittent short-circuit to ground according to Checking wiring and terminals. Intermittent faults See: Testing and Inspection/Component Tests

and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Intermittent Faults.
Connect special tool951 1506 Test dummy See: Tools and Equipment/951 1506 Test Dummy to the airbag connector (green) on the driver's side.
Check the contact reel wiring: Disconnect the contact reel connector. Connect an ohmmeter between terminals #1 and #2 (driver's airbag side). The ohmmeter should read infinite resistance. Take the readings again while turning the steering slowly to full lock in each direction. The ohmmeter should read infinite resistance.
Remedy as necessary.

Other information:

- To access and replace the SRS control module connector, see Control module SRS (supplemental restraint system), replacing See: Relays and Modules/Relays and Modules - Restraint Systems/Air Bag Control Module/Service and Repair
- To access the connector for the driver's airbag, see Airbag driver's side (SRS), replacing See: Restraint Systems/Air Bag Systems/Air Bag/Service and Repair/Airbag Driver's Side (SRS), Replacing
- To access and replace the contact reel, see Contact reel / steering wheel angle sensor, replacing See: Restraint Systems/Air Bag Systems/Clockspring Assembly / Spiral Cable/Service and Repair/Removal and Replacement/Contact Reel / Steering Wheel Angle Sensor, Replacing
- To connect the breakout box, see Connecting the breakout box See: Restraint Systems/Air Bag Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box, Supplemental Restraint System Module (SRS)
- With the ignition off and the contact reel connector disconnected, the resistance between terminals #1 and #2 on the contact reel connector (SRS control module side) should be approximately 22 kohms.
- With the ignition off and the connectors for the contact reel and the control module disconnected, the resistance between the terminals #1 and #2 on the contact reel connector (SRS control module side) should be infinite
- For information about the repair of SRS wiring, see Cable harness SRS system, repair See: Restraint Systems/Air Bag Systems/Air Bag/Air Bag Harness/Service and Repair/Procedures

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition

One of the following diagnostic trouble codes (DTCs) will be stored if the resistance in any of the wiring circuits is lower than 10 ohms for longer than 10 seconds:
SRS-0016, SRS-001E,
SRS-0036, SRS-003E,
SRS-0046, SRS-004E,
SRS-0056, SRS-005E,
depending on which wiring circuit the fault is in.

Possible source

- If the SRS control module identifies that an airbag or a seat belt tensioner is installed, despite the control module being programmed that neither should be installed.

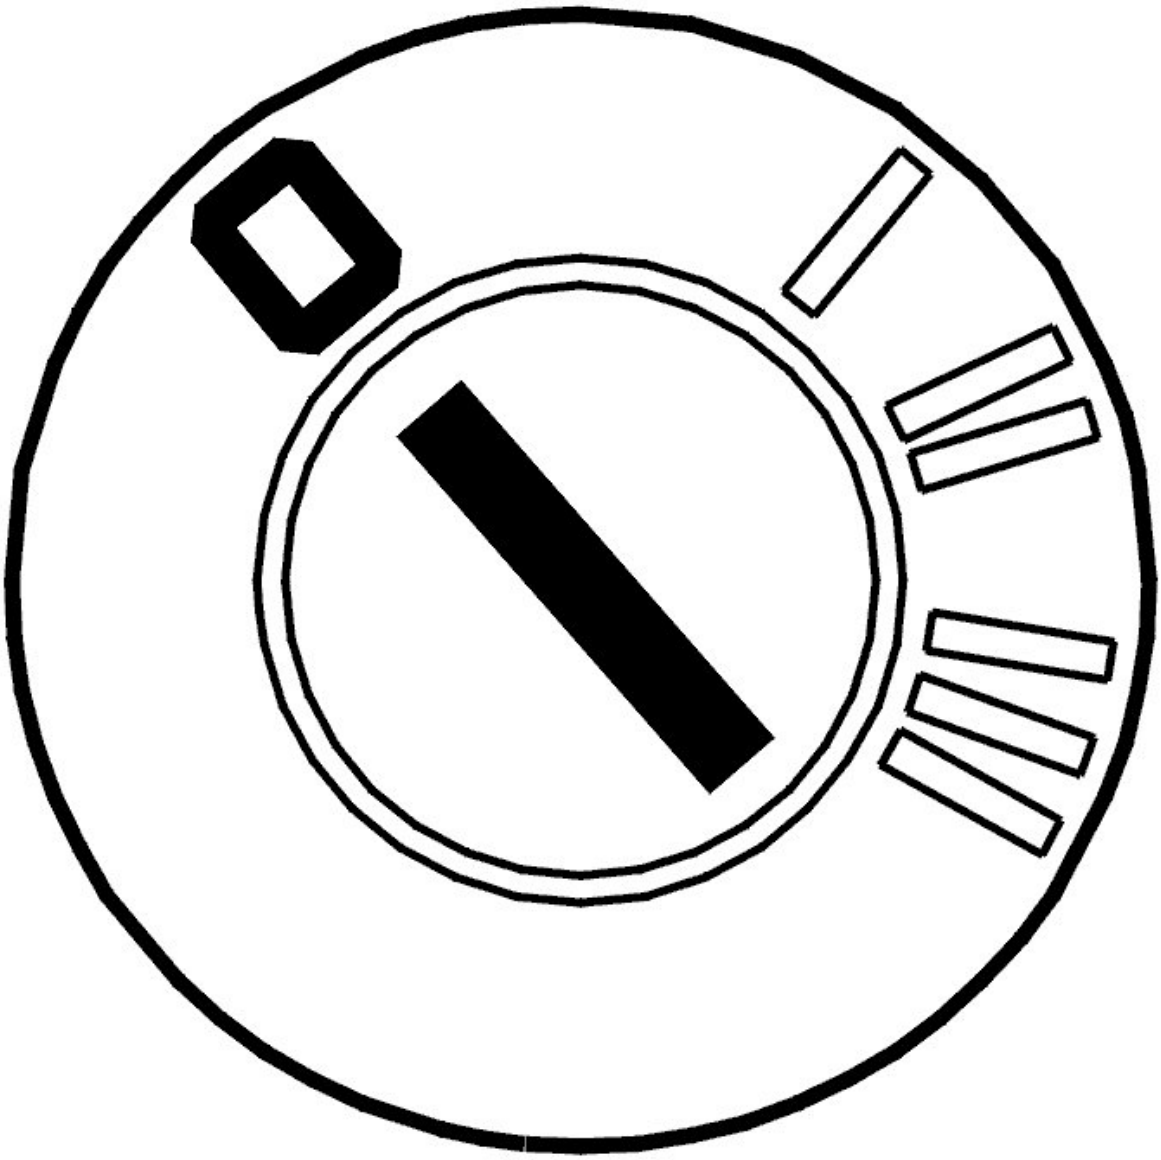
Fault symptom[s]

The SRS indicator lamp is lit.

Configuration Fault

Configuration fault. Permanent fault

Checking the component



- Ignition off.

Check the control module and SRS system connectors to ensure that no terminal pins are damaged. Also check the wiring.
Check that the correct SRS control module is installed in the car. Read off by clicking the VCT2000 symbol.
Replace the control module if no fault is found.

Other information:

- To access or replace the control module, see Control module SRS (supplemental restraint system), replacing See: Relays and Modules/Relays and Modules - Restraint Systems/Air Bag Control Module/Service and Repair
- For other values, see Signal specification See: Restraint Systems/Air Bag Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Specification, Supplemental Restraint System Module (SRS).

Diagnostic trouble code (DTC) information SRS-0018

Condition

Diagnostic trouble code (DTC) SRS-0018 is stored if the control module registers that voltage in the circuit is high for longer than 10 seconds.

Substitute value
- None.

Possible source
- Short-circuit to supply voltage in the SRS ignition cable or in the connector between the airbag and the SRS control module.
- Short-circuit to supply voltage in the airbag.
- Short-circuit to supply voltage in the contact reel.

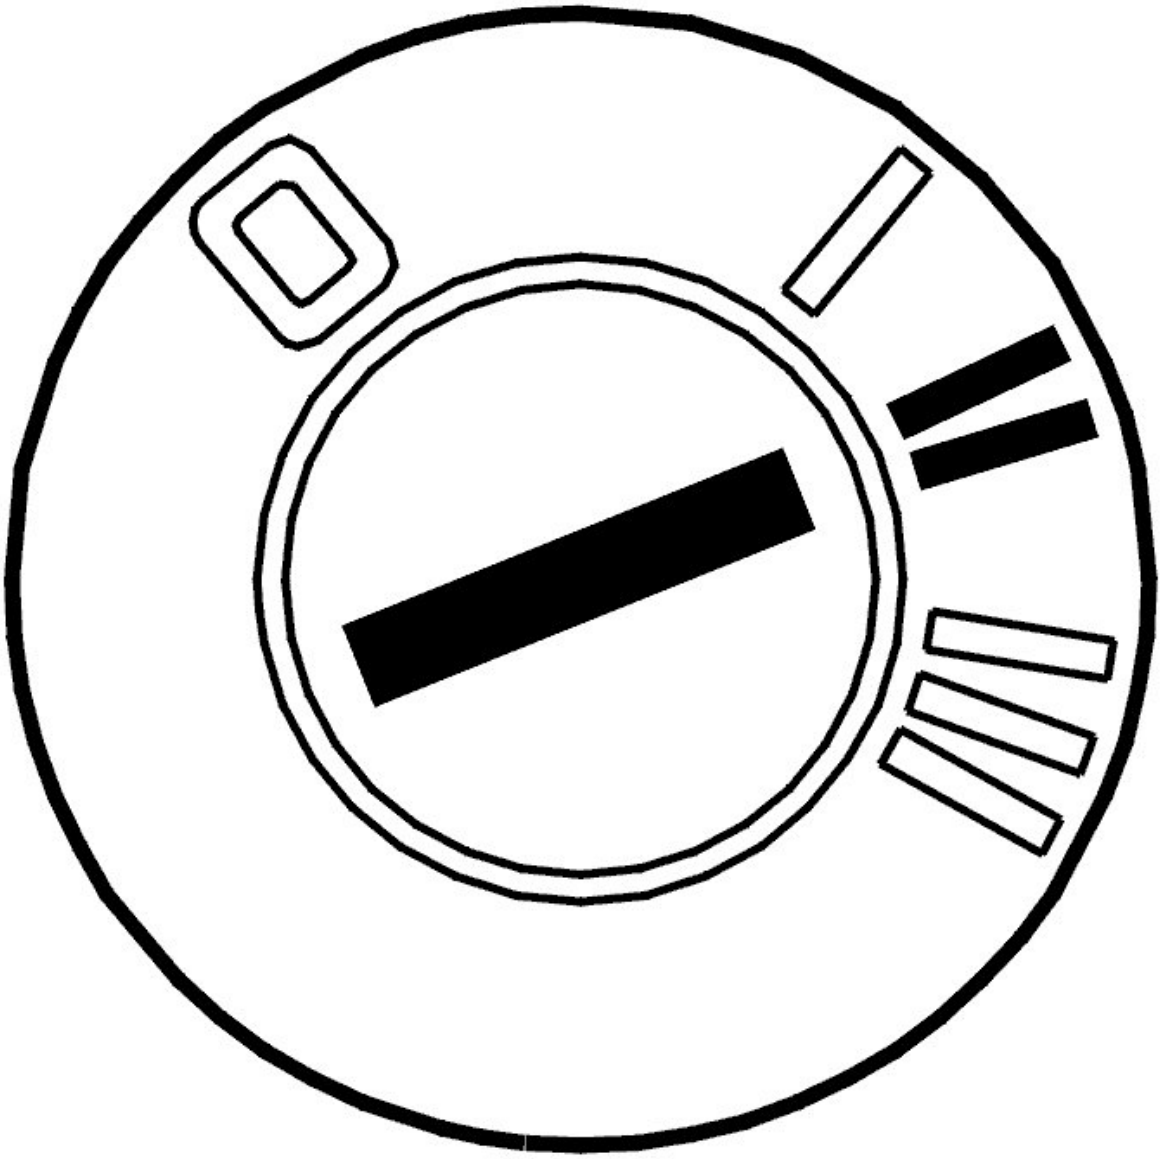
Fault symptom[s]

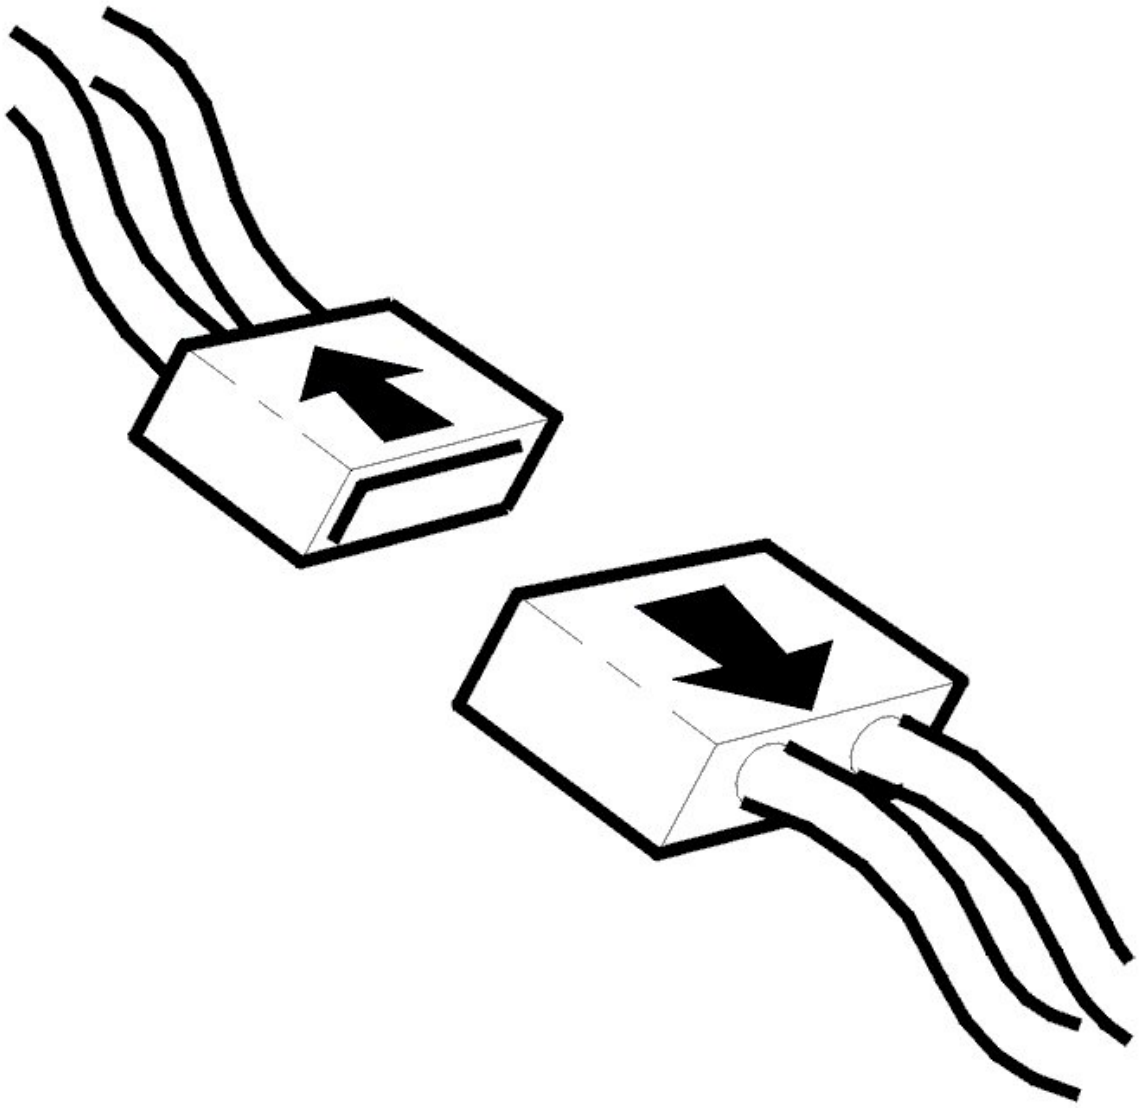
- The SRS indicator lamp is lit.

Signal Too High

Signal too high. Permanent fault

Checking the component





- Ignition off
- Disconnect the (violet) connector from the airbag on the driver's side
- Connect special tool 951 1506 Test dummy See: Tools and Equipment/951 1506 Test Dummy to the airbag connector (violet) on the driver's side

Warning! Under no circumstances use an ohmmeter or other live measuring instrument to take readings on a disconnected, non-deployed, pyrotechnical airbag. This could deploy the airbag!

Note! The special tool must be checked and fault-free. If the tool is defective, the diagnosis readings will be incorrect. This will make fault-tracing harder.

- Switch on the ignition. Wait 10 seconds.

Read off diagnostic trouble codes (DTCs).
Try a new airbag on the driver's side if the diagnostic trouble code (DTC) changes status from a permanent to an intermittent fault.

Other information:

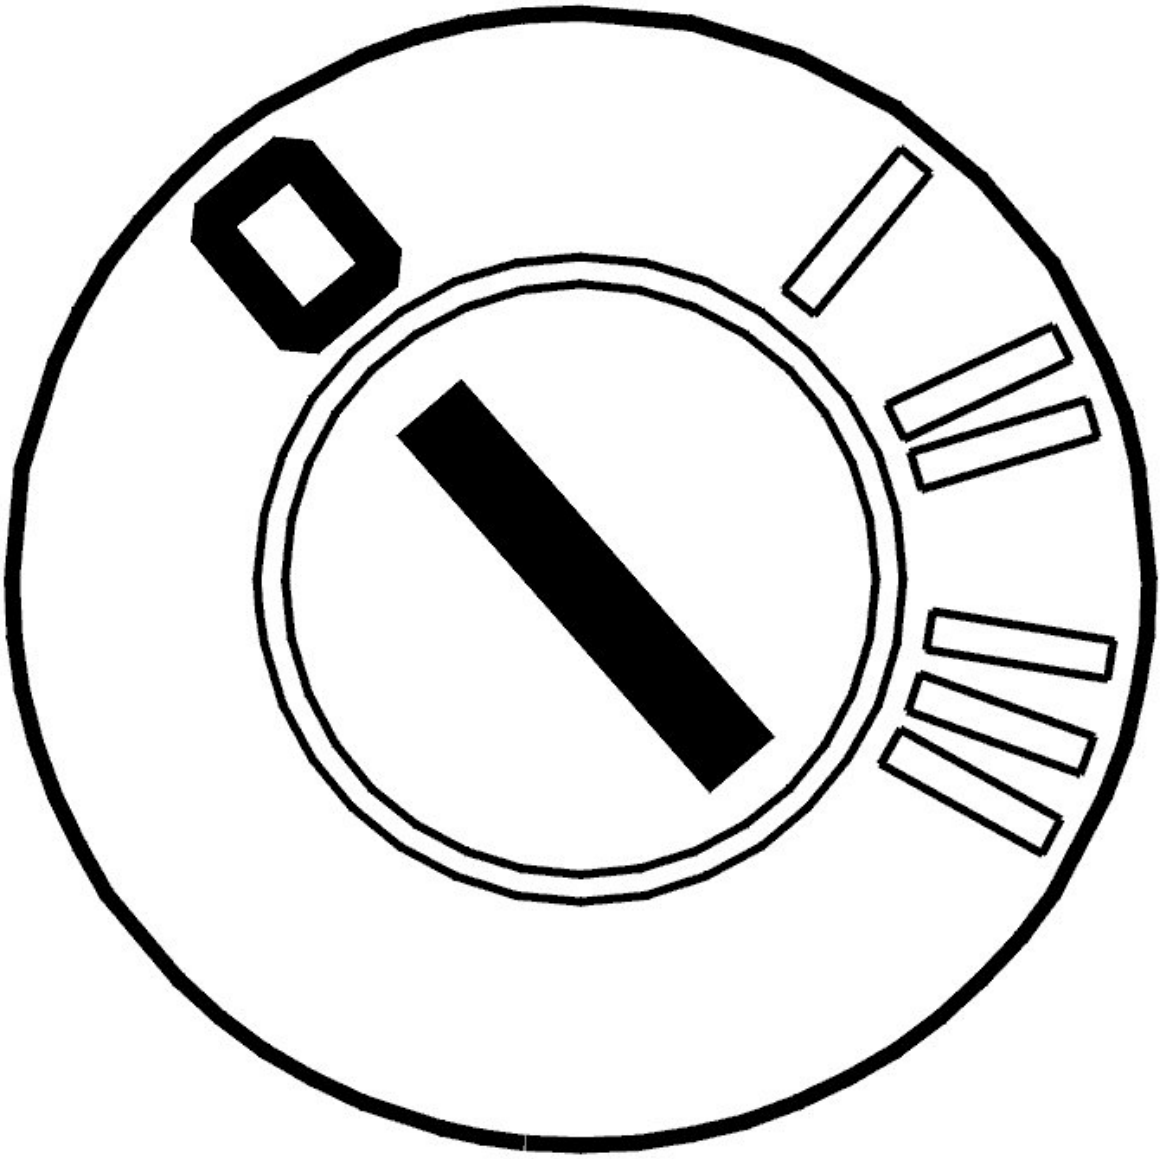
- To access and replace the airbag on the driver's side, see Airbag driver's side (SRS), replacing See: Restraint Systems/Air Bag Systems/Air Bag/Service and Repair/Airbag Driver's Side (SRS), Replacing
- To check the special tool, see Calibration See: Restraint Systems/Service and Repair/Calibrating the Special Tool.

Does the status of the diagnostic trouble code (DTC) change?

Yes - Verification

No - Checking the component and wiring

Checking the component and wiring



- Ignition off
- Disconnect special tool 951 1506 Test dummy See: Tools and Equipment/951 1506 Test Dummy from the airbag connector (violet) on the driver's side.

Warning! Under no circumstances use an ohmmeter or other live measuring instrument to take readings on a disconnected, non-deployed, pyrotechnical airbag. This could deploy the airbag!

Caution! Do not touch the terminal pins in the SRS control module. There is a risk of static discharge. This could damage the SRS control module.

Check the cable between SRS control module terminals #9B (37) and #10B (38) and connector (violet) terminals #1 and #3 on the driver's side airbag for a short-circuit to supply voltage according to Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault.
Check the contact reel wiring: Disconnect the contact reel connector. Connect an ohmmeter between terminals #3 and #4 (driver's airbag side) and the disconnected battery positive terminal. The ohmmeter should read infinite resistance. Take the readings again while turning the steering slowly to full lock in each direction. The ohmmeter should read infinite resistance for all steering wheel positions.
Remedy as necessary.

Try a new airbag on the driver's side if the diagnostic trouble code (DTC) changes status from a permanent to an intermittent fault.

Other information:

- To access and replace the airbag on the driver's side, see Airbag driver's side (SRS), replacing See: Restraint Systems/Air Bag Systems/Air Bag/Service and Repair/Airbag Driver's Side (SRS), Replacing
- To check the special tool, see Calibration See: Restraint Systems/Service and Repair/Calibrating the Special Tool.

Does the status of the diagnostic trouble code (DTC) change?

Yes - Verification

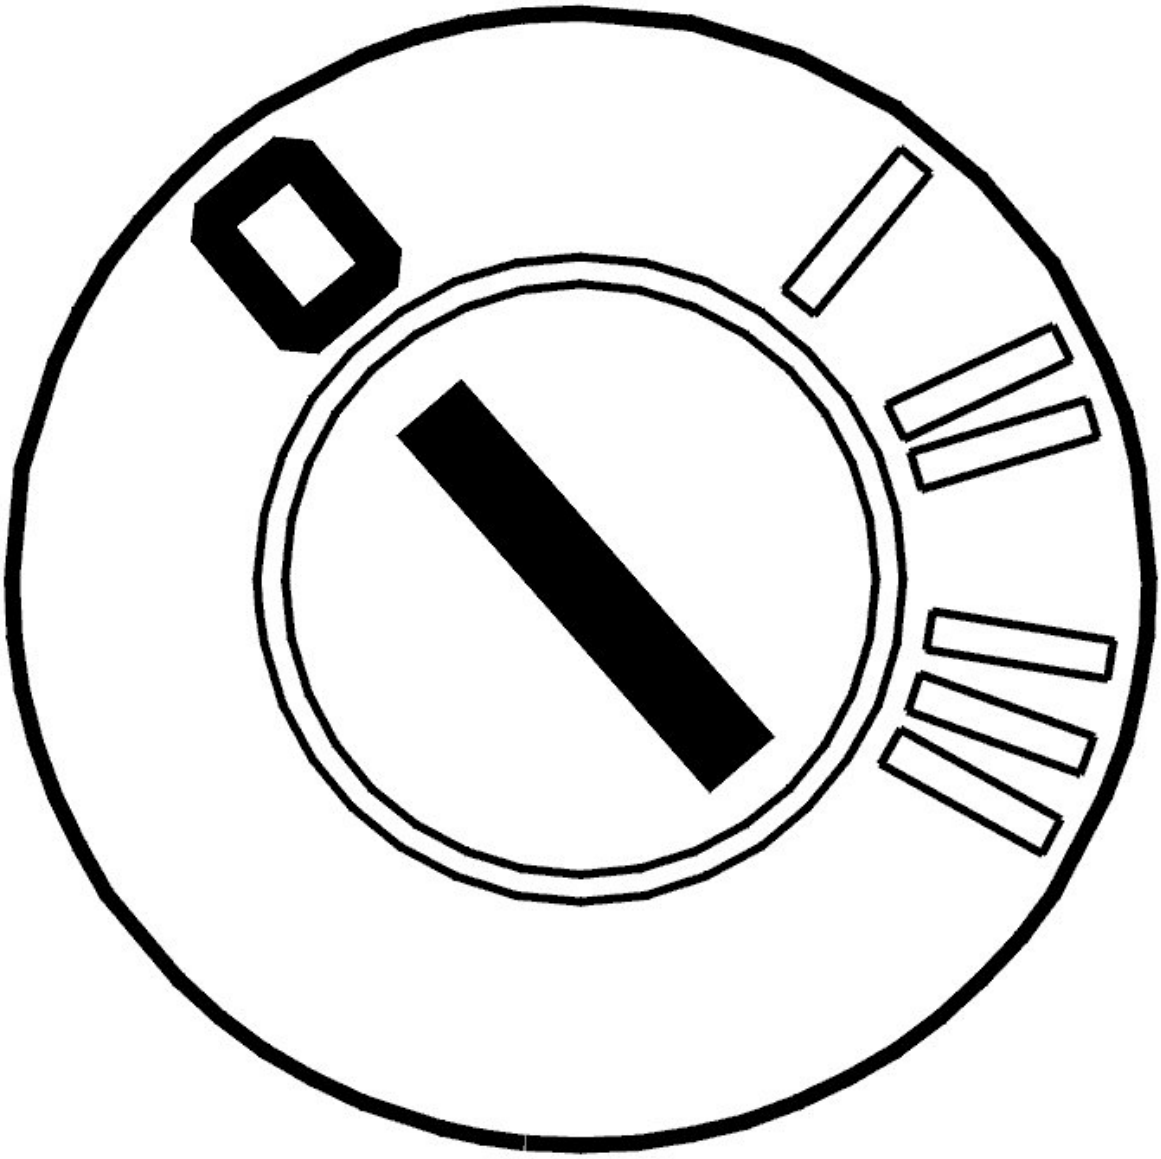
No - Checking components and wiring

Checking components and wiring



- Ignition off
- Disconnect special tool951 1506 Test dummy See: Tools and Equipment/951 1506 Test Dummy from the airbag connector (violet) on the driver's side.

Warning! Under no circumstances use an ohmmeter or other live measuring instrument to take readings on a disconnected, non-deployed, pyrotechnical airbag. This could deploy the airbag!

Caution! Do not touch the terminal pins in the SRS control module. There is a risk of static discharge. This could damage the SRS control module.

Check the cable between terminals #9B (37) and #10B (38) on the SRS control module and terminals #1 and #3 on the connector (violet) on the driver's side airbag for a short-circuit to ground according to Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault.
Connect special tool951 1506 Test dummy See: Tools and Equipment/951 1506 Test Dummy to the airbag connector (violet) on the driver's side.
Check the contact reel wiring: Disconnect the contact reel connector. Connect an ohmmeter between terminals #3 and #4 (driver's airbag side). The ohmmeter should read infinite resistance. Take the readings again while turning the steering slowly to full lock in each direction. The ohmmeter should read infinite resistance.
Remedy as necessary.

Other information:

- To access and replace the SRS control module connector, see Control module SRS (supplemental restraint system), replacing See: Relays and Modules/Relays and Modules - Restraint Systems/Air Bag Control Module/Service and Repair
- To access the connector for the driver's airbag, see Airbag driver's side (SRS), replacing See: Restraint Systems/Air Bag Systems/Air

Bag/Service and Repair/Airbag Driver's Side (SRS), Replacing

- To access and replace the contact reel, see Contact reel / steering wheel angle sensor, replacing See: Restraint Systems/Air Bag Systems/Clockspring Assembly / Spiral Cable/Service and Repair/Removal and Replacement/Contact Reel / Steering Wheel Angle Sensor, Replacing
- To connect the breakout box, see Connecting the breakout box See: Restraint Systems/Air Bag Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box, Supplemental Restraint System Module (SRS)
- With the ignition off and the connectors for the contact reel and the control module disconnected, the resistance between the terminals #3 and #4 on the contact reel connector (SRS control module side) should be infinite
- For information about the repair of SRS wiring, see Cable harness SRS system, repair See: Restraint Systems/Air Bag Systems/Air Bag/Air Bag Harness/Service and Repair/Procedures
- For other values, see Signal specification See: Restraint Systems/Air Bag Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Specification, Supplemental Restraint System Module (SRS).

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information SRS-001B

Condition

Diagnostic trouble code (DTC) SRS-001B is stored if the control module registers that capacitance in the circuit is too low for more than 10 seconds.

Substitute value

- None.

Possible source

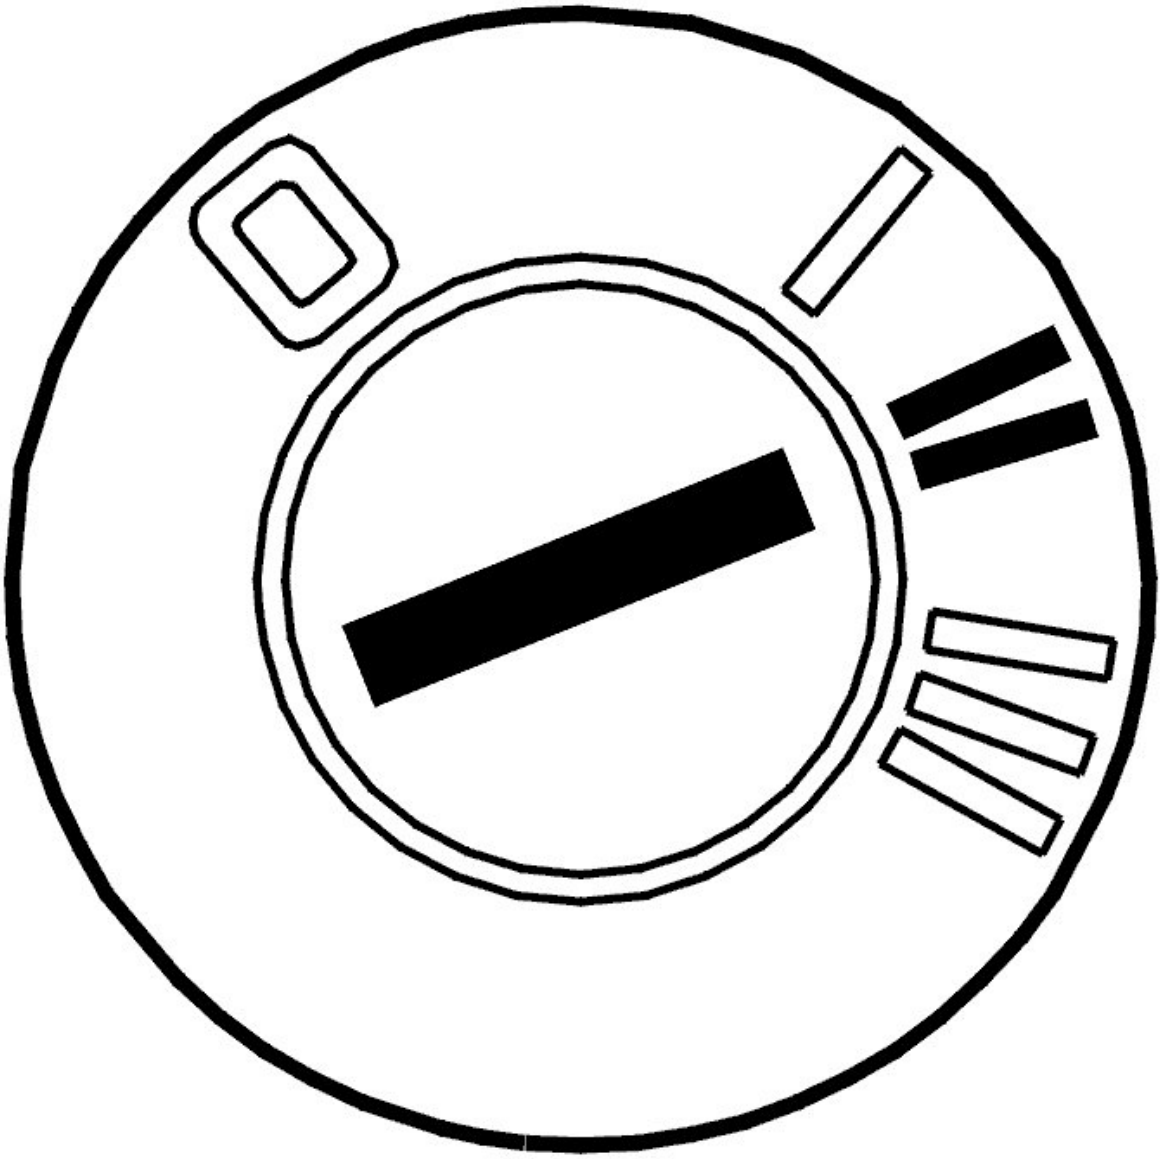
- The capacitance is too low or there is an open-circuit in the integrated capacitor in the connector for the SRS ignition cable.

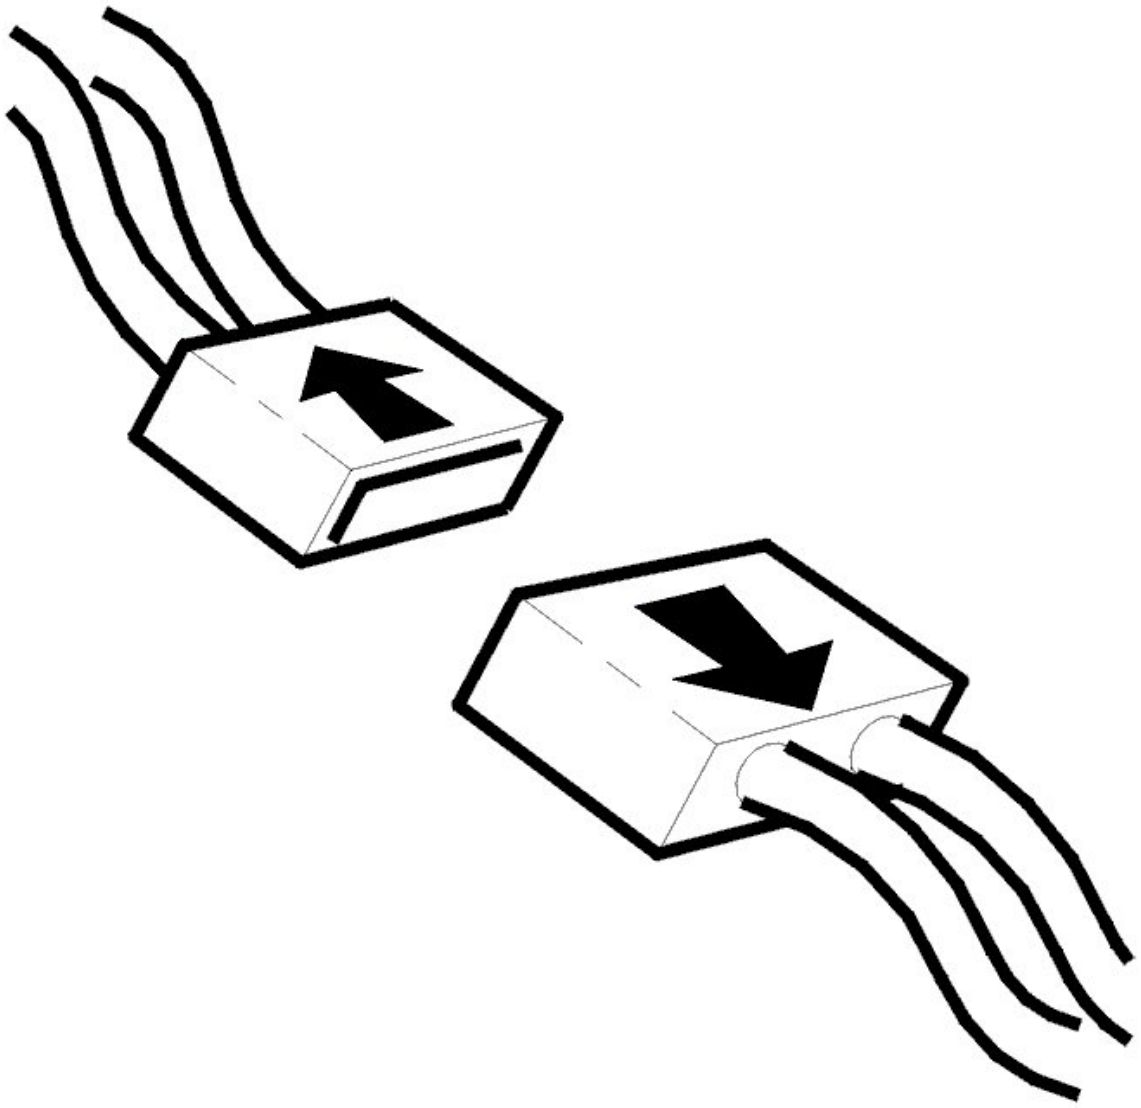
Fault symptom[s]
- The SRS indicator lamp is lit.

Capacitance Too Low

Capacitance too low. Permanent fault

Checking the component





- Ignition off
- Disconnect the (violet) connector from the airbag on the driver's side
- Connect special tool951 1506 Test dummy See: Tools and Equipment/951 1506 Test Dummy to the airbag connector (violet) on the driver's side

Warning! Under no circumstances use an ohmmeter or other live measuring instrument to take readings on a disconnected, non-deployed, pyrotechnical airbag. This could deploy the airbag!

Note! The special tool must be checked and fault-free. If the tool is defective, the diagnosis readings will be incorrect. This will make fault-tracing harder.

- Switch on the ignition. Wait 10 seconds.

Read off diagnostic trouble codes (DTCs).
Try a new airbag on the driver's side if the diagnostic trouble code (DTC) changes status from a permanent to an intermittent fault.

Other information:

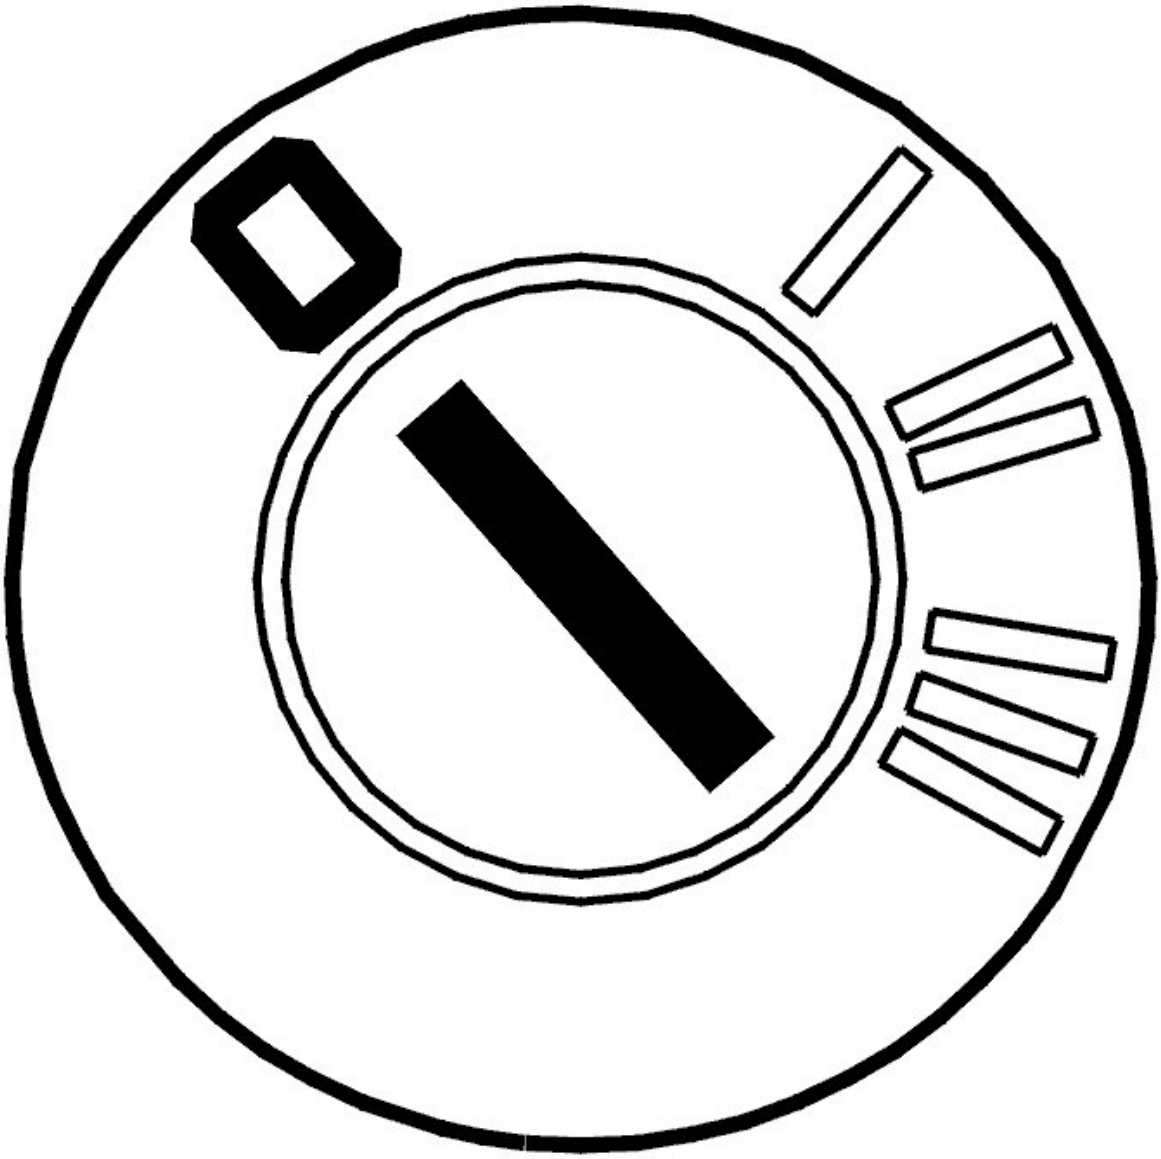
- To access and replace the airbag on the driver's side, see Airbag driver's side (SRS), replacing See: Restraint Systems/Air Bag Systems/Air Bag/Service and Repair/Airbag Driver's Side (SRS), Replacing
- To check the special tool, see Calibration See: Restraint Systems/Service and Repair/Calibrating the Special Tool.

Does the status of the diagnostic trouble code (DTC) change?

Yes - Verification

No - Checking the component and wiring

Checking the component and wiring



- Ignition off
- Disconnect special tool951 1506 Test dummy See: Tools and Equipment/951 1506 Test Dummy from the airbag connector (violet) on the driver's side.

Warning! Under no circumstances use an ohmmeter or other live measuring instrument to take readings on a disconnected, non-deployed, pyrotechnical airbag. This could deploy the airbag!

Caution! Do not touch the terminal pins in the SRS control module. There is a risk of static discharge. This could damage the SRS control module.

Disconnect the connector from:
- the SRS control module
- the contact reel.

Check the cable terminals in the female and male sections of the connector. The cable terminals must not be damaged or pressed back.
Check the cable between SRS control module terminals #8B (36) and #7B (35) and terminals #1 and #3 on the driver's airbag connector (violet) for an open-circuit according to Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault.

Hint: Check the integrated capacitor in the igniter connector: Measure the resistance.
With the ignition off, connect the test instrument probes between terminals #1 and #3 on the connector (violet) for the driver's airbag. The ohmmeter reading should rise rapidly to infinity.
Reverse the position of the ohmmeter positive and negative test probes. Connect them to the connector as in the previous measurement. The ohmmeter reading must drop rapidly to approximately 0 ohms and then increase to an infinite value.

Check the contact reel wiring: Disconnect the contact reel connector. Connect an ohmmeter between terminals #4 and #3 (driver's airbag side) and terminals #1 and #3 on the driver's airbag connector (violet). The ohmmeter should read approximately 0 ohms. Take the readings again while turning the steering slowly to full lock in each direction. The ohmmeter must read 0 ohms for all positions of the steering wheel.
Remedy as necessary.

Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault.
Connect special tool951 1506 Test dummy See: Tools and Equipment/951 1506 Test Dummy to the airbag connector (violet) on the driver's side.
Check the contact reel wiring: Disconnect the contact reel connector. Connect an ohmmeter between terminals #3 and #4 (driver's airbag side). The ohmmeter should read infinite resistance. Take the readings again while turning the steering slowly to full lock in each direction. The ohmmeter should read infinite resistance.
Remedy as necessary.

Other information:

- To access and replace the SRS control module and connector, see Control module SRS (supplemental restraint system), replacing See: Relays and Modules/Relays and Modules - Restraint Systems/Air Bag Control Module/Service and Repair
- To access the connector for the driver's airbag, see Airbag driver's side (SRS), replacing See: Restraint Systems/Air Bag Systems/Air

Bag/Service and Repair/Airbag Driver's Side (SRS), Replacing

- To access and replace the contact reel, see Contact reel / steering wheel angle sensor, replacing See: Restraint Systems/Air Bag Systems/Clockspring Assembly / Spiral Cable/Service and Repair/Removal and Replacement/Contact Reel / Steering Wheel Angle Sensor, Replacing
- To connect the breakout box, see Connecting the breakout box See: Restraint Systems/Air Bag Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box, Supplemental Restraint System Module (SRS)
- With the ignition off and the contact reel connector disconnected, the resistance between terminals #3 and #4 on the contact reel connector (SRS control module side) should be approximately 22 kohms.
- With the ignition off and the connectors for the contact reel and the control module disconnected, the resistance between the terminals #3 and #4 on the contact reel connector (SRS control module side) should be infinite
- For information about the repair of SRS wiring, see Cable harness SRS system, repair See: Restraint Systems/Air Bag Systems/Air Bag/Air Bag Harness/Service and Repair/Procedures
- For other values, see Signal specification See: Restraint Systems/Air Bag Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Specification, Supplemental Restraint System Module (SRS).

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition

One of the following diagnostic trouble codes (DTCs) will be stored if the resistance in any of the wiring circuits is lower than 10 ohms for longer than 10 seconds:
SRS-0016, SRS-001E,
SRS-0026, SRS-002E,
SRS-0036, SRS-003E,
SRS-0046, SRS-004E,
SRS-0056, SRS-005E,
SRS-0066, SRS-006E
depending on which wiring circuit the fault is in.

Possible source

- If the SRS control module identifies that an airbag or a seat belt tensioner is installed, despite the control module being programmed that neither should be installed.

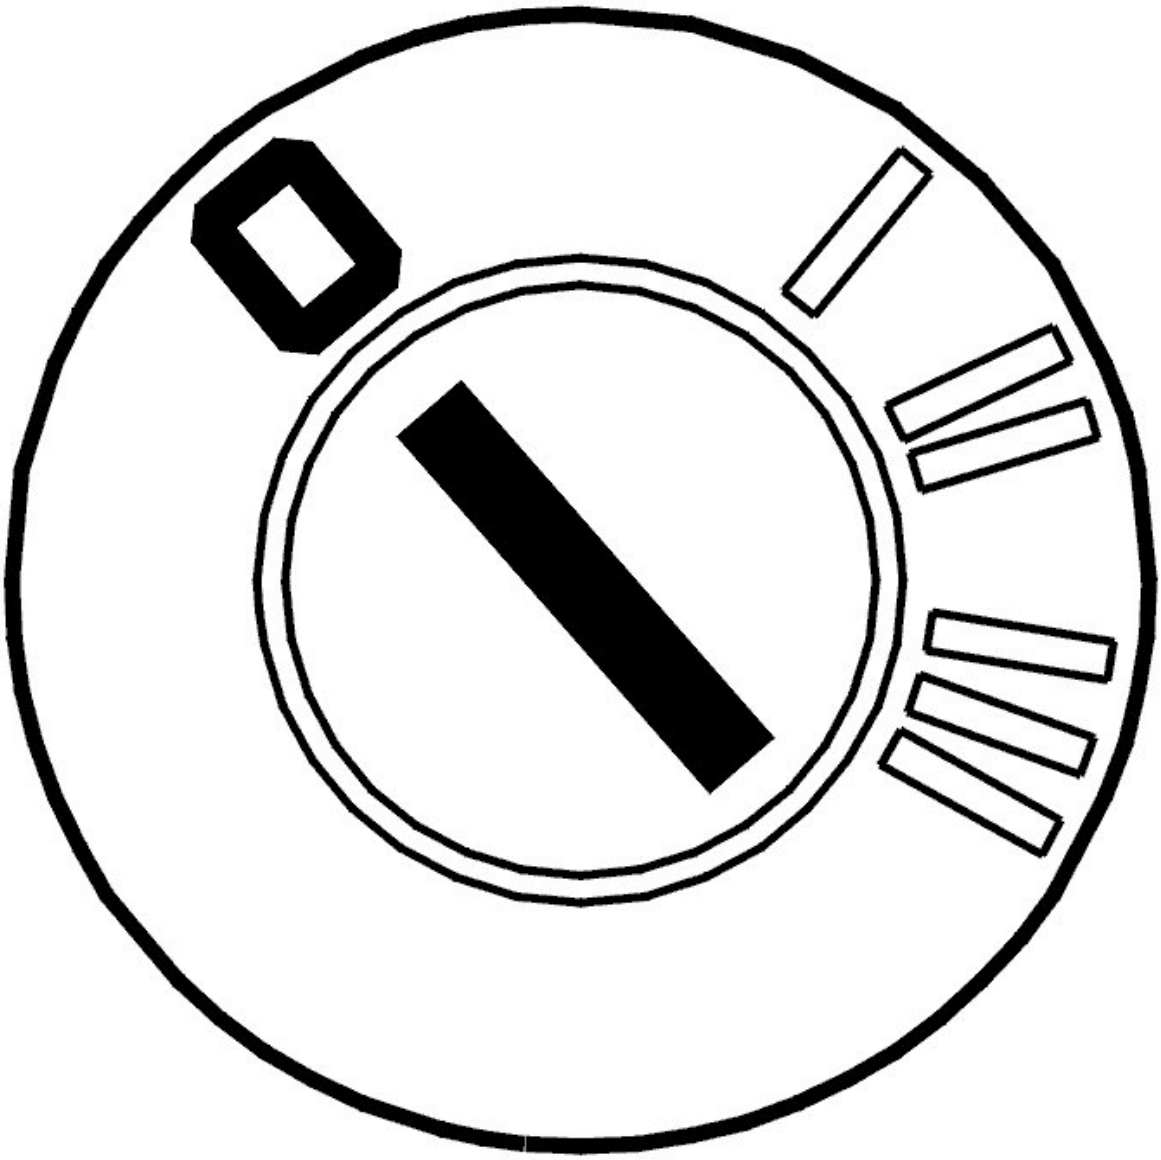
Fault symptom[s]

The SRS indicator lamp is lit.

Configuration Fault

Configuration fault. Permanent fault

Checking the component

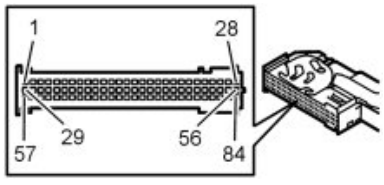


- Ignition off.

Check the control module and SRS system connectors to ensure that no terminal pins are damaged. Also check the wiring.
Check that the correct SRS control module is installed in the car. Read off by clicking the VCT2000 symbol.
Replace the control module if no fault is found.

Other information:

- To access or replace the control module, see Control module SRS (supplemental restraint system), replacing See: Relays and Modules/Relays and Modules - Restraint Systems/Air Bag Control Module/Service and Repair
- For other values, see Signal specification See: Restraint Systems/Air Bag Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Specification, Supplemental Restraint System Module (SRS).



Select "Continue".

Fault-tracing information

Information

Fault-tracing information

If the fault is intermittent, do not verify fault-tracing if the fault does not recur.

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

It is possible to view the information again, or leave fault-tracing for this diagnostic trouble code (DTC).

Do you want to view the information again?

Yes - Attempt New Test

No - Fault Found

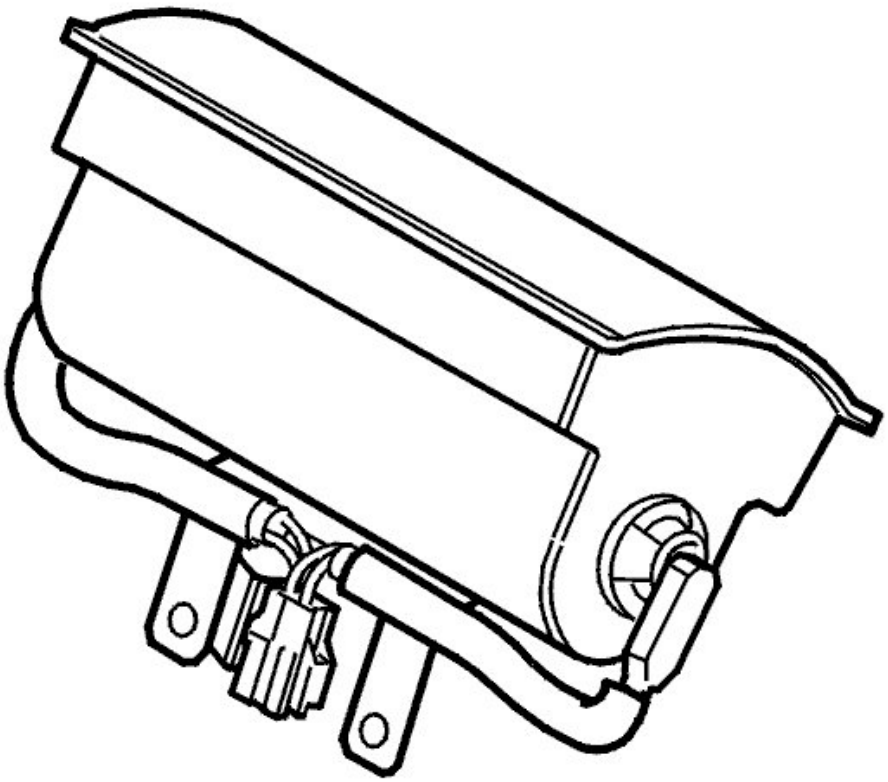
Attempt New Test - Intermittent fault

FAULT FOUND - DONE

Diagnostic Trouble Code (DTC) Information

SRS-0023 Diagnostic trouble code information

Condition



If the circuit capacitance is too low for more than 10 seconds, diagnostic trouble code SRS-0023 is displayed.

Substitute value
- Nothing.

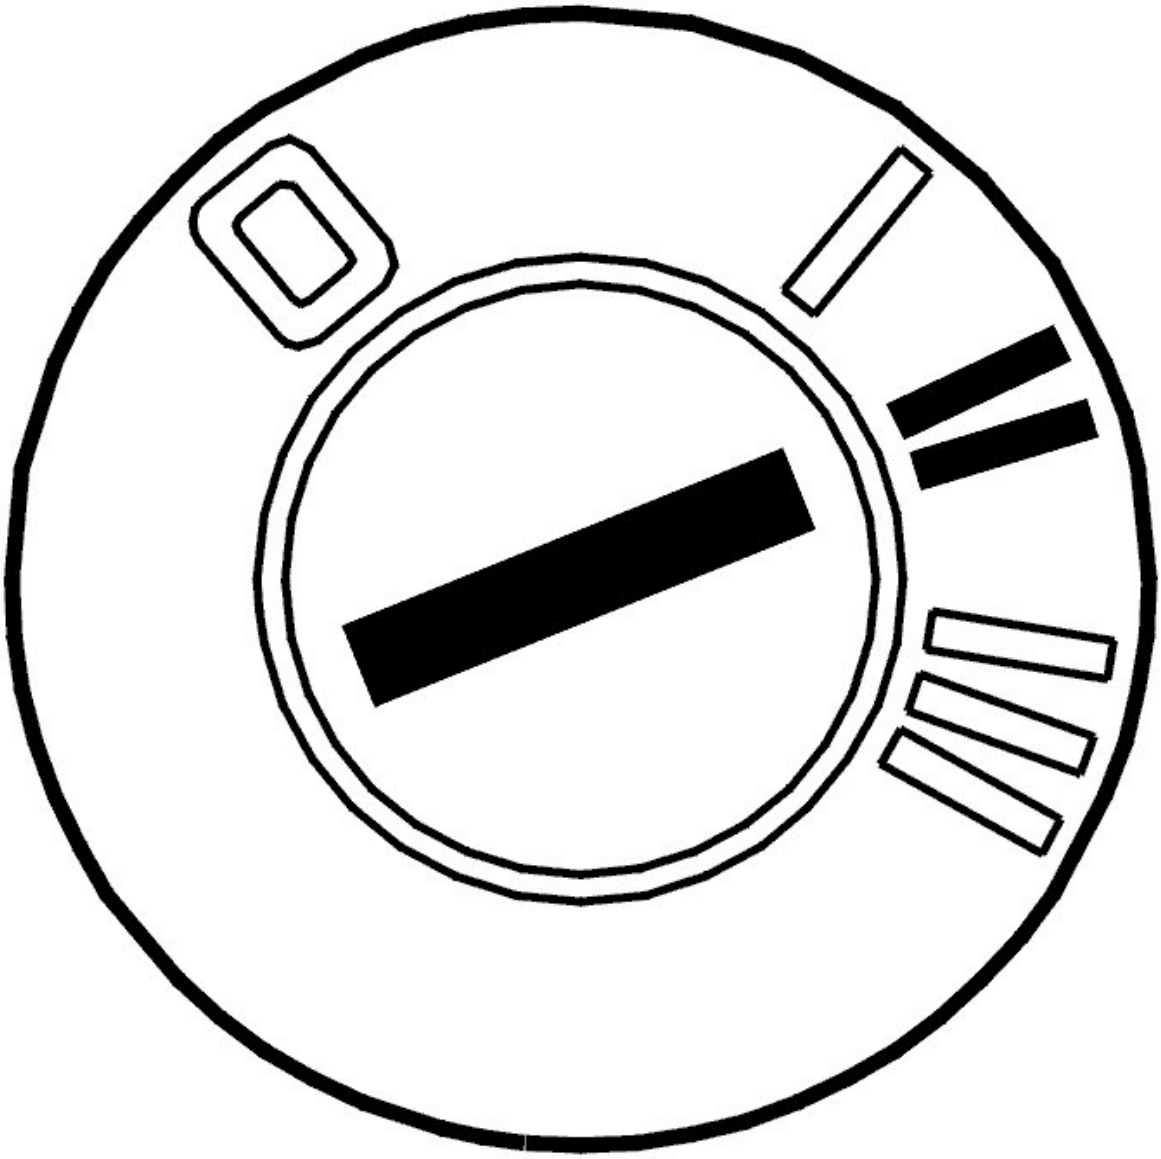
Possible source
- Capacitance too high or short circuit in in-built capacitor in igniter wire connector.

Fault symptom[s]
- SRS warning lamp on.

Capacitance Too Low

Capacitance too low. Permanent fault

Checking the component



- Ignition off
- Disconnect the (green) connector from the airbag on the passenger side
- Connect special tool951 1506 Test dummy See: Tools and Equipment/951 1506 Test Dummy to the airbag connector (green) on the passenger side

Warning! Under no circumstances use an ohmmeter or other live measuring instrument to take readings on a disconnected, non-deployed, pyrotechnical airbag. This could deploy the airbag!

Note! The special tool must be checked and fault-free. If the tool is defective, the diagnosis readings will be incorrect. This will make fault-tracing harder.

- Switch on the ignition. Wait 10 seconds.

Read off diagnostic trouble codes (DTCs).
Try a new airbag on the passenger side if the diagnostic trouble code (DTC) changes status from a permanent to an intermittent fault.

Other information:

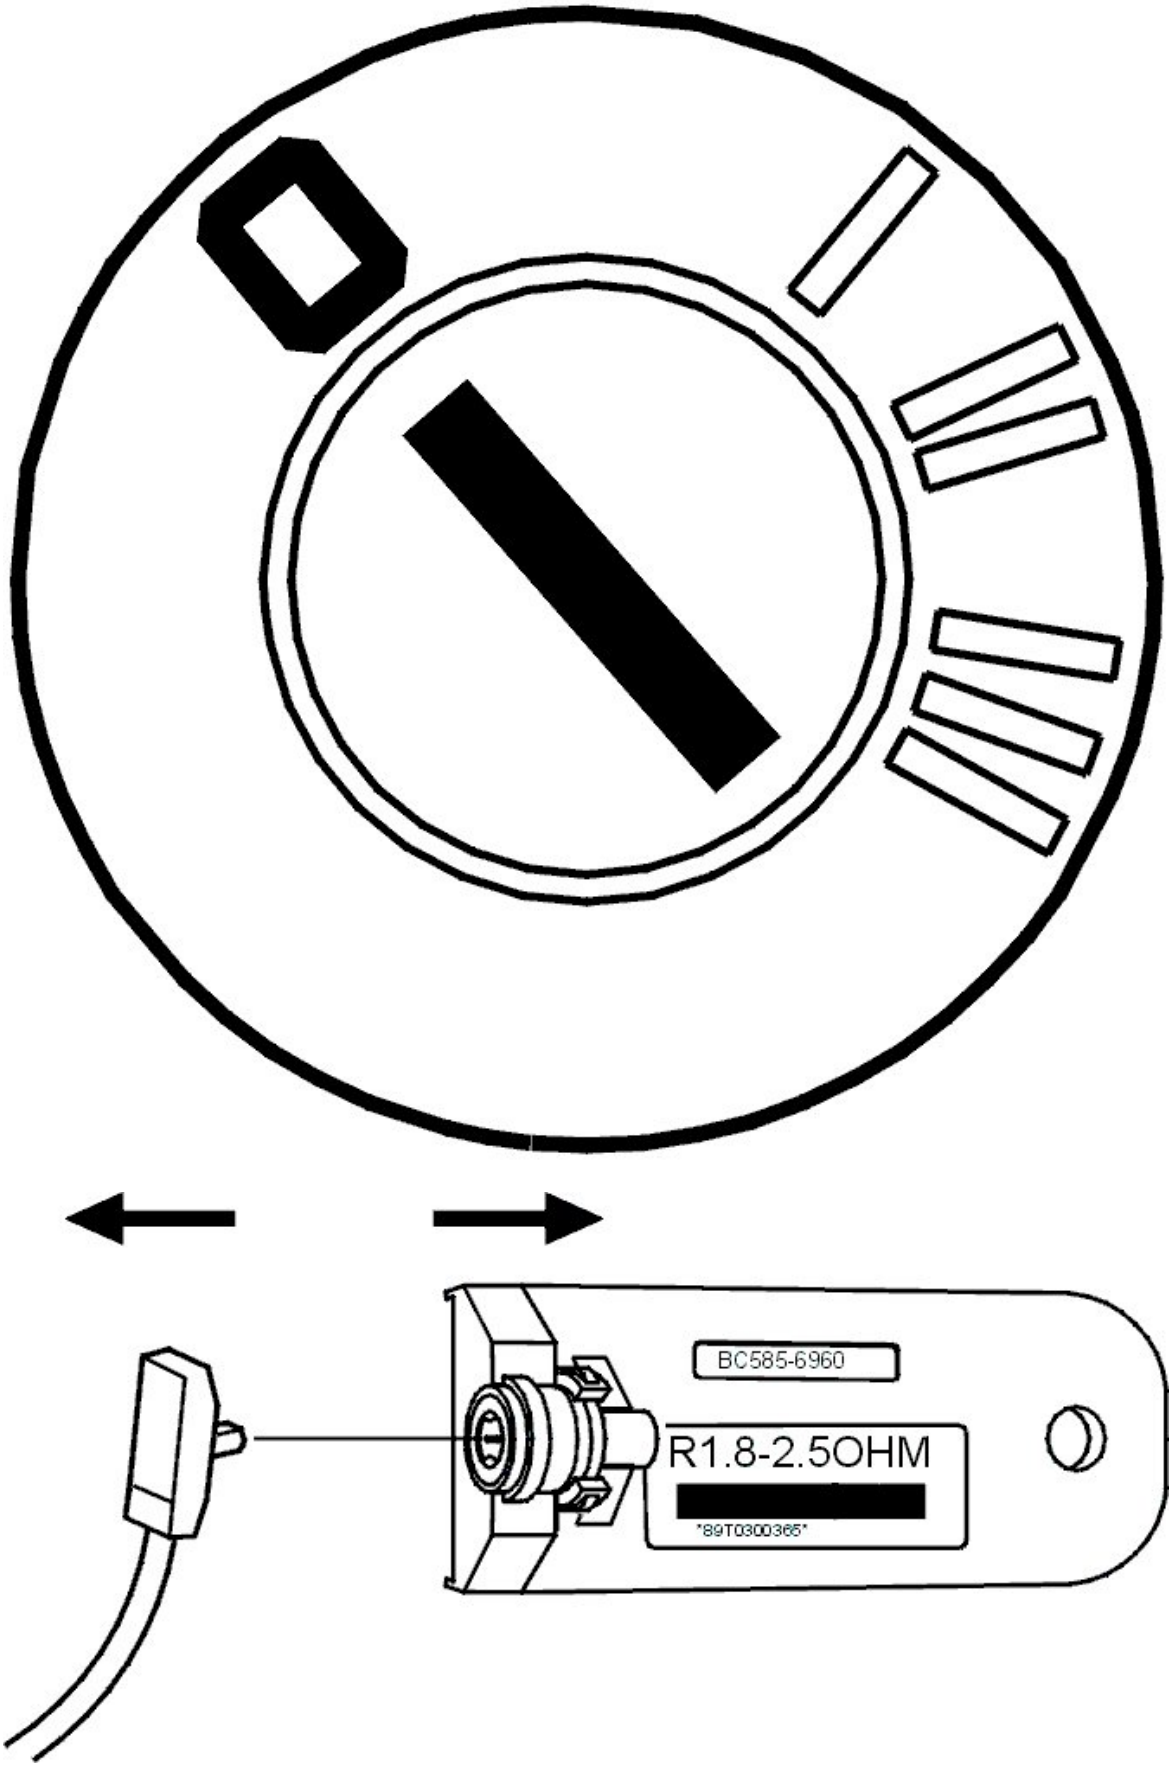
- To access or replace the airbag on the passenger side, see Airbag passenger (SRS), replacing See: Restraint Systems/Air Bag Systems/Air Bag/Service and Repair/Airbag Passenger (SRS), Replacing
- To check the special tool, see Calibration See: Restraint Systems/Service and Repair/Calibrating the Special Tool.

Does the status of the diagnostic trouble code (DTC) change?

Yes - Verification

No - Checking components and wiring

Checking components and wiring



- Ignition off
- Disconnect special tool951 1506 Test dummy See: Tools and Equipment/951 1506 Test Dummy from the airbag connector (green) on the passenger side.

Warning! Under no circumstances use an ohmmeter or other live measuring instrument to take readings on a disconnected, non-deployed, pyrotechnical airbag. This could deploy the airbag!

Caution! Do not touch the terminal pins in the SRS control module. There is a risk of static discharge. This could damage the SRS control module.

Check the female and male sections of the connector for the SRS control module and the 4-pin connector. The cable terminals must not be damaged or pressed back.
Check the cable between SRS control module terminal #12B (40) and terminal #1 of the connector (green) on the passenger side airbag for an open-circuit according to Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault.
Check the cable between SRS control module terminal #11B (39) and terminal #3 of the connector (green) on the passenger side airbag for an open-circuit according to Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault.

Hint: Check the integrated capacitor in the igniter connector: Measure the resistance.
With the ignition off, connect the test instrument probes between terminals #1 and #3 on the driver's airbag connector (green). The ohmmeter reading should rise rapidly to infinity.
Reverse the position of the ohmmeter positive and negative test probes. Connect them to the connector as in the previous measurement. The ohmmeter reading should drop rapidly to approximately 0 ohms and then increase to infinity.

Remedy as necessary.

Other information:

- To access and replace the SRS control module and connector, see Control module SRS (supplemental restraint system), replacing See: Relays and Modules/Relays and Modules - Restraint Systems/Air Bag Control Module/Service and Repair
- To access the connector (green) for the passenger airbag, see Airbag passenger (SRS), replacing See: Restraint Systems/Air Bag Systems/Air Bag/Service and Repair/Airbag Passenger (SRS), Replacing
- To connect the breakout box, see Connecting the breakout box See: Restraint Systems/Air Bag Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box, Supplemental Restraint System Module (SRS)
- With the ignition off and the 4-pin connector disconnected, the resistance between terminals #1 and #2 on the 4-pin connector (SRS control module side) should be approximately 22 kohms.
- To repair the wiring, see Cable harness SRS system, repair See: Restraint Systems/Air Bag Systems/Air Bag/Air Bag Harness/Service and Repair/Procedures
- For other values, see Signal specification See: Restraint Systems/Air Bag Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Specification, Supplemental Restraint System Module (SRS).

VERIFIED - Fault Found

VERIFICATION FAILED - Fault-tracing information

Diagnostic Trouble Code (DTC) Information

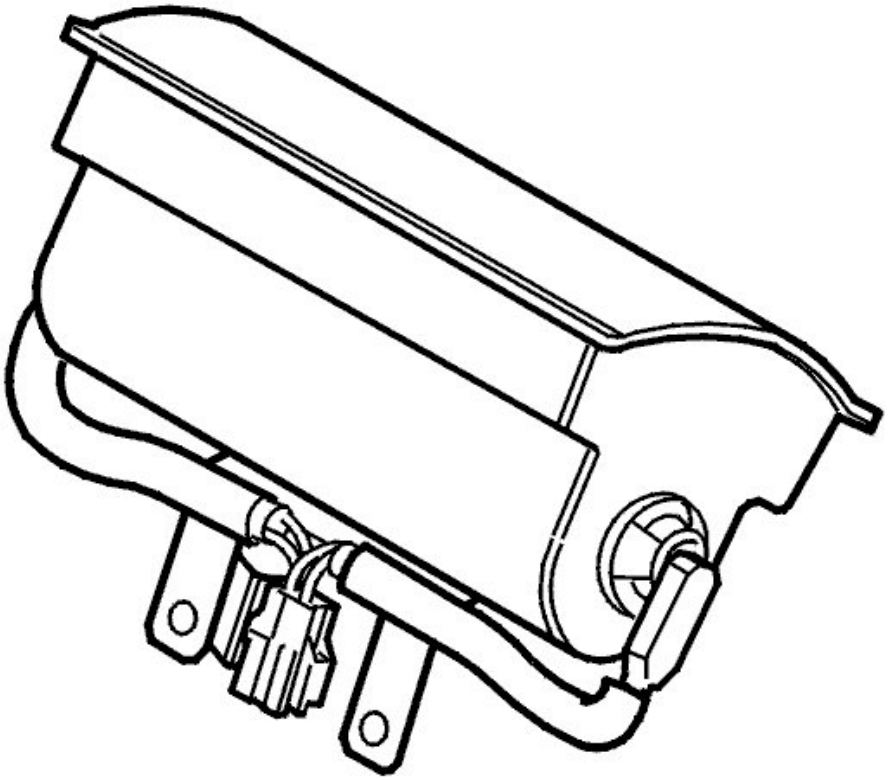
SRS-0028 Diagnostic trouble code information

Condition



If the circuit voltage is too high for more than 10 seconds, diagnostic trouble code SRS-0028 is displayed.

Substitute value
- Nothing.

Possible source
- Short circuit to voltage supply in igniter wire or connectors between the air bag and SRS sensor unit
- Short circuit to voltage supply in air bag.

Fault symptom[s]
- SRS warning lamp on.

Signal Too High

Signal too high. Permanent fault

Checking the component

- Ignition off
- Disconnect the (violet) connector from the airbag on the passenger side
- Connect special tool 951 1506 Test dummy See: Tools and Equipment/951 1506 Test Dummy to the airbag connector (violet) on the passenger side

Warning! Under no circumstances use an ohmmeter or other live measuring instrument to take readings on a disconnected, non-deployed, pyrotechnical airbag. This could deploy the airbag!

Note! The special tool must be checked and fault-free. If the tool is defective, the diagnosis readings will be incorrect. This will make fault-tracing harder.

- Switch on the ignition. Wait 10 seconds.

Read off diagnostic trouble codes (DTCs).
Try a new airbag on the passenger side if the diagnostic trouble code (DTC) changes status from a permanent to an intermittent fault.

Other information:

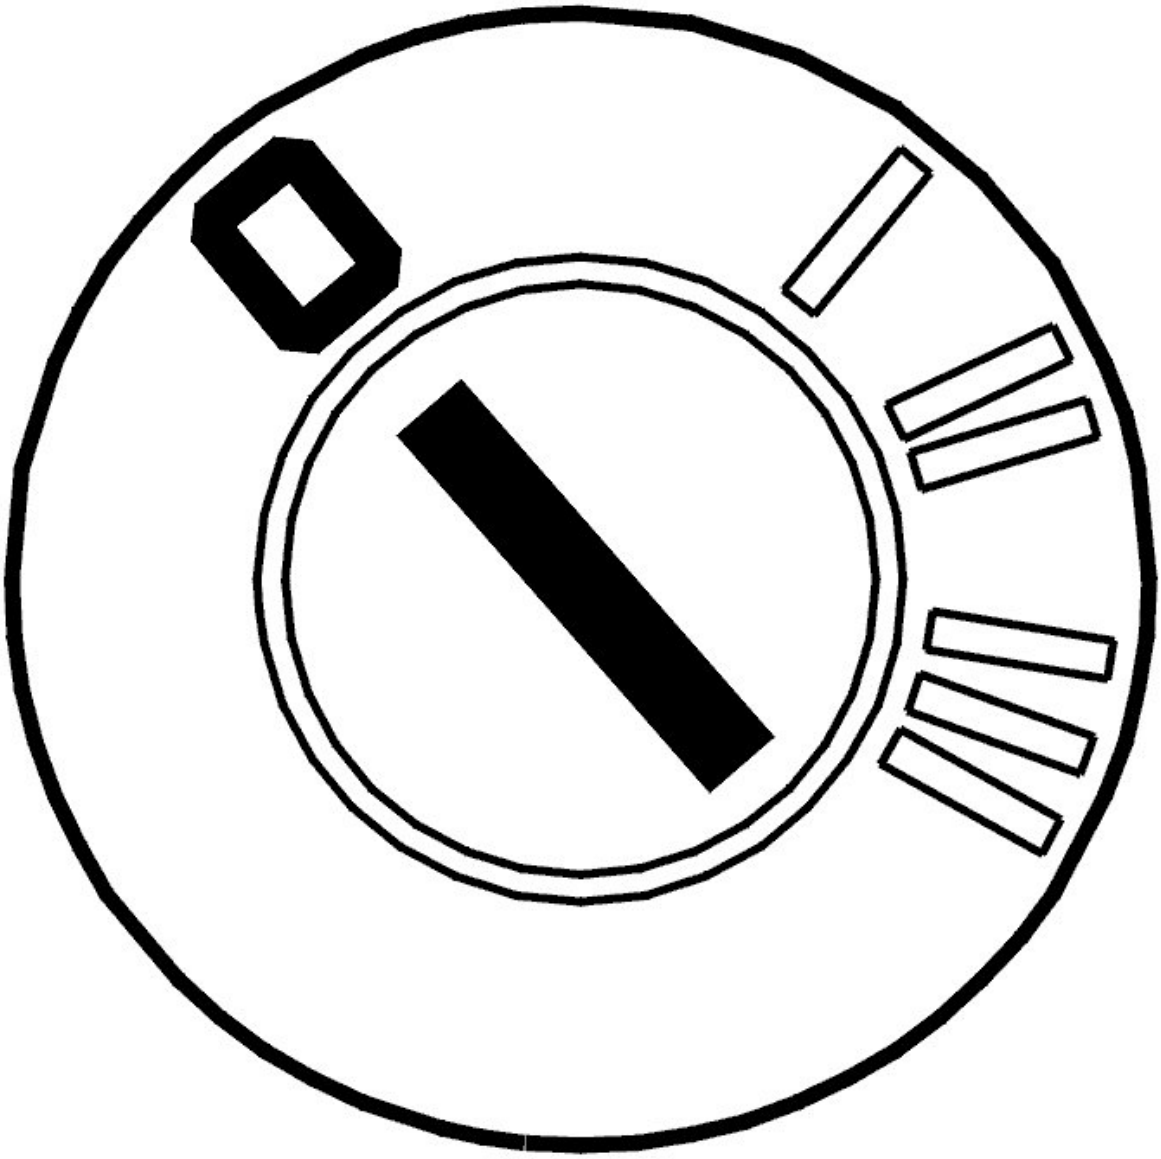
- To access or replace the airbag on the passenger side, see Airbag passenger (SRS), replacing See: Restraint Systems/Air Bag Systems/Air Bag/Service and Repair/Airbag Passenger (SRS), Replacing
- To check the special tool, see Calibration See: Restraint Systems/Service and Repair/Calibrating the Special Tool

Does the status of the diagnostic trouble code (DTC) change?

Yes - Verification

No - Checking components and wiring

Checking components and wiring



- Ignition off
- Disconnect special tool 951 1506 Test dummy See: Tools and Equipment/951 1506 Test Dummy from the airbag connector (green) on the passenger side.

Warning! Under no circumstances use an ohmmeter or other live measuring instrument to take readings on a disconnected, non-deployed, pyrotechnical airbag. This could deploy the airbag!

Caution! Do not touch the terminal pins in the SRS control module. There is a risk of static discharge. This could damage the SRS control module.

Check the cable between SRS control module terminal #12B (40) and connector (violet) terminal #1 on the passenger side airbag for a short-circuit to supply voltage according to Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault.
Check the cable between SRS control module terminal #11B (39) and connector (violet) terminal #3 on the passenger side airbag for a short-circuit to supply voltage according to Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault.

Other information:

Diagnostic Trouble Code (DTC) Information

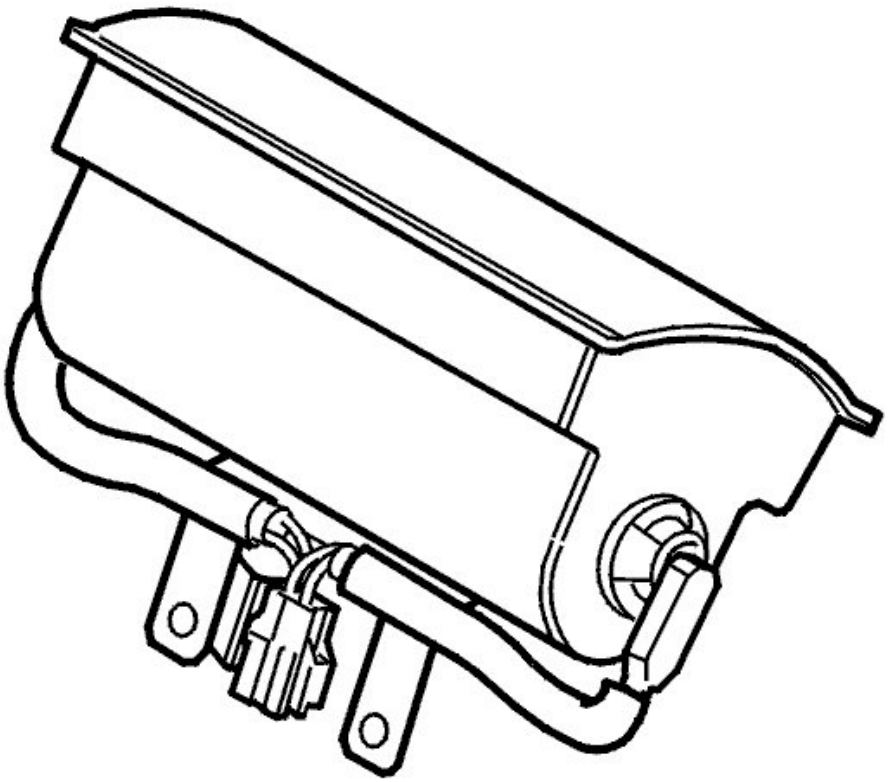
SRS-002B Diagnostic trouble code information

Condition



If the circuit capacitance is low for more than 10 seconds, diagnostic trouble code SRS-002B is displayed.

Substitute value
- Nothing.

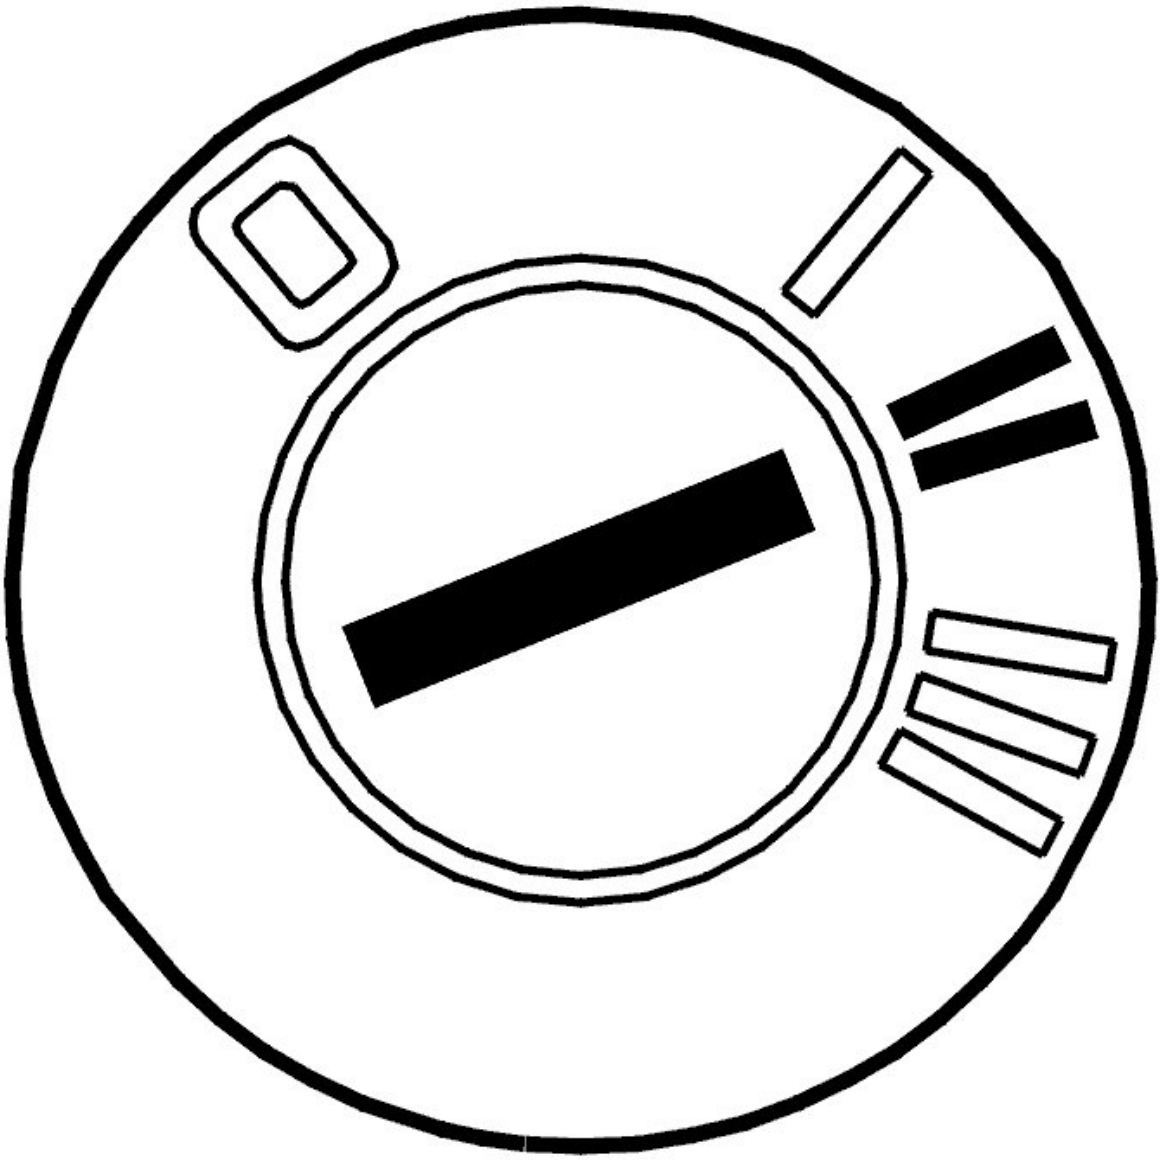
Possible source
- Capacitance too low or open circuit in in-built capacitor in igniter wire connector.

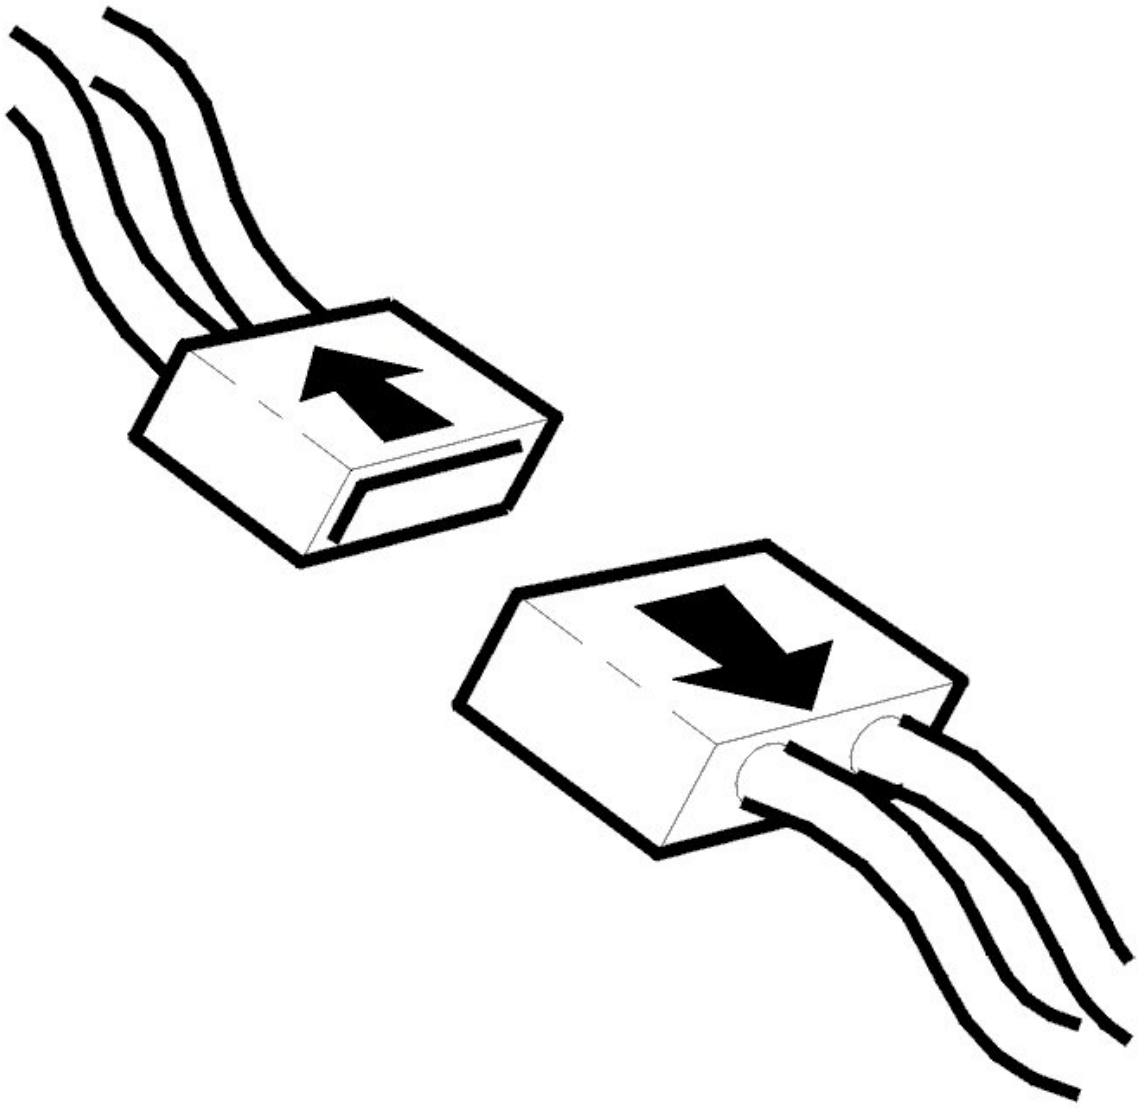
Fault symptom[s]
- SRS warning lamp on.

Capacitance Too Low

Capacitance too low. Permanent fault

Checking the component





- Ignition off
- Disconnect the (violet) connector from the airbag on the passenger side
- Connect special tool951 1506 Test dummy See: Tools and Equipment/951 1506 Test Dummy to the airbag connector (violet) on the passenger side

Warning! Under no circumstances use an ohmmeter or other live measuring instrument to take readings on a disconnected, non-deployed, pyrotechnical airbag. This could deploy the airbag!

Note! The special tool must be checked and fault-free. If the tool is defective, the diagnosis readings will be incorrect. This will make fault-tracing harder.

- Switch on the ignition. Wait 10 seconds.

Read off diagnostic trouble codes (DTCs).
Try a new airbag on the passenger side if the diagnostic trouble code (DTC) changes status from a permanent to an intermittent fault.

Other information:

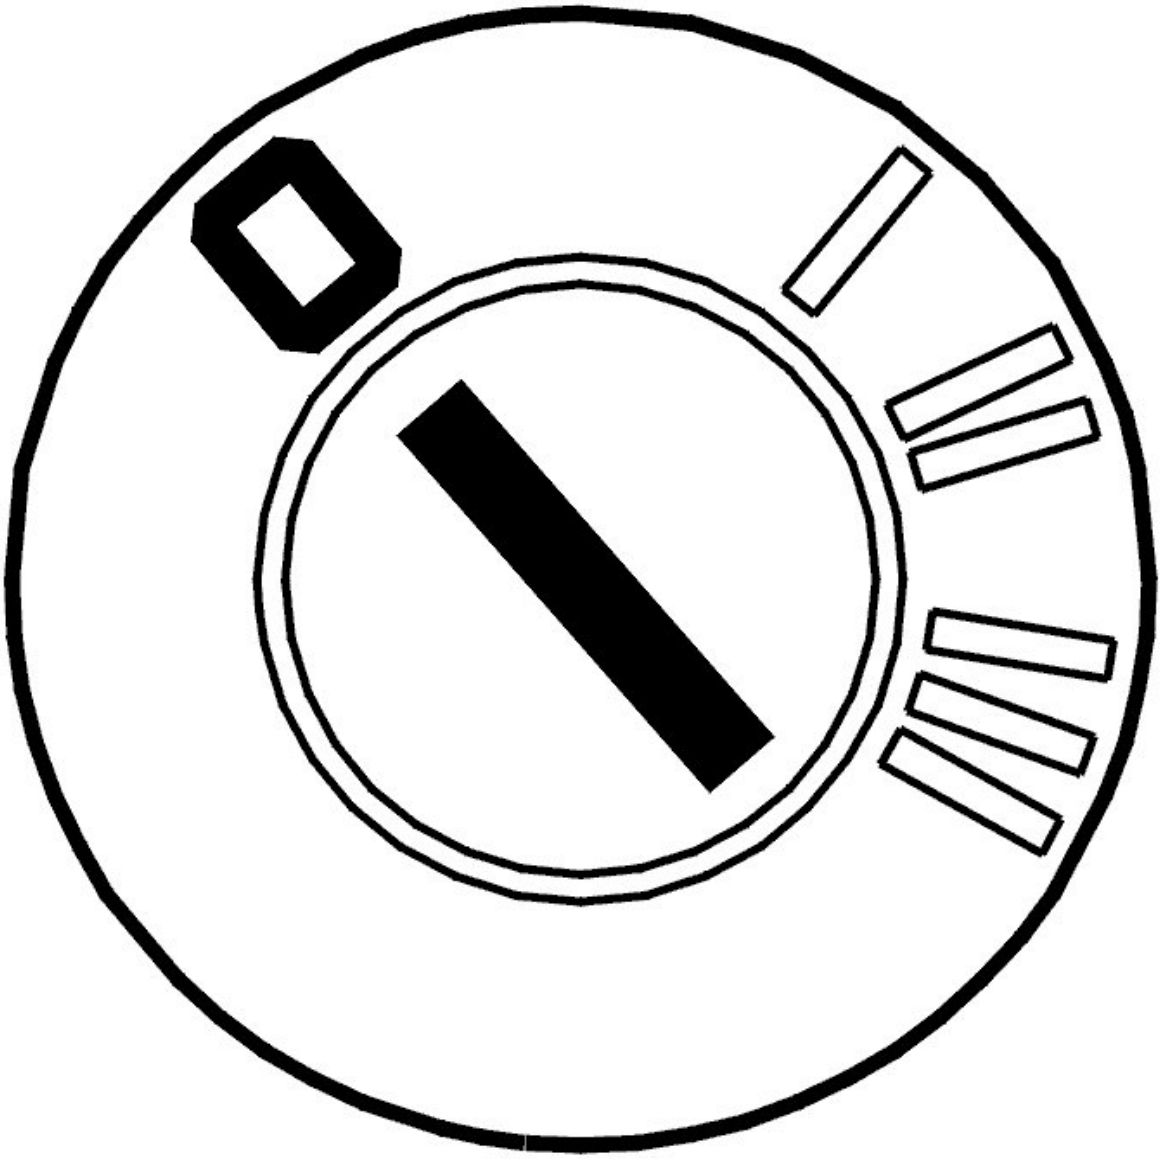
- To access or replace the airbag on the passenger side, see Airbag passenger (SRS), replacing See: Restraint Systems/Air Bag Systems/Air Bag/Service and Repair/Airbag Passenger (SRS), Replacing
- To check the special tool, see Calibration See: Restraint Systems/Service and Repair/Calibrating the Special Tool

Does the status of the diagnostic trouble code (DTC) change?

Yes - Verification

No - Checking components and wiring

Checking components and wiring



- Ignition off
- Disconnect special tool951 1506 Test dummy See: Tools and Equipment/951 1506 Test Dummy from the airbag connector (violet) on the passenger side.

Warning! Under no circumstances use an ohmmeter or other live measuring instrument to take readings on a disconnected, non-deployed, pyrotechnical airbag. This could deploy the airbag!

Caution! Do not touch the terminal pins in the SRS control module. There is a risk of static discharge. This could damage the SRS control module.

Check the female and male sections of the connector for the SRS control module and the 4-pin connector. The cable terminals must not be damaged or pressed back.
Check the cable between SRS control module terminal #13B (41) and connector (violet) terminal #1 on the passenger side airbag for an open-circuit according to Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault.
Check the cable between SRS control module terminal #14B (42) and connector (violet) terminal #3 on the passenger side airbag for an open-circuit according to Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault.

Hint: Check the integrated capacitor in the igniter connector: Measure the resistance.
With the ignition off, connect the test instrument probes between terminals #1 and #3 on the connector (violet) for the driver's airbag. The ohmmeter reading should rise rapidly to infinity.
Reverse the position of the ohmmeter positive and negative test probes. Connect them to the connector as in the previous measurement. The

ohmmeter reading should drop rapidly to approximately 0 ohms and then increase to infinity.

Remedy as necessary.

Other information:

Fault-tracing information

The fault should have been detected and remedied. As this is not the case fault-tracing has failed.

Exit fault-tracing for this diagnostic trouble code (DTC) or make another attempt.

Do you want to exit fault-tracing?

Yes - FAULT-TRACING FAILED

No - Attempt New Test

FAULT-TRACING FAILED - FAULT-TRACING FAILED

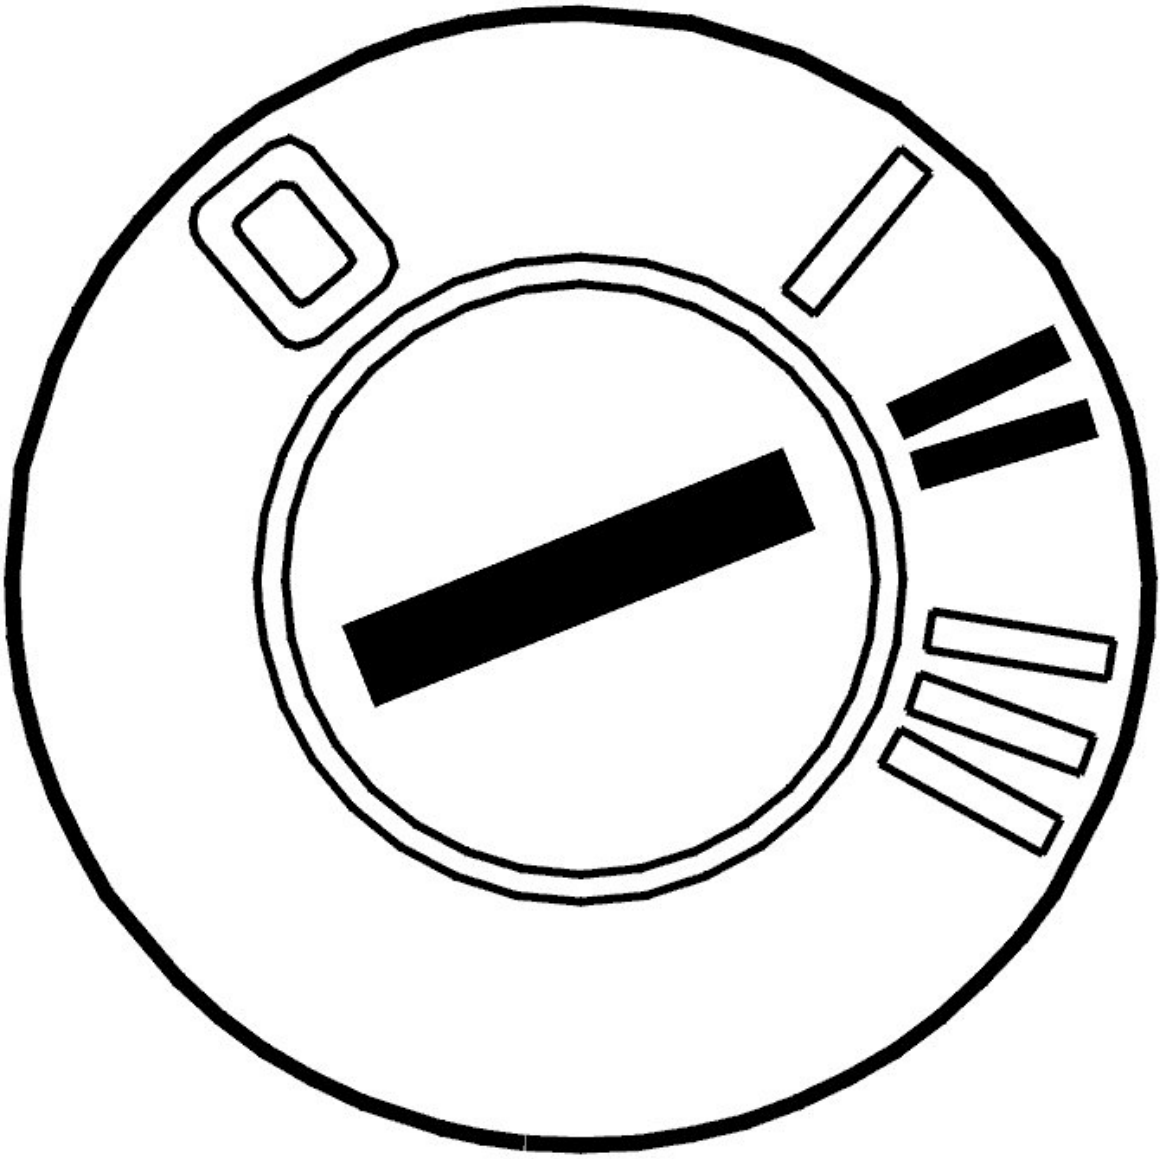
Attempt New Test - Checking the component

Verification

Verification

Verification

Hint: After carrying out the repair, check that the fault has been remedied.



- Ignition off
- Disconnect the battery negative lead
- Reinstall the connectors, components etc.
- Ignition on
- Connect the battery negative lead.

Warning! There must not be anyone inside the passenger compartment when the battery is connected.

- Read off diagnostic trouble codes (DTCs).

The fault is no longer present if the diagnostic trouble code (DTC) status is intermittent.

Is the diagnostic trouble code (DTC) intermittent?

Yes - VERIFIED

No - VERIFICATION FAILED

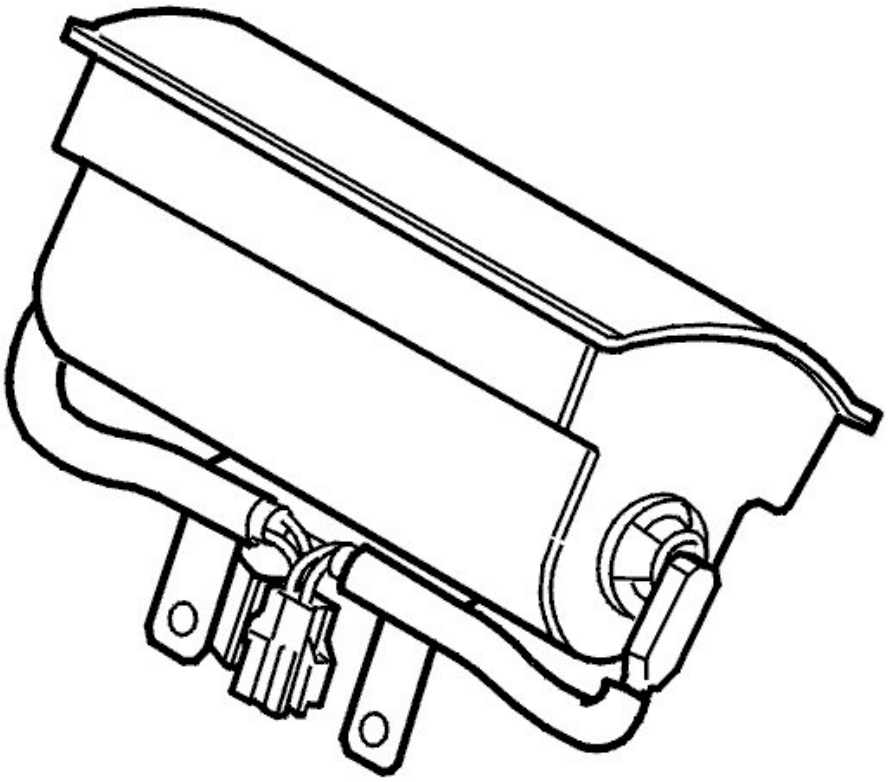
VERIFIED - Fault Found

VERIFICATION FAILED - Fault-tracing information

Diagnostic Trouble Code (DTC) Information

SRS-002B Diagnostic trouble code information

Condition



If the circuit capacitance is low for more than 10 seconds, diagnostic trouble code SRS-002B is displayed.

Substitute value

- Nothing.

Possible source

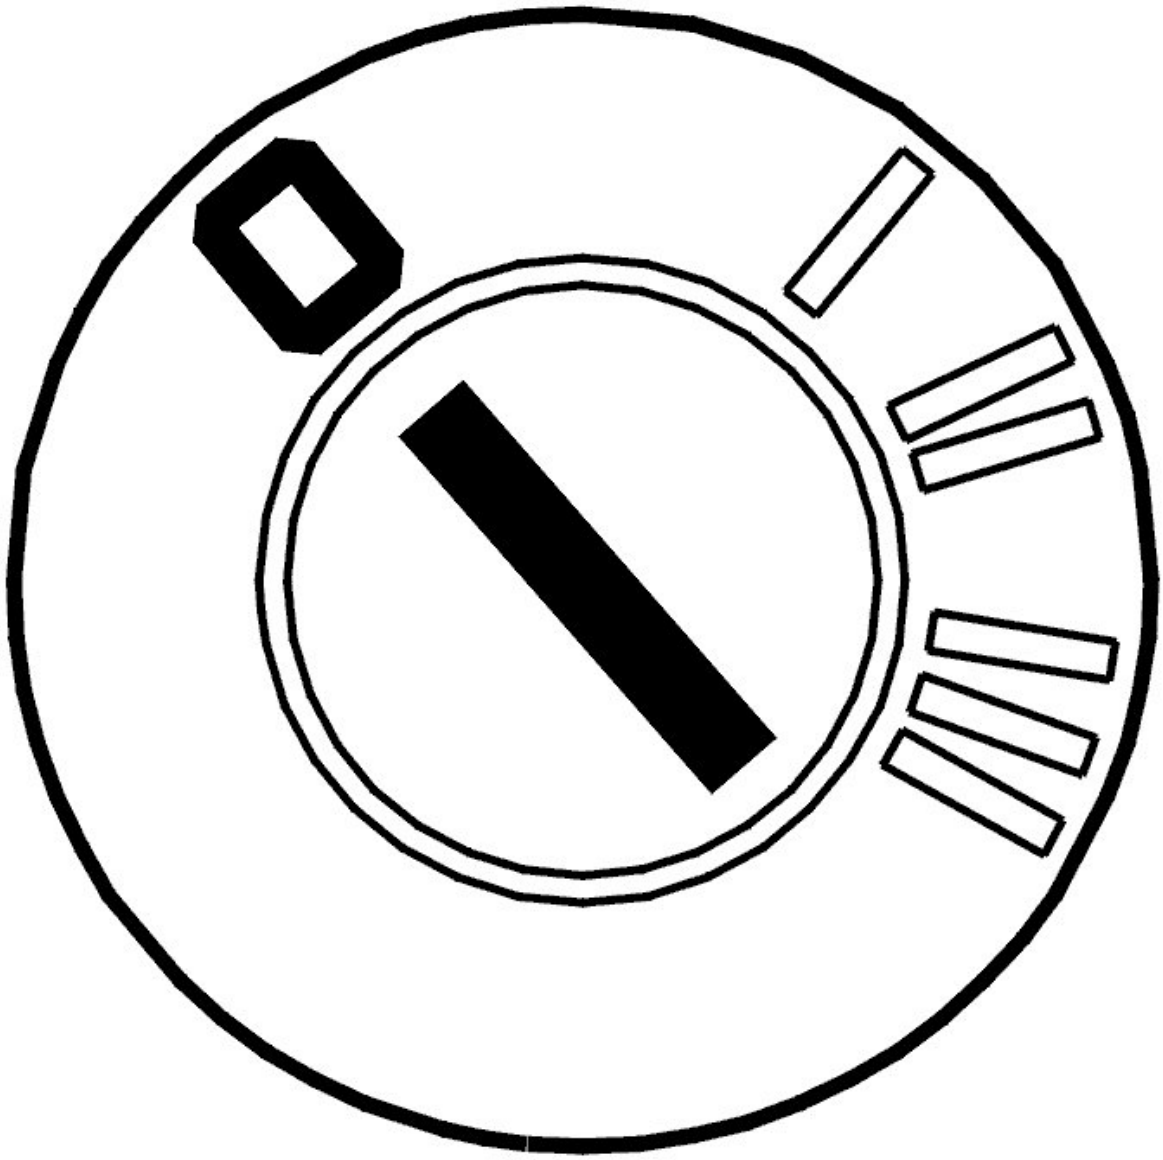
- Capacitance too low or open circuit in in-built capacitor in igniter wire connector.

Fault symptom[s]
- SRS warning lamp on.

Capacitance Too Low

Capacitance too low. Intermittent fault

Intermittent fault



- Ignition off.

Warning! Under no circumstances use an ohmmeter or other live measuring instrument to take readings on a disconnected, non-deployed, pyrotechnical airbag. This could deploy the airbag!

Caution! Do not touch the terminal pins in the SRS control module. There is a risk of static discharge. This could damage the SRS control module.

Check the connectors for:
- the airbag on the passenger side
- 4-pin
- the SRS control module.

check for contact resistance and oxidation. See Checking wiring and terminals. Intermittent faults See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Intermittent Faults. Check for loose connections. See Checking wiring and terminals. Intermittent faults See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Intermittent Faults.
Check the female and male sections of the connector for the SRS control module and the 4-pin connector. The cable terminals must not be damaged or pressed back.
Check the cable between SRS control module terminal #13B (41) and connector (violet) terminal #1 on the passenger side airbag for an intermittent open-circuit according to Checking wiring and terminals. Intermittent faults See: Testing and Inspection/Component Tests and General

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Intermittent Faults.
Check the cable between SRS control module terminal #14B (42) and connector (violet) terminal #3 on the passenger side airbag for an intermittent open-circuit according to Checking wiring and terminals. Intermittent faults See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Intermittent Faults.

Hint: Check the integrated capacitor in the igniter connector: Measure the resistance.
With the ignition off, connect the test instrument probes between terminals #1 and #3 on the connector (violet) for the driver's airbag. The ohmmeter reading should rise rapidly to infinity.
Reverse the position of the ohmmeter positive and negative test probes. Connect them to the connector as in the previous measurement. The ohmmeter reading should drop rapidly to approximately 0 ohms and then increase to infinity.

Remedy as necessary.

Other information:

- To access and replace the SRS control module and connector, see Control module SRS (supplemental restraint system), replacing See: Relays and Modules/Relays and Modules - Restraint Systems/Air Bag Control Module/Service and Repair
- To access the connector (green) for the passenger airbag, see Airbag passenger (SRS), replacing See: Restraint Systems/Air Bag Systems/Air Bag/Service and Repair/Airbag Passenger (SRS), Replacing
- To connect the breakout box, see Connecting the breakout box See: Restraint Systems/Air Bag Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box, Supplemental Restraint System Module (SRS)
- With the ignition off and the 4-pin connector disconnected, the resistance between terminals #1 and #2 on the 4-pin connector (SRS control module side) should be approximately 22 kohms.
- To replace the wiring, see Cable harness SRS system, repair See: Restraint Systems/Air Bag Systems/Air Bag/Air Bag Harness/Service and Repair/Procedures

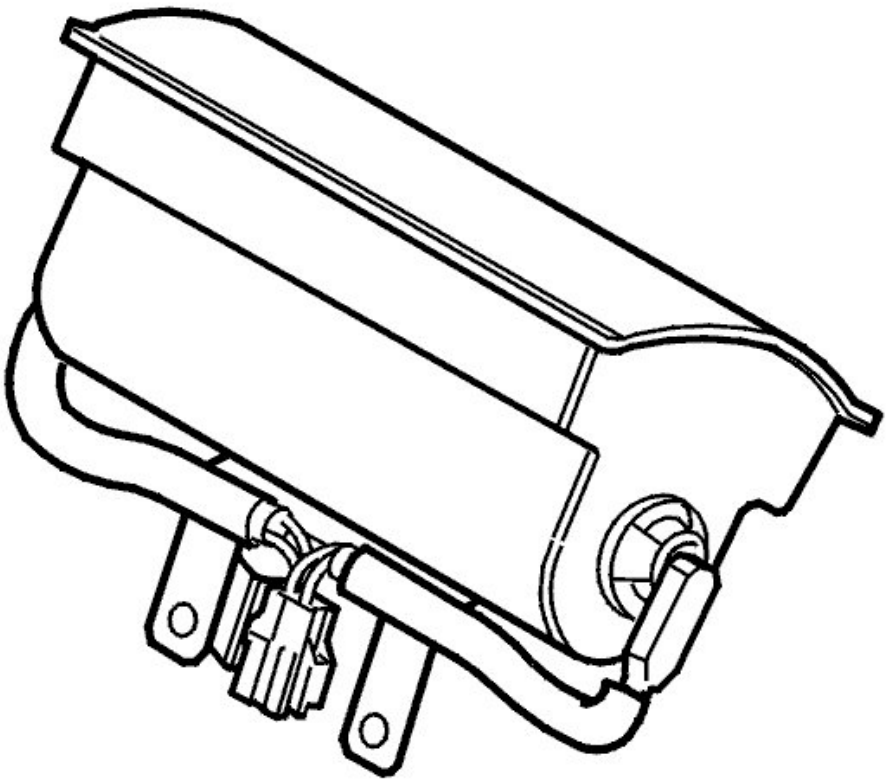
Diagnostic Trouble Code (DTC) Information

SRS-002C Diagnostic trouble code information

Condition



If the circuit resistance is too high for more than 10 seconds, diagnostic trouble code SRS-002C is displayed.

Substitute value
- Nothing.

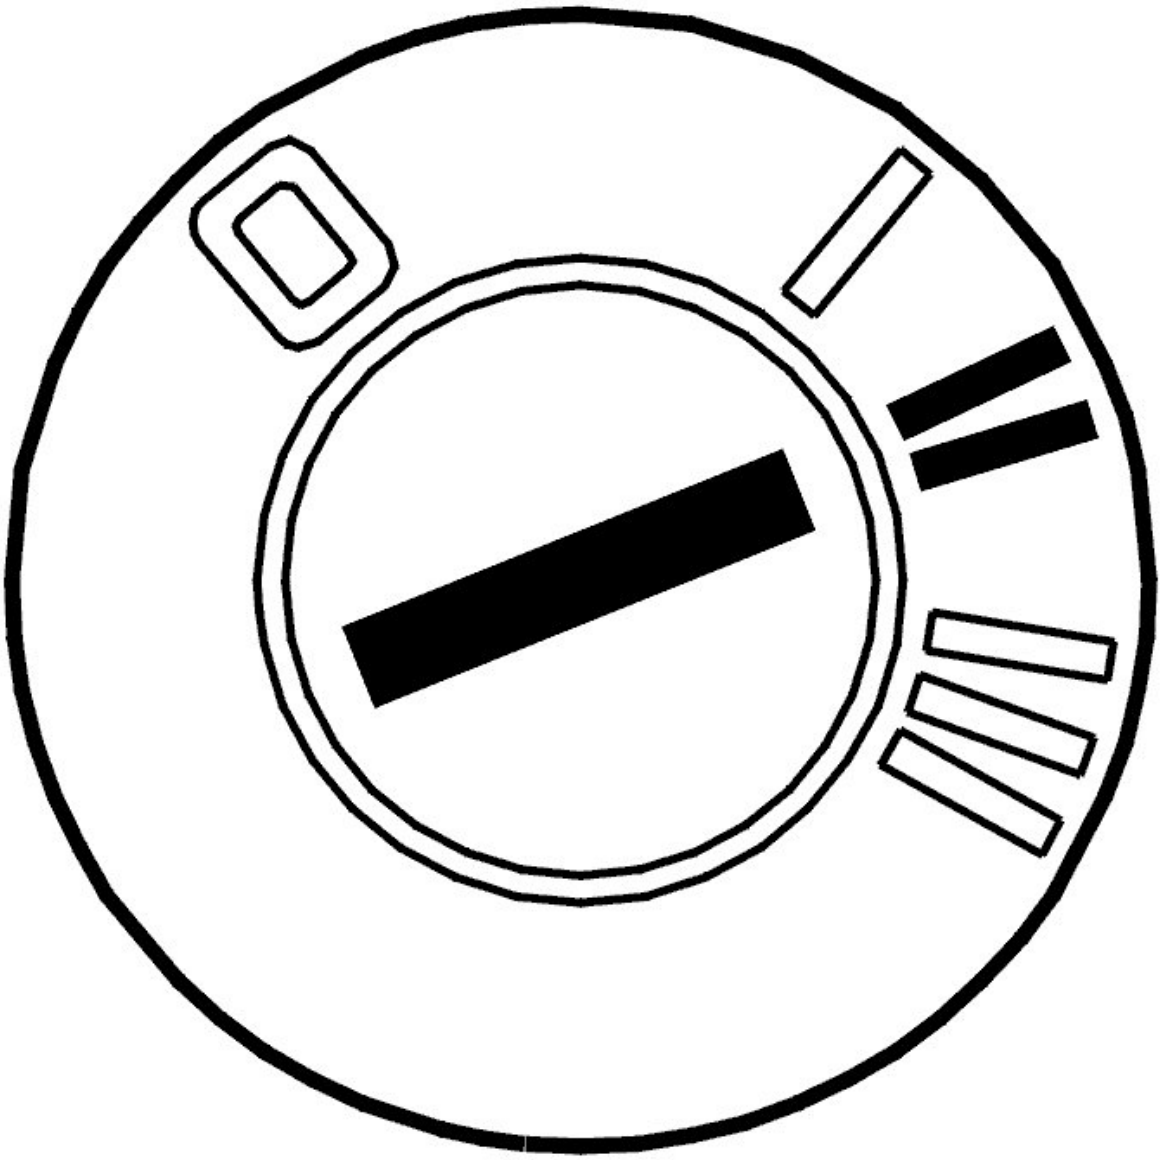
Possible source
- Open circuit in igniter wire or connectors between the air bag and the supplemental restraint system (SRS) control unit
- Open circuit in air bag (resistance in igniter too high).

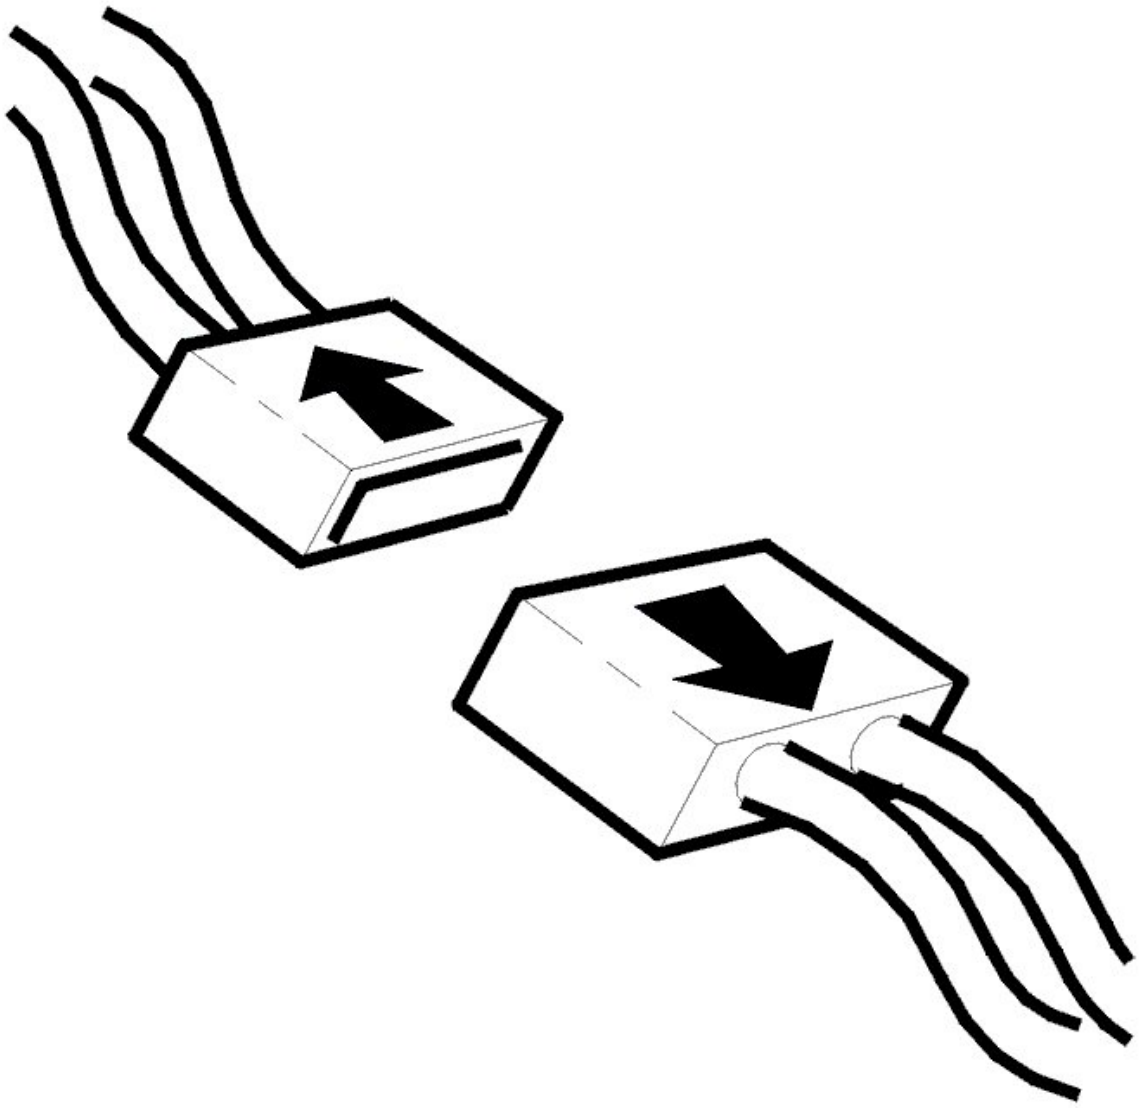
Fault symptom[s]
- SRS warning lamp on.

Resistance Too High

Resistance too high. Permanent fault

Checking the component





- Ignition off
- Disconnect the (violet) connector from the airbag on the passenger side
- Connect special tool951 1506 Test dummy See: Tools and Equipment/951 1506 Test Dummy to the airbag connector (violet) on the passenger side

Warning! Under no circumstances use an ohmmeter or other live measuring instrument to take readings on a disconnected, non-deployed, pyrotechnical airbag. This could deploy the airbag!

Note! The special tool must be checked and fault-free. If the tool is defective, the diagnosis readings will be incorrect. This will make fault-tracing harder.

- Switch on the ignition. Wait 10 seconds.

Read off diagnostic trouble codes (DTCs).
Try a new airbag on the passenger side if the diagnostic trouble code (DTC) changes status from a permanent to an intermittent fault.

Other information:

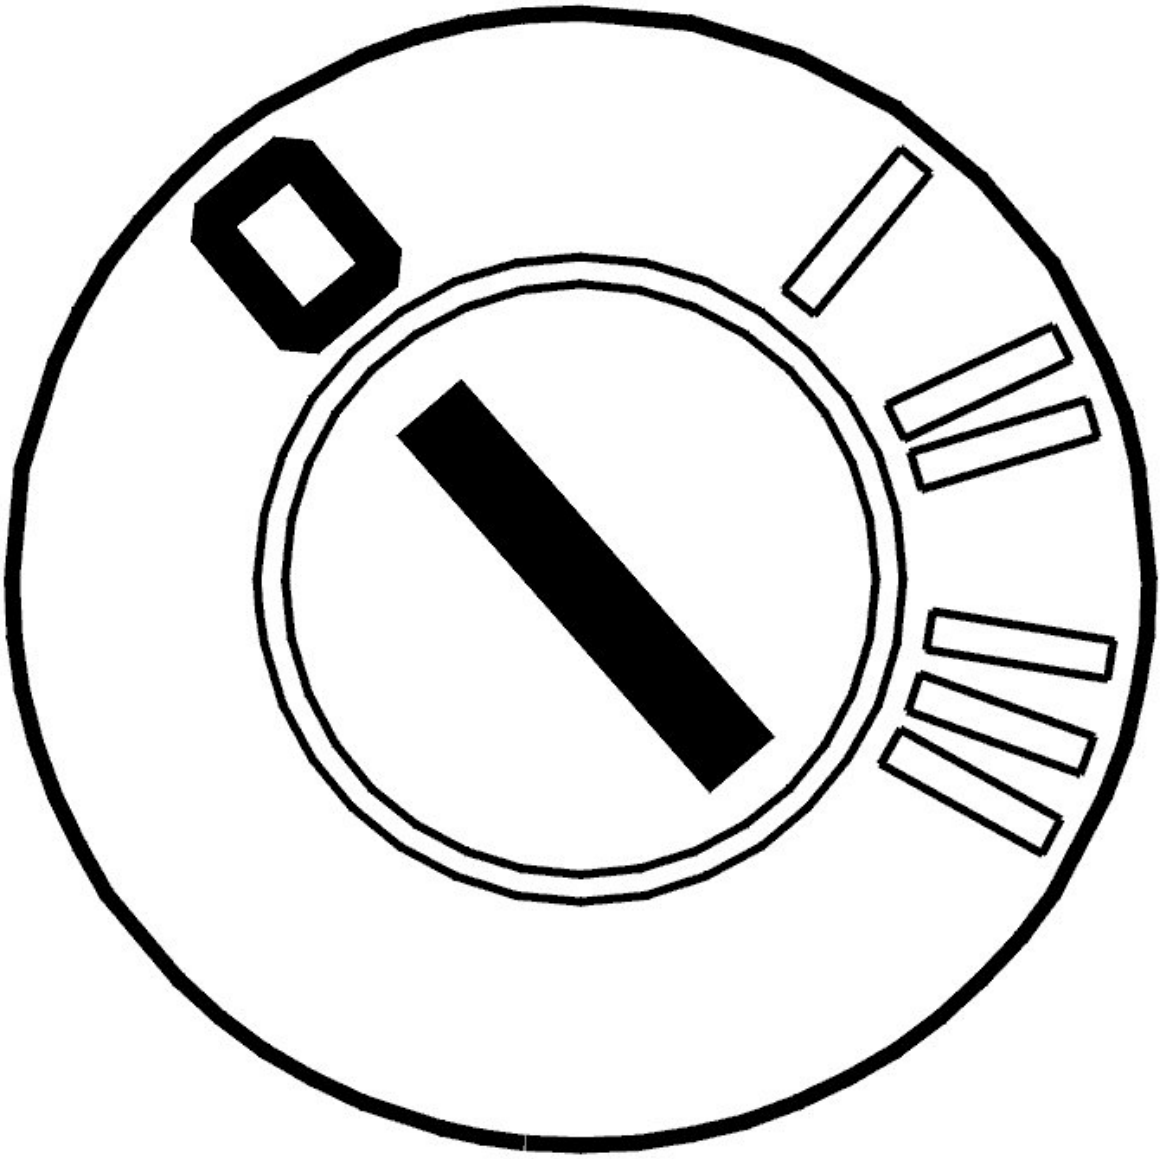
- To access or replace the airbag on the passenger side, see Airbag passenger (SRS), replacing See: Restraint Systems/Air Bag Systems/Air Bag/Service and Repair/Airbag Passenger (SRS), Replacing
- To check the special tool, see Calibration See: Restraint Systems/Service and Repair/Calibrating the Special Tool.

Does the status of the diagnostic trouble code (DTC) change?

Yes - Verification

No - Checking components and wiring

Checking components and wiring



- Ignition off
- Disconnect special tool951 1506 Test dummy See: Tools and Equipment/951 1506 Test Dummy from the airbag connector (violet) on the passenger side.

Warning! Under no circumstances use an ohmmeter or other live measuring instrument to take readings on a disconnected, non-deployed, pyrotechnical airbag. This could deploy the airbag!

Caution! Do not touch the terminal pins in the SRS control module. There is a risk of static discharge. This could damage the SRS control module.

Check the female and male sections of the connector for the SRS control module and the 4-pin connector. The cable terminals must not be damaged or pressed back.
Check the cable between SRS control module terminal #13B (41) and connector (violet) terminal #1 on the passenger side airbag for an open-circuit according to Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault.
Check the cable between SRS control module terminal #14B (42) and connector (violet) terminal #3 on the passenger side airbag for an open-circuit according to Checking wiring and terminals. Fault-tracing information

If the fault is intermittent, do not verify fault-tracing if the fault does not recur.
It is possible to view the information again, or leave fault-tracing for this diagnostic trouble code (DTC).

Do you want to view the information again?

Yes - Attempt New Test

No - Fault Found

Attempt New Test - Intermittent fault

FAULT FOUND - DONE

Diagnostic Trouble Code (DTC) Information

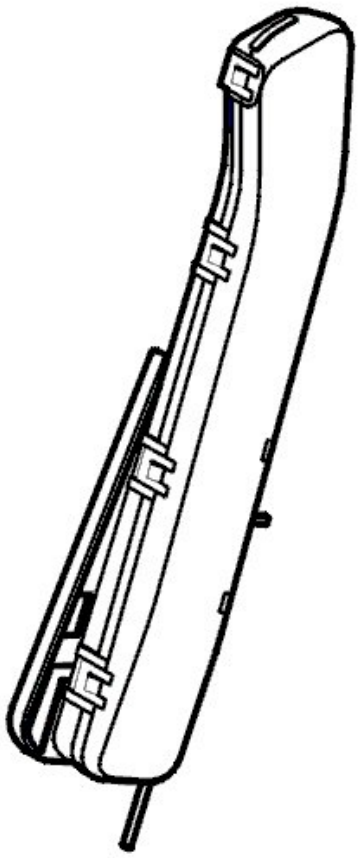
SRS-0030 Diagnostic trouble code information

Condition



If the circuit voltage is high for more than 10 seconds, diagnostic trouble code SRS-0030 is displayed.

Substitute value
- Nothing.

Possible source
- Short circuit to voltage supply in igniter wire or connectors between the front left/right side air bags and the supplemental restraint system (SRS) control unit
- Short circuit to voltage supply in the front left side air bag.

Fault symptom[s]
- SRS warning lamp on.

Signal Too High

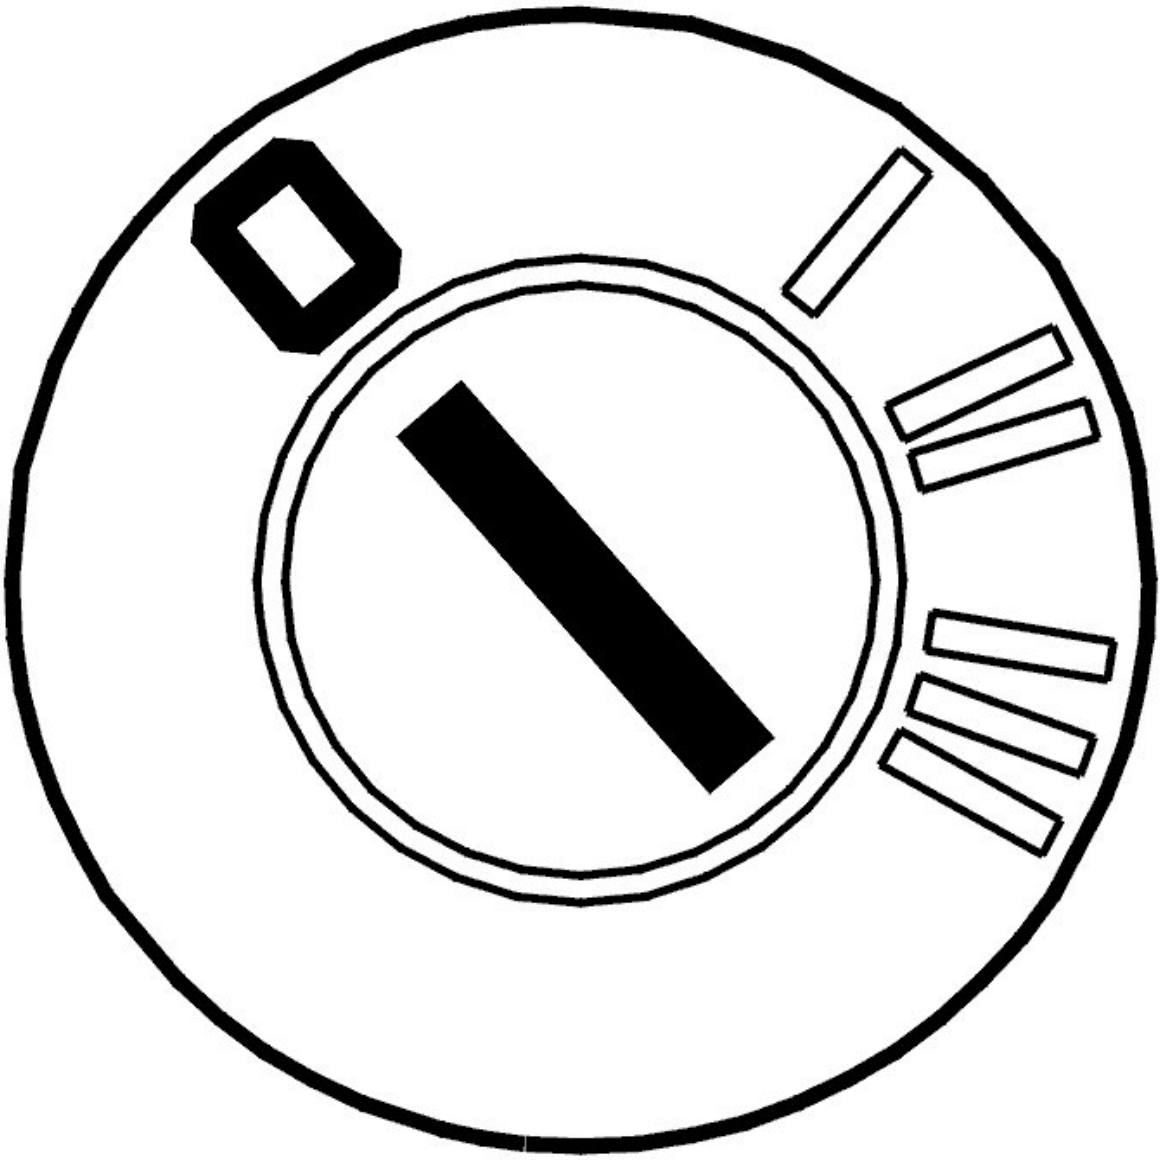
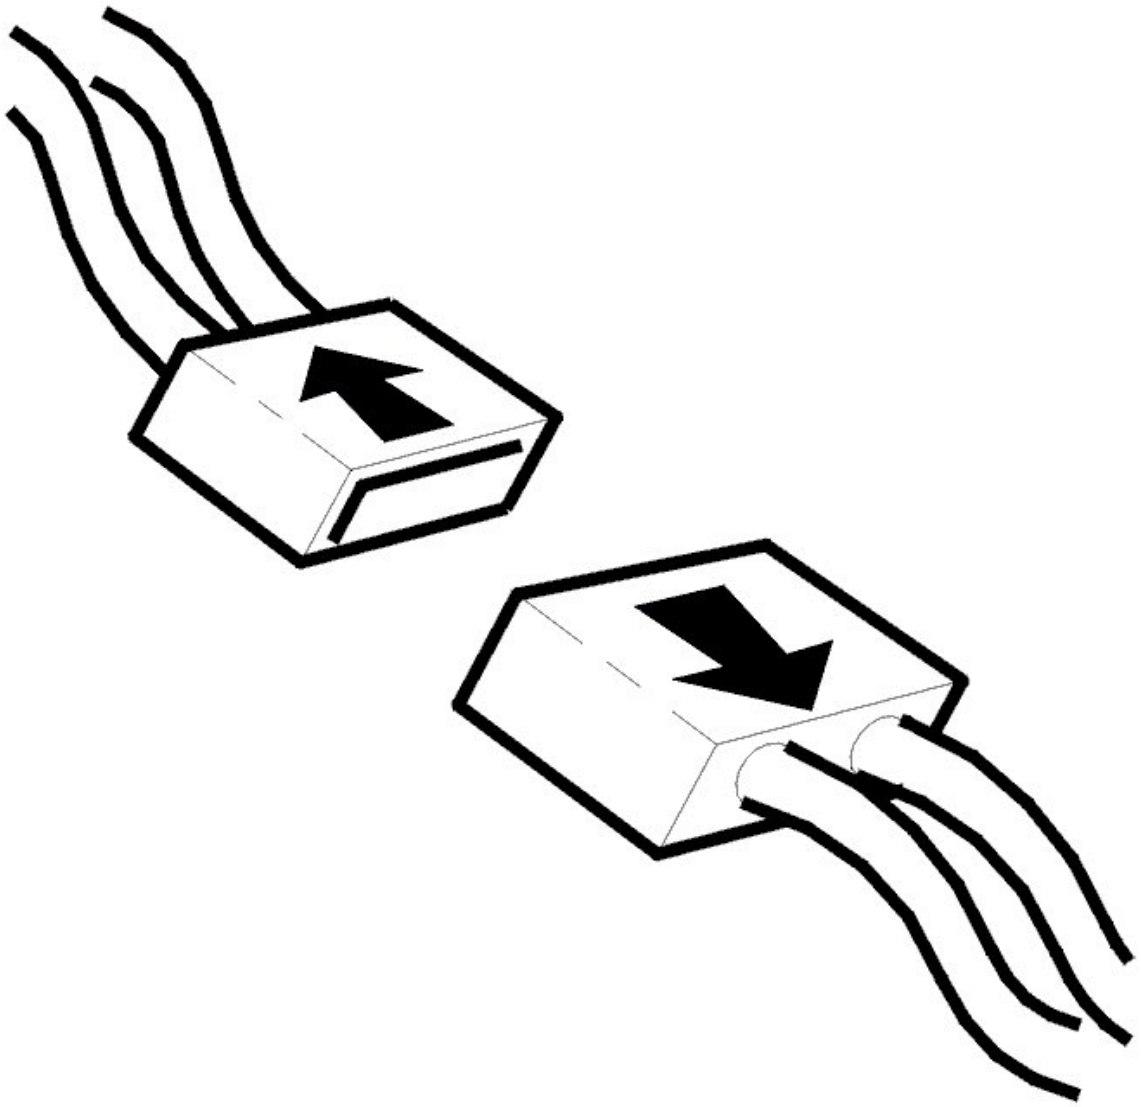
Signal too high. Permanent fault

Checking the cable





- Ignition off
- Disconnect the 2-pin connector under the left-hand seat.

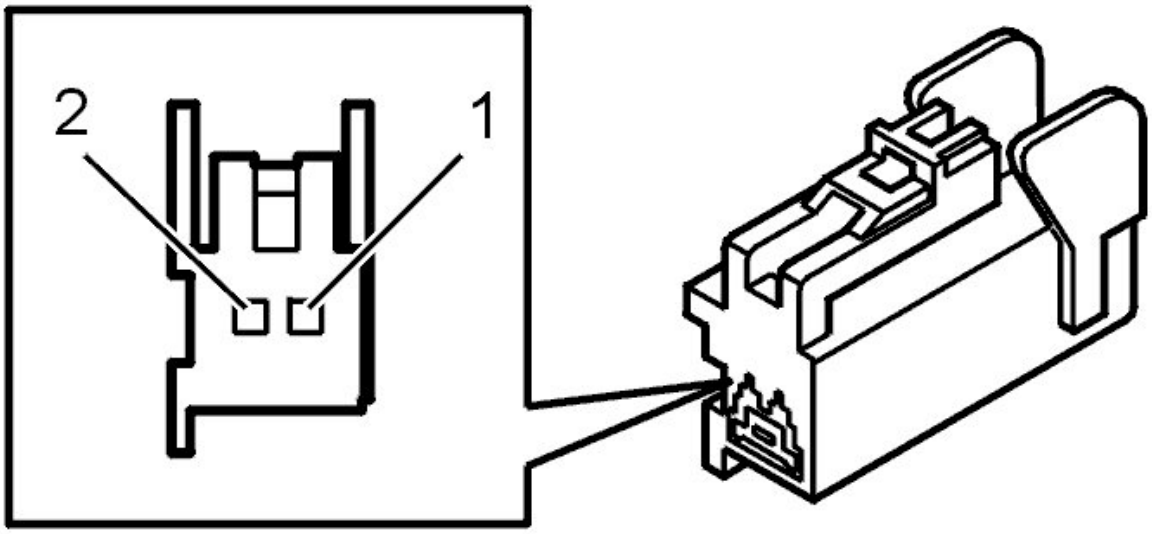
Warning! Under no circumstances use an ohmmeter or other live measuring instrument to take readings on a disconnected, non-deployed, pyrotechnical airbag. This could deploy the airbag!

Caution! Do not touch the terminal pins in the SRS control module. There is a risk of static discharge. This could damage the SRS control module.

Check the cable between the SRS control module terminal #4A (4) and the 2-pin connector terminal #1 for a short-circuit to supply voltage according to Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault.
Check the cable between the SRS control module terminal #3A (3) and the 2-pin connector terminal #2 for a short-circuit to supply voltage according to Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault.

Other information:

- To access and replace the SRS control module and connector, see Control module SRS (supplemental restraint system), replacing See: Relays and Modules/Relays and Modules - Restraint Systems/Air Bag Control Module/Service and Repair
- To connect the breakout box, see Connecting the breakout box See: Restraint Systems/Air Bag Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box, Supplemental Restraint System Module (SRS)
- For information about the repair of SRS wiring, see Cable harness SRS system, repair See: Restraint Systems/Air Bag Systems/Air Bag/Air Bag Harness/Service and Repair/Procedures
- For other values, see Signal specification See: Restraint Systems/Air Bag Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Specification, Supplemental Restraint System Module (SRS).



Were any faults found in the cable?

Yes - Verification

No - Checking the resistance

Replacing the component

Try replacing the side impact protection (SIPS) bag according to Airbag module seat (SIPS), replacing See: Restraint Systems/Air Bag Systems/Air Bag/Service and Repair/Airbag Module Seat (SIPS), Replacing.

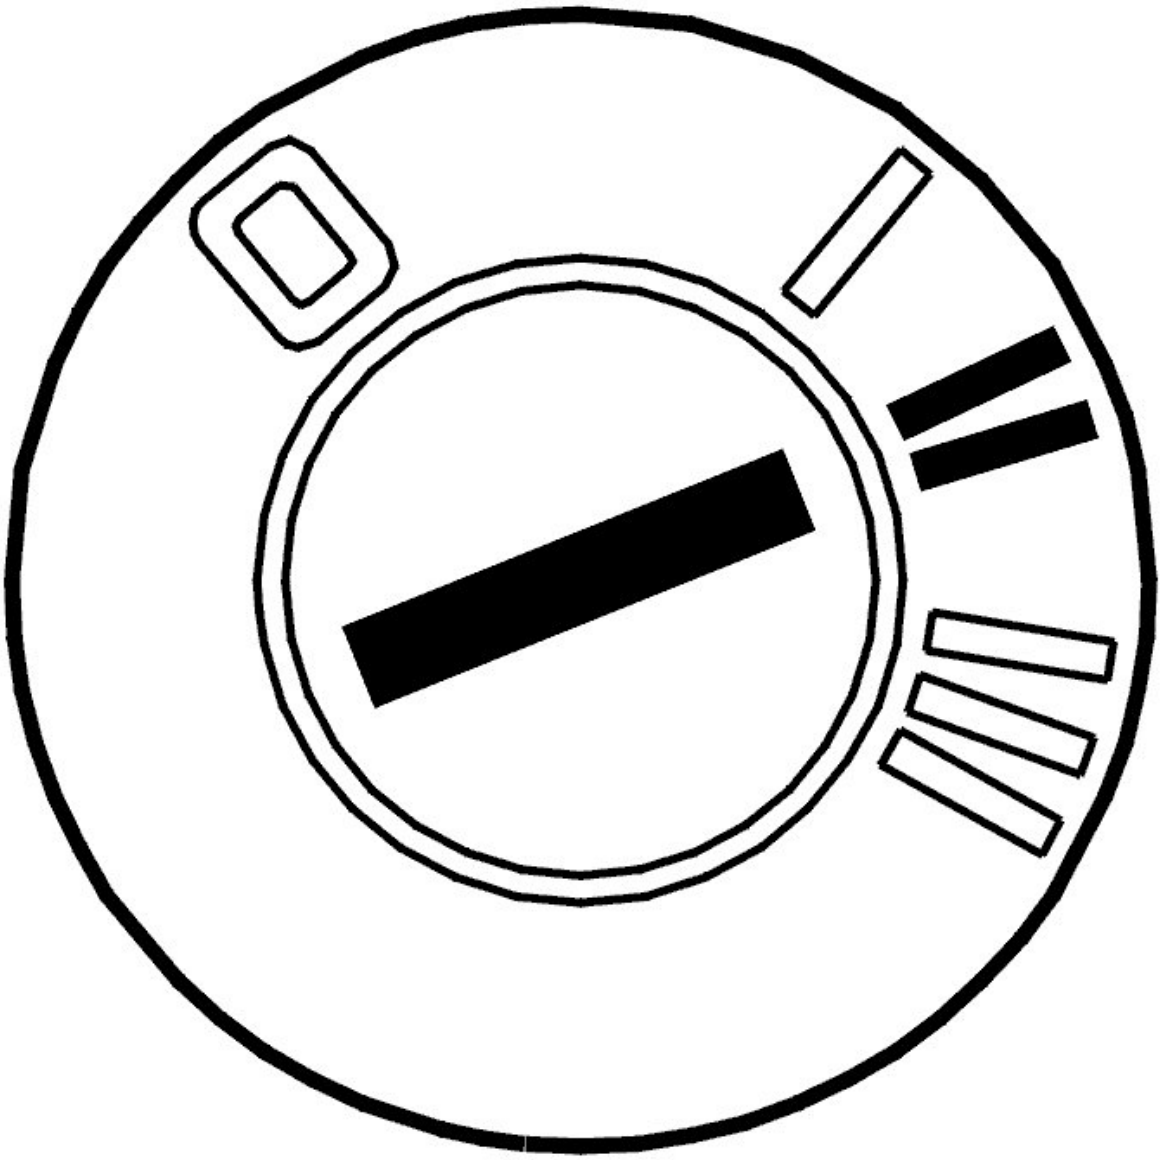
Continue - Verification

Verification

Verification

Verification

Hint: After carrying out the repair, check that the fault has been remedied.



- Ignition off
- Disconnect the battery negative lead
- Reinstall the connectors, components etc.
- Ignition on
- Connect the battery negative lead.

Warning! There must not be anyone inside the passenger compartment when the battery is connected.

- Read off diagnostic trouble codes (DTCs).

The fault is no longer present if the diagnostic trouble code (DTC) status is intermittent.

Is the diagnostic trouble code (DTC) intermittent?

Yes - VERIFIED

No - VERIFICATION FAILED

VERIFIED - Fault Found

VERIFICATION FAILED - Fault-tracing information

Fault-tracing information

Information

Fault-tracing information

The fault should have been detected and remedied. As this is not the case fault-tracing has failed.
Exit fault-tracing for this diagnostic trouble code (DTC) or make another attempt.

Do you want to exit fault-tracing?

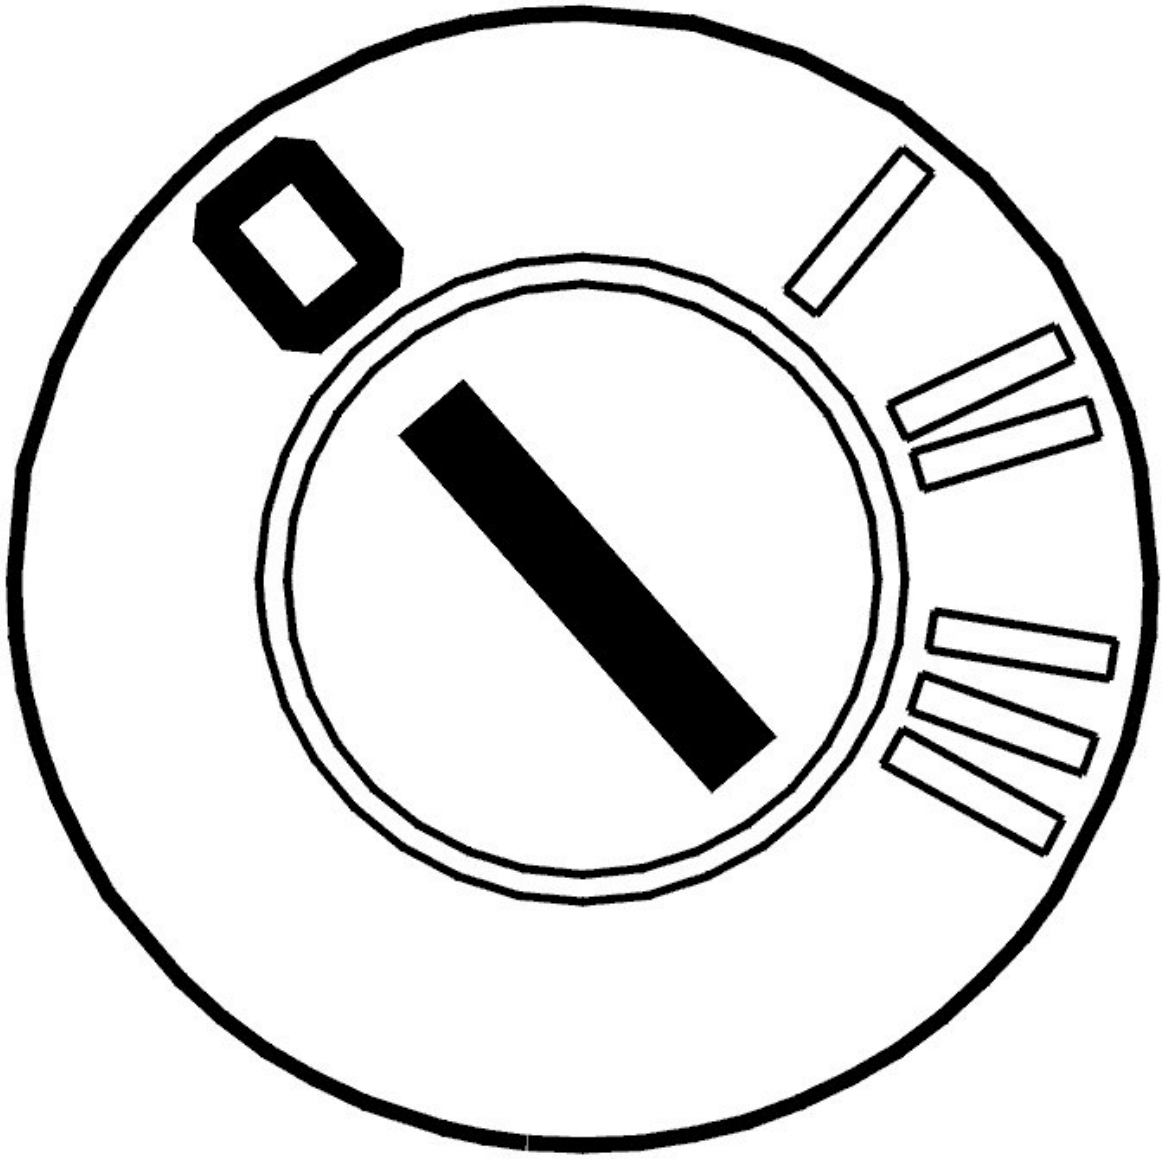
Yes - FAULT-TRACING FAILED

No - Attempt New Test

FAULT-TRACING FAILED - FAULT-TRACING FAILED

Attempt New Test - Checking the cable

Checking the resistance



- Ignition off.

Measure the resistance between the 2-pin connector #1 and #2 (against Supplemental Restraint System Module (SRS)).

The resistance shall be approx. 22 kohms.
If the value does not match the likely cause is some internal defect in Supplemental Restraint System Module (SRS) or in its connectors.
Remedy as necessary.

Other information

- Control module SRS (supplemental restraint system), replacing See: Relays and Modules/Relays and Modules - Restraint Systems/Air Bag Control Module/Service and Repair

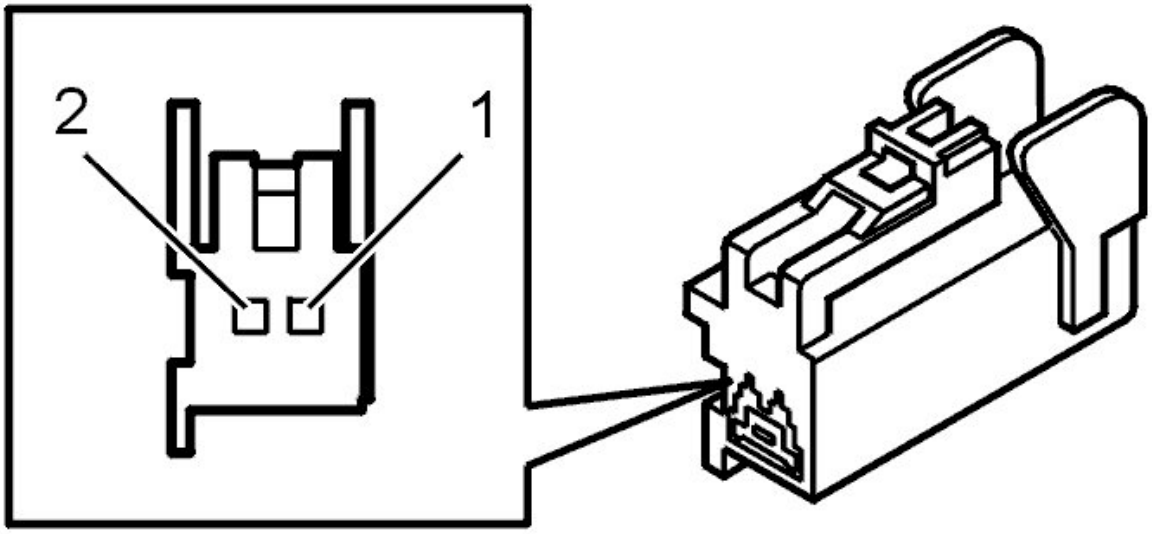
- Signal specification See: Restraint Systems/Air Bag Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Specification, Supplemental Restraint System Module (SRS)



Has the fault been remedied?

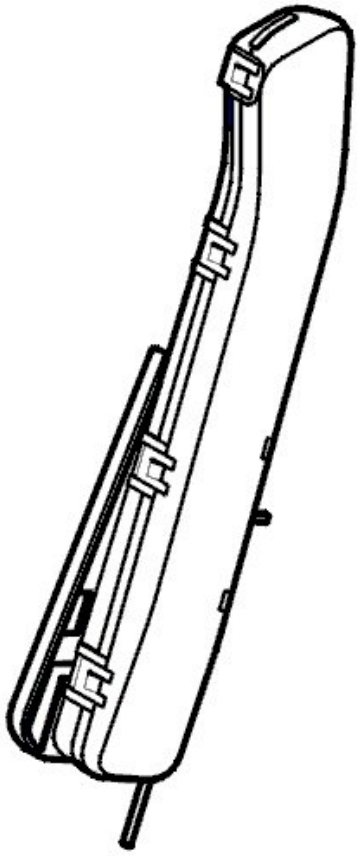
Yes - Verification

No - Replacing the component

Diagnostic Trouble Code (DTC) Information

SRS-0031 Diagnostic trouble code information

Condition



If the circuit voltage is low (0 V) for more than 10 seconds, diagnostic trouble code SRS-0031 is displayed.

Substitute value
- Nothing.

Possible source
- Short circuit to ground in igniter wire or connectors between the front left/right side air bags and the supplemental restraint system (SRS) control unit.

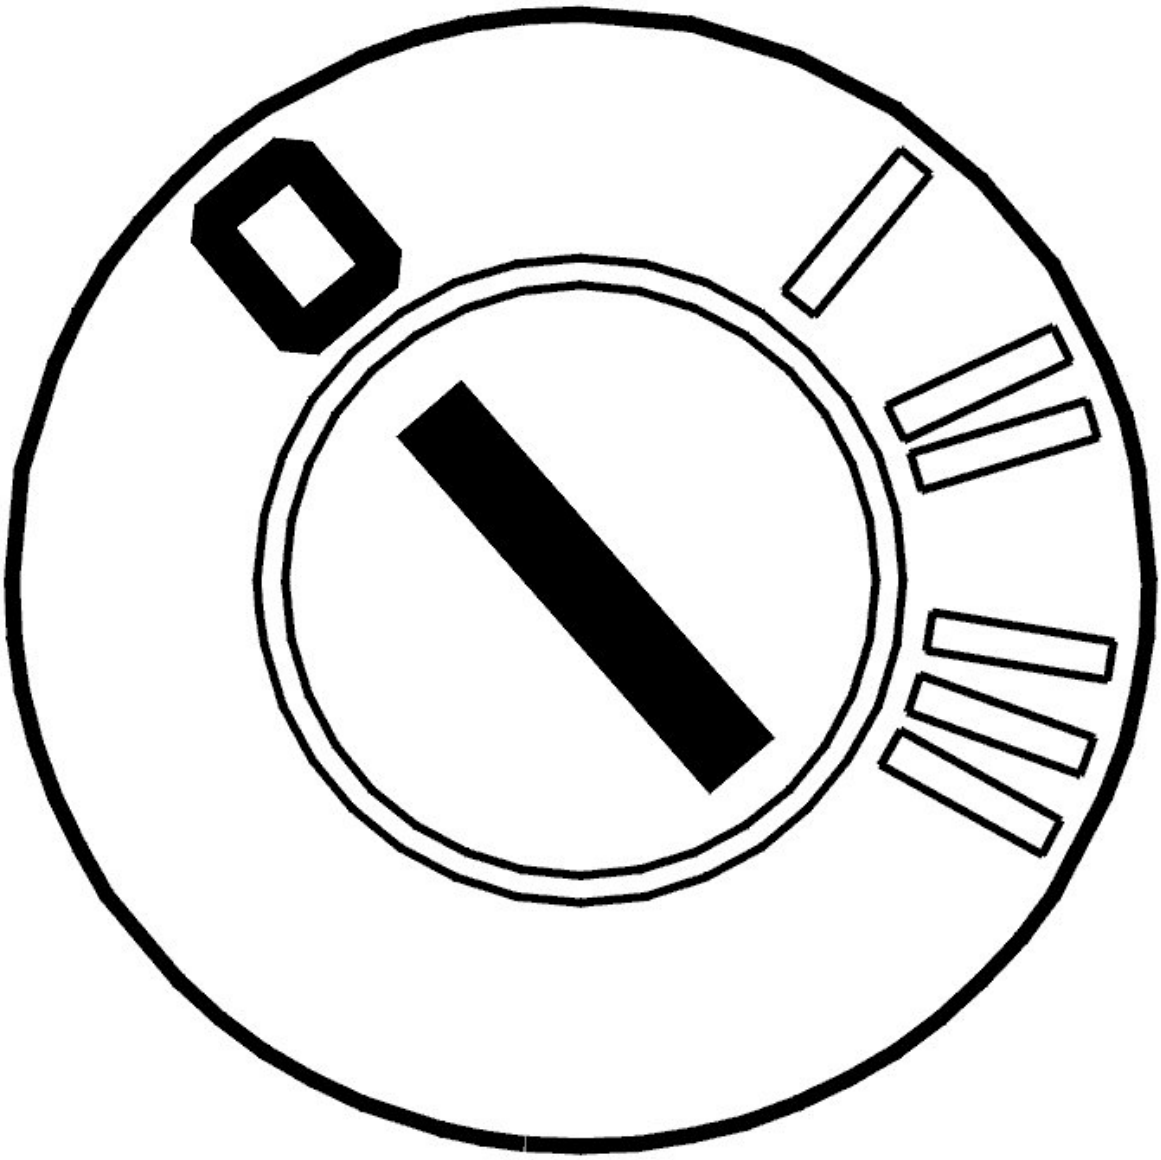
- Short circuit to ground in the front left side air bag.

Fault symptom[s]
- SRS warning lamp on.

Signal Too Low

Signal too low. Intermittent fault

Intermittent fault



- Ignition off.

Warning! Under no circumstances use an ohmmeter or other live measuring instrument to take readings on a disconnected, non-deployed, pyrotechnical airbag. This could deploy the airbag!

Caution! Do not touch the terminal pins in the SRS control module. There is a risk of static discharge. This could damage the SRS control module.

Check the connectors for:
- 2-pin
- the SRS control module.

check for contact resistance and oxidation. See Checking wiring and terminals. Intermittent faults See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Intermittent Faults. Check for loose connections. See Checking wiring and terminals. Intermittent faults See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Intermittent Faults.
Check the cable between the SRS control module terminal #4A (4) and the 2-pin connector terminal #1 for an intermittent short-circuit to ground according to Checking wiring and terminals. Intermittent faults See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Intermittent Faults.
Check the cable between the SRS control module terminal #3A (3) and the 2-pin connector terminal #2 for an intermittent short-circuit to ground according to Checking wiring and terminals. Intermittent faults See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Intermittent Faults.
Remedy as necessary.

Other information:
- To access and replace the SRS control module and the connector, see Control module SRS (supplemental restraint system), replacing See: Relays and Modules/Relays and Modules - Restraint Systems/Air Bag Control Module/Service and Repair
- To connect the breakout box, see Connecting the breakout box See: Restraint Systems/Air Bag Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box, Supplemental Restraint System Module (SRS)
- With the ignition off and the 2-pin connector disconnected, the resistance between terminals #1 and #2 on the 2-pin connector (SRS control module side) and ground should be infinite

- With the ignition off and the 2-pin connector disconnected, the resistance between the 2-pin connector terminals #1 and #2 (SRS control module side) should be approximately 22 kohms.
- For information about the repair of SRS wiring, see Cable harness SRS system, repair See: Restraint Systems/Air Bag Systems/Air Bag/Air Bag Harness/Service and Repair/Procedures

The fault is no longer present if the diagnostic trouble code (DTC) status is intermittent.

Is the diagnostic trouble code (DTC) intermittent?

Yes - VERIFIED

No - VERIFICATION FAILED

VERIFIED - Fault Found

VERIFICATION FAILED - Fault-tracing information

Fault-tracing information

Information

Fault-tracing information

The fault should have been detected and remedied. As this is not the case fault-tracing has failed.
Exit fault-tracing for this diagnostic trouble code (DTC) or make another attempt.

Do you want to exit fault-tracing?

Yes - FAULT-TRACING FAILED

No - Attempt New Test

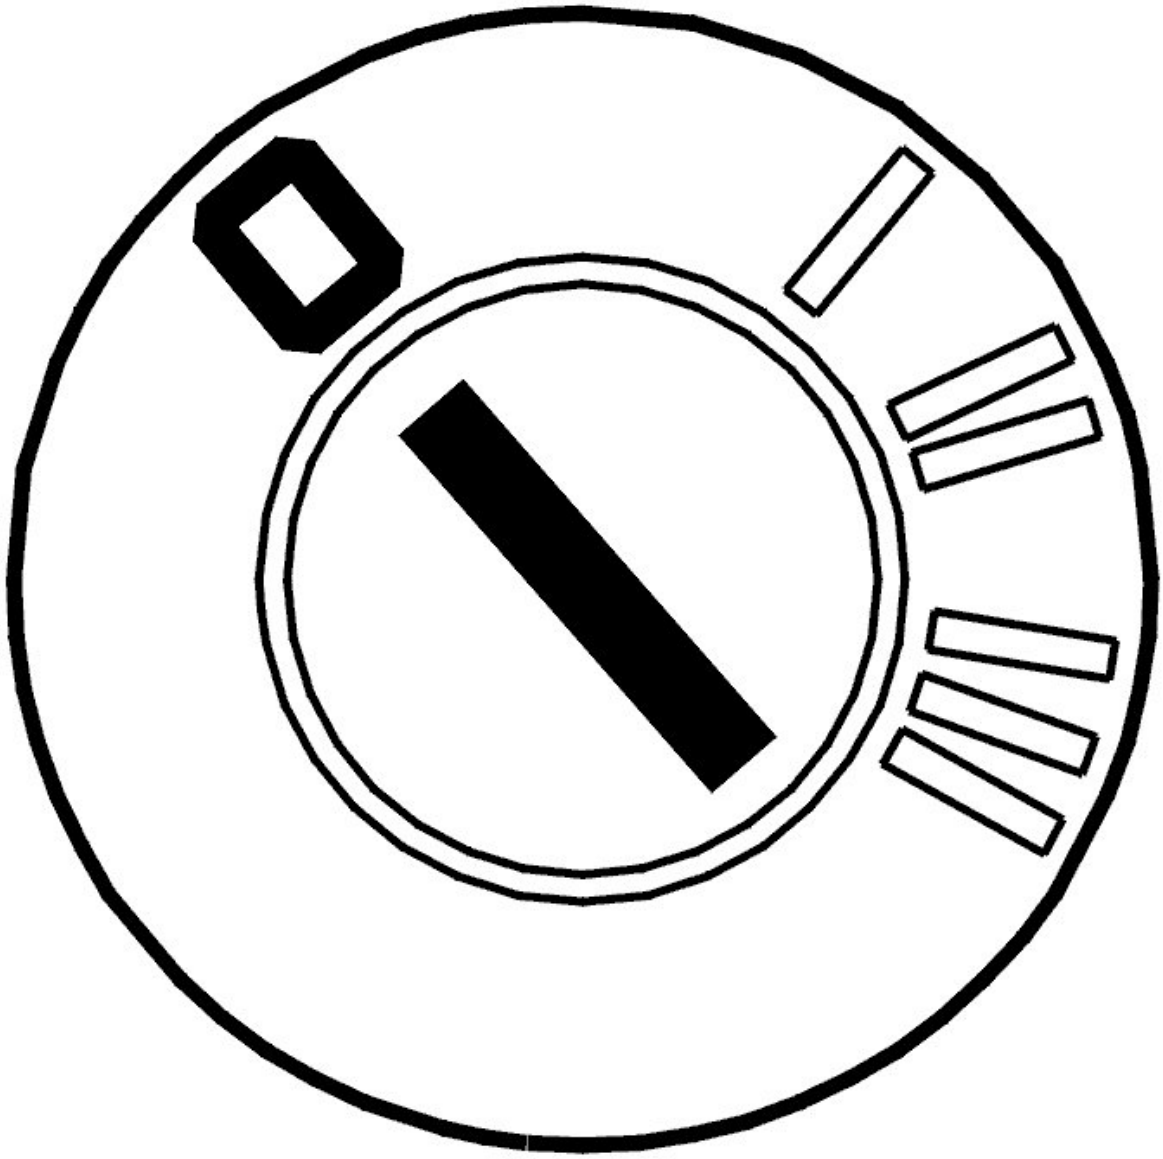
FAULT-TRACING FAILED - FAULT-TRACING FAILED

Attempt New Test - Checking the cable

Checking the resistance



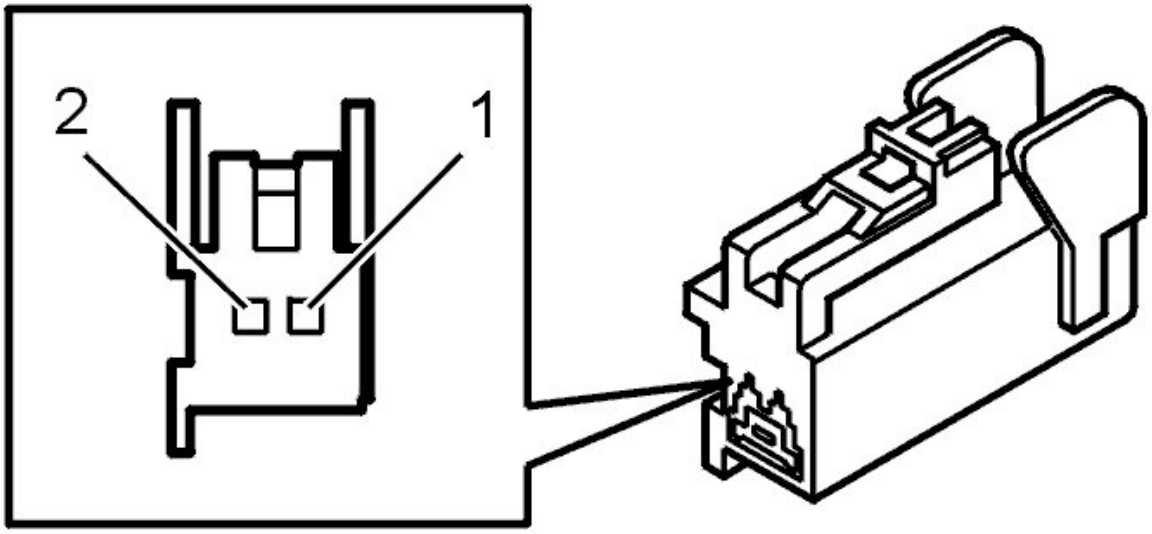
- Ignition off.

Measure the resistance between the 2-pin connector #1 and #2 (against Supplemental Restraint System Module (SRS)).

The resistance shall be approx. 22 kohms.
If the value does not match the likely cause is some internal defect in Supplemental Restraint System Module (SRS) or in its connectors.
Remedy as necessary.

Other information

- Control module SRS (supplemental restraint system), replacing See: Relays and Modules/Relays and Modules - Restraint Systems/Air Bag Control Module/Service and Repair
- Connecting the breakout box See: Restraint Systems/Air Bag Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box, Supplemental Restraint System Module (SRS)
- Signal specification See: Restraint Systems/Air Bag Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Specification, Supplemental Restraint System Module (SRS)



Has the fault been remedied?

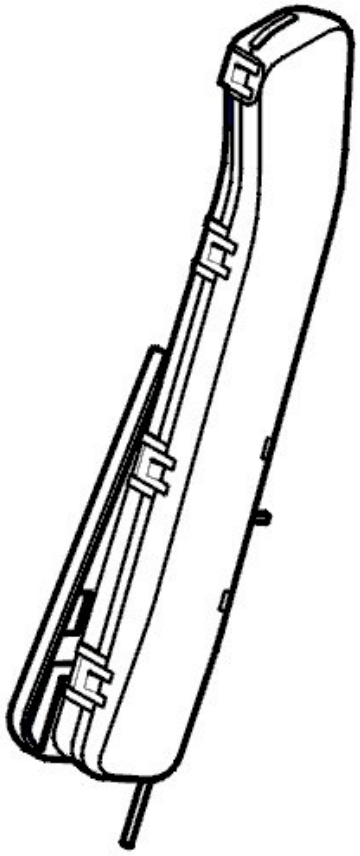
Yes - Verification

No - Replacing the component

Diagnostic Trouble Code (DTC) Information

SRS-0034 Diagnostic trouble code information

Condition



If the circuit resistance is too high for more than 10 seconds, diagnostic trouble code SRS-0034 is displayed.

Substitute value
- Nothing.

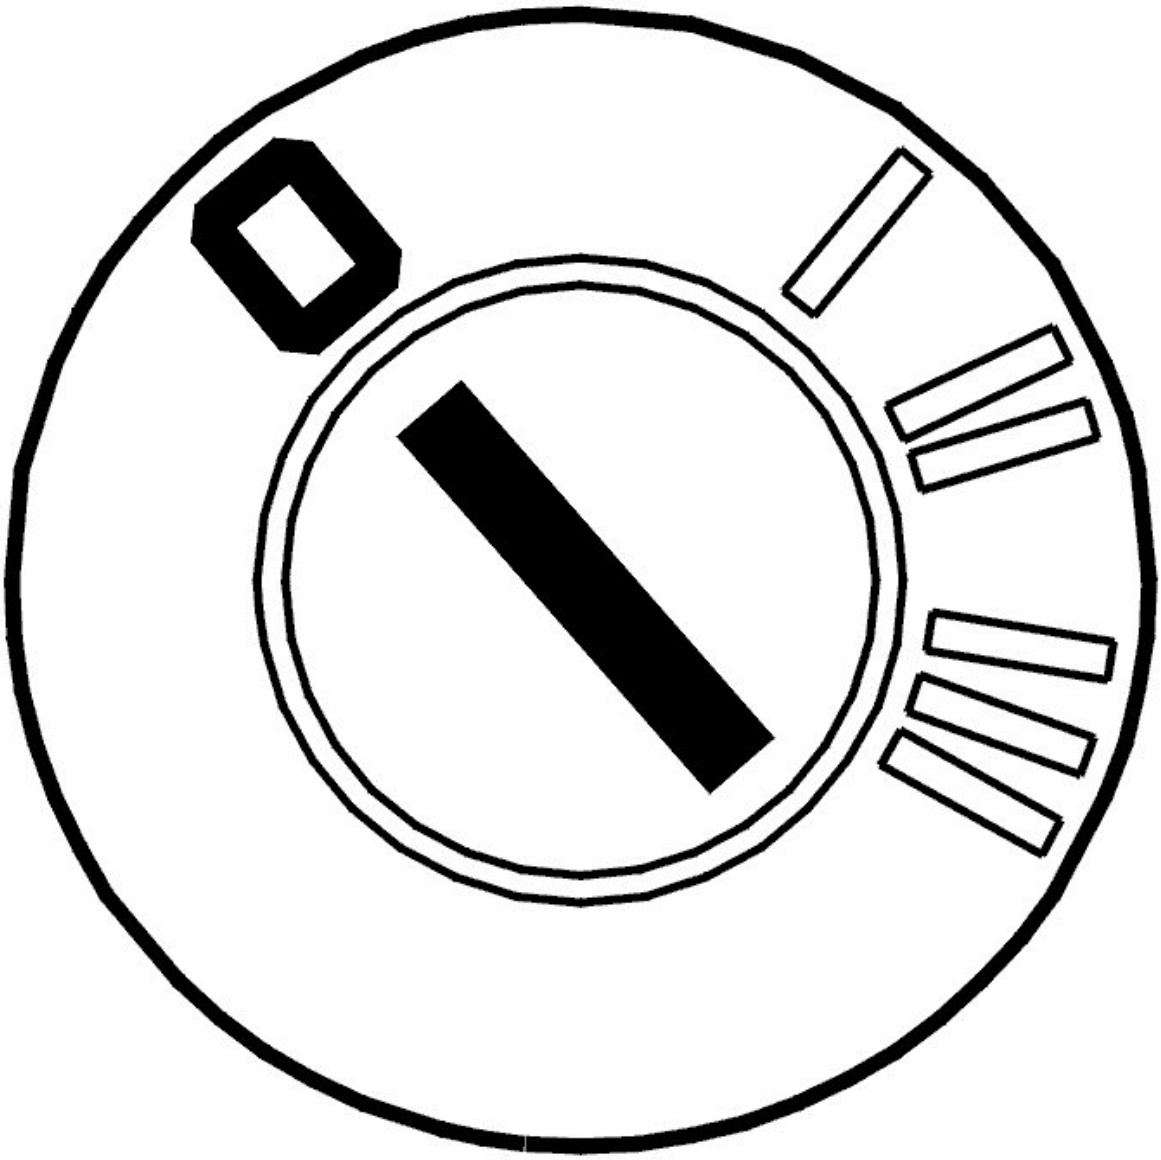
Possible source
- Open circuit in igniter wire or connectors between the front left side air bag and the supplemental restraint system (SRS) control unit
- Open circuit in the front left side air bag (resistance in igniter too high).

Fault symptom[s]
- SRS warning lamp on.

Resistance Too High

Resistance too high. Intermittent fault

Intermittent fault



- Ignition off.

Warning! Under no circumstances use an ohmmeter or other live measuring instrument to take readings on a disconnected, non-deployed, pyrotechnical airbag. This could deploy the airbag!

Caution! Do not touch the terminal pins in the SRS control module. There is a risk of static discharge. This could damage the SRS control module.

Check the connectors for:
- 2-pin
- the SRS control module.

check for contact resistance and oxidation. See Checking wiring and terminals. Intermittent faults See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Intermittent Faults. Check for loose connections. See Checking wiring and terminals. Intermittent faults See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Intermittent Faults.
Check the cable between the SRS control module terminal #4A (4) and the 2-pin connector terminal #1 for an intermittent open-circuit according to Checking wiring and terminals. Intermittent faults See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Intermittent Faults.
Check the cable between the SRS control module terminal #3A (3) and the 2-pin connector terminal #2 for an intermittent open-circuit according to Checking wiring and terminals. Intermittent faults See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Intermittent Faults.
Remedy as necessary.

Other information:
- To access and replace the SRS control module and connector, see Control module SRS (supplemental restraint system), replacing See: Relays and Modules/Relays and Modules - Restraint Systems/Air Bag Control Module/Service and Repair
- To access the connector for the left-hand side impact protection (SIPS) bag, see Airbag module seat (SIPS), replacing See: Restraint Systems/Air Bag Systems/Air Bag/Service and Repair/Airbag Module Seat (SIPS), Replacing
- To connect the breakout box, see Connecting the breakout box See: Restraint Systems/Air Bag Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box, Supplemental Restraint System Module (SRS)

- With the ignition off and the 2-pin connector disconnected, the resistance between terminals #1 and #2 on the 2-pin connector (SRS control module side) should be approximately 22 kohms.
- For information about the repair of SRS wiring, see Cable harness SRS system, repair See: Restraint Systems/Air Bag Systems/Air Bag/Air Bag Harness/Service and Repair/Procedures
- For other values, see Signal specification See: Restraint Systems/Air Bag Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Specification, Supplemental Restraint System Module (SRS).

FAULT FOUND - DONE

Diagnostic Trouble Code (DTC) Information

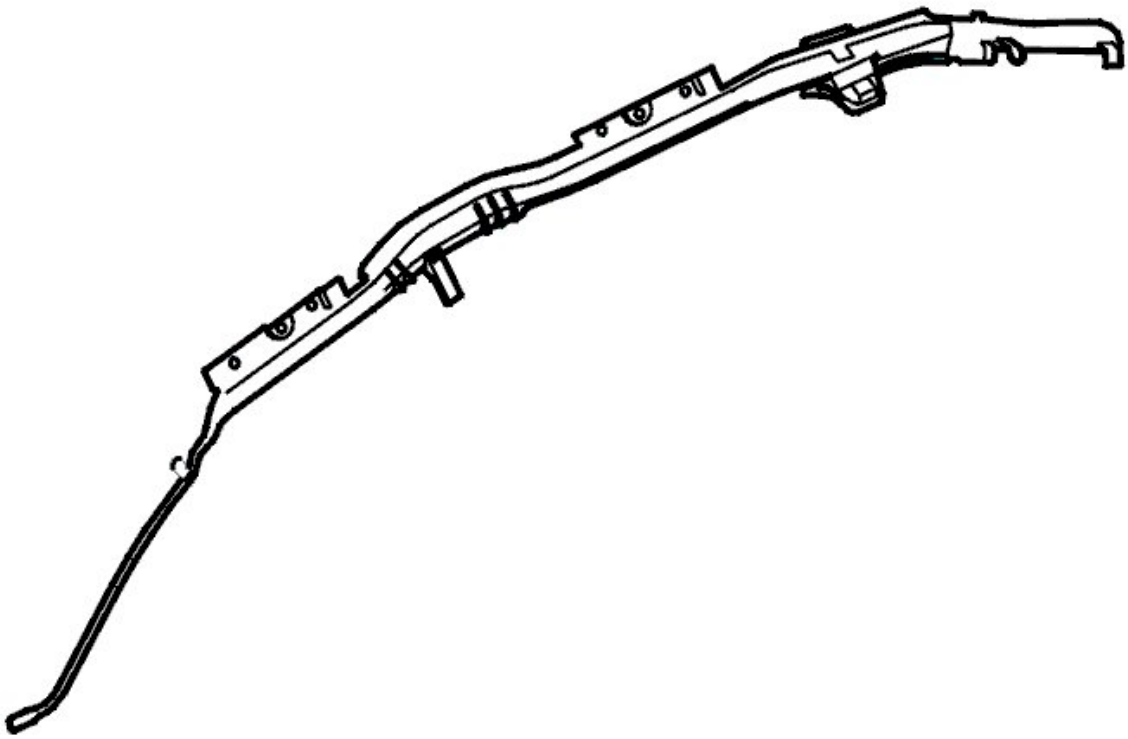
SRS-003A Diagnostic trouble code information

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

Condition



If the capacitance in the circuit is high for more than 10 seconds, diagnostic trouble code SRS-003A is displayed.

Substitute value
- Nothing.

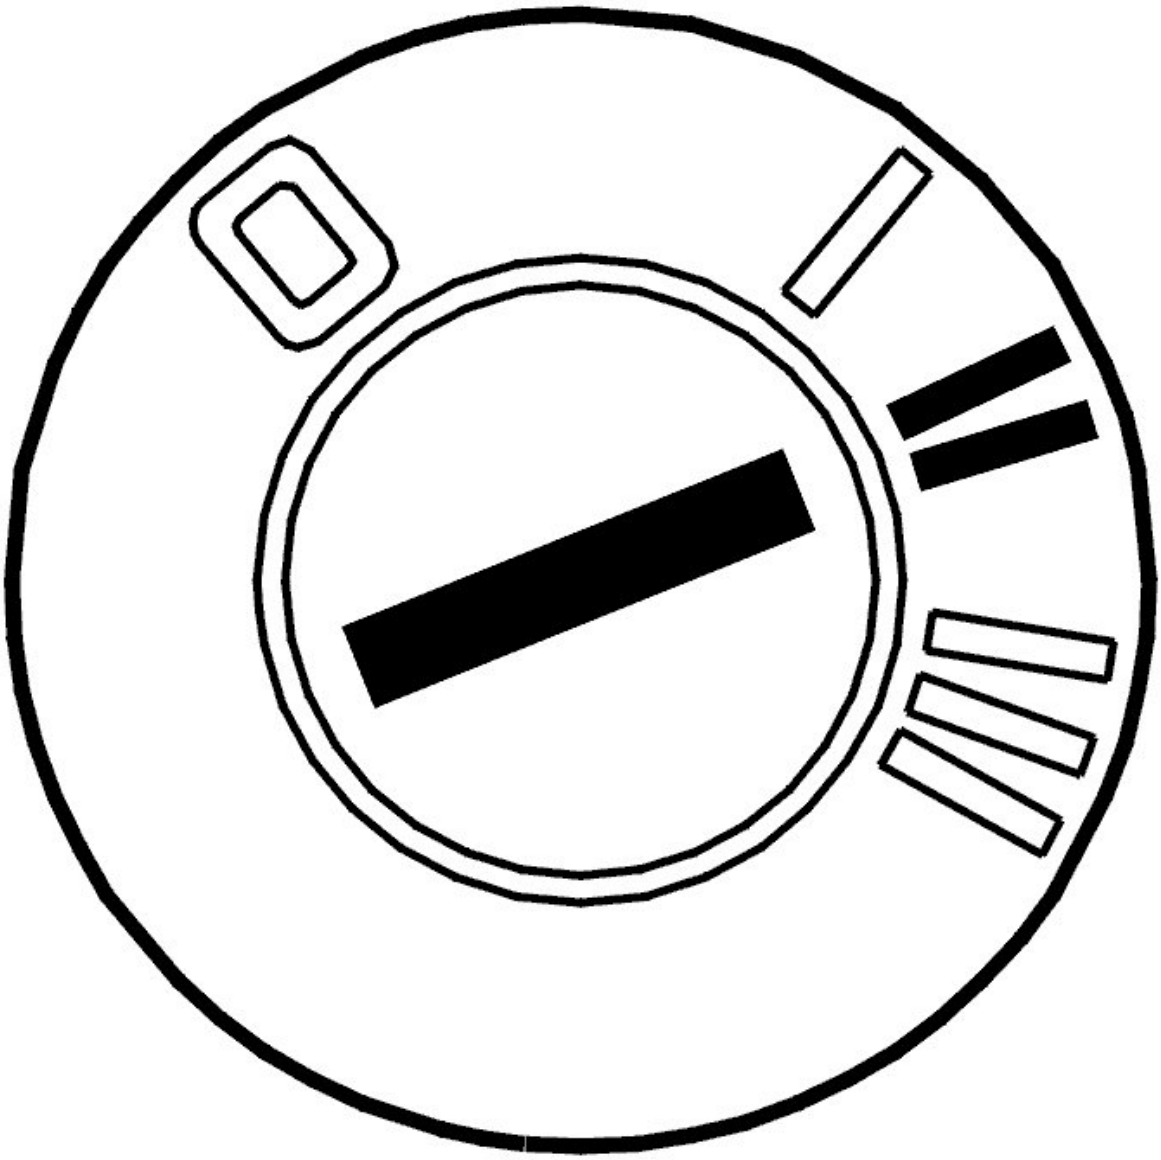
Possible source
- Capacitance too high or short circuit in built-in capacitor in igniter wire connector.

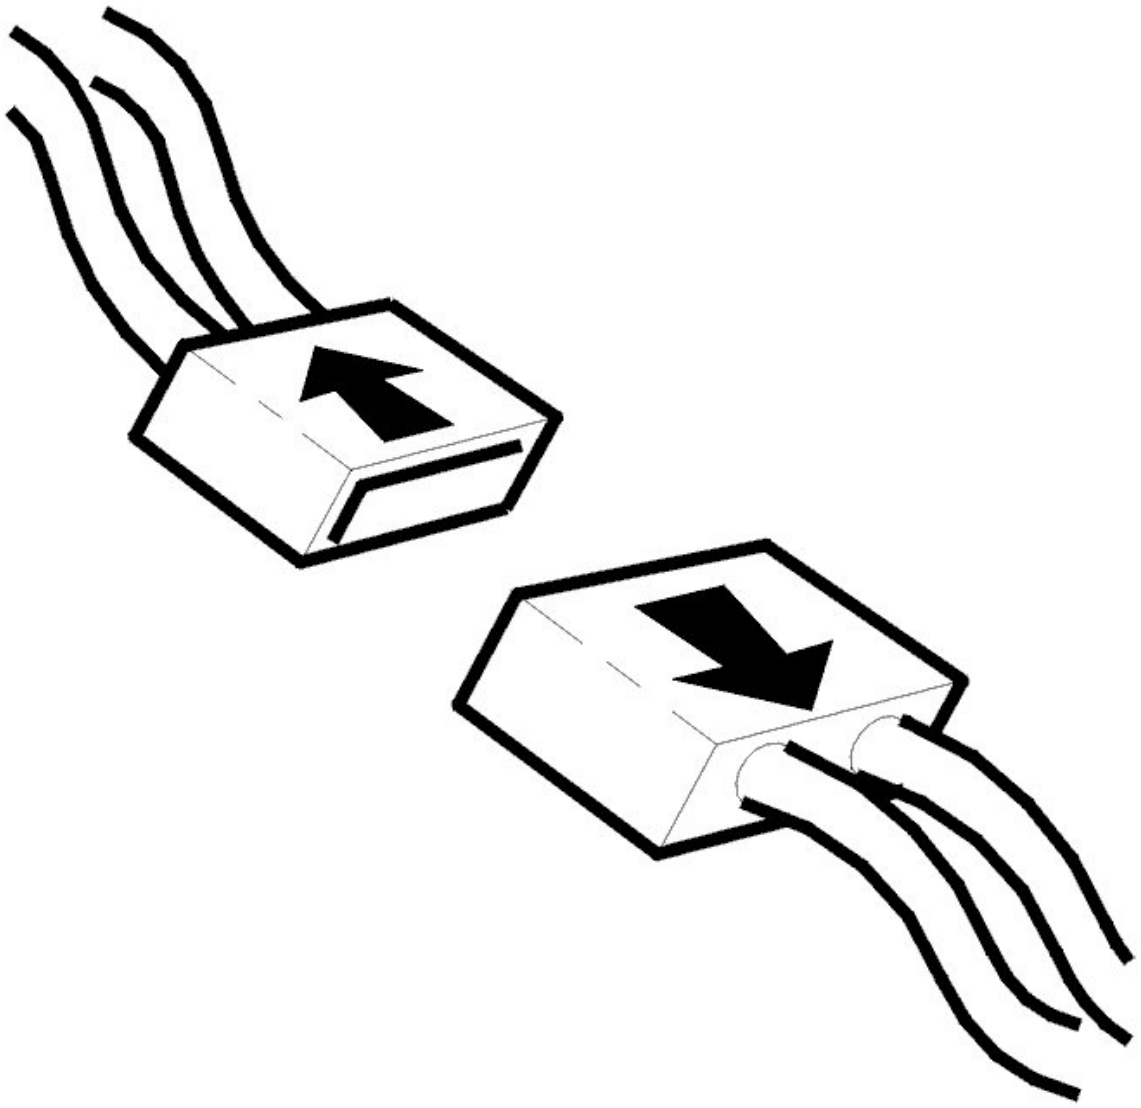
Fault symptom[s]
- SRS warning lamp on.

Capacitance Too High

Capacitance too high. Permanent fault

Checking the component





- Ignition off
- Disconnect the connector from the left-hand inflatable curtain
- Connect special tool951 1506 Test dummy See: Tools and Equipment/951 1506 Test Dummy to the connector for the left-hand inflatable curtain

Warning! Under no circumstances use an ohmmeter or other live measuring instruments to take readings on a disconnected, non-deployed, pyrotechnical inflatable curtain. This could deploy the inflatable curtain!

Note! The special tool must be checked and fault-free. If the tool is defective, the diagnosis readings will be incorrect. This will make fault-tracing harder.

- Switch on the ignition. Wait 10 seconds.

Read off diagnostic trouble codes (DTCs).
If the diagnostic trouble code (DTC) changes status from a permanent fault to an intermittent fault, try replacing the left-hand inflatable curtain.

Other information:

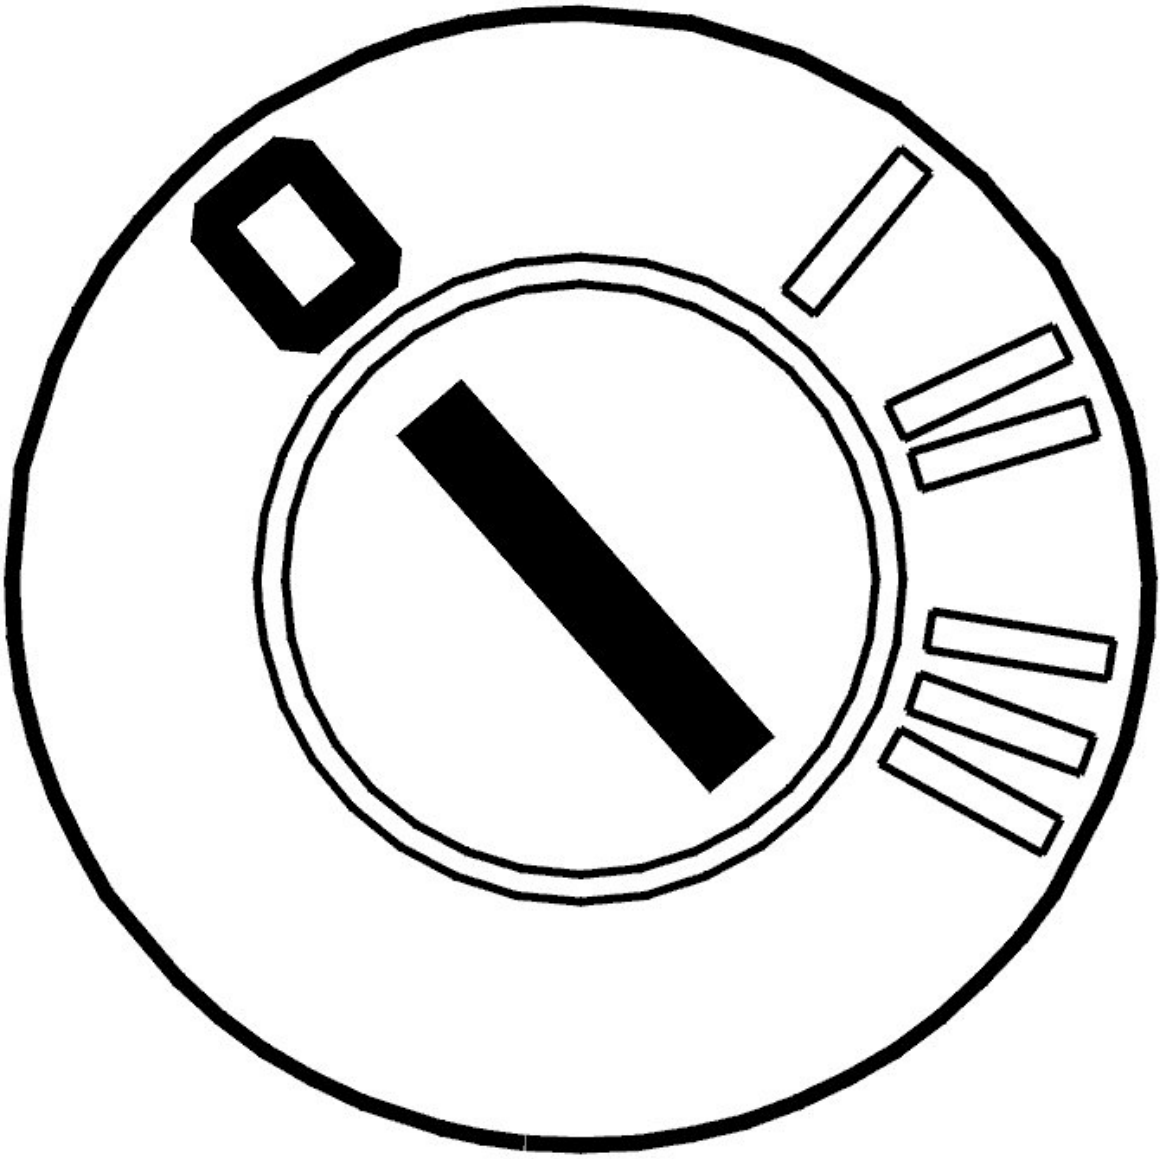
- To access and replace the left-hand inflatable curtain, see IC (inflatable curtain) module, replacing See: Restraint Systems/Air Bag Systems/Air Bag/Service and Repair/IC (Inflatable Curtain) Module, Replacing
- To check the special tool, see Calibration See: Restraint Systems/Service and Repair/Calibrating the Special Tool.

Does the status of the diagnostic trouble code (DTC) change?

Yes - Verification

No - Checking components and wiring

Checking components and wiring



- Ignition off
- Disconnect special tool951 1506 Test dummy See: Tools and Equipment/951 1506 Test Dummy from the connector for the left-hand inflatable curtain.

Warning! Under no circumstances use an ohmmeter or other live measuring instruments to take readings on a disconnected, non-deployed, pyrotechnical inflatable curtain. This could deploy the inflatable curtain!

Caution! Do not touch the terminal pins in the SRS control module. There is a risk of static discharge. This could damage the SRS control module.

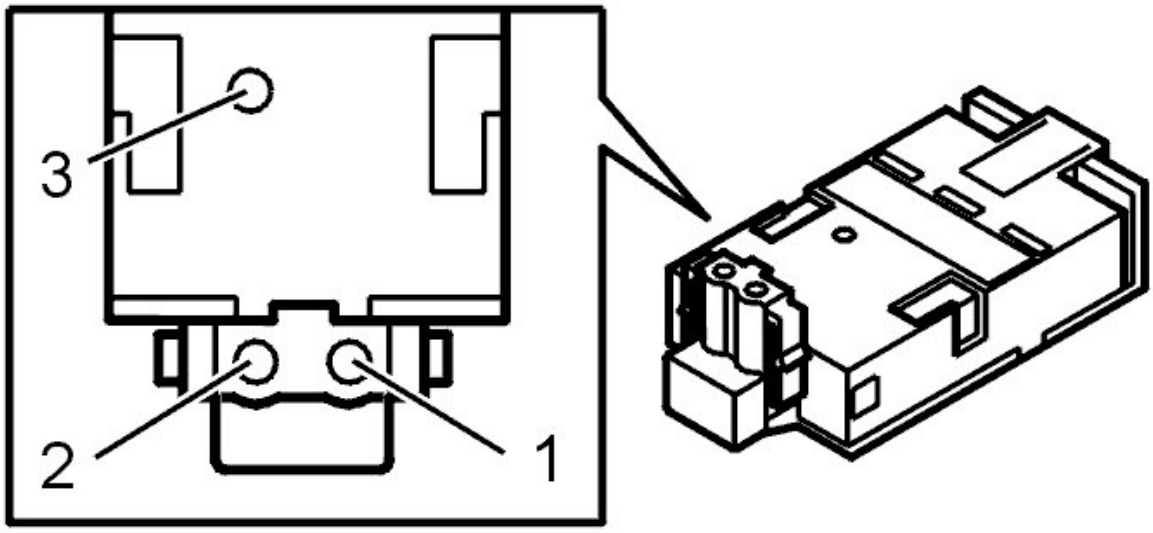
Check the cable between the control module for the SRS terminals #A21 (21), #A22 (22) and connector terminals #1 and #3 on the left-hand inflatable curtain for short-circuit to ground according to Checking wiring and terminals. Permanent fault See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Permanent Fault.
Remedy as necessary.

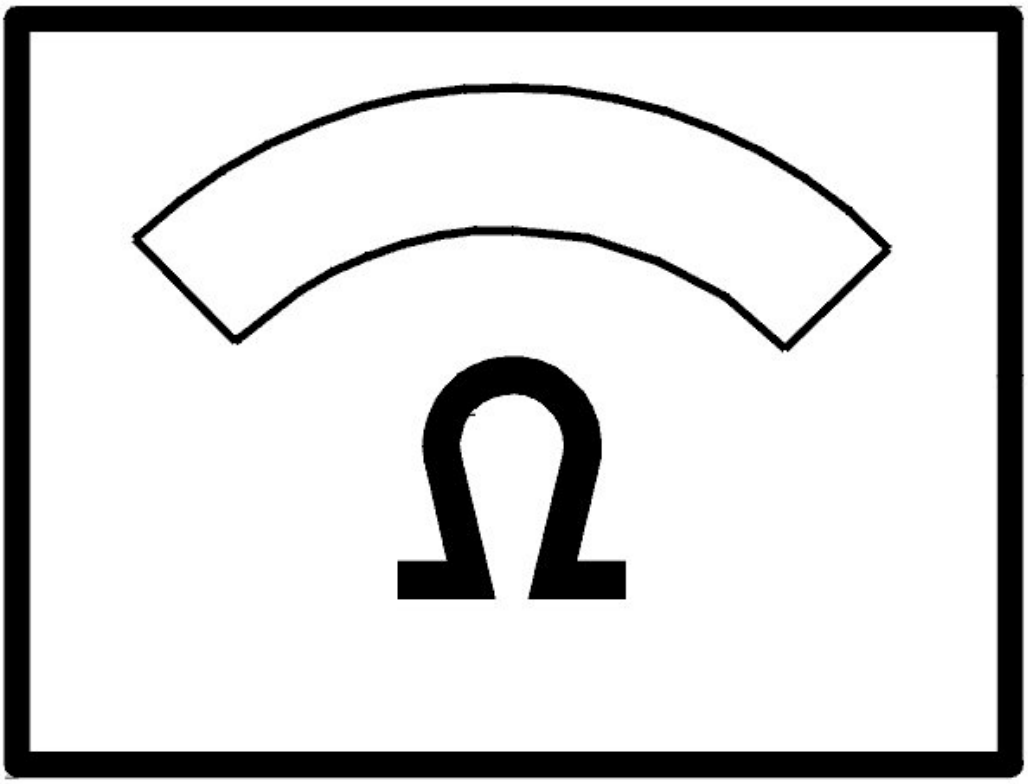
Other information:

- To access and replace the SRS control module connector, see Control module SRS (supplemental restraint system), replacing See: Relays and Modules/Relays and Modules - Restraint Systems/Air Bag Control Module/Service and Repair
- To access and replace the connector for the left-hand inflatable curtain (IC), see IC (inflatable curtain) module, replacing See: Restraint Systems/Air Bag Systems/Air Bag/Service and Repair/IC (Inflatable Curtain) Module, Replacing
- To connect the breakout box, see Connecting the breakout box See: Restraint Systems/Air Bag Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box, Supplemental Restraint System Module (SRS)
- With the ignition off and with the left-hand inflatable curtain connector and special tool951 1506 Test dummy See: Tools and Equipment/951

1506 Test Dummy connected, the resistance between terminals #21A (21) and #22A (22) on the SRS control module connector (inflatable curtain side) should be infinite

- With the ignition off and the connectors for the left-hand inflatable curtain and for the SRS control module disconnected, the resistance between terminals #1 and #3 on the inflatable curtain connector (SRS control module side) and ground should be infinite
- For information about the repair of SRS wiring, see Cable harness SRS system, repair See: Restraint Systems/Air Bag Systems/Air Bag/Air Bag Harness/Service and Repair/Procedures
- For other values, see Signal specification See: Restraint Systems/Air Bag Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Specification, Supplemental Restraint System Module (SRS).





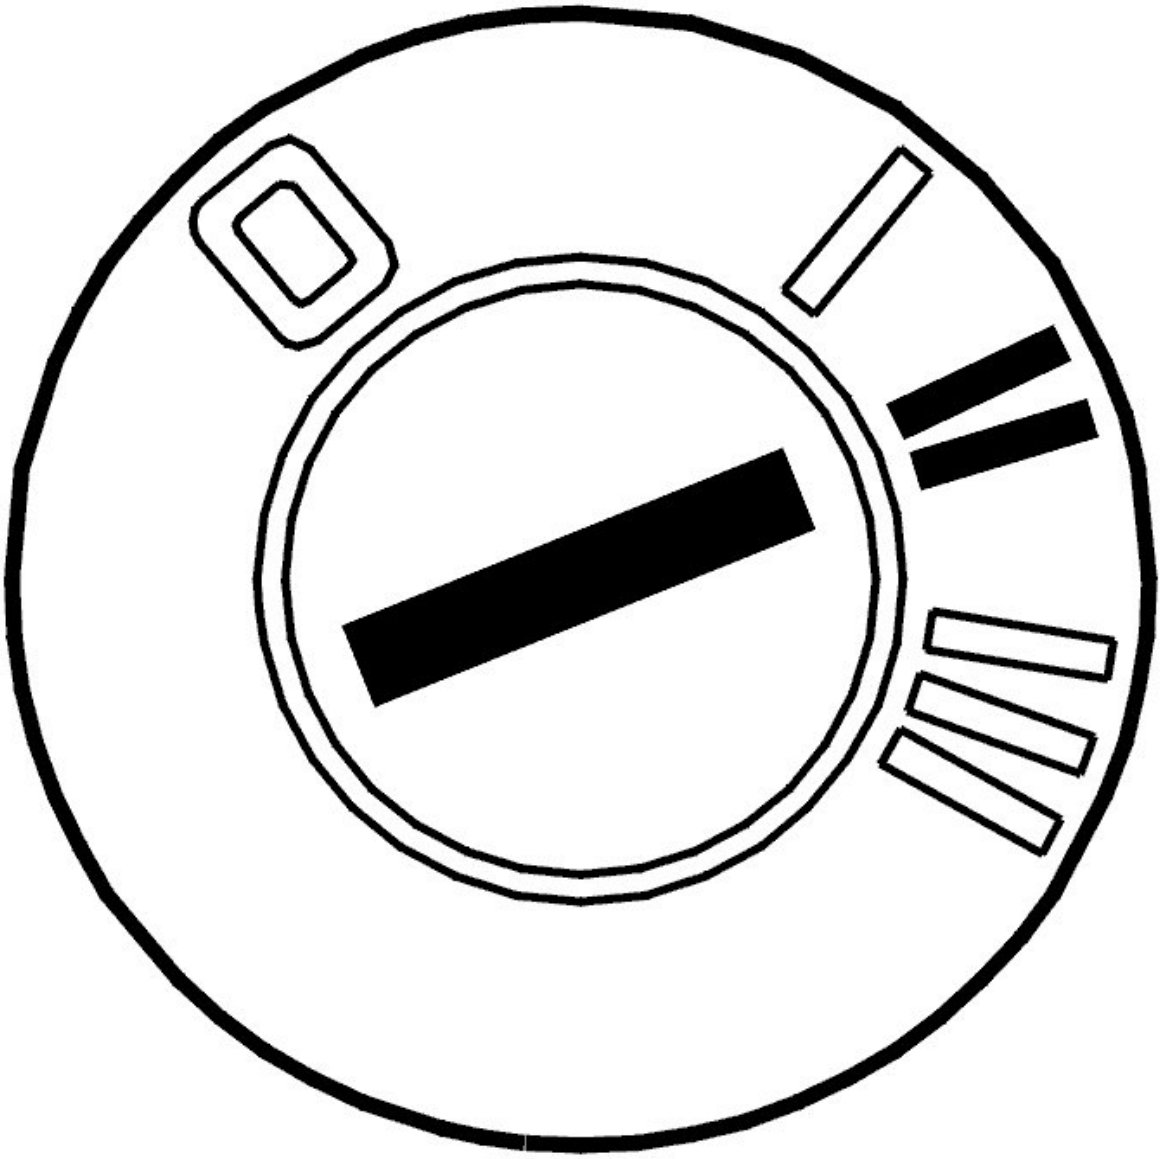
Continue - Verification

Verification

Verification

Verification

Hint: After carrying out the repair, check that the fault has been remedied.



- Ignition off
- Disconnect the battery negative lead
- Reinstall the connectors, components etc.
- Ignition on
- Connect the battery negative lead.

Warning! There must not be anyone inside the passenger compartment when the battery is connected.

- Read off diagnostic trouble codes (DTCs).

Diagnostic Trouble Code (DTC) Information

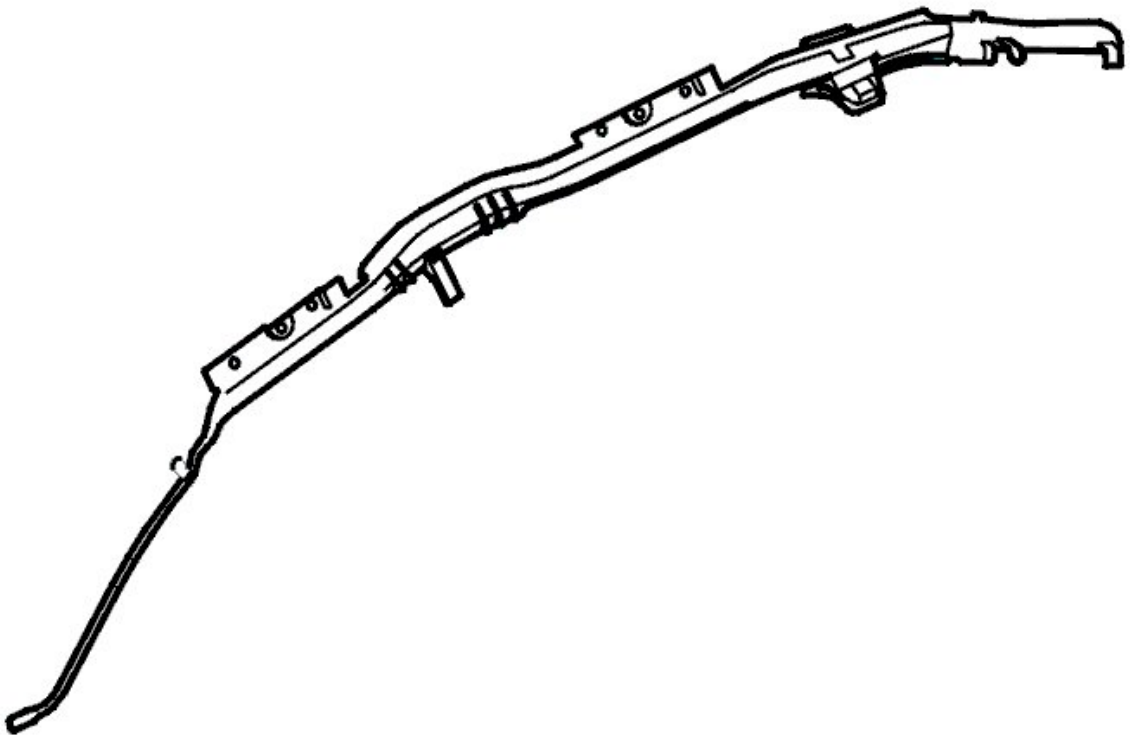
SRS-003B Diagnostic trouble code information

Condition



If the capacitance in the circuit is low for more than 10 seconds, diagnostic trouble code SRS-003B is displayed.

Substitute value
- Nothing.

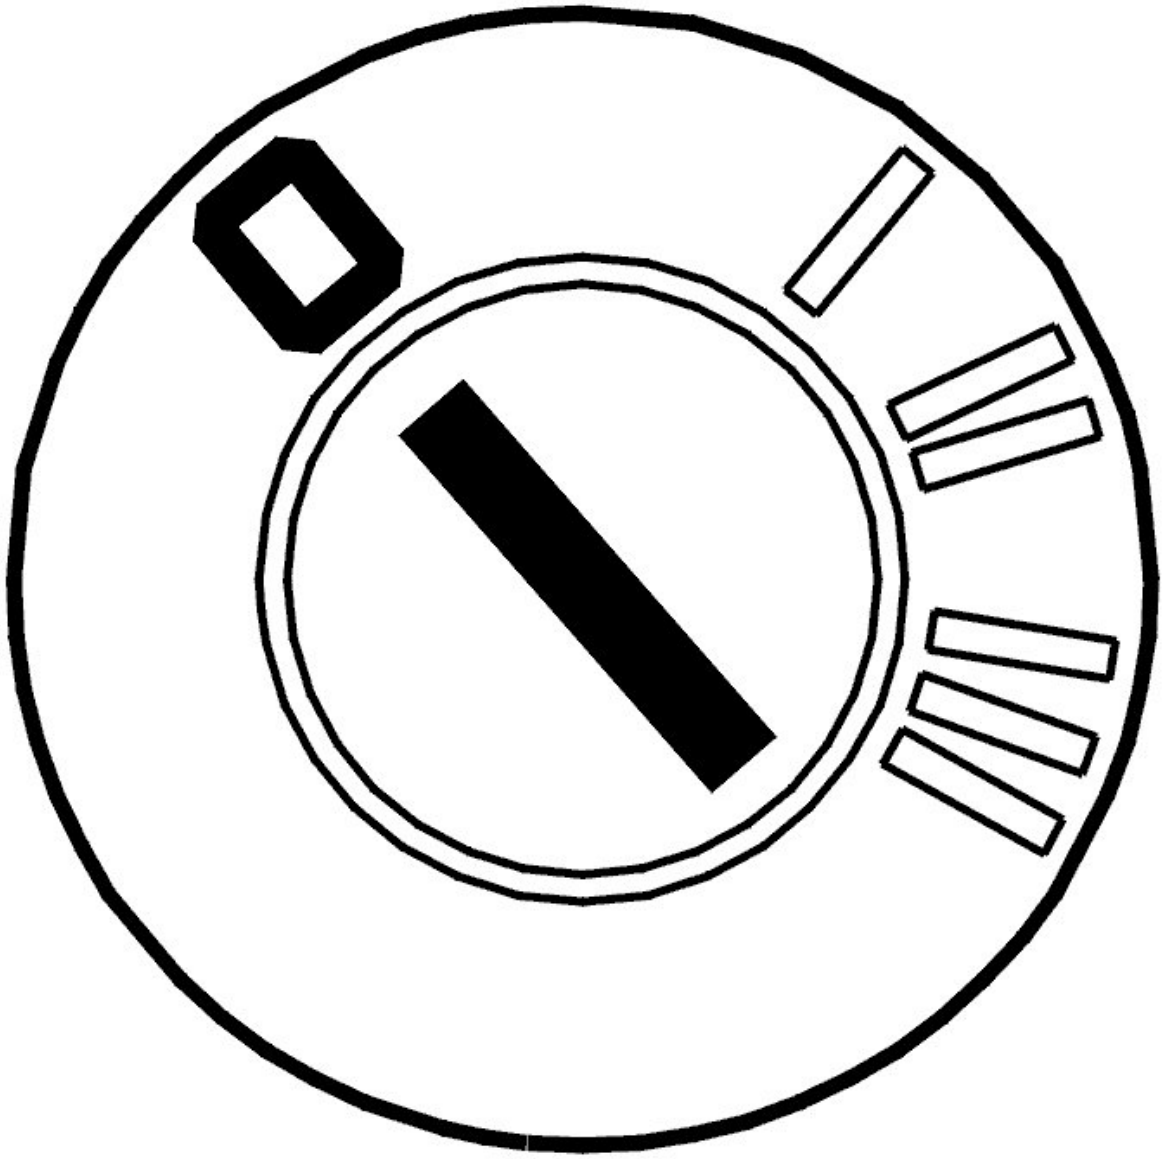
Possible source
- Capacitance too low or open circuit in built-in capacitor in igniter wire connector.

Fault symptom[s]
- SRS warning lamp on.

Capacitance Too Low

Capacitance too low. Intermittent fault

Intermittent fault



- Ignition off.

Warning! Under no circumstances use an ohmmeter or other live measuring instruments to take readings on a disconnected, non-deployed, pyrotechnical inflatable curtain. This could deploy the inflatable curtain!

Caution! Do not touch the terminal pins in the SRS control module. There is a risk of static discharge. This could damage the SRS control module.

Check the connectors for the SRS module and inflatable curtain. Check for contact resistance and oxidation. See Checking wiring and terminals. Intermittent faults See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Intermittent Faults. Check for loose connections. See Checking wiring and terminals. Intermittent faults See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Intermittent Faults.
Check the cable terminals in the female and male sections of the connector. The cable terminals must not be damaged or pressed back.
Check the cable between SRS control module terminals #21A (21) and #22A (22) and connector terminals #1 and #3 on the left-hand inflatable curtain for an intermittent open-circuit according to Checking wiring and terminals. Intermittent faults See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Intermittent Faults.

Hint: Check the integrated capacitor in the igniter connector: Measure the resistance.
With the ignition off, connect the test instrument probes between driver's airbag connector terminals #1 and #3. The ohmmeter reading should rise rapidly to infinity.
Reverse the position of the ohmmeter positive and negative test probes. Connect them to the connector as in the previous measurement. The ohmmeter reading should drop rapidly to approximately 0 ohms and then increase to infinity.

Remedy as necessary.

Diagnostic Trouble Code (DTC) Information

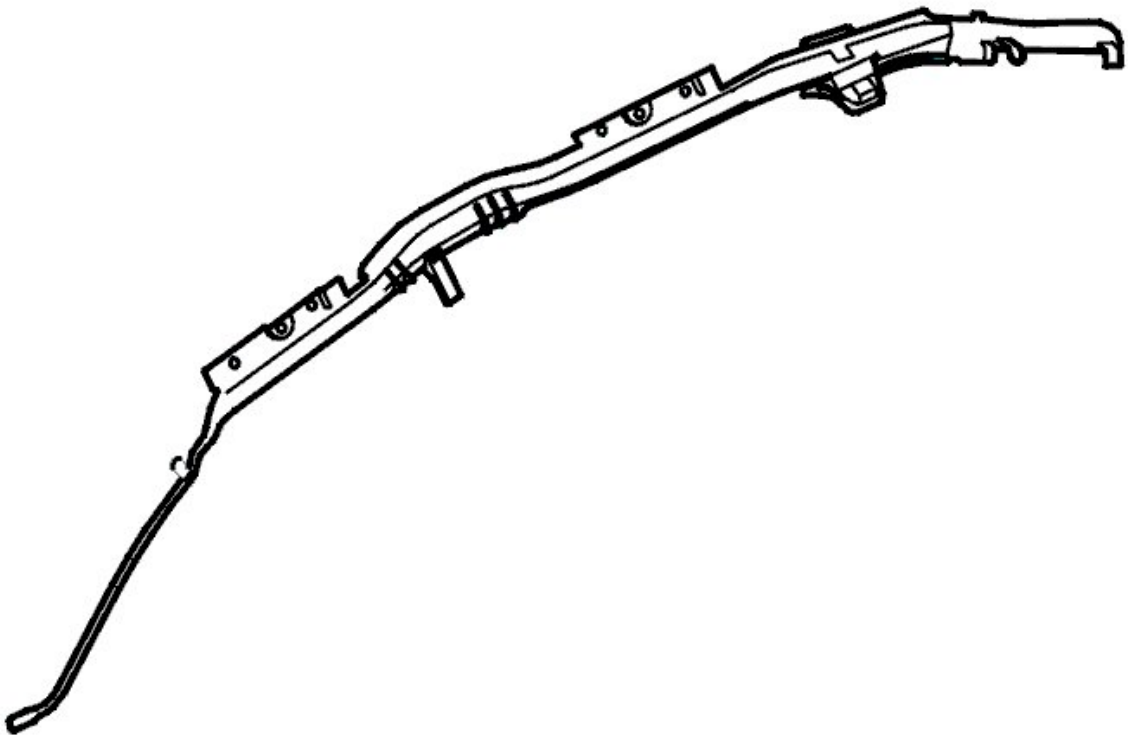
SRS-003D Diagnostic trouble code information

Condition



If the circuit resistance is low for more than 10 seconds, diagnostic trouble code SRS-003D is displayed.

Substitute value
- Nothing.

Possible source
- Short circuit in igniter wire or connectors between the inflatable curtain and the supplemental restraint system (SRS) control unit
- Short circuit in inflatable curtain (resistance in igniter too low).

Fault symptom[s]
- SRS warning lamp on.

Resistance Too Low

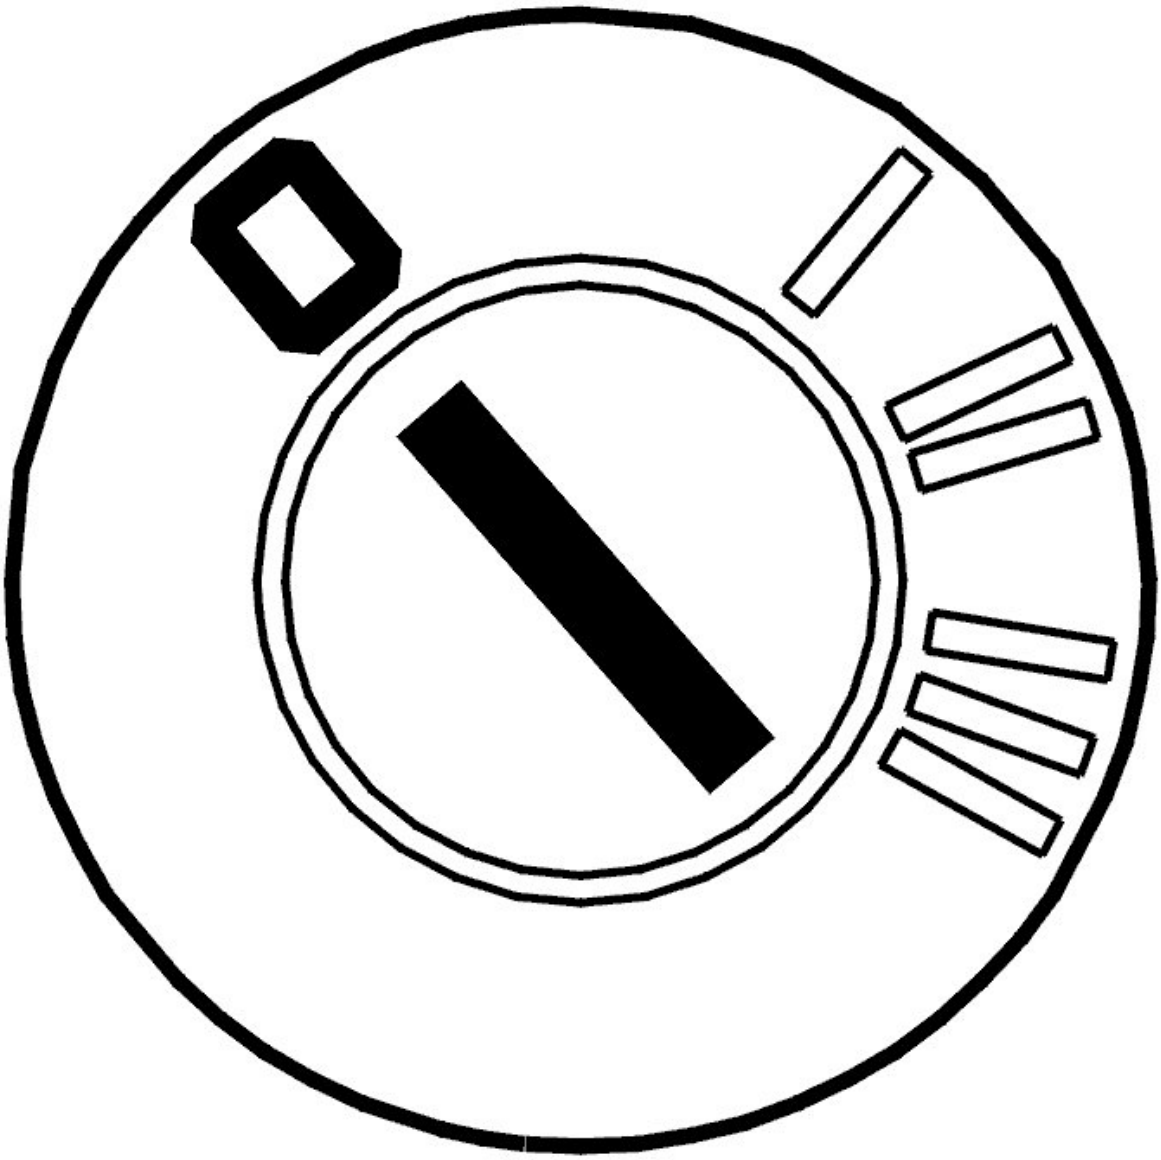
Resistance too low. Intermittent fault

Intermittent fault



- Ignition off.

Warning! Under no circumstances use an ohmmeter or other live measuring instruments to take readings on a disconnected, non-deployed, pyrotechnical inflatable curtain. This could deploy the inflatable curtain!

Caution! Do not touch the terminal pins in the SRS control module. There is a risk of static discharge. This could damage the SRS control module.

Check the connectors for the SRS module and inflatable curtain. Check for contact resistance and oxidation. See Checking wiring and terminals. Intermittent faults See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Intermittent Faults. Check for loose connections. See Checking wiring and terminals. Intermittent faults See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Intermittent Faults. Check the cable between the SRS control module terminals #21A (21) and #22A (22) and connector terminals #1 and #3 on the left-hand inflatable curtain for an intermittent short-circuit to ground according to Checking wiring and terminals. Intermittent faults See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Intermittent Faults. Remedy as necessary.

Other information:

- To access and replace the SRS control module connector, see Control module SRS (supplemental restraint system), replacing See: Relays and Modules/Relays and Modules - Restraint Systems/Air Bag Control Module/Service and Repair
- To access and replace the connector for the left-hand inflatable curtain (IC), see IC (inflatable curtain) module, replacing See: Restraint Systems/Air Bag Systems/Air Bag/Service and Repair/IC (Inflatable Curtain) Module, Replacing
- To connect the breakout box, see Connecting the breakout box See: Restraint Systems/Air Bag Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box, Supplemental Restraint System Module (SRS)
- With the ignition off and with the left-hand inflatable curtain connector and special tool951 1506 Test dummy See: Tools and Equipment/951 1506 Test Dummy connected, the resistance between terminals #A21 (21) and #A22 (22) on the SRS control module connector (inflatable curtain side) should be infinite
- With the ignition off and the connector for the left-hand inflatable curtain and for the SRS control module disconnected, the resistance between terminals #1 and #3 of the inflatable curtain connector (SRS control module side) and ground should be infinite
- For information about the repair of SRS wiring, see Cable harness SRS system, repair See: Restraint Systems/Air Bag Systems/Air Bag/Air

Bag Harness/Service and Repair/Procedures

- For other values, see Signal specification See: Restraint Systems/Air Bag Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Specification, Supplemental Restraint System Module (SRS).

Diagnostic Trouble Code (DTC) Information

Diagnostic trouble code (DTC) information

Condition

One of the following diagnostic trouble codes (DTCs) will be stored if the resistance in any of the wiring circuits is lower than 10 ohms for longer than 10 seconds:
SRS-0036
SRS-003E
SRS-0046
SRS-004E
SRS-0056
SRS-005E
depending on which wiring circuit the fault is in.

Possible source

- If the SRS control module identifies that a side impact protection (SIPS) bag is installed, despite the control module being programmed that a side impact protection (SIPS) bag is not installed.

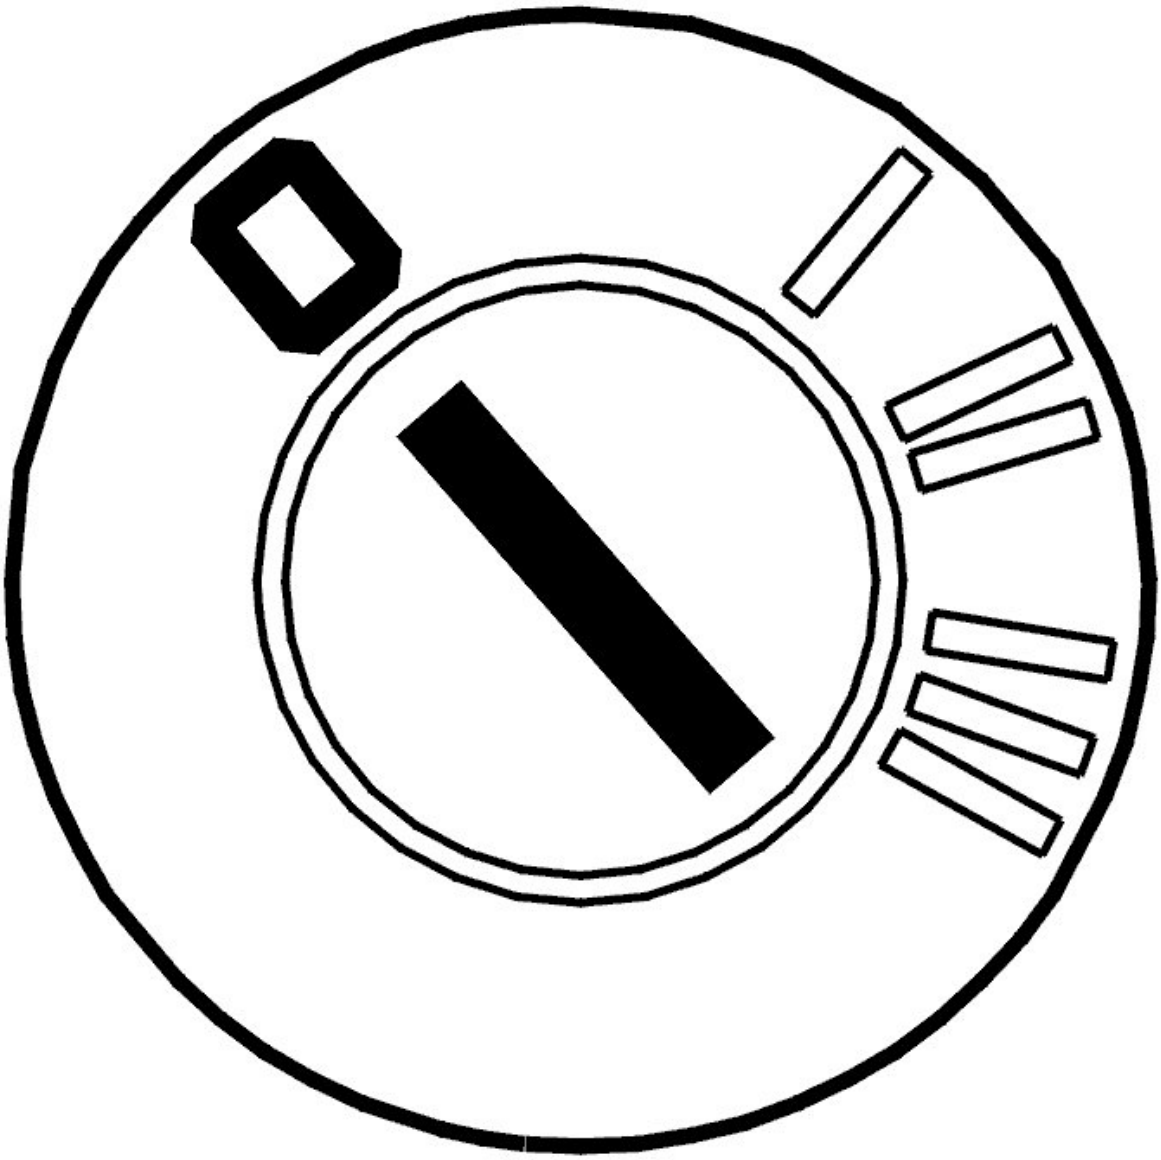
Fault symptom[s]

The SRS indicator lamp is lit.

Configuration Fault

Configuration fault. Permanent fault

Checking the component



- Ignition off.

Check the control module and SRS system connectors to ensure that no terminal pins are damaged. Also check the wiring.
Check that the correct SRS control module is installed in the car. Read off by clicking the VCT2000 symbol.
Replace the control module if no fault is found.

Other information:

- To access or replace the control module, see Control module SRS (supplemental restraint system), replacing See: Relays and Modules/Relays and Modules - Restraint Systems/Air Bag Control Module/Service and Repair
- For other values, see Signal specification See: Restraint Systems/Air Bag Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Specification, Supplemental Restraint System Module (SRS).

Has the fault been remedied?

Yes - Verification

No - Replacing the component

Diagnostic Trouble Code (DTC) Information

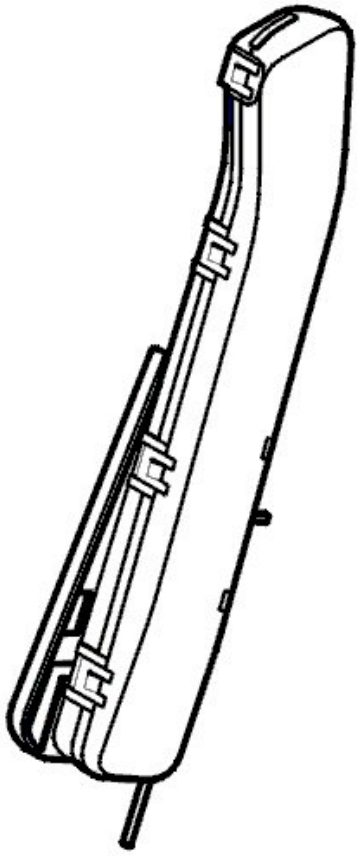
SRS-0043 Diagnostic trouble code information

Condition



If the circuit capacitance is too low for more than 10 seconds, diagnostic trouble code SRS-0043 is displayed.

Substitute value
- Nothing.

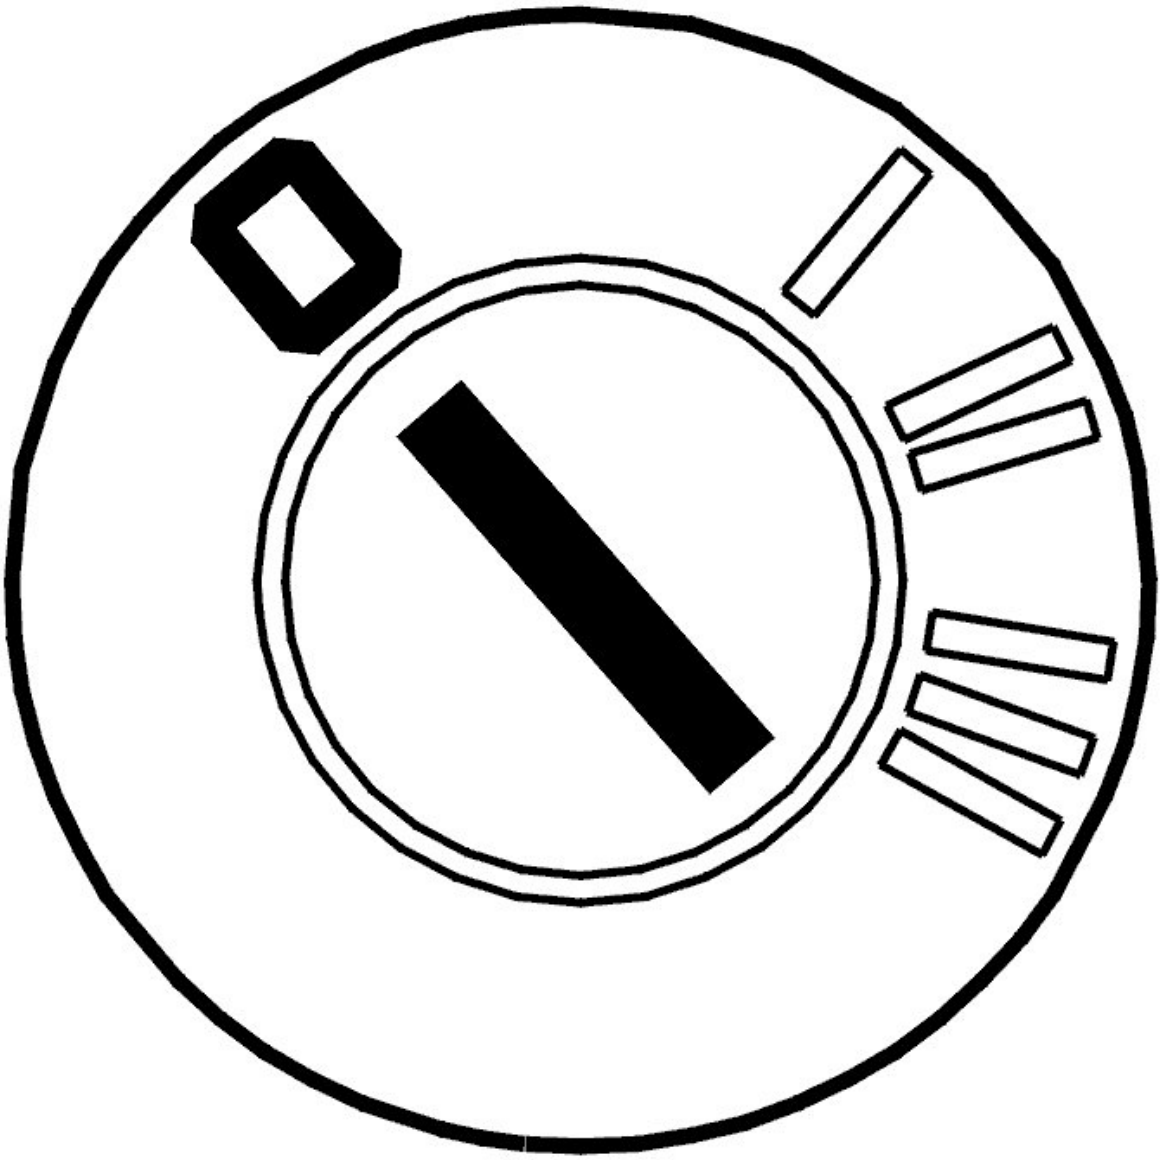
Possible source
- Capacitance too low or open circuit in in-built capacitor in igniter wire connector.

Fault symptom[s]
- SRS warning lamp on.

Capacitance Too Low

Capacitance too low. Intermittent fault

Intermittent fault



- Ignition off.

Warning! Under no circumstances use an ohmmeter or other live measuring instrument to take readings on a disconnected, non-deployed, pyrotechnical airbag. This could deploy the airbag!

Caution! Do not touch the terminal pins in the SRS control module. There is a risk of static discharge. This could damage the SRS control module.

Check the connectors for:
- 2-pin
- the SRS control module.

check for contact resistance and oxidation. See Checking wiring and terminals. Intermittent faults See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Intermittent Faults. Check for loose connections. See Checking wiring and terminals. Intermittent faults See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Intermittent Faults.
Check the female and male sections of the connector for the SRS control module and the 2-pin connector. The cable terminals must not be damaged or pressed back.
Check the cable between SRS control module terminal #4C (60) and connector terminal #1 on the right-hand side impact protection (SIPS) bag for an intermittent open-circuit according to Checking wiring and terminals. Intermittent faults See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Intermittent Faults.
Check the cable between SRS control module terminal #3C (59) and the 2-pin connector terminal #2 for an intermittent open-circuit according to Checking wiring and terminals. Intermittent faults See: Testing and Inspection/Component Tests and General Diagnostics/Checking Wiring and Terminals/Checking Wiring and Terminals. Intermittent Faults.
Remedy as necessary.

Other information:
- To access and replace the SRS control module and connector, see Control module SRS (supplemental restraint system), replacing See: Relays and Modules/Relays and Modules - Restraint Systems/Air Bag Control Module/Service and Repair
- To connect the breakout box, see Connecting the breakout box See: Restraint Systems/Air Bag Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box, Supplemental Restraint System Module (SRS)

- With the ignition off and the 2-pin connector disconnected, the resistance between the 2-pin connector terminals #1 and #2 (SRS control module side) should be approximately 22 kohms.
- For information about the repair of SRS wiring, see Cable harness SRS system, repair See: Restraint Systems/Air Bag Systems/Air Bag/Air Bag Harness/Service and Repair/Procedures
- For other values, see Signal specification See: Restraint Systems/Air Bag Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Signal Specification, Supplemental Restraint System Module (SRS).

Fault symptom[s]

Volvo XC70 L5-2.5L Turbo VIN 59 B5254T2

- SRS warning lamp on.

Signal Too High

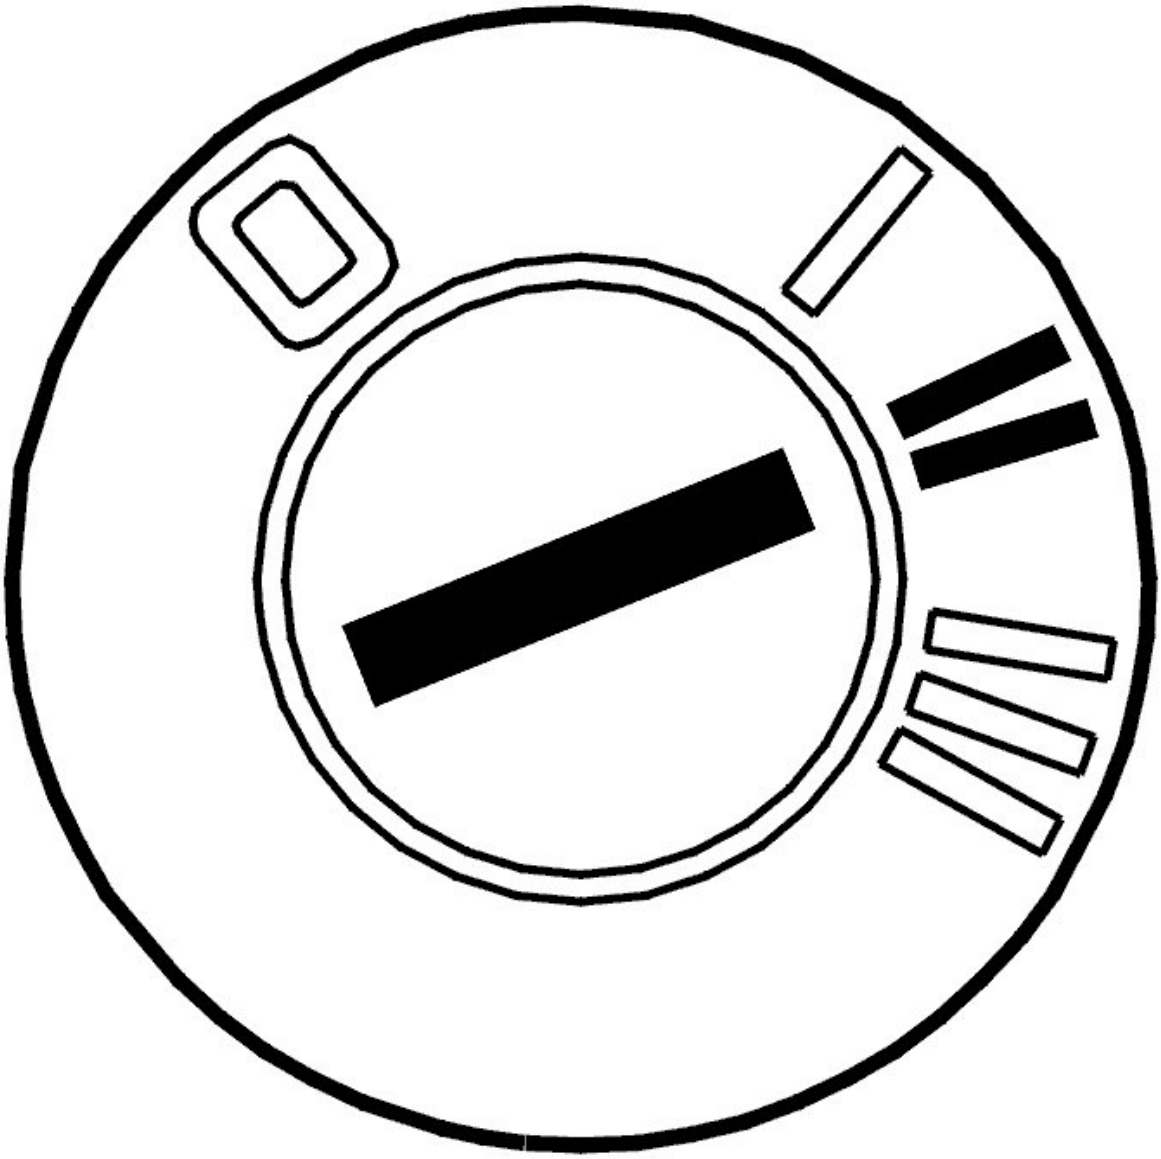
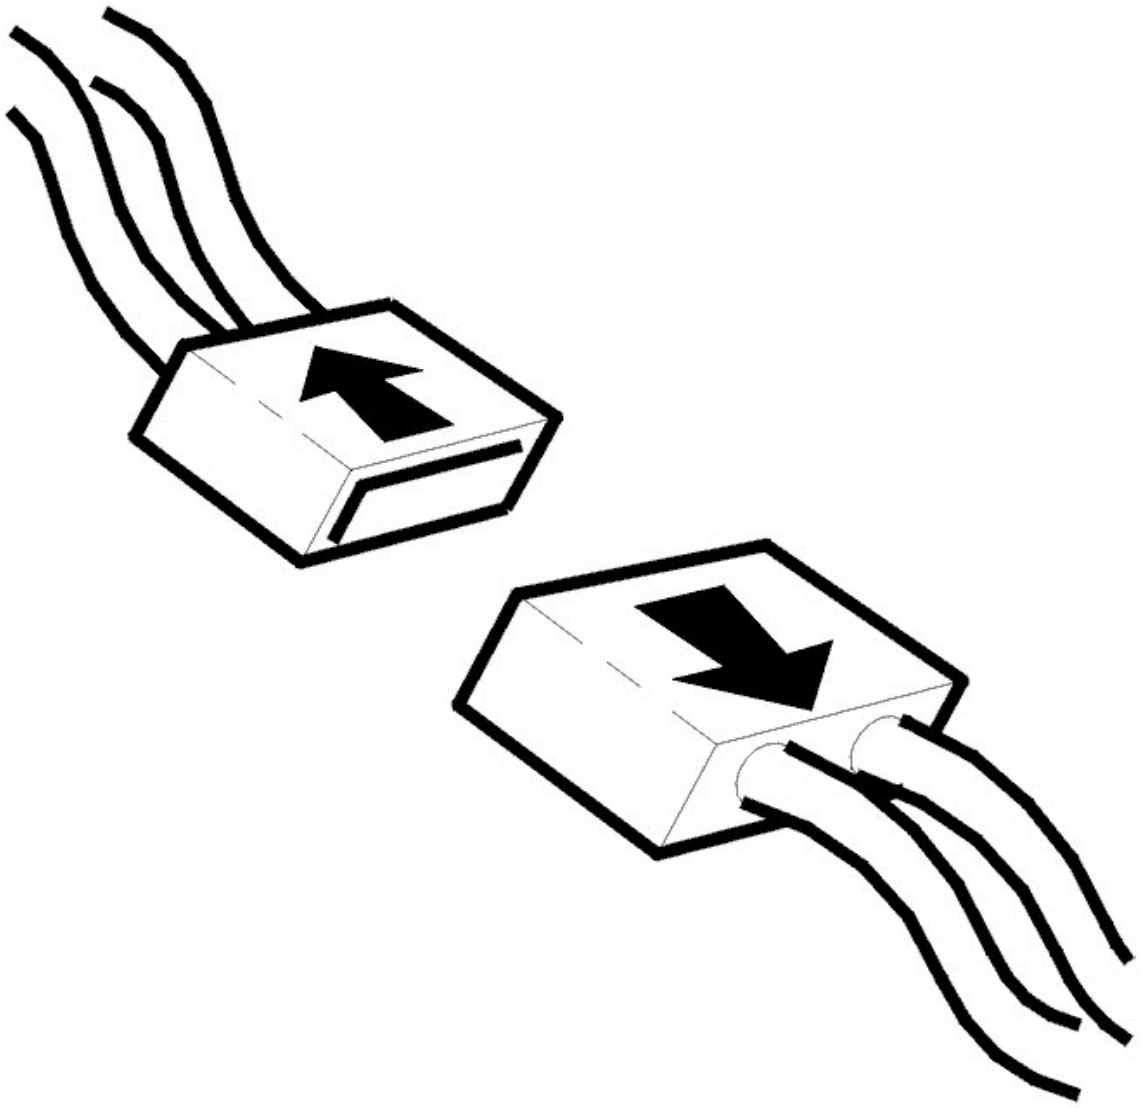
Signal too high. Permanent fault

Checking the component





- Ignition off
- Disconnect the connector from the right-hand inflatable curtain
- Connect special tool 951 1506 Test dummy See: Tools and Equipment/951 1506 Test Dummy to the connector for the right-hand inflatable curtain

Warning! Under no circumstances use an ohmmeter or other live measuring instruments to take readings on a disconnected, non-deployed, pyrotechnical inflatable curtain. This could deploy the inflatable curtain!

Note! The special tool must be checked and fault-free. If the tool is defective, the diagnosis readings will be incorrect. This will make fault-tracing harder.

- Switch on the ignition. Wait 10 seconds.

Read off diagnostic trouble codes (DTCs).
If the status of the diagnostic trouble code (DTC) changes from permanent fault to intermittent fault, try replacing the right-hand inflatable curtain.

Other information:

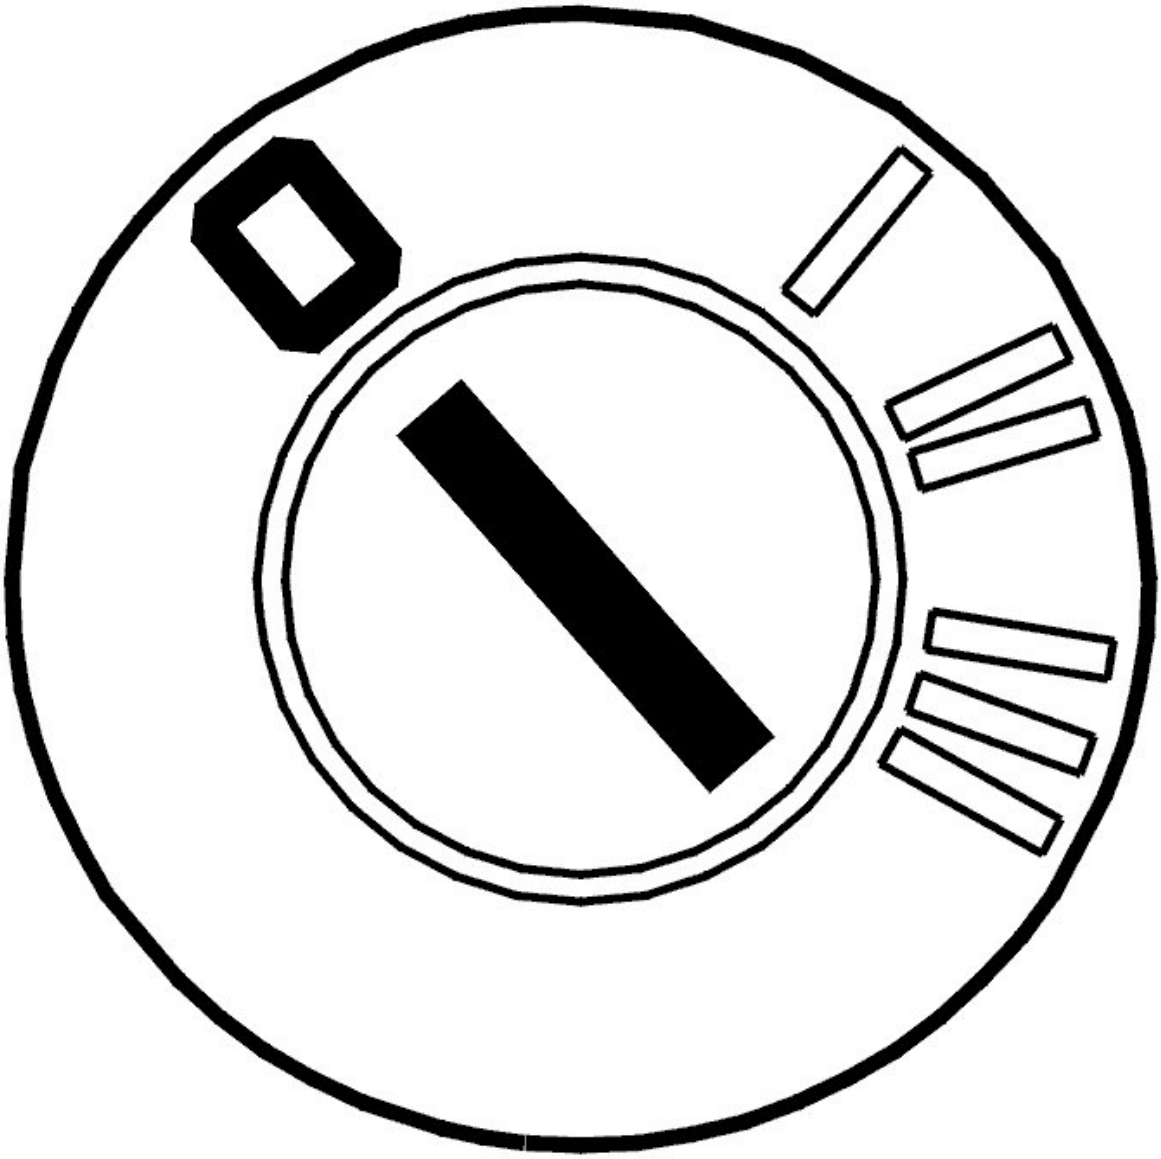
- To access and replace the right-hand inflatable curtain, see IC (inflatable curtain) module, replacing See: Restraint Systems/Air Bag Systems/Air Bag/Service and Repair/IC (Inflatable Curtain) Module, Replacing
- To check the special tool, see Calibration See: Restraint Systems/Service and Repair/Calibrating the Special Tool.

Does the status of the diagnostic trouble code (DTC) change?

Yes - Verification

No - Checking components and wiring

Checking components and wiring



- Ignition off
- Disconnect special tool 951 1506 Test dummy See: Tools and Equipment/951 1506 Test Dummy from the connector for the right-hand inflatable curtain.

Warning! Under no circumstances use an ohmmeter or other live measuring instruments to take readings on a disconnected non-deployed pyrotechnical inflatable curtain. This could deploy the inflatable curtain!

Caution! Do not touch the terminal pins in the SRS control module. There is a risk of static discharge. This could damage the SRS control module.

Check the cable between the SRS control module terminals #21C(17) and #22C(18) and connector terminals #1, #3 on the right-hand inflatable curtain for a short-circuit to supply voltage according to approproate procedure.
Remedy as necessary.

Other information:

- To access and replace the SRS control module and connector, see Control module SRS (supplemental restraint system), replacing See: Relays and Modules/Relays and Modules - Restraint Systems/Air Bag Control Module/Service and Repair
- To access and replace the connector for the right-hand inflatable curtain, see IC (inflatable curtain) module, replacing See: Restraint Systems/Air Bag Systems/Air Bag/Service and Repair/IC (Inflatable Curtain) Module, Replacing
- To connect the breakout box, see Connecting the breakout box See: Restraint Systems/Air Bag Systems/Testing and Inspection/Pinout Values and Diagnostic Parameters/Connecting the Breakout Box, Supplemental Restraint System Module (SRS)
- With the ignition off and the connector for the right-hand inflatable curtain and for the SRS control module disconnected, the resistance between inflatable curtain connector terminals #1 and #3 (SRS control module side) and the disconnected battery positive terminal should be

infinite

- For information about removing the battery cables, see Battery, disconnecting See: Starting and Charging/Battery/Service and Repair/Procedures/Battery, Disconnecting
